Preface

Track 1: Nature positive/design for transformation
- Introduction
- Design methodology
- Design education
- Design materialization
- Biophilic approaches in design
- Eco-social transitions
- Fashion innovations
- Urban design & citizen inclusion
- Design & digitisation

Track 2: Digital futures/hybrid reality
- Introduction
- New crafts and craftspeople
- Research through design in the cyber-physical era
- Redefining the role of design(ers)
- Usability and performance of innovations
- Design for and with extended reality
- Design for and with digital fabrication
- The digital on urban scale
- Technology driven design education
- Digital fashion

Track 3: Handle with care
- Introduction
- Design for/as communication
- Design for diverse users
- Care(ful) spaces
- Co-creating care(ful) design
- Design(ers) & learning
- Design ethos
- Inclusive approaches to intangible cultural heritage
- Adaptation of the built environment
- Participation and role of communities

Introduction

The Track Nature Positive/Design for Transformation started off with a few big questions: Even if we are technologically able to do so, are we still allowed to create our designed environment as we see fit? How can we navigate through sustainable transitions and within planetary boundaries? Can a systemic lens help us creating an overview to better overcome the present and imminent future conflicts? And can we regenerate ecological and social damage done? Indeed, the futures we want tomorrow are enabled by the actions we take today. Shaping societies, industries, buildings, products, and behaviours is a task to tackle by those able to cut across different disciplines and become agents for change. A call out to designers around the globe to put nature positive transformation at the heart of their actions. Many of them have responded within the framework of this Cumulus Conference.

We received 150 abstracts that, after a double-blind review process, resulted in 37 high-quality academic papers. Furthermore, out of 17 workshop proposals, 5 were selected for the conference. In addition, the program for our track includes several visual papers and posters. 8 themes were identified that determined the final division in paper sessions.

The attention for ***Design Methodology***, a theme to which 2 sessions were allocated, is not surprising, since existing methods and tools are to be critically assessed with respect to the challenges we face. The envisioned transformation concerns a large-scale systems integration of deep ecology strategies, which is a complex endeavor. Departing from the notion that current design approaches are incapable of dealing with *uncertain* conditions of critical complexity, as argued by an increasing number of scholars, we need to break away from attraction to *existing* systems and values. At the same time, high levels of complexity pose new questions concerning ***Design Education***, which comprises another theme within our program. Philosophical and pedagogical concepts concerning design education are discussed, as well as the role of the physical learning space. Trans-disciplinarity is put forward as a mode of collaboration that looks beyond bridging divides in academia, engaging directly with external sources of knowledge. Internalizing environmental and social awareness has inherent material implications. A third theme has thus been dedicated to ***Design Materialization***. Within this theme, the future of material selection for products and interior design is discussed, amongst other topics. Enhanced guidelines for Life Cycle thinking are addressed in one of the papers, making the connection with circular material use: a hot topic in practices and policies alike. The act of repairing and caring for living systems in truly *restorationist ways* is closely connected to this, but often neglected in simplified circular concepts towards material use. The theme of ***Biophilic Approaches in Design*** elaborates further on such notions of restoration. Bio-receptive Design, as an example, embeds living organisms in design processes through the creation of materials and artefacts, whilst connecting design and biology. In another article, boundaries between living and non-living are pushed through the parametrical control of plants in the creation of furniture. As such, the biophilic approach centers on both local and global human/nature relationships. Other perspectives on those human/nature relationships are brought to the fore in the theme ***Eco-Social Transitions***. Here, the concepts of systems thinking, and co-creation have been connected to leadership and business, for example. One paper takes the role of Design as central to sustainable change processes, underscoring the transformative power of the designer to unlock solutions by sequencing seemingly distant dots and generating new meanings. One theme has been allocated completely to ***Fashion Innovations***. The diversity of angles varies from negotiations with fabrics, form, and future for re-balancing design thinking, to issues of greenwashing and brand communication, and from the importance of indigenous textiles and know-how to difficulties in changing unsustainable lifestyles. Although we have grouped these articles into one topical session, it can be observed that challenges and opportunities are in many ways overlapping with those in other fields of design. From that perspective, also the urban scale shows parallels, based on the rationale that human-centric approaches transcend scales through conscientious contextualization, as can be found in the session on ***Urban Design and Citizen Inclusion***. Time-limited planning of urban living circles, for instance, reconnects the physical proximity of urban residents with basic daily needs, such as food, health, and education. This gives way to slower means of traffic, such as walking and cycling, whilst reducing negative effects to human well-being, climate, and the environment. A similar scope can be found in yet another research, in which an innovative form of development is proposed to radically change the urban landscape in favor of a human-centric approach, by means of a quantitative measuring method. End-user inclusion is also central to a paper on Do-It-Yourself studies to establish new

'partnerships' between products and users. This can be filed under the act or process of *democratizing design*. And that aspect seems to join the various tracks within this Cumulus '23 Conference: no matter from which way one approaches it – nature positive, inclusion and care, hybrid realities, or otherwise – the *human scale* is paramount for understanding contemporary challenges and finding solutions. Talking of new methods to facilitate this, the digital world is never far away. The theme ***Design & Digitization*** showcases assets of computation regarding the shift from a degenerative societal paradigm, to a regenerative one. For example, through serious gaming to create awareness, understanding, and – ultimately – behavioral change. To increase imaginative capabilities, less conventional methods have been proposed for approaching unsustainable behavior. One study does not shy away from using dystopian futures, fantasy-scape, and even zombies, exploring new ways of inquiry and how (sub)conscious perceptions of time and space affect people's beliefs and the choices they make.

Choices made through design should always be 'nature-positive'. The opposite is no longer viable. If there is anything this selection of papers shares, it is that: in the transition we are all agents of change.

Scenario building through a systemic lens: a new perspective on tools and methods to design for sustainability transitions

Abstract

The connection between sustainability and the future has its roots in the early days of environmental movements. The report 'The Limits to Growth' (Meadows et al., 1974) highlights how sustainable action implies wide-ranging, systemic considerations and forward-looking thinking. This is also reflected in the definition of Sustainable Development provided in the Report 'Our Common Future' (WCED, 1987). Working for sustainability, in fact, usually means taking a long-term approach, which also ties in with radical and socio-technical innovations. In recent times, however, the world has faced complex systemic social, technical, and environmental challenges, which will be increasingly interconnected and interdependent. Systems theory allows us to rethink such phenomena as isolated elements and complex systems made up of many interacting parts (Vargo et al., 2017). Placed in a timeline, it is possible to highlight how changing events are getting closer and vertical, showing us a new vision of time and the future. Scenario Building is a widely used method in design to generate future visions. By applying a systemic lens to this methodology, this paper aims to provide a new awareness through which it can emphasise the relationships that a new future implies and underlies. The analysis has made it possible to define new characteristics of Scenario Building that emphasise its relationships and spatio-temporal connections. These new considerations converge in the Design for Sustainability Transitions perspective, showing how the designer, thanks to the connections capacity and envisioning, plays a crucial role in transforming a socio-technical system (Ceschin & Gaziulusoy, 2019).

Systemic Design; Scenario Building; Design for Sustainability Transitions; Sustainability.

Introduction

In recent years the world has been facing significant systematic complex challenges such as climate change, inequities, and lack of natural resources heightened especially because of the Covid-19 pandemic, the conflict in Ukraine, and the climate crisis. The nature of these problems is multidimensional, and because of this, they will become increasingly intertwined and interdependent in the next years. Moreover, when placed on a timeline, these events show a shattering peculiarity that lies on a new vision of time and future that is not spread out linearly but is increasingly rhythmic and vertical, showing shorter and closer time gaps. As a result, many academics and industry professionals are looking at novel models that employ design skills, techniques, and expertise to inspire futuristic ideas and creative solutions. Consequently, in a world where the future is constantly crumbling and getting closer and closer, what are the new parameters to be considered? And yet, what contribution can Systemic Design make in this challenging task to be able to act concretely in the short-term with a long-term impact?

Using a systemic lens, this paper seeks to offer an overview of the tools and processes related to Scenario Building techniques. The paper initially analyse a theoretical background that explores the conceptual pillars of the three topics addressed: Scenario Building, Systemic Design and Design for Sustainability Transitions. Subsequently, the methodology implemented to analyse Scenario Building techniques through a systemic lens is shown. Insights from the analysis are reported in the last part of the paper highlighting a new perspective of Scenario Building, which is more relational, contextual and ecosystemic. Finally, limitations and opportunities are reported to foster further and subsequent research questions.

Theoretical background

Scenario building

Scenario Building is one of the most popular methods for defining possible futures. It is based on the fundamental scenario concept, often considered a synonym for vision (Carella & Marengoni, 2022). Historically, the first text on this methodology dates back to the 19th century, however, they spread from the Second World War onwards, moving from the military to the public and finally into the private sphere (Bradfield et al., 2005; von Reibnitz, 1988). Since they deal with the future, scenarios fall within the discipline of Future Studies (also known as futures field or foresight), i.e. the systematic study of possible, probable and preferable futures (Carella & Marengoni, 2022). Scenarios are considered the archetypal products of the discipline and are condensed representa-

tions of possible futures with different plausible paths and endings, told in coherent and engaging forms (Bishop et al., 2007; Buehring & Bishop, 2020). These contain a vast amount of information on a single topic that is useful in defining a historical, social, cultural, manufacturing, technological and environmental context, thus composing the points of view, relationships and flows between the elements (Bistagnino, 2009). Thus, scenarios require a comprehensive look, where the present is a fundamental part, to provide a holistic schematic view of futures that are not only possible but also desirable (Sardesai et al., 2021). The capability of the designer is to use the vast amount of information to create narratives that are open, interpretable, and exciting, yet concrete and palpable. A correct balance of technical feasibility, economic viability, and desirability (Zurlo et al., 2020). This is also thanks to the designer's freedom and ability to observe multiple levels, understood as different dimensional scales (from product to systems) and different times and insights. Design is, therefore, a carrier of values and beliefs, but also tools and methods capable of helping those who make strategic decisions in uncertain times. In particular, Strategic Design can confront this uncertainty, defining strategic directions through scenarios and glimpsing opportunities in the external environment (Zurlo et al., 2020). Here is possible to find a common goal between design disciplines and foresight; both seek to make sense of uncertain futures through scenarios, inspiring and communicating possible (better) futures (Buehring & Bishop, 2020). The role of the designer in scenario building is also to act both as a facilitator in the realisation of scenarios and as a mediator in defining the steps to reach these futures (Gaziulusoy & Ryan, 2017). Scenario development for designers can be a means for both stakeholder engagement, realisation of strategic pathways and alternative systems for sustainable transition (Gaziulusoy & Oztekin, 2019).

Systemic design

In the previous paragraph a strong need emerged for interconnections and relationships between events, people, and phenomena, all essential elements of systems thinking and Systemic Design. The latter stems from the opportunity to integrate systems thinking theory into design through the three levels of sustainability: environmental, social, and economic (Barbero & Pereno, 2020; van der Bijl-Brouwer & Malcolm, 2020). Systems thinking emerged about 100 years ago and is based on the axiom that the *"whole is much more than the sum of its parts"* (van der Bijl-Brouwer & Malcolm, 2020). Systemic Design (or System-Oriented Design) has been formalised by Luigi Bistagnino in 2009 as a local economic model based on networks of relationships capable of exploiting the waste of one production system into resources for another. It is a design approach inspired by natural models, where resources are never wasted, but with a relational and territorial focus typical of industrial ecology (Ceschin & Gaziulusoy, 2019). Because of this, the goal of Systemic Design is not only to design products, but rather complex industrial systems where flows of energy and matter never become waste and damage the environment but are metabolised, reducing environmental impact and creating new economic opportunities (Barbero & Toso, 2010; Bistagnino & Campagnaro, 2014). Although similarities can be made with other design approaches, such as System Design, Service Design or Life-Cycle Design, Systemic Design differs in terms of scale, complex social systems, and integration (Jones, 2020). The Systemic Design approach, however, calls for capabilities from the designer that are also recurrent in other approaches, such as his strong relational and mediation skills, or his ability to grasp causal relationships between different elements (Barbero & Cozzo, 2009; Bistagnino & Campagnaro, 2014). Visualisation skills are also recurrent, necessary to trace and communicate the flows and relationships between actors and the system context (Mosca et al., 2015). The designer is assisted by methods and tools that have emerged in the last decade to support the practical application of Systemic Design. Namahn, in collaboration with shiftN, SDA, MaRS have developed the Systemic Design toolkit to guide the designer (van Ael et al., 2019). The toolkit consists of several frameworks and templates, which guide the designer step by step, from analysing the system to fostering the transition.

Design for Sustainability Transitions

It is important to emphasise the topic of transition since this represents the meeting point of both Scenario Building and Systemic Design. The former, as previously mentioned, aims to imagine the future to define new products, services, and strategies; the latter triggers a change, a transition from one state to another, of a territory or a community. Design for Sustainability Transitions (DfST) or Transition Design focuses on the transformation of socio-technical systems by promoting technological, social, organisational and institutional innovation (Ceschin & Gaziulusoy, 2019). The transformations that DfST aims to promote are *de facto* systemic changes affecting both production and consumption systems, as well as social systems, through a change in institutions, organisations, socio-cultural constructs and technology (Geels, 2005; Loorbach, 2010). However, technology is not seen as a unique and pre-determined means through which these changes can be achieved, but rather as a system element supporting the transition. Such complexity is often associated with wicked problems, i.e. ill-defined, political and systemic problems (Rittel & Webber, 1973). Designers, and strategic design are used to tackle such problems by analysing them, re-framing, looking ahead and proposing innovative solutions (Zurlo, 2022). Transitions are achieved by promoting long-term visions and transition pathways with step-forwards and step-backs made of materials, products, services, new behaviours and new policies necessary to achieve the imagined futures (Ceschin & Gaziulusoy, 2019). Indeed, transitions need to imagine new futures. Still, they also need new configurations of actors, new systems, but also facilitators of participatory processes and strategic decision-making (Gaziulusoy & Ryan, 2017). We can conclude that DfST frames Scenario Building and Systemic Design in a transformational perspective, giving them a clear direction and not just absorbing their methods and tools. Since DfST is a young approach, it is necessary to consolidate and clarify its theoretical foundations, initiating a dialogue with real experiences in which methods and tools are applied and possibly adapted to different contexts and situations.

Methodology

The aim of this paper is to identify the contribution of Systemic Design in introducing new parameters to lead the Scenario Building methodology toward a sustainable transition perspective. Therefore, an exploratory case study methodol-

ogy was planned, in order to obtain insights from real experiences and best practices.

Empirical setting

Six cases that apply the Scenario Building methodology has been identified to be analysed trough a systemic lens. We selected and identified the cases according to the following parameters:

- Cases with different time horizons (short, mid and long term);
- Cases in which the application of Scenario Building has different objectives (reading a phenomenon, identifying strategic directions, defining project briefs ...)
- Cases that have had a real potential fallout/impact.

The case studies differ in the trigger of the process, but all address concrete problems faced mainly by organization of the secondary and third sector from different industries.

Data collection

We conducted semi-structured interviews to get first-hand data with senior design researchers, responsible and actively involved in the design research and Scenario Building activities of the analysed case studies. Each interview lasted on an average of 1 hour. We applied a research protocol structured in four main sections:

- **General information:** aims at collecting information on the project typology, content, aim, time horizon, people involved (quantity and professional background);
- **Scenario Building process:** aim at understanding activity conducted in the research phase (typologies and relevance in the process), and in the scenario generation phase (format, people involved, output);
- **Results and Impact:** aim at understanding the Scenario results, their usage and impact (realization, adoption and feasibility), if measurable;
- **Self-assessment:** aim at understanding pro and cons of the process adopted and what could be changed.

Data analysis

Based on the interviews, factual elements were examined with the aim of identifying commonalities and differences in the use of Scenario Building. More specifically, data were clustered according to the following variables:

- **Client typology**, to highlight the different sectors and company typologies commissioning the project, if any;
- **Content**, to analyse the territorial, socio-economic and sectoral variables that define the context in which the scenario is to be set;
- **Time**, to identify the time horizon of each case study;
- **Format**, to highlight the different ways in which the process is conducted;
- **Participant typology**, to identify the variety of people involved in the process;
- **Journey**, to analyse the sequence of the different actions performed during the process;
- **Research activities**, to highlight the different research activities conducted and understand their role in the process;
- **Involvement of experts**, if any, to identify when they were involved and in what role;
- **Output**, to examine the variety of formats in which a scenario is delivered;
- **Outcome**, to investigate how the scenario's results are used;
- **Impact**, to verify the impact of the scenarios in terms of fulfilment and feasibility.

Then we searched for regularities and patterns, trying to understand which of the above variables had a greater role and weight in the Scenario Building process and its realisation. Finally, we looked at the variables used to analyse the Scenario Building process through a systemic lens, to understand whether Systemic Design can help turn Scenario Building into a tool for the sustainable transition. To do this, we studied a number of Systemic Design toolkits, in particular the Social Ecosystem Map developed by Namahn and shiftN in 2016, to understand the different levels of an ecosystem and its importance in the systemic approach as opposed to that in the Scenario Building process, where context is usually considered one of the elements to be observed in the definition of a user-centred vision. With the toolkit, we began analysing the Scenario Building process of the selected cases by observing whether the different levels of the ecosystem had been considered within the research phase and whether the impact of the scenarios on the different levels of the ecosystem had been reached.

Results & discussion

Thanks to the literature review and the analysis, it was possible to recognise and highlight patterns and reflections with Scenario Building and Systemic Design as their common point (Fig.1). Before exploring the outcomes of this research, it is necessary to cluster the results that emerged into two macro groups, those relating to the process of Scenario Building and those relating to its context. Regarding the former, it was interesting to note how the various research phases are fundamental to creating a solid base of work and envisioning capabilities. It is a common and consolidated practice to perform at the beginning of the Scenario Building methodology an initial research that allows the researchers or designers to grasp the conditions of the context of the users that characterise the background in which the project will be placed. This is done mainly through PEST analysis (political, economic, social, and technological) and user research. The former is that desk research activity that allows the participants to gather data regarding the context by extrapolating socio-cultural and technological trends, giving a snapshot as both a starting and ending point of the market, society, and context. Within this research category, it is possible to find blue sky research, trend, and mega trend research. The exploratory case study analysis showed how those trends, whether inspirational or innovative, strongly linked to the imposed time frame allow the designers or researchers to make the subsequent envisioning work truly feasible. On the other hand, the user research makes it possible to collect qualitative and quantitative data on the user under consideration. In the case studies with the most significant impact, it is possible to see how user research offers a more excellent systemic vision of the context where the analysis focuses not only on the user, but on the entire ecosystem of actors surrounding him. This means identifying, investigating, synthesising, and visualising not only the latent or non-latent needs of the user but the re-

lationships that exist in the context as an ecosystem of actors, actions, and touchpoints.

Figure 1. Pathway of research and analysis of Scenario Building towards sustainable transition through the systemic lens. The contribution of this work of revision, analysis and updating of the Scenario Building methodology, therefore, sees the importance of the research phase not as a critical and superfluous step offering volatile hints without a possibility of concreteness; indeed, it is a fundamental phase, especially if spread throughout the process and not just its initial steps, because it empowers the scenario researcher or designer, creating awareness and helpful knowledge to make the scenario real, be it in the short, medium or long term. Just as the system is increasingly recognised as a living ecology that grows, declines, changes, and evolves (Sevaldson, 2022; Walker et al., 2004) the scenario has indeed similar intrinsic peculiarities. Even more revealing is the fact that a new awareness of Scenario Building towards sustainable transition has emerged from this analysis, namely the realisation that the scenario is not a static snapshot of something to be achieved, but is a dynamic ecosystem of actors, relationships, and actions in constant evolution. In recent years, scholars and practitioners have been able to verify and agree on how reality is increasingly showing its complexity and how systemic and strategic skills are increasingly valuable for visualising, anticipating, and dealing with these complex realities or systems. The complexity lies in the network of relationships between different actors, actions, and touchpoints, which inevitably imply new research and design methods. And it is here that Systemic Design comes into play, the encounter between systems thinking and design thinking, skills that are useful for grasping the nodes and edges of every system, be it micro, meso or macro, ranging from the individual to society to the environment and so on. It is no coincidence that new design trends incite us to think and consider non-humans as well, both for the benefit of humanity and the entire planet. Therefore, it has become necessary to try to grasp those patterns useful for building dynamic ecosystem scenarios, capable of affecting and intervening both the small to the large and vice versa. In order to aspire to a sustainable transition, it is necessary to research, ideate and implement this new awareness that the scenario is a dynamic ecosystem based on two fundamental characteristics and dimensions:

1. **Scenario as a set of contextual relationships:** that considers the entire network of actors and relationships that exist in its given context.
2. **Scenario as a spatio-temporal ecosystem:** that considers its positioning and evolution in a spatio-temporal dimension.

An example that can be briefly reported is one carried out in collaboration with a prefab house manufacturer in southern Italy, performed in 2018, with a two-year time horizon. The process saw an initial research phase followed by the brief reframing and then the development of scenarios, presented through cards with visual stimuli, and possible design directions. The scenarios stimulated the company's designers in the realisation of a modular and reusable product, later launched on the market. The analysis phase focused on the ecosystem of actors and stakeholders, looking at their needs, socio-cultural and value context, as well as the market, the brand partner and blue-sky stimuli. As previously mentioned, this information highlighted the network of actors and their relationships, not only understood as exchanges of money, information or goods, bringing out critical points and possibilities (scenario as a set of contextual relationship). It also highlighted possible changes in time and space of the actors, context and relationship giving the possibility to imagine their evolution in an organic sense (scenario a spatio-temporal ecosystem).

The new characteristics presented must be considered throughout the entire scenario process, especially in its implementation. This awareness should therefore contribute to a strategic plan of sense and purpose to make the scenario viable, feasible and sustainable aware.

Conclusion

Through the systemic lens, it was possible to highlight how the scenario is inherently relation-based and a spatio-temporal ecosystem. In this new interpretation, scenarios are seen as dynamic systems, changing in time and space. Scenario analysis and development with this in mind should allow companies, organisations, institutions, and communities to be guided through a sustainable transition, connecting the needs of today with those of tomorrow, avoiding blind spots. Such awareness opens further research opportunities. First of all, it is important to ask whether the skills and capabilities of today's designers are adequate to deal with the complexity that a systemic scenario requires, and if so, which of these

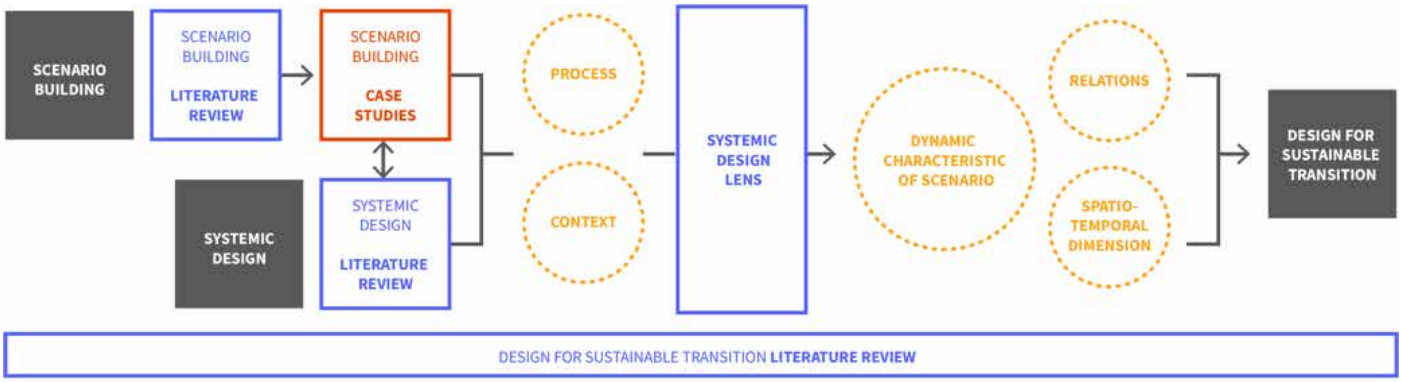

Figure 1. Pathway of research and analysis of Scenario Building towards sustainable transition through the systemic lens.

should be implemented. Furthermore, it would be interesting to understand whether the tools used for Scenario Building support or limit such systemic vision, both in research, scenario development and narration. If necessary, it might be interesting to develop new ones. This aspect can also be interpreted as a limitation of this research, since a systematic analysis of the tools might bring out new considerations. The tools connect us to a more participative and actionable dimension, so a further opportunity could be to test scenario development from a systemic perspective with organisations and company figures. This allows to understand how these concepts fit into organisational strategic and operational terms and how non-academic figures react to such complexity. To conclude, from a field-testing perspective, it would be interesting to understand if and how this perspective allows for the strengthening or creation of new relationships between different stakeholders to foster collaboration and implementation towards increasingly complex objectives and the sustainable transition of socio-technical systems.

Intimacy/Integrity: a framework for thinking about epistemological styles in design activity

Ariel Guersenzvaig[1], David Casacuberta[2]

Abstract

Design research has established several dichotomies around styles of knowing and thinking, such as 'thinking vs. doing' (e.g., Bagchi, 2020), 'intuitive vs. deliberate" (e.g., Schaathun, 2022; Jones, 1992), or 'rational problem solving vs. reflective practice' (e.g., Dorst, 1997). In this paper, the authors explore and integrate these dichotomies using the 'intimacy/integrity' framework proposed by Kasulis (2002). The 'intimacy' and 'integrity' pair is presented as a heuristic device that can help us characterize two broad ways people develop and present arguments, generate knowledge, establish values, and even develop a metaphysics. An integrity orientation separates object and subject, and knowledge is objective and verifiable. In contrast, an intimacy orientation blurs the line between object and subject, and the self is relational. In an integrity framework, the knower and the known (whether a thing or another being) have each an individual, well-delineated identity, while in the intimacy orientation knower and known (the self and the other) are interdependent and intertwined with one another, and can't be seen as separated units. The paper centrally argues that his framework serves to examine alternative individual styles of thinking in design practice. Furthermore, the authors posit that Kasulis' framework is a useful lens to examine design theory and methodology and can enrich ongoing debates. In particular, the paper explores the aforementioned dichotomies to show they can be advantageously subsumed into Kasulis' conceptual apparatus, which is more overarching and has greater explanatory power.

Author keywords

Epistemological difference, ethics, intuition, rationality, problem-solving.

Introduction

Several interrelated dichotomies around styles of knowing and thinking in design activity have been established in the field of scholarly design research over the years, such as 'rational problem solving vs. reflective practice' (e.g., Dorst, 1997). In this paper, we engage with these dichotomies through the lens of a framework for conceptualising different styles of knowing and thinking proposed by philosopher Thomas Kasulis (2002). This framework, itself a heuristic device, gravitates around two central notions: those of 'intimacy' and 'integrity', which characterise two broad cultural orientations in the way people develop and present arguments, generate knowledge, establish values, and even develop a metaphysics.

Building on an analysis of well-known dichotomies, we posit that Kasulis's heuristic framework is a useful lens to examine design reasoning. We are of the view that the 'intimacy-integrity' perspective can extend and enrich ongoing professional and academic debates and perspectives on epistemological diversity in design activity. What's more, we argue that Kasulis' conceptual apparatus serves to subsume frequent terminology ('intuition', 'rationality', 'doing', etc.) into a richer and more overarching heuristic that has greater explanatory power than the traditional opposites we are familiar with in design research and practice. It is, however, not our intention to argue that either of these terms and taxonomies is wrong or false. All of them have explanatory power and have proven to be useful to advance design theory and methodology. Our claim is simply that the integrity/intimacy framework encapsulates and links many of these.

The content of the paper proceeds as follows. In the next section, we introduce and briefly discuss three conflicting perspectives—i.e., dichotomies—for conceptualising design activity. This section is followed by an overview of Kasulis' framework. Together, the dichotomies and Kasulis' framework serve as a springboard for the constructive argument we'll develop in the Discussion section. We close with a general conclusion.

Dichotomies in design

We will concentrate on three well-discussed dichotomies: 'thinking vs. doing' (e.g., Bagchi, 2020), 'intuitive vs. deliberate" (e.g., Schaathun, 2022; Jones, 1992), and 'rational problem solving vs. reflective practice' (e.g., Dorst, 1997). These are particular lenses through which different styles of knowing and thinking are often approached and studied. They are the result of different normative and descriptive perspectives on the design process and design activity.

Furthermore, because they are directly linked to deep-seated ways of understanding what design *is*, they are still enormously popular and part of the professional and scholarly design vocabulary. Nonetheless, their putative conflicting nature has also been challenged in recent years (see e.g., Schaathun, 2022; Guersenzvaig, 2015). Before we attempt to present Kasulis' framework as a suitable alternative; i.e., a richer way of conceptualising different styles of knowing and thinking in design, we will briefly introduce these perspectives.

Thinking vs doing

One dichotomy we frequently encounter is an elementary one: the distinction between thinking and doing, in which these activities are conceptualised as distinct modes of knowing and acting.

'Thinking', in the context of this dichotomy, has a meaning akin to 'reasoning', involving the contemplating, examining and evaluating that are classically involved in analytical problem-solving:

> You're a [design] thinker if you like understanding every aspect of the problem statement, solving it in the abstract confines of your mind before you even put pen to paper. People know you for being thoughtful, precise and consistent (Bagchi, 2020).

On the other hand, 'doing' is a portmanteau term for imagining and shaping activities *as a way* to solve and explore problems without the need for a preceding full-blown problem definition. Thus, as a design doer:

> You love solving problems and believe in rapid iterations. People know you for making decisions and moving quickly. You're known for being adaptable and tactical. [...] You're not afraid to be scrappy and find quick ways to test your ideas (Bagchi, 2020).

The distinction between thinking and doing, however, is as helpful as problematic. Bryan Lawson (2006, p. 137), although using a somewhat different vocabulary, questions it here:

> If reasoning and imagining were truly independent categories of thought, one should not be able to speak sensibly of 'creative problem-solving' or a 'logical artistic development', which are both quite meaningful concepts.

We follow Lawson in that 'thinking' and 'doing' are just different epistemological styles employed by designers, not monolithic and exclusionary descriptions of personality types. Rather, these modes are alternative—though interrelated, as we shall see—styles of knowing, reasoning, and acting. Claiming that no designer exclusively employs one single epistemological style is an uncontroversial statement, as modal shifts between, for instance, drawing and evaluating have been consistently shown in design research since the mid-nineties (see e.g. Cross, Christiaans and Dorst, 1994; Akin and Lin, 1996). What's more, one of the most crucial findings in design research is that given the nature of design problems, the designer is in most cases unable to move linearly from problem to solution precisely because these entities co-evolve. These modal shifts obey the logic of the constructivist task of co-defining problem and solution (see e.g., Dorst, 2017, pp. 21, 24, 25, 28, 71).

Despite all this, the dichotomy between thinking and doing is persistent and ubiquitous in design activity. Plausibly, it might be even constitutive of the Western way of understanding knowledge itself, as it was no one less than Aristotle, who famously divided knowledge into *theoria* (Greek for theoretical knowledge), *praxis* (practical knowledge), and *poiēsis* (productive knowledge) (*Meta* 1025b 25). Hence its inclusion in this list.

Intuitive vs. deliberate processes

Another frequent dichotomy is the distinction between 'intuitive' and 'deliberate processes'. We find a canonical instantiation of the dichotomy in the classification of designers as 'black boxes' and 'glass boxes' made by John Chris Jones (1992).

On the black box extreme, Jones describes the designer as a kind of magician whose mind performs mysterious creative leaps that produce a result through an unknowable process. According to Jones (1992, p. 46), for the defenders of this view: '[the designer] is capable of producing outputs in which he has confidence, and which often succeed, without his being able to say how these outputs were obtained.'

The black box view of designing is anchored on common definitional features of intuition. Herbert Simon (1992, p.13) highlights the (at least partial) lack of awareness that, in line with black box design, is characteristic of intuition: 'a performance that is speedy and for which the expert is unable to describe in detail the reasoning or other process that produced the answer.' Intuition is more a category than a homogeneous cognitive process and there is both agreement and controversy about what intuition is. Glöckner & Witteman (2010, pp. 5-6) find common ground between alternative views:

> Intuition is based on automatic processes that rely on knowledge structures that are acquired by (different kinds of) learning. They operate at least partially without people's awareness and result in feelings, signals, or interpretations.

The intuitive 'black box' perspective can be contrasted to the deliberate, conscious processes that are characteristic of 'glass box' designing. The designer as a Glass Box operates computationally to produce an optimal result. In this view, designers carry out a perfectly discernible design process which is transparent, hence the glass, and it can be rationally explained. A canonical sequential process (see e.g., Cross, 2008) is structured around at least three clear stages: (1) a stage of analysis consisting of a list of requirements and a performance specification, (2) a stage of synthesis consisting in finding solutions for every performance specification, and (3) evaluating these solutions according to various criteria (e.g. cost-effectiveness, ease of use, commercial impact, etc.). The characteristics of these models are: (1) objectives and criteria are fixed in advance, (2) analysis is completed before solutions are sought, (3) evaluation is logical (not empirical), and (4) strategies are fixed in advance (Jones, 1992). An early example of a deliberate process is the systematic model of design proposed by Archer in 1965 and a more recent example is the one proposed by Pahl & Beitz in 1999 (see Jones 2008, pp. 34-41).

Granted, these are just two models of design activity and many other models do not proceed linearly from problem to solution but highlight the co-evolution of the problem-solution pair (Dorst, 2017, p. 21). However, the logical linearity embedded in the 'glass box' methods has been for decades hailed as a standard even in process models that are purportedly iterative and less rationalistic than the classic ones—think of the all ubiquitous 'Double Diamond' model of design (Ball, 2019).

Paradigms of rational problem-solving vs. reflective practice

We based this dichotomy on a distinction made by Dorst (1997), in which design methods can be seen to belong to either one of two paradigmatic perspectives on design:

1. The paradigm of design as rational problem solving
2. The paradigm of design as reflective practice

Let's consider the first paradigm. In line with 'The Sciences of the Artificial' (Simon, 1996 [1969]), the most influential work within this paradigm, design can be understood as a rational search process: the designer defines the problem space that has to be examined in search of a satisfactory solution. This paradigm is registered within a positivist outlook on science with a strong emphasis on rigour: objective observation and logical analysis must lead to general formal models of the design process. The *rationalistic*, deliberate models and methods discussed above can be assigned to this paradigm. While more could be said about it, due to space reasons we switch to the other part of the dichotomy.[1]

The publication of 'The Reflective Practitioner' (Schön, 1983) marks a point of inflexion in design methodology whereby early rationalistic methods are superseded by the paradigm of the designer as a *reflective practitioner*, in which the design process can be seen as a reflective conversation with the situation. This paradigm views design as inherently argumentative and constructivist, in the words of Schön (1983, p.79):

> Because of [...] complexity, the designer's moves tend, happily or unhappily, to produce consequences other than those intended. When this happens, the designer may take account of the unintended changes he has made in the situation by forming new appreciations and understanding and by making new moves. He shapes the situation in accordance with his initial appreciation of it, the situation 'talks back', and he responds to the situation's back-talk.
>
> In a good process of design, this conversation with the situation is reflective. In answer to the situation's back-talk, the designer reflects-in-action on the construction of the problem, the strategies of action, or the model of the phenomena, which have been implicit in his moves.

The reflective turn moves the designer away from technical rationality and thus from the separation of knowing from doing. It fully positions the designer in a situated rationality of reflection *in practice*. Schön highlights alternative epistemic styles other than applying general principles and standard scientific knowledge to dealing with ill-defined problems. This new stage in methodology and epistemology 'tried to embrace a wide range of issues (poetical, rhetorical, phenomenological, hermeneutical, and ethical) in order to obtain greater insights and an improved understanding of the design phenomenon' (Bousbaci, p. 39).[2]

The paradigm of design as a reflective practice is a constructionist epistemology, where means and ends are inevitably intertwined. Knowledge is often tacit and situated in a practice. It is thus a radically different paradigm that arises in reaction to the rationalist paradigm. For Dorst (1997, p.70), in 'reflective practice design tasks may be analysed and subdivided in a number of different ways, and there is no a priori way to determine which approach will be the more fruitful. Therefore, design task and solution are always and inherently developed together.'

As Dorst argues, both paradigms are useful in approaching different design problems and each of them can be applied to one of the two fundamental classes of design activities:

1. *Objective interpretation* activities in which the interpretations of design or solution are based on an impression caused by something beyond the designer, which prints meaning on the subject. In this case, the designer behaves according to the rational problem-solving paradigm.
2. Activities that suggest *subjective interpretation* or the modification of the design tasks print meaning or value on it—Schön (1984) calls it framing; i.e., a particular way to perceive a design situation. In this case, it is the subject that prints meaning on something. These kinds of activities can be better addressed from the paradigm of reflective practice.

To Schaathun (2022), Simon and Schön have more in common than suggested. Namely, they share the view that practical reason is indispensable to deal with real-world problems. However, one important difference remains. Unlike Simon, Schön invokes a distinctly human power to *see-as* for goal setting; i.e., for figuring out what to do in terms of being a human individual, in a way that is different from the prevailing scientific paradigm.

Mapping dichotomies: the 'generation game' in design methodology

Design's methodological and epistemological developments since the 1960s are discussed in a historical timeline called the 'generation game' (Cross, 1981; Bousbaci, 2008). The 'generation game' illustrates the profound changes that occurred in design methodology from the first generation of rationalistic design methods, at one extreme of the timeline, to the reflective turn at the other extreme.

We believe the dichotomies we explored above come back as conceptual building blocks in this well-known historical timeline. The dichotomous terminology can be mapped onto this timeline rather neatly. Consider, for instance, Bousbaci's (2008, p. 38) description of the origin of the first-generation design methods in terms of 'a strong reaction against the intuitive, artistic, and 'beaux-arts'' vision of the design process [in favour of a] very logical, systematic, and rationalist view of design activities'.

Along these lines and using the terminology from the dichotomies, first-generation methods could be characterised as thinking-centred, deliberate, rational problem-solving, with the glass-box as a model for the designer. There's a caveat, we can see that to obtain a rich description we need to interlace terminology from several dichotomies. More needs to be said about this but we will expand on these themes later through the integrity-intimacy lens. First, we need to introduce Kasulis' framework in the next section.

The integrity/intimacy framework

Originally, Kasulis's intimacy versus integrity framework is presented as a way of understanding and analysing cultural differences in styles of generating, validating and transmitting knowledge. According to this framework, cultures, relationships and thinking models can be characterised as either emphasising

1 Simon made profound changes to his own theory in the third edition of his influential book in 1996, conceding that due to their limited cognitive capabilities, humans cannot oversee all aspects of a problem, which invalidates the early methods to a certain extent due to their psychological implausibility.

2 Due to space reasons, we take no issue with establishing whether more recent streams in design research and practice such as 'Speculative design' (e.g., Dunne & Raby, 2013) or 'Design for the pluriverse' (e.g., Escobar, 2018) are part of the reflective turn, an evolution thereof, or something new altogether. We believe that for the purposes of this paper, answering this question isn't necessary.

intimacy or integrity.[3] Even though Kasulis is more interested in comparative philosophy (i.e., comparing cultures and geographies), we believe his framework serves also to examine alternative individual styles of thinking, which also manifest within a given subculture or practice, such as design practice.

Intimacy

Kasulis characterises 'intimacy' as making known to a close friend what is innermost (Kasulis 2002, p. 42). Intimacy-oriented cultures place a high value on emotional connections and personal relationships, to create a feeling of belonging-with. According to Kasulis (2002, p 46), the main characteristics of an intimacy mindset are:

1. Intimacy is objective but it is personal, not public.
2. Within an intimate relationship, self and other are connected in a way that it is not easy to distinguish them.
3. Intimate knowledge has an emotional, affective dimension.
4. Because of such an emotional dimension, besides being a psychological state, intimacy is also somatic.
5. In general, the ground of intimacy is not self-conscious, reflective or self-illuminating.

When these five characteristics are present, the subject will build a feeling of belonging with the situation they are in. Intimate knowledge is therefore extensive as well as intensive: someone knows something intimately if that knowledge is key for them; i.e., if it is part of their definition as a person.

A relevant process of learning within an intimacy framework is empathic imagination. According to Kasulis, this is a learning-by-imitation process, in a non-discursive way. This imitation process does not relate only to a mechanical level of know-how, but it implies putting on the teacher's shoes, imagining how the teacher thinks, feels and acts, and then putting all this into practice, learning by doing, without following a specific model. (Kasulis 2002, pp. 54, 58)

This implies that knowledge is transmitted in an esoteric manner. That is, key aspects of knowledge are only accessible to insiders, who have practised for several years, and that knowledge cannot be transmitted in a public manner, even if one states all the steps logically (Kasulis 2002, p. 62).

Integrity

Integrity is understood as the ability to remain whole, in one piece. It is the ability to have an autonomous identity that is not influenced or corrupted by whatever is outside (Kasulis, 2002, p. 67). The main characteristics that define integrity are the following (Kasulis, 2002, pp. 70-79):

1. Integrity is impersonal. Knowledge should be established objectively, independently of the individuals that generate or test it. Evidence should speak for itself, and subjectivities are irrelevant.
2. Integrity establishes a 'belonging to' type of relationship. That is, if A and B establish a relationship between them, they both belong to such a relationship, but they remain the same in essence. The fact of belonging to such a relationship doesn't change them.
3. Integrity is purely intellectual. Emotions are irrelevant, or even worse, counterproductive. One should mistrust emotions and be guided just by reason if one wants to find out the truth
4. Integrity leads to pure conceptual knowledge. That means that any somatic component is suspicious and should be eliminated. That implies that knowledge is exoteric, public and accessible to everyone, without the need for years of practice to reach the expert state.
5. Integrity is bright and clear. Knowledge is accessible to everybody if they apply their intellect and reason to find the truth, so it is self-illuminating.

Discussion: Integrity and intimacy in design research

In this section, we will present two examples of how the integrity/intimacy pair could be used to discuss and analyse design methodology and epistemology. In the first example, we will try to show that the framework could be used *instead* of the dichotomous vocabulary that is already used in discussions of design methodology. In the second example, we will attempt to use intimacy and integrity in an altogether *different* and quite *unrelated* discussion (design negotiations). If our descriptions are cogent, then we will have succeeded in showing the strong descriptive and explanatory capacities of the intimacy/integrity framework.

The generation game: from integrity to intimacy

As we mentioned earlier, the dichotomies are insufficient when used individually—in the sense that they need to be interlaced with one another to produce rich descriptions of design broad phenomena. The integrity/intimacy framework solves this by offering an overarching terminological approach. To illustrate the potential of Kasulis' framework, we will augment the 'generation game' conceptual apparatus by using the intimacy/integrity pair as an overarching and integrative approach *instead* of using more fragmentary dichotomous terminology.

We find Integrity at the foundation of the first generation of design methods, which were a reaction against the artistic and *ad hoc* design methods that were in use before 1960. The new methods proposed variations of scientific, logical models of the design process, anchored in a view of unlimited rationality. These models would release the designer from their bonds with the traditions from the past and idiosyncratic, arbitrary decision-making. This is directly related to an integrity-centred conception of what can count as a legitimate basis for knowledge. The dominant orientation in Western thinking has to do with the expectation of supporting assertions with evidence so that everyone can investigate for themself. Truth is thus underwood as something others can verify. Unbeknownst to the early methodologists, everything in their methods was guided by integrity reasoning.

The second and third-generation design methods moved away from this ambition of modelling an omniscient designer with unlimited rationality and a transparent and complete process of design activity that characterised the first-generation methods. During these years (the 1970s and early 1980s), we see moves towards intimacy and a growing rejection of integ-

3 The locus of Kasulis' framework is cultural differences across the world. Yet, while it highlights cultural differences (especially detectable when comparing Asian and Western thought), it does not in the least suggest that different cultures are monolithic and unchangeable nor perfectly demarcated. Rather, Kasulis shows how particular facets of human experience are emphasised in some settings, while others are placed in a secondary role. So, in every culture, we can find instances of both intimacy and integrity.

rity. For instance, consider Alexander's famous rejection of the Design Methods Movement ('I would say forget it, forget the whole thing') (cited in Cross, 1981, p. 3) and Rittel's proposal for participatory and argumentative methods (Cross, 1981; Bousbaci, 2008, p. 38).

Another important move towards intimacy is the 'primary-generator model' proposed by Jane Darke (1979), which draws not on the integrity of rational analysis as a starting point of the design process but on a profoundly personal conjecture that blurs the separation between analysis and synthesis. This model famously describes how empirical, situated, and expert knowledge are intertwined to yield that type of knowledge Kasulis has characterised as *intimate*. Because of design's intractability, an initial, subjective narrowing down and framing occurs when early ideas or organising principles define the boundaries of the problem space and suggest the nature of its possible solution.

Yet, integrity was far from gone. Despite a manifest recognition of the complexity and intractability of design problems, second and third-generation methodologists still maintained the view of design as an essentially problem-solving activity, all of which entails 'some shared beliefs in a certain degree of rationality, logics, and objectivity which fundamentally characterise the design process' (Bousbaci, 2008, p. 41).

Because of their complexity, design problems or briefs can seldom be solved simply by examining requirements and processing information mechanically in a detached manner. Integrity is insufficient. Arguably, the very failure of the early design methods was due to erroneous premises centred on integrity. Design problems are not to be taken as a given but actually start with a particular action of framing (Kolko, 2010), in which subjective interpretation is a fundamental aspect of sensemaking and synthesis; that is, intimacy.

Does this mean we go back to viewing the designer's mind as a black box? To the 'beaux-arts' vision of the design process? Not at all.

Intimacy doesn't reject or exclude the possibility of 'objective' knowledge, it just accepts that a legitimate basis for making claims about certain aspects of reality needn't be necessarily publicly verifiable (Kasulis 2002, p. 33). Objectivity is preserved by reconsidering it; while an Integrity mindset understands objectivity as publicly verifiable knowledge that is based on hard facts that can be computed (i.e., the glass box model), an intimate form of knowing, even without publicly verifiable knowledge, retains objectivity in a substantive sense (the designer as a reflective practicer). Kasulis (2002, pp. 35-36) writes that intimate knowledge's objectivity:

> is accessible only to those within the appropriate intimate locus, those who have achieved their expert knowledge through years of practical experience. Trust in intimate knowledge's objectivity, like that in positivistic knowledge's objectivity, relies on an assumption of universality, but this universality has a somewhat different formulation.

The key aspect here is that knowledge that is acquired 'through years of practical experience' becomes a legitimate source, regardless of its verifiability. This, of course, aligns with the Schönian perspective of reflective practice and other scholarly work on design expertise (Lawson & Dorst, 2009).

A short detour before proceeding to the next subsection. The orientations of intimacy and integrity can also be applied to analyse the creation of the very models of design we formulate as design methodologists, which are the main characters in the 'generation game'. But what are models? A model is a representation of a phenomenon; i.e., a fact or situation that is observed, inferred or assumed to exist or happen. For Frigg and Hartmann (2020):

> Models can perform two fundamentally different representational functions. On the one hand, a model can be a representation of a selected part of the world (the 'target system'). [...] On the other hand, a model can represent a theory in the sense that it interprets the laws and axioms of that theory.

Any model necessarily embodies a particular way of understanding and framing phenomena. In other words, they are grounded on particular styles of knowing and thinking. From an intimacy mindset we get different models than when approaching an issue from an integrity perspective. Both the black box and the glass box models we referred to above are Aristotelian idealisations; i.e., simplifications aiming at making reality more tractable. The model maker only models those and only those properties that they have reason to believe are relevant to the problem at hand. We believe that Kasulis's apparatus serves well to explain how the decision occurs concerning what to include or exclude in a model. What counts as relevant and how relevance is judged is dependent on the employed epistemological style.

Kasulis (2002, p. 80) uses the metaphor of a computer operating system to understand the frameworks of intimacy and integrity. Choosing between them implies that certain procedures will work differently, that some ways of reasoning will be available while others won't, just as the way we sort documents and folders or the software we have access to varies depending on the OS in our computers.

To round up this part of the discussion, Bousbaci (2008, p. 40) convincingly argues that 'each shift in the evolution of design thinking in fact corresponds to a major shift in the implicit models of the designer included within the analogous theoretical discourses.' We add that any shift in design thinking, such as the fluctuation from first-generation methods to the reflective practitioner, is also a shift in the implicit epistemic models. Intimacy and integrity seem to be well-fitted to illustrate and explain what these implicit models of styles of knowing and thinking in design activity consist of.

Design negotiations as 'belonging-with'

Our second exploration is about negotiations in design. Let's start with a quote in which Paula Scher (cited in Millman, 2007, pp. 50-51) talks about this issue:

> There are all kinds of problems and compromises that [one] must negotiate. Things that have to be held on to, things that have to be protected to make something move forward. And it's very, very, very hard work.

What's important to note is that Scher is not merely *wishing* to hold on to the elusive things she alludes to. She makes these things especially her own; they truly matter to her because she intimately *identifies* with them and it would be a personal loss if what she cares about was diminished. For Kasulis (2002, 37), 'my intimate relations are more than connections I have made; they are actually part of what I am or have become.'

Scher's intimate relation with her work highlights how design work and the designer as a whole person are irremediably intertwined: there is no external work that is fully separated from the person who creates it. In an intimate relation, the work overlaps the person and is thus *internalised*. In this sense, the work belongs *with* the designer; it is not merely a separate object. One of us has explored this in more detail elsewhere (Guersenzvaig, 2021; Guersenzvaig & Ventura, 2022).

As per Kasulis, this phenomenon of being intimate with the work is known to be 'known only to those within the locus of intimacy' (p. 38). In this sense, a work—a design—overlaps in an intimate relation first with the design team and the project commissioner, but when the design is instantiated in a real-world artefact, it can also be part of an intimate relation with others. So, in principle, every stakeholder, design participant, or user could have this intimate relation.

Indeed, we are intimately connected to a myriad of objects and things, and some of them end up mattering very much to us. We all have a special chair or T-shirt with which we are intimately related. These relationships have an anthropological dimension. Not only do designers and project commissioners engage in meaning-making, but also people carve meaning into their own possessions. A friend of one of us had one wheel of his favourite bicycle compacted into a metal cube. He *belonged with* the bike—just like Paula Scher was intimately connected to her own work. Naturally, a classical Western rationalist—integrity—mindset would suggest that this is utter nonsense as the bicycle and the cyclist can't possibly be anything but separated entities. A view from intimacy suggests otherwise.

Conclusion

Throughout this article, we have presented how supposedly unrelated dichotomies used to describe design activity can be subsumed into Kasulis' more overarching distinction between integrity and intimacy. A simpler, yet richer, heuristic facilitates a more comprehensive approach to describing design thinking styles, without the need to rely *ad hoc* on ambiguous opposites such as thinking versus doing or intuitive versus deliberate.

As we saw in the previous section, thinking about design in terms of intimacy and integrity helps us to better understand the development and evolution of design methods and epistemology as a transition from an assumed but inarticulate integrity approach to a more nuanced understanding of design processes based on an intimacy lens. In other words, it can be argued that design methods and epistemology have moved from integrity towards intimacy.

Here, we want to insist on the somatic, embodied, and situated nature of intimacy and its relation to praxis. Intimacy needs to be enacted. Surely, one can learn a lot about, say, spacing type from books and lectures, but it is only by *actually* spacing type and reflecting upon it that one can develop expertise and become an expert. The more we engage in this 'reflective conversation with the situation'—to express it in Schönian terminology—the more intimate the knowledge about spacing type becomes and the more this expertise becomes our second nature. In short, 'Intimacy deepens as the praxis is repeated or habitualized' (Kasulis 2002, p. 43).

In other words, having an intimate knowledge of type (whether about its history or about designing or spacing type) means that the designer, in this case, is not fully separated from the known object. There is an overlap between the known (type) and the knower (designer, typographer, or historian).

However, using the intimacy/integrity heuristic does not invalidate the knowledge gained through other approaches like the ones discussed above. Instead, the heuristic presented here is a powerful way of thinking about design that can help us become aware of relevant aspects that may remain unobserved when using other terminology.

To end, due to space reasons we have chosen to only explore epistemological examples, we believe, however, that the framework can be aptly employed for ethical discussions; for instance, on the issue of contrasting an individual understanding of responsibility based on autonomy and duty with a relational one, based on care and belonging-with.

Democratizing design: the development of a 'Design for Do-It-Yourself' framework

Introduction: an unsustainable human-product relationship

Traditionally, design merely focuses on satisfying the increasing 'need' of consumption. However, (1) a higher level of consumption does not elevate the perceived happiness of people (Lipovetsky, 2006; Porritt, 2003). (2) Maintaining the economic principles of growth and profit, in a mass production context, promotes and accelerates the exhaustion of nature; it impedes a healthy human-product relationship and a proper relation with nature (Hirsch & Pauw, 2022). In this context, designers have been 'active agents of an un-sustainable idea of well-being', says Manzini (2006). An alternative "...Interpretation of well-being is (...) required, disconnected from a perceived need to increase consumption" (Thorpe, 2010). A reconnection would help counter so-called 'alienation' and it would align to the views of various scholars (Ehn, 2008; Pacey, 1992; Papanek, 1985) who advocate for a 'new partnership' between people and the products they use and own.

Design for DIY

Anticipating (a) today's distant human-product relationship in a mass-production context (Cerny, 1999; D. Ehrenfeld, 2003), (b) people's desire to create (Csikszentmihalyi, 1998; J. R. Ehrenfeld, 2008; Maslow, 1943; Press, 2007; Sanders, 2006; Sennett, 2008), and (c) anticipating the great potential of novel making tools and the availability of online information (Anderson, 2010, 2012; Bonvoisin, Galla, & Prendeville, 2017; Salvia, Bruno, & Canina, 2016), this paper introduces a 'Design for DIY' scenario and a novel 'Design for DIY' framework. A variety of scholars suggest that the practice of DIY promises to support a sustainable relationship between things and people, respectively between people and nature (Bianchini & Maffei, 2013; Bonvoisin et al., 2017; Hoftijzer, 2012; Salvia, 2013; Van Abel, Klaassen, Evers, & Troxler, 2011). More specifically, this paper addresses the facilitation of DIY activity, the role and responsibility of design therein, and the grounding and design of a 'Design-for-DIY' framework to help designers facilitate DIY activity.

Do-It-Yourself (DIY)

As the opposite of 'passive consumption', designing and making things for oneself aligns better with people's natural motivations (Franke, Schreier, & Kaiser, 2010). DIY enables people to express their intentions, capabilities and identity (Atkinson, 2006; Shove, Watson, & Ingram, 2005; Wolf & McQuitty, 2011). According to Schreier (2006), as a result people benefit from functional advantages, from the uniqueness of the outcome, from enjoyment of the process and from the 'pride of authorship', even in case of limited input. DIY activity enhances awareness and product attachment; it imbues a product with meaning (Csikszentmihalyi & Halton, 1981; Maldini, 2016; Mugge, Schoormans, & Schifferstein, 2009; Seldis, 2017). In short, DIY brings people closer to 'Being' (Helne & Hirvilammi, 2016; Maslow, 1998), and aligns well with Ehrenfeld's definition of sustainability (J. R. Ehrenfeld, 2008) which involves ethics, human and nature. Despite these advantages in the long run, it would be fair and valid to state that DIY activity has the potential of asking a lot time from people, and of producing waste and of littering the environment with DIY experimental results, in the short term (Hulbert, 2015).

The role of the designer, the Design for DIY scenario

According to various authors, the designer has a moral responsibility to try solving the imperfect human-product relationship (Kries et al., 2018; Myerson, 2016; Papanek, 1985; Schumacher, 2010; Sparke, 1987). Schumacher and Myerson suggest that designers need to reverse their thinking and concentrate on 'scaling down': adopting a mind-set of participation, designing for people and aiming for engagement (Myerson, 2016; Schumacher, 2010). In line with Manzini's view (2012), who suggests that designers can no longer maintain their 'monopoly on design, this paper proposes a Design-for-DIY scenario in which the designer takes responsibility and facilitates the layperson's DIY activity. The designer's role thus changes from being a directive, decisive authority to that of a facilitator.

'Design-for-DIY' studies: exploration of the 'Design-for-DIY' process

In order to gain knowledge of the process of designing for DIY, this study considers a series of four 'Design-for-DIY' studies (Table 1). The study presented here focuses on the design steps a designer can perform to facilitate a layperson's DIY

name	method	data	facilitators	participants laypersons	partiparts design students
1. 'DfDIY' of a coffee maker	research through design	observation of process and results, and interviews	1 to 3	17

3. 'DfDIY' of headphones	idem	observation of process and results	1	8	4
4. 'DfDIY' re-using plastics	idem	observation of process and results	1	2	

Table 1. Design-for-DIY studies

activity. The studies were exploratory in nature and designed to help bring to the surface issues to take into account in developing a Design-for-DIY framework. They also helped to discern whether the notion of a generic framework capturing all the various approaches taken and design challenges addressed would be feasible. The data that support the findings of this study are available from the corresponding author, upon reasonable request.

Design-for-DIY studies conclusions

The insights and models from the studies serve as valuable and relevant information in search of a suitable, preferably generic, Design-for-DIY framework. They helped to map the development steps taken by the facilitator, which supported the identification of numerous common aspects of the Design-for-DIY process. All four projects included instructional media and a concrete kit that distinguished fixed elements from the free design space available to the layperson concerned. To reach their intended audiences, all the cases included a DIY platform environment to enable laypersons to enrol in the DIY project and obtain the necessary support materials. All four studies had to consider the varying layperson's skills and level of experience, which was done by distinguishing means of facilitation, accommodation and support. In line with conclusions drawn from DIY practices in history (Atkinson, 2006; Bonvoisin et al., 2017; Goldstein, 1998; Hollinetz, 2015), the studies highlighted the importance of collaboration, templates and tools for manipulation, adjusted to the layperson's level. As a general conclusion following the studies, the DIY projects appeared to be possible, feasible and doable, and the Design-for-DIY processes were reasonably similar. A generic step-by-step scenario of a Design-for-DIY process was derived from the studies.

Taxonomies of design models and frameworks

To learn and to serve as a reference for the development of a generic Design-for-DIY framework, this paper explores a relevant selection of existing frameworks and design models.

Schön's reflective practitioner model though approaches designing as a process of solving a unique problem, not as a generic step-by-step process (Schön, 1984). Roozenburg & Eekels' (1998) basic design cycle, similar to Schön's model, emphasizes its circular, thus reflective, intention. Similarly, Evans has long ago proposed a spiral-shape process model to 'highlight the iterative nature of the design process' (Evans, 1959; Vossen, Kleppe, & Randi, 2013; Wynn & Clarkson, 2018). He argues that a design project cannot be run through following a sequential process alone. He suggests a procedure of iteration, reflection, and refining; a spiral shape.

Since 'Design for DIY' specifically and clearly comprises the elements of reflecting and experimenting, as the 'endless' learning cycles of Kolb (Kolb & Kolb, 2008) and Gibbs (Gibbs, 1988) do, a cyclic and 'prescriptive' character would suit best for the Design for DIY framework.

DIY process models

When regarding specific design models or frameworks for DIY or Design for DIY, Fablab (Bo-Kristensen, 2018; Gershenfeld, 2012) has depicted its 'designing the design process' model in their Fablab manual, approaching it from an educational perspective: the model clearly distinguishes the concentric shells of (1) setting learning goals, (2) arranging design materials, and (3) design activities. Although this model does not operationally guide the designer in facilitating DIY, the model is relevant for this study, as it distinguishes the different cycles of preparation, and the design stages inside the most centric design activities shell.

Set up of a Design-for-DIY framework

The knowledge gained in this research serves as input for the construction of the Design-for-DIY framework, a means to help the designer set up DIY projects. Additional to the aforementioned challenges, the Design-for-DIY framework should address both the designer tasks and the steps to be taken by the layperson, each of which forms a design process by itself. The framework, consequently, needs to describe a process model inside a process model. All has led to the insight that 'Design-for-DIY' requires a novel Design-for-DIY process model.

Key elements from that gained knowledge have served as requirements for the shape and structure or the framework (see Table 2). We highlight two of them.

Table 2. Knowledge and requirements for the setup of the Design for DIY framework

(1) The Design-for-DIY scenario and the Design-for-DIY studies have taught us that the entire process is represented by a 'sequential' range of distinctive design cycles, to be executed one cycle after the other, and that each of those tasks can be seen as a process by itself. Additional to the consideration of example frameworks from literature (Bo-Kristensen, 2018; Vossen et al., 2013) and from the Design-for-DIY studies, this pleads for a multi-level approach. (2) Both literature (Peppler & Bender, 2013) and the Design-for-DIY studies indicate the pedagogic character of 'Design-for-DIY' and the importance to support creativity, elements associated with circular and even with spiral shapes and structures that represent designers' cognitive processes.

All the findings together in this study have contributed to the development of the multi-cyclic Design-for-DIY framework depicted in Figure 2, comprising two dimensions: (1) the dimension of concentric design cycles (tasks, functions) to perform, and (2) the analytical and iterative design stages that are part of each cycle.

Design levels represented in the cycles of a Design-for-DIY framework

The proposed Design-for-DIY framework represents the major design tasks to be done, at different decision levels. The

model aims to facilitate a dialogue between the designer and the layperson. The concentric shape also reflects the iterative cyclical character of models for teaching and learning documented by various scholars (Gibbs, 1988). The option of re-running a cycle resonates with the 'learning-by-doing' approach.

Figure 1 shows the proposed spiral shaped Design-for-DIY framework. Each cycle prepares for the next, in centripetal direction. The order in which successive cycles are positioned in the framework is considered fixed, however the designer is free to improvise, and choose his or her preferred path.

Figure 1. The proposed Design-for-DIY Framework and its elements, visualizing its dimensions: the cycles and the stages.

Referring to Figure 1, cycles 1 to 4 represent preparatory and facilitating tasks by the owner/designer, while the fifth (the DIY cycle) is where the layperson actually undertakes the DIY project, guided by the designer.

Cycle 1: The Project cycle helps to define the goals and contents. The layperson's interests, the product's suitability and accessibility, all need to be considered, as was e.g. the case in study #1. *Cycle 2:* The pre-design serves as a preliminary product design and as a reference for the project, as well as an example for the layperson. Activities in the Pre-design cycle are geared towards anticipating DIY options. The need for such a cycle was observed in all four case studies. *Cycle 3:* The design of the toolkit, a fundamental element of all Design-for-DIY cases run, should include clear task allocation (to what extent is the layperson involved, and for which aspects), specific tools and instructions, and e.g. a specific design-space medium that supports relevant techniques. *Cycle 4:* The Platform cycle considers designer support, tangible and digital materials for inspiration, examples, and e.g. community and network. Related to this, this cycle should cater for a 'post-design' re-interpretation step, in respect of manufacturing, safety, aesthetics and so on. The Design-for-DIY studies #2 and #3 indicated the value of such a 'Post-design' step. The Platform should be inviting, attractive and accessible, and potentially offer multiple projects. *Cycle 5:* The DIY Design cycle is when the layperson is invited to perform their DIY task, guided to a greater or lesser extent by the facilitating designer.

Design process stages represented in each of the framework's cycles

Explained, each of these cycles comprises a full and iterative design process. Either a model as e.g. the Double Diamond model (Design-Council, 2019) or Roozenburg and Eekels' Basic Design cycle could represent the stages within each of the cycles. The latter has served as a reference here.

Validation

An experiment was conducted to evaluate the Design-for-DIY framework as a method, in which twelve designers were asked to develop a DIY project for laypersons to facilitate them in designing and making their own radio receiver. The experiment's research questions, the procedure, the results and conclusions are described below.

Goals and experiment research questions

The goal of the experiments was to evaluate the quality of the Design-for-DIY framework using questionnaires for numerical assessment. The research questions addressed in undertaking the Design-for-DIY experiments centred on the quality and usability of the Design-for-DIY framework as a method and tool to support the designer in establishing a DIY project for the layperson. The specific Experiment Research Questions (ERQ's) were as follows:

ERQ (1). Do designers judge the Design-for-DIY framework as complete?

ERQ (2). Is the Design-for-DIY framework clear?

ERQ (3). Is the Design-for-DIY instructional video clear?

ERQ (4). Do designers perceive the framework as providing sufficient freedom to design?

ERQ (5). Is the Design-for-DIY framework sufficiently accessible?

ERQ (6). Does the Design-for-DIY framework provide new knowledge for building DIY projects?

ERQ (7). Do designers understand the reasoning behind the Design-for-DIY framework?

ERQ (8). How can the Design-for-DIY concept (the vision of Design-for-DIY) and the Design-for-DIY framework be implemented?

Experiment set up and method

The experiments concerned six runs (Table 3), I to VI, each conducted by a different pair of collaborating designers. In doing the experiments, each pair of designers were assigned to the task of running a 'Design-for-DIY' project' by using a set of tools for support: The Design-for-DIY framework (presented as a board game), sketching tools, paper, glue, tape, radio electronics (for indicating the size of the components).

name	method	data	facilitators
experiment I	research through design	observation of process and results, and interviews (Lickert scale)	2
experiment II	idem	idem	2
experiment III	idem	idem	2
experiment IV	idem	idem	2
experiment V	idem	idem	2
experiment VI	idem	idem	2

Table 3. Design-for-DIY experiments: Design-for-DIY of a radio

Detailed spreadsheets and footage showing all the experiment results are available from the corresponding author, upon reasonable request. The experiments concentrated on cycles 2 to 4 of the framework, respectively on the stages from 'problem' to 'concept' within each cycle.

Results and findings

The questionnaires subsequently completed by the twelve participants have generated numerical data on a Lickert scale (graded responses to closed questions). These are presented below, in turn. The data that support the findings of this study are available from the corresponding author, upon reasonable request. Table 4 shows the results from the questionnaire completed by participants following the experiments. It shows only significant results. The maximum number of responses to each question was 12, since there were 12 participants. As we were interested only in retrieving the positive and negative opinions, since the random results would have been either positive or negative, all neutral scores were omitted from the X^2 analysis.

Research Question (ERQ)	Questionnaire question		N	Positive answers	χ^2
ERQ (1)	Q5	To what extent was the process you ran complete?	10	9	6,40
ERQ (1)	Q20	How would you rate the completeness of the framework?	12	10	9,33
ERQ (1)	Q1	How confident are you that the layman is capable to create his own radio with the kit you designed?	12	12	12,00
ERQ (2)	Q4	To what extent did you specifically address the division between the fixed part by the designer and the design space for the layman?	12	12	12,00
ERQ (2)	Q26	How would you rate the cycle arrangement? (order of cycles)	9	8	5,44
ERQ (2)	Q28	Please rate the clarity of the position of the predesign cycle in relation to the entire DfDIY framework.	11	11	11,00
ERQ (2)	Q29	Please rate the clarity of the position of the toolkit cycle in relation to the entire DfDIY framework.	11	10	7,36
ERQ (2)	Q31	How would you rate the suitability of the followed process steps for other DfDIY cases?	11	9	4,45
ERQ (3)	Q36	How would you rate the clarity of the movie used in this experiment?	11	10	7,36
ERQ (4)	Q9	How would you rate the amount of design freedom you had when creating the kit?	12	11	8,33
ERQ (5)	Q10	To what extent did you feel comfortable to start designing	9	8	5,44
ERQ (6)	Q32	To what degree did the use of the framework increase your knowledge, considering 'Design for DIY'?	8	7	4,50
ERQ (7)	Q33	How do you rate the clarity of the reasoning behind the framework (why the framework is developed)?	10	10	10,00
Q = questionnaire question					
X2 = Chi square					
ERQ = experiment research question					
N = answers except neutral answers					

Table 4. Numerical results from experiments I - VI: Only significant results are shown (df=1, p<0.05). Results are significant if $X^2 > 3,84$ (a result from df=1, p<0.05, according to standard X^2 table).

Discussion and conclusions

Reflecting on the quality of the Framework

The framework does address the different design tasks and design abstraction levels, it offers freedom to design your own path as a designer, and it addresses the iterative and pedagogic character that was required. It seems plausible to conclude that the participating designers judged the quality of the proposed framework as positive. The framework provided guidance, appeared to be fairly clear, suitable and complete. The outcomes of the experiment allow us to conclude that the goal of 'creating a Design-for-DIY framework that sufficiently helps the designer to develop and establish a DIY project' has been achieved, which contributes to a sustainable approach to product design and making, through the small-scale and democratised approach of design for DIY. Hence, the outcomes align to the ambition of the paper.

Limitations

Albeit the results of the questionnaire answers in Table 4 are significant, according to the X^2 analysis methodology, which means that the answers are definitely not random, it would be valuable to conduct further experiments in search for potential areas for improvement, and in search for the character of these improvements. Further, the authors advice to carry out studies that include an active role of the layperson to whom the Design-for-DIY framework is addressed, and so learn from the implementation of the Design-for-DIY framework.

Implications and future research

To sketch an optional scenario for what Design-for-DIY could entail, the designer's capacity could be envisioned as serving the supplier of either DIY materials, DIY tools, or the platform (compare Maker Nexus). The designer could also be subsidized by the (local) government to propel people to engage in DIY and making activity. As attitudes and contexts change, the Design-for-DIY approach has the potential to gain ground. Our framework and the accompanying vision could help to increase awareness and so inspire the democratization of design, e.g. through teaching the concept of Design-for-DIY as part of design curricula. In manifesting the Design-for-DIY vision, the framework stresses the importance of the responsibility designers should take.

The power of imagination: Immersive and experiential counterfactuals to engage with sustainability

Alessandro Ianniello

Design Department, Politecnico di Milano, Italy

alessandro.ianniello@polimi.it

Abstract

Imagination is a faculty that can underlie the transformations towards alternative futures, which are central in the discourses developed in Futures Studies and Design Futures, composed of different approaches and methodologies, such as Speculative Design (Dunne & Raby, 2013), Design Fiction (Bleecker, 2009) and Experiential Futures (Kelliher & Byrne, 2015). All these share a common goal: the crafting of questions related to futures to foster dialogues about present wicked issues rather than problem-solving (Angheloiu et al., 2020).

Focusing on the topics of interest, imagination has demonstrated to be able to influence transformations towards sustainable and just futures (Moore & Milkoreit, 2020) and, if fostered and enhanced, it can be become a powerful medium to engage with more-than-human actors (Romani et al. 2022); however, as R. Bendor (2018) argues there is still a lack of collective ability to imagine rich possibilities for building alternative futures. Wapner and Elver (2016) note the same lack of options and pathways to achieve them. Imagination turns out to be necessary to draw experience and knowledge from the present and the past and to reconstruct this knowledge with a new meaning, thus acquiring a new (Abrahams, 2020; Salis & Frigg, 2020). This characteristic of imagination, also referred to as counterfactual thinking, and strongly linked to what-if questions, introduces an initial gap found both in the discipline of Futures Studies and Design Futures: it is clear the connection between counterfactual thinking and future thinking, and, consequently, the link that exists between pasts, alternative pasts and possible futures, which is a still poorly researched subject by future scholars and practitioners (Bendor et al., 2021). Like the future, also the past may be seen as a plurality and a sort of repository for opportunities and possibilities (Bendor et al., 2021) that can deepen and strengthen the engagement with alternative futures and their potentiality in shaping, in return, new worldviews and mindsets in the present. Within the field of Design Futures, several researchers highlight a second gap that can be defined as an experiential gap: the difficulty in making futures livable and tangible.

To overcome this gap, immersive technologies can represent an important design opportunity, capable of implementing the frameworks, methods and tools related to Design Futures. In this direction, the research introduces the concept of Immersive and Experiential Counterfactuals, as an approach to be integrated to Experiential Futures.

Author keywords

Imagination; Counterfactual thinking; Immersive experience; Nature-human interaction; Alternative pasts.

Introduction

Imagination can underlie the transformations towards alternative futures, which are central in the discourses developed in Future Studies and Design Futures, a Design field that tries to nurture questions, reflections, and dialogues about current and potential trends, issues and opportunities, by projecting possible scenarios in the future and backcasting them in the present to define and design the paths to achieve what is considered to be desirable.

The research introduced in this contribution focuses on the interaction between human beings and nature and the relationship with more-than-human actors, by identifying imagination and immersive experiences as potential media to raise people's awareness and involvement on the topics of interest.

It is interesting to note that imagination, in its complex functioning, contributes both to our ability to think about future and to our capacity to remember past situations: it can be seen as a medium that let us to travel backward and forward in time, of which the latter, as stated above, constitutes one of the fundamental pieces for the Design Futures field. These aspects allow to introduce a first disciplinary gap, which is a key focus of the research being presented: the link that exists between pasts, present and futures is still a poorly researched subject by future and design scholars and practitioners (Bendor et al., 2021). By traveling backwards in time, it is possible to pluralize the past, and then, moving forward to present, the result is a set of alternative and desirable presents that can be projected forward in time, exponentially multiplying the pathways to achieve future goals.

Both futures and (distant) pasts are inherently nearly impossible to actually experience, precisely because of their temporal placement: this aspect represents a second gap, which can be defined experiential, and which led to the definition of the framework of Experiential Futures (Candy & Dunagan, 2017), that, exploiting Design tools, tries to bridge this gap, making futures liveable and tangible. To utterly overcome this issue, immersive technologies can play an important role and opportunity: in this direction, the research introduces the concept of Immersive and Experiential Counterfactuals, as an approach to be integrated by Experiential Futures.

The first part of the paper presents a discussion on imagination; the second deals with the theme of immersive experience and immersive technologies, while the third briefly presents the field of Design Futures, with particular attention to speculative approach, Design Fiction and Experiential Futures. The fourth part is dedicated to the introduction of Immersive and Experiential Counterfactuals. The contribution ends with the conclusions that summarize what was previously stated.

Imagination

From a general perspective, imagination is a speculative state of mind that allows us to consider situations outside of the here and now (Kind, 2017); it is also capable of producing ideas and images without direct sensory stimulus, often by combining fragments of previous sensory experiences into new syntheses (Van Den Bos, 2007). It presents perceptual, recollective, generative, phenomenological, and altered-state-of-mind (Abraham, 2020) facets.

Focusing on the topics of interest, imagination has demonstrated to be able to influence transformations towards sustainable and just futures (Moore & Milkoreit, 2020), but as R. Bendor (2018) argues there is still a lack of collective ability to imagine rich possibilities for building alternative futures. Wapner and Elver (2016) note the same lack of options and pathways to achieve them. Imagination turns out to be necessary to draw experience and knowledge from the present and the past and to reconstruct this knowledge with a new meaning, thus acquiring a new (Abrahams, 2020; Salis & Frigg, 2020). However, it also represents a form of liberation from reality (Kind & Kung, 2016), becoming a resource for the creation of ideas that does not suffer from the constraints given by rationality (Hairston, 2016), and, so, a source for novelty and change (Hawlina et al., 2020).

Interestingly, imagination is strongly situated and influenced by different factors, such as physical, social and ecological realities that shape our memory and experiences (Whyte, 2018).

It can enable transformation-focused agency (Moore, 2017), helping in identifying goals and actions to support the realization of the hypothesized situations (Galafassi et al., 2018). Finally, it needs time and spaces for interaction and collaboration, to let people share ideas and thoughts (Yussof & Gabrys, 2011) about alternative worldviews. There are other agents capable of

influencing individual and collective imagination which clearly contribute to transformations and transitions towards alternative futures: nature (Milkoreit, 2017) and technology (Balsamo, 2011).

The technological imagination can be defined as the mindset which enhances people to think and perform with technology, and to transform the unknown into possibilities (Balsamo, 2011).

Other authors define the concept of imagination in relation with technology: for example, G. Wellner (2018) defines the posthuman imagination, from an examination of the concept of imagination in modern and postmodern philosophy: a faculty that works by layer and it is co-formed by the relationships between human beings and technologies, which empower, mediated and shift; it is distributed and incorporated by humans and technologies.

Through this process of analysis, it has been possible to define imagination as "the recollective (related to experience and memory), generative (related to hypothetical reasoning and counterfactual thinking), immersive (related to action and interaction), and phenomenological process (related to emotions, engagement, and sensemaking), that enables to experience past, present and future situations and generates peculiar conditions to embrace alternative possibilities" (Fig. 1).

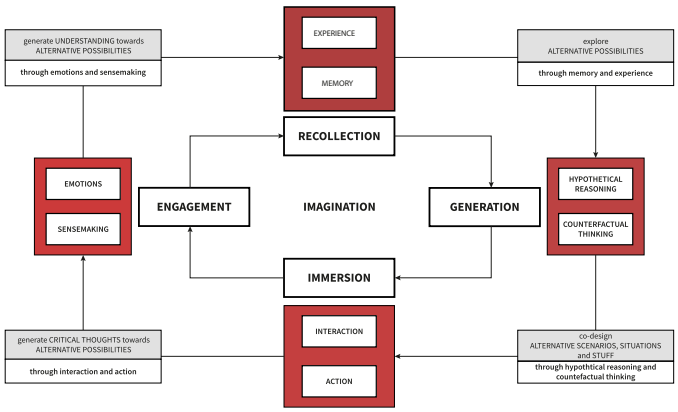

Figure 1. The imaginative framework

Immersive experience

Imagination is strongly connected to and influenced by experience, which represents, in its immersive aspect, the second subject of the research, with particular attention for immersive technologies. Regarding this topic, it has been decided to provide a single taxonomy (Milgram & Kishino, 1994; Skarbez et al., 2021), to define the reality-virtuality continuum: starting from reality, and moving to the right, the degree of virtuality of possible environments and interactions increases, finding Augmented Reality (AR), Augmented Virtuality (AV), Virtual Reality (VR), and what has been defined as Matrix-like Virtual Environment).

To make clear the connections between this topic and the subject of imagination, it is interesting to cite the research by Stapleton and Davies (2013) which is focused on extended and mixed reality technologies and the role that imagination can play in relation to these: it becomes a third reality in the reality-virtuality continuum that benefits from mixed reality as a new medium to be exercised in different fields. The combination of immersive technologies with the activities among different fields creates what is known as immersive experiences (Lucho Lingan et al., 2021). In order to define and achieve an immersive experience, various aspects must be evaluated and taken into consideration: sensorial fidelity (Bowman & MacMahan, 2007), sensorial immersion (Dangxiao et al., 2019), sensorial stimuli (Bowman & MacMahan, 2007; O'Brein & Toms, 2008), "being there" (Bowman & MacMahan, 2007; Shin, 2017), challenges (Ermi & Mäyrä, 2005; O'Brein & Toms, 2008), connection participation (Pine & Gillmour, 1999), involvement (Pine & Gillmour, 1999; Slater & Wilbur, 1997), imagination (Ermi & Mäyrä, 2005; Pine & Gillmour, 1999), presence (Shin, 2017), interaction (Dangxiao et al., 2019), and, finally, engagement (O'Brein & Toms, 2008; Shin, 2017). Starting from this analysis, Lucho Lingan et al. (2021) proposed a framework to map, ideate, design, and produce immersive experience, namely Immersive Cycle, divided into different steps, for which they also developed guidelines (Fig. 2).

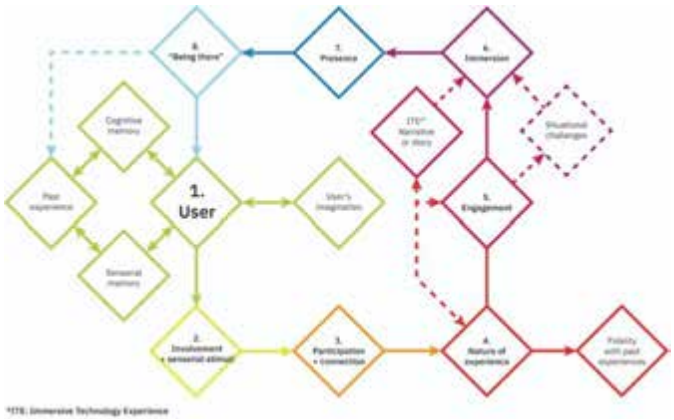

Figure 2. The immersive cycle.
(Credit: Lucho Lingan et al, 2021. Graphic revision by the author)

It is interesting to note the different overlaps between the Immersive Cycle and the framework developed to define Immersive Imagination, especially noticeable in the IC areas of the user (step 1) and in the ones dedicated to engagement (step 5) and immersion (step 6).

Merging the two frameworks may result in an effective starting point for developing a set of guidelines to facilitate the design of alternative situations (Candy, 2010), and, therefore, to let people be able to experience these, utterly facilitating the identification and the immediacy of the user's experience itself, and, thus, the bridging of what Candy (2010) indicated as the experiential gap.

The research recognizes Augmented Reality as the most suitable and promising technology to be applied in the field of interest, for several reasons: its accessibility and ease of use and less complex design compared to other immersive technologies, due to the numerous tools and platforms available. Finally, by working through layers, it allows us to experience multiple alternatives and realities simultaneously, thus enabling the collapse of different timelines onto each other. In ontological terms, this characteristic brings it closer to the field of design futures and to certain intrinsic traits of imagination.

Design Futures

Throughout the last two decades, the intersection between the field of Design and the field of Future Studies has generated various approaches such as Speculative Design (Dunne & Raby, 2013), Design Fiction (Bleecker, 2009) and Experiential Futures (Kelliher & Byrne, 2015). Although they are not structured methodologies, it is possible to identify common strategies in these approaches, taking into consideration what reaction is intended to be triggered in the people who benefit from the designed outputs in some way: at a first level, there is an exploratory strategy, whose aim is to make people aware about the topics of interest and alternatives and possibilities; the second strategy deals with reflection and it aims to provoke or stimulate the creation of critical thinking regarding the topics and the explored alternatives and possibilities; finally, there is a strategy that aims at a real understanding of the topics and alternatives and, therefore, at embracing the possibility for a change. These highlighted strategies informed the design of the framework that will be described in the next section. Speculative Design is an approach that deals with long-term futures, focusing on technologies, social and environmental trends, weak signals and wild cards, to stimulate the critical thinking of projects' users (Kerridge, 2016). Design Fiction can be defined as a design practice that creates provocations about possible futures, narrated through designed and diegetic artefacts (Kirby, 2010). The aim of Design Fiction is to facilitate and foster conversations regarding issues of interest, related to alternative presents and near possible futures (Coulton et al., 2017). Finally, Experiential Futures refers to a set of approaches to make alternative futures present, cognitively and culturally understandable (Candy & Dunagan, 2017) and to produce multisensory, transmedia, and diegetic representations of images of the future (Candy & Kornet, 2019).

Compared to what has been previously stated, the last approach presented turns out to be the most interesting for the research, which aims at integrating the knowledge derived from the study on imagination and immersive experiences, together with those related to alternative pasts (explained in the next part), to further discourses related to alternative and sustainable futures.

Immersive and experiential counterfactuals

Counterfactual thinking, a concept already explored in relation to imagination, is a psychological concept that indicates the human tendency to create and explore alternative situations to events that already occurred, and it is usually based on "what if" questions. One of the most interesting and important characteristics of counterfactual thinking is the analysis of past errors in order to avoid them in the future, revolving around the idea that similar situations may take place again (Epstude & Roese, 2008). Another important aspect is its capacity to facilitate behavioural change (Scholl & Sassenberg, 2014), and to drive collective actions, since they can increase the level of group identification and efficacy (Van Zomeren et al., 2010).

Yet strongly dealing with past experiences and the potential of "what if" questions in exploring alternative situations, it is clear the connection between counterfactual thinking and future thinking, and, consequently, the link that exists between pasts, alternative pasts and possible futures, which is a still poorly researched subject by future scholars and practitioners (Bendor et al., 2021).

Like the future, also the past may be seen as a plurality and a sort of repository for opportunities and possibilities (Bendor et al., 2021) that can deepen and strengthen the engagement with alternative futures and their potentiality in shaping, in return, new worldviews and mindsets in the present. Therefore, past-facing approaches are a tool to extend the imagination and, with it, the realm of possibilities, to reflect on past decisions, events and situations (Bendor et al., 2021). Furthermore, past-facing approaches are extremely useful to learn from the past in order to understand all the paths undertaken throughout the histories of humankind (Voros, 2019), and the influence that every timeline (pasts, presents, futures) have on the others (Poli, 2018). They can also be seen as a temporal device that creates an interesting context for considering anticipation, due to their capability in providing forks in the past from which futures may flow forward (Light, 2021).

The Immersive and Experiential Counterfactuals framework is to be intended as a set of tools and guidelines which, in the first steps, facilitate the process of scenario and alternative situation building, exploiting counterfactual thinking and what if questions, filtered by the above-mentioned strategies, and simulating the typical approach of Experiential Futures; while in the second stage, drawing on the designed scenarios and alternative situations, it proposes guidelines to design immer-

sive experiences, mediated by augmented reality and useful to make more tangible what has been hypothesized (Fig. 3).

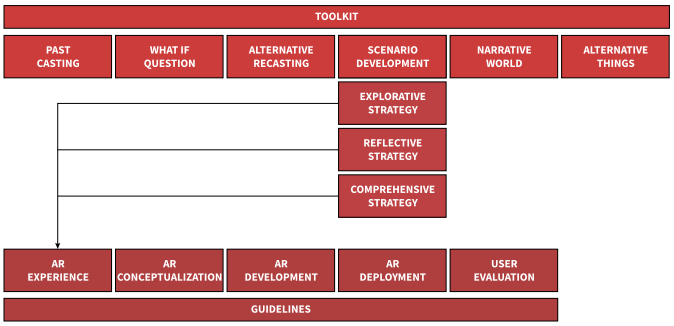

Figure 3. The general view of Immersive and Experiential Counterfactuals framework.

Conclusion

The contribution suggests the definition of a framework entitled Immersive and Experiential Counterfactuals, which is based on counterfactual thinking, an integral part of the imaginative process, and on Augmented Reality technology as a medium to make temporal alternatives and new possible points of view more livable and tangible, capable of building new relationships with the natural world and non-human actors.

The framework, consisting of a series of tools and guidelines, is positioned within the field of Design Futures - and in particular stands as an integration to the framework of Experiential Futures - a design domain that aims at building alternative and future visions concerning issues of interest, often related to the concepts of sustainability and regeneration of more balanced relationships with nature.

The design of this framework attempts to address two gaps inherent in the discipline of interest: a historical gap, which can be further defined as a lack of comprehensive research and literature, within the field of Design Futures, regarding the correspondence between counterfactual thinking and future thinking and, consequently, between the past, alternative pasts and futures scenarios construction; and an experiential gap, conceivable as the challenge in making experiential events and situations that happened far back in time or have not yet happened.

Abstract

According to the 2019 Revision of World Population Prospects, by 2050, people aged 65 and above will account for 25% of the population in Europe and Northern America. The number of people aged 80 or above is estimated to triple to 426 million by this time. Global aging has widespread implications for our society. With the emergence of technological and biomedical advances, people now hold higher expectations for their physical and mental health throughout their longer lifespans. People expect to live not only longer, but also better, calling for improved quality of living and working environments to support later adulthood (Coughlin, 2017). This new longevity presents complex opportunities for participatory and systems-oriented design thinking and processes (Nightingale & Rhodes, 2015; Lee, Zhu et al., 2020). It has become more important than ever for multidisciplinary teams of designers and engineers to contend with older age, including considering the role of immersive empathy and service tools in educating innovators on the importance of global aging and moving them towards collective action in making more inclusive decisions in their work. The purpose of our study is to rebuild and refine a current age empathy tool, AGNES (Age Gain Now Empathy System), through the application of a Human-Centered System Design (HCSD) framework (Lee et al., 2021; Lee, Rudnik et al., 2020).

This age empathy suit was originally developed by a team of social scientists, designers, engineers, and an occupational therapist to simulate the physical constraints associated with certain parts of the body and their possible functions in older age (Lavallière et al., 2017). For example, AGNES empathy suit can mimic common changes we may experience in an aging body such as changes to balance, stride length, joint mobility (e.g., wrist, elbow, shoulder, and cervical spine), muscle loss, tactile sensation, and vision and hearing loss. In this study, we propose a new age suit with modular components and a focus on service design to more accurately simulate various physical and cognitive functions associated with specific body conditions. HCSD consists of design thinking paired with systems engineering approaches; a focus on participatory design will be used to create a new age empathy suit. This case study will explore and prototype a more immersive simulation experience of older age for people and with people. This study intends to not only redesign a new AGNES suit, but also to examine the role of the HCSD framework and participatory design process in contributing to the development of empathy and service tools in pursuit of an age-inclusive society.

Keywords

Human-Centered System Design; AGNES; Service Design; System Design; Design Methodology

Introduction

A world of longevity is already here. By 2050, the U.S. Census Bureau has predicted that people aged 65 and older will outnumber people 18 and younger. Human beings' lifespans have become longer (Golden, 2022), which comes with huge potential business opportunities across industries (e.g., smart home, fintech) to reshape our society. We need to learn how to live meaningfully, not just survive, in the era of a longevity economy (Coughlin, 2017) and to re-frame and solve the complicated, systemic social-technological problems associated with population aging. Therefore, we introduce the AGNES (Age Gain Now Empathy System) age empathy suit, a learning tool to simulate common, chronic physical conditions that are associated with older age, build empathy, and provide education for younger generations, multidisciplinary teams and others to better understand the physical lived experiences of older adults.

AGNES was designed and developed by human factors engineers, health scientists, physical therapists, mechanical and electrical engineers, and product designers at the Massachusetts Institute of Technology's (MIT) AgeLab. In the following study, we explored service-related components embedded in the AGNES suit's design experience by considering four actions: 1. prepare, 2. transport, 3. engage, and 4. maintain, across the journey of service recipients (participants who wear the empathy suit) and service providers (MIT AgeLab

researchers who guide participants in their use of the AGNES suit). This study was driven by the desire to re-design and update the age empathy suit experience through a service innovation lens. A modified service blueprint approach based on the concept of Human-Centered System Design (HCSD) can be used to frame this study's approach to iterating on the immersive empathy-learning experience (Lee, 2022).

Literature Review

To build a more immersive empathy simulation and service-driven experience with AGNES, the suit's development history and existing features and the literature surrounding HCSD is reviewed.

The AGNES (Age Gain Now Empathy System) Suit

Empathy training originated from experiential learning theory (Kolb, 1984), which indicates that people can learn from transformational experiences. AGNES, as a suit, was designed for age and ability empathy training. The suit was designed to simulate physical limitations commonly experienced by older adults including impaired vision and hearing, increased muscle fatigue, postural imbalance, reduced joint range of motion, and limited dexterity (Lavallière et al., 2017). The suit becomes an impactful educational tool through engaging its users in an immediate total body experience of sensory loss through visual, auditory, olfactory, and tactile systems (Lavallière et al., 2017).

In addition to the AGNES suit, there are similar types of simulation tools that have been used similarly in educational contexts (e.g., pregnancy, impaired driving) (Empathy Resources LLC, 2019). Existing academic studies with AGNES have focused on measuring the effectiveness of the suit's specific simulation components: a rock-climbing harness, coverall suit, knee and elbow braces, resistance band straps for arms and legs, helmet, neck brace, yellow glasses, earplugs, shoes modified with foam, gloves and wrist braces (see Figure 1) (Gennis & Godfrey, 2011). In contrast to the functional focus of this work, we explored the design of the AGNES age empathy suit through the lens of HCSD to better understand the whole experience design of the suit from the perspective of its service providers and service recipients.

Our motivation to redesign the AGNES suit lies in considering the suit-wearing experience not only from the suit's participants or users' angles, such as its level of comfort or 'simulative realness', but also thinking through the lens of the suit's service providers, such as the experiences of lab scientists who guide participants through the journey of wearing an AGNES suit. In addition, we applied the service design process to help us gain a more comprehensive and in-depth view of all the service touchpoints across the user journey to better inform us of the potential parts (e.g., different product features or instruction design) of the AGNES suit that we can prototype and refine.

Figure 1. Explanation of an AGNES empathy suit (adapted from Lavallière et al., 2017)

Human-Centered Design, System Thinking and System Engineering

Human-centered design (HCD) is a creative problem-solving process for understanding target users' needs, brainstorming ideas, making physical and digital prototypes, testing selected concepts, and refining final design solutions to address target users' pain points (IDEO, 2022). Tim Brown, Executive Chair of IDEO (an international design consultancy) has said that HCD is a design-thinking approach to innovation (Brown & Katz, 2019). System theory, including system thinking and system engineering (SE), was established after World War II to solve complicated systemic engineering challenges that emerged from military, aeronautics and astronautics industries, and other relevant engineering fields (Leveson & Thomas, 2018). Crawley et al. (2016) has said that system thinking is not a call to think systemically, but rather to view each thing as a system to analyze. It also helps us understand and differentiate between systemic design, system design, and system thinking. De Weck, for example, has encouraged engineers, educators, and scholars facing hypercomplex and large-scale sociotechnical and economic systems to be aware of, consider, and learn system thinking and system engineering to address human needs to build a better world adapting to the requirements of digital and organizational transformation (De Weck, 2022; De Weck et al., 2012).

Human-Centered System Design (HCSD)

Human-Centered System Design (HCSD) is the intersection of HCD and SE to curate a set of problem-solving processes to give designers, engineers, and researchers guidance to understand which of the various selected methodologies to use, when and how (Lee et al., 2020). For example, one experimental study applied the 5E experience model (Sontag, 2018) integrated with Object-Process Method (OPM) from SE to solve campus tour experience design challenges (Lee et al., 2020). In another experimental case study, the researcher used user journeys combined with ConOps (Concept of Operation) to envision a moon-based conceptual space project hosted by NASA (Lee et al., 2020). MIT AgeLab designers have previously used HCSD to redesign smart footwear for an aging population, including initiating early concepts, product prototyping, and experience simulation as applied to innovative business models and platform design (Lee, 2022; Lee et al., 2022). The intention of applying HCSD is to help researchers have enough innovative capabilities to solve problems by zooming in and out while dealing with the various complexities of social-technological challenges. Therefore, in our study, we integrated HCSD with a modified service blueprint to model AGNES' service providers and service users' journeys across four critical experience actions: 1. prepare, 2. transport, 3. engage, and 4. maintain (Figure 2).

Adapted Human-Centered System Design (HCSD) Service Blueprint

A service blueprint is an informative mapping tool to help researchers visualize the participant journey from frontstage (user-facing side) to backstage (operational side) and organ-

ize the relationships between different service touchpoints including people, props, and process (Gibbons, 2017). A service blueprint can also be viewed as an advanced version of the journey map, which extends the scope from individual customers and users to other people in the experience ecosystem: businesses, operations, and other service providers. In this study, based on the structure and definition of HCSD and service blueprint, we modified the five terms: time, participant journey, frontstage, backstage, and support process and applied them to describe the subsystems and components in the journey of preparing, transporting, engaging with, and maintaining an AGNES age empathy suit. Further study can focus on how to improve the modified HCSD service blueprint in a more precise manner considering the dimension of time (e.g., pre, during, and after) and space (e.g., different environmental conditions or user scenarios) within various service touchpoints in the context beyond the four suggested experience actions: prepare, transport, engage and maintain (Figure 2).

Research Methods

The study's research approaches are based on the concept of HCSD, integrating the theory into a modified service blueprint to visualize an AGNES empathy suit experience through the lens of systems and subsystems. This section includes an overview of this approach, including: 1) identifying four actions of using the AGNES suit, and 2) modifying the definitions of five key terms from the service blueprint, which both significantly improve the research quality and its result.

Study Context and Interdisciplinary Research Team

We selected the retail (demo restroom) and home (dorm restroom) environment as two environments often the most relevant to people's lives. Two field studies were conducted in an in-store Kohler demo restroom and in a standard restroom in a three-bedroom apartment. Each study's testing process followed AGNES age empathy suit protocols, and each study was approximately three hours in length. We observed a five-person design team consisting of two product designers, one design strategist, one social worker, and one university lab researcher to see how the team interacted with the AGNES empathy suit to evaluate the users' experience of the restroom.

Four Actions of Using the AGNES Age Empathy Suit

We defined, observed, and documented the participant journey containing the four interconnected and non-linear actions: 1. prepare, 2. transport, 3. engage, 4. maintain (Table 1).

Five Modified Key Terms from Service Blueprint

Based on the structure and definition of the service blueprint, we modified five terms: time, participant journey, frontstage, backstage, and support process to make them relevant to the context of the AGNES age empathy suit (Table 2).

Table 2. Explanations and examples of five terms applied to AGNES.

Term	Modified definition in the context of using the AGNES age empathy suit
Time	Estimated time of each section that participants use an AGNES age empathy suit to interact, experience, and engage with people, activities, or services.
Participant Journey (Action)	Key engaging moments when participants wearing the AGNES age empathy suit interact, including different activities, decision-making, and reactions.
Frontstage	Incidents that happened directly in the view of the participants, including various types of interfaces: interacting with people or technology.
Backstage	Events or processes that operate behind the scenes to maintain and support the AGNES age empathy suit, services, and systems.
Support process	Internal activities that support participants using an AGNES age empathy suit to experience empathy simulation experiences and services.

In addition, we identified the participants' journey based on the two field studies and the four defined actions (Table 1) as a starting point to capture insight, summarize takeaways, and analyze opportunities to contribute to the suit's future re-design by using a modified service blueprint and HCSD.

Research Results

After synthesizing the available data, we propose an AGNES-related service blueprint that connects the service providers and service users' pain points and innovation opportunity areas (Figure 2). Visualizing the whole service of using the AGNES suit can effectively empower us to re-think some of the design aspects. For example, based on the four participants' journeys (actions), we can consider creating a new age suit with more adaptive and flexible modular components that cater to each action/touchpoint and focus on service design around the AGNES suit to more accurately simulate various physical and cognitive functions associated with specific body conditions.

Proposed AGNES Age Empathy Suit Service Blueprint

Based on the five terms in Table 2 and four actions from Table 1, we propose the AGNES empathy suit service blueprint depicted in Figure 2. In the study, the term "modified service

Table 1. Explanations and examples of four actions.

Action	Prepare	Transport	Engage	Maintain
Explanation	Focuses on under-standing partici-pants' learning objectives to better prepare to docu-ment and evaluate the process of expe-riencing the AGNES empathy suit.	Includes a discrete time period and way the research team packs, organ-izes, transports, and unpacks the AGNES empathy suit and its toolkits to the site for a study.	An interactive touch point when participants are using the AGNES empathy suit to experience aging, discussing their observations, and documenting their learnings.	Cleaning and organizing all components of the AGNES empathy suit before and after using it to maintain the principles and instructions of using the suit.

blueprint" means we simplified the original service blueprint structure by emphasizing five key elements for analysis: time, participant journey, frontstage, backstage, and supporting process. Arrows in the diagram indicate the relationships between components and subsystems to clarify their dependencies. We clustered these components and subsystems and mapped them into three lines by different interfaces: 1. interaction: the direct interactions between the participants and the AGNES suits, 2. visibility: what participants can see and experience from the frontstage apart from backstage, which is not visible, and 3. internal interaction: people who do not have direct contact with the participants.

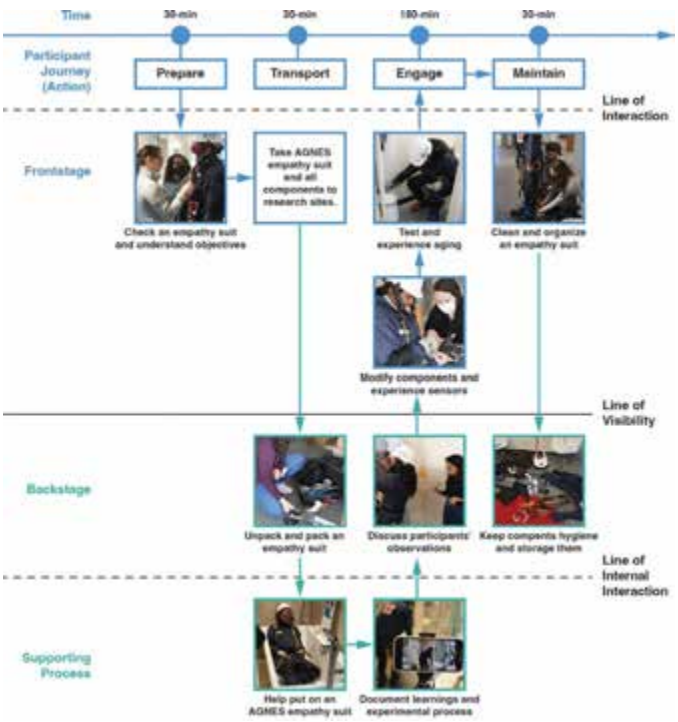

Figure 2. A modified service blueprint to describe AGNES empathy suit and services.

Further Research

Based on the research results and onsite observations, further research is needed to expand the current study's focus to diverse service experiences and service users. Leveraging mixed methodologies with the service providers might also be useful to gain a deeper understanding of these users' experiences with the four actions. Additional research will enable us to better shape a context-driven and human-centered system service model for the next iteration of AGNES.

Applying Materials Science to Make Fabrication Smarter and more Adaptable

The latest applications from materials science can provide more flexibility, adaptability, and accuracy to control, prototype, and simulate multiple scenarios with participants of different ages. For example, Tangible Media Group from the MIT Media Lab applied a reconfigurable fiber technology to control thin fluidic fiber actuators in a closed-loop strain design for movement-based interactions. The invention of artificial muscle-based devices, sensors, and research have demonstrated the potential application of these materials to empathy-learning tool design (Chandler & MIT Media Lab Tangible Media Group, 2021). The advances in materials science and its potential applications can offer us emerging opportunities to innovate the AGNES suit and even further encourage us to envision service strategies and business models to help not only improve the suit design but also promote the importance of the empathy suit globally and integrate it to various industries to make a positive social impact.

Suggested Research Directions

Three further research directions can be proposed from this study: 1. cognitive performance, 2. virtual tools, and 3. service design education. Although the field of cognitive science has already conducted many studies with older adults, we want to further understand how we can accurately simulate older adults' cognitive performance (e.g., stress, declining memory, emotional problems) in AGNES' embodied experience. How do we establish a matrix of measurement to evaluate the effectiveness of such a simulation? Emerging technologies like AR, VR, and IoT wearable smart devices have already transformed our lives. How can we re-think how to leverage AR or VR as useful simulation tools to help make experiences with AGNES even more technology-enabled, immersive and authentic? Ultimately, education has played a critical role in service design, and design generally. As a next step, we consider leveraging and emphasizing empathy-tool experiences and consider the modified design aspects from shifting the view of the AGNES age empathy suit as a *product-design* to an *experience-design* process considering the engaging moments of before, during, and after using the AGNES age empathy suit.

Discussion and Conclusion

The following three key takeaways: 1. product, 2. process, and 3. platform can be understood from this study to illustrate the future of empathy-learning tools and services. Future research approaches should leverage HCSD and systemic service innovation.

Product: An Age Empathy Suit as an Experience-Driven Service

In this study, four actions were applied—prepare, transport, engage, and maintain—across the journey of service providers and service receivers to review the AGNES age empathy suit design. This approach considers not only the physical product design, but also the service around the product that can benefit participants who put on the AGNES age empathy suit (service recipients) and the lab scientists who maintain and use the suit (service providers).

Process: A Modified Service Blueprint Approach Helps Identify Service Touchpoints

The service blueprint approach was modified by integrating the HCSD concept, which gave us more room to play with creative methodologies and system thinking. It has greatly benefited future AGNES empathy suit design since it blurred the boundary between service and product design. The methodology itself can involve more participants in the co-creation and co-development process of the AGNES age empathy suit. A modified service blueprint can help make future iterations of the empathy design process more interactive and engaging.

Platform: Service Innovation Takes Many Aspects to Consider

Re-designing the AGNES empathy suit through the layer of products, services, and experience considers many aspects. The platform can be considered a vehicle to the right conditions to deliver a full age empathy experience for participants. Platform thinking and awareness can equip designers and researchers with comprehensive views of creating immersive empathy product design, service innovation, and user experiences for an increasingly aging population.

Acknowledgments

We appreciate the great support and sponsorship of this research project from the Massachusetts Institute of Technology AgeLab. We also want to express our gratitude to Dr. Lisa D'Ambrosio, Dr. Chaiwoo Lee, Saloni Bedi, Eunah Kim, and Nihara Kurian.

Abstract

This article proposes the basis of an *integral design project management* approach as a strategy to empower transformative processes. It is believed that in a context of humanitarian crisis it is vital and urgent to think of design guided by spirituality, and this as a means, facilitator of transformative processes to favor the recovery, flourishing and continuity of life. The study takes place within the framework of design project management, an area that currently does not sufficiently recognize dimensions of spirituality. The *Design Thinking* design project management approach and the *Theory U* management methodological framework are critically discussed, promoting possibilities to develop prototypes for future testing and implementation. It is proposed that the spiritual dimension should be a fundamental component of a design project management strategy that intends to be integral: multidimensional and holistic, where spirituality is presented in an expanded, defragmented and contemporary vision. The concept of *integral design project management* is presented as a differentiation from the two aforementioned models: it draws on different classical and contemporary outlooks. Theoretical references on wisdom for contemporary complexity, design and spirituality, spirituality for contemporaneity and the *Souths* communities are analysed. These become a source of inspiration for design, as well as the identification of components of spirituality for empirical and theoretical construction. Following a qualitative, deductive and inductive approach, the fieldwork takes place in an online and face-to-face ethnographic and auto-ethnographic format with three *Souths* communities from Portugal and Brazil that have implicit spirituality-driven design project management approaches. As a conclusion, we propose the *Pulse Approach* model, based on the ancestral wisdom philosophies of *quilombola* and Afro-Brazilian communities from Brazil, and of a family farming community that preserves ancestral wisdom philosophy around the linen cycle in Portugal. The proposal is grounded on the observations and experiences in the fieldwork, as well as with special emphasis on Mãe Beata de Yemonjá (Costa, 2000, 2002, 2017), Bispo dos Santos (Santos, 2015, 2018, 2019), Steiner (1962; Lanz, 1983), Buber (1923), Osho (Jain, 2012) e Escobar (2016, 2018), also based on 13 main and common components of spirituality identified in the activities of the three *Souths* communities that collaborate with our study, namely: the present (the here and now), presence, organicity (the circularity, the spin, the circle), interdependence among all that exists, relationality, the feminine, matriarchy, love, affection, care, ethics, intuition and ancestry.

Introduction

This article proposes the basis for an *integral design project management* approach as a strategy to empower transformative processes. These processes aim at the recovery, flourishing and continuity of life. Transformative processes are understood as those that promote diversity; respect; self-development; quality of life; health; education; cultural sustainability; environment preservation; human rights protection; socio-economic transformation. They also encourage territoriality; autonomy; organic, creative and circular wisdoms, economies and communities. The objectives are: 1) contributions to a critical discussion on *Design Thinking* and *Theory U* towards a definition of *integral design project management*; 2) presentation of a theoretical framework based on authors who address themes of design and spirituality as well as spirituality for contemporaneity: sources for empirical and theoretical construction. 3) reflection on the themes of wisdom for contemporary complexity and the *Souths* communities, and legitimisation of communities of this nature as learning references; 4) identification of main and common spirituality components through the work with three analysed *Souths* communities; 5) the proposal of *Pulse Approach*, based on ancestral wisdom philosophies of *Souths* communities from Portugal and Brazil.

The focus of the research is design project management, an area currently lacking in recognising dimensions of spirituality. We propose that a spiritual dimension should be a fundamental component of design project management strategy that intends to be integral. This is regarded as a research gap as, to date, the present study has yet to identify the existence of *integral design project management* approaches with ref-

erences to *Souths* communities from Portugal, Brazil and/or the Community of Portuguese Language Countries. We believe that in contexts of humanitarian crises, it is essential to consider forms of design guided by spirituality. To promote such forms and to remedy the aforementioned theoretical gap, the *Pulse Approach* is hereby proposed: it is based on the ancestral wisdom philosophies of *quilombola* (Conaq, n.d.) and Afro-Brazilian communities from Brazil, (Batiste, 1961; Santos, 1988) and of family farming community that preserves the ancestral wisdom of the linen cycle in Portugal (Oliveira, et al, 1991).

Theoretical foundations

Humanitarian collapse and wisdom for contemporary complexity

Over the past 40 years, we have observed a dominance of Western, Anglo and Eurocentric values and practices by force of capitalist, neoliberal, industrial, colonialist, Christian, patriarchal, racist, massified and globalized thoughts (Gutierrez, 2015b, 2021; Santos, 2009; Santos, 2015). These have promoted, and continue to promote, environmental devastation, climate change, failures of economic development together with extreme social inequality, conflicts, exclusions, wars, and migrations (Latour, 2020). As a result, we find the 21st century is largely characterised by broad humanitarian crises that may more accurately be described as a collapse, as they no longer seem transitional or reversible.

As a framework for the above scenario, we closely follow the writings of the following authors:

- **Ailton Krenak** – who highlights the importance of realizing that *"we are going through a transformation (...) our collective dream of the world and the insertion of humanity in the biosphere will have to happen in a different way (...) (Krenak, 2020: 44)"*. Krenak refers to the praxis of indigenous peoples, the use of our body as the main tool for observing the earth, the sky, to bring out the feeling that we are not disconnected from other beings (Krenak, 2020: 45), the importance of dreams as *"(...) a place for the transmission of affections (...) (Krenak, 2020: 37)"*;
- **Antônio Bispo dos Santos** – who signals the importance of being inspired by the organic and circular wisdoms, looks and attitudes of the *quilombolas* and native peoples from Brazil that refer to being, to relationships, to community, to see the other and to the relationship with the cosmos. These are rooted in the understanding and implementation of beginnings, means and new beginnings based on the wisdom of their ancestors (Santos, 2015, 2018, 2019);
- **Bruno Latour** – who suggests *a repolitisation of the soil*, it is necessary *"coming down to Earth"* (Latour, 2020; Costa, 2020 In: Latour, 2020: 154, 155);
- **Donna Haraway** – who affirms our duty to build collaborations as *"humus", "to live well as terrestrial beings", "to make muti-species relations"*, in the here and now, without projecting towards the future, while understanding that the present moment enables our responses to the now in turbulent times (Haraway, 2016; Haraway, 2020 In: Torres, 2020);
- **Anna Lovenhaup Tsing** – who shows us that through disturbance we find the beginning of action, the possibility of transformative encounters. Tsing presents the now as an opportunity *"to realize the precariousness and in the process, looking around, without looking ahead"*, also in collaboration and coordination with other terrestrial beings, we provide *"the possible life"* (Tsing, 2022: 227, 229, 233, 234; Tsing, 2021 In: Gonçalves Brito, 2021).

Design project management

Within the scope of design project management for sustainability, *Design Thinking* (Brown, 2010) is often used to facilitate the creation of creative and collaborative projects that can promote social innovation and sustainability. In the area of management, the closest reference oriented by spirituality is known as *Theory U* (Scharmer, 2009). Its basic concept is *presencing*, merging the words presence and sensing: it refers to the learning of collectivity and intuition to enhance new visions and intentions.

Both of the above promote the development of prototypes to be tested and implemented in the future. This study performs a critical reading on Brown and Scharmer, as *Design Thinking* is a design project management reference that uses collaborative, collective, social, human, and empathy aspects, but does not acknowledge extended and contemporary dimensions of spirituality in its approach. Inversely, *Theory U* is a *head (think) – heart (sense) – hands (act)* management methodology, inspired by anthroposophy spiritual science founded on its *presencing* base concept, and is geared towards implementing future projects. As a dynamic and differentiation from these two references, we propose the concept of *integral design project management*, and define it as a design project management with an integral vision, i.e. multidimensional and holistic, recognizing spirituality in an expanded, defragmented and contemporary perception. Its foundation on the philosophies of ancestral wisdom of the *Souths* communities (in this study, from Portugal and Brazil) facilitates ideas, approaches, processes, systems and projects in the present as well as in organic and circular format.

Design, Spirituality and Contemporaneity

The subject of design and spirituality was analysed from the perspectives of Papanek (1995), Schumacher (1974), Walker (2011, 2020), Margolin (2014), and Escobar (2018). In this analysis, we identified 66 components of spirituality, and their concepts were interpreted (Lopes, Franqueira, Alvelos, & Parente, 2021). Further analysis was subsequently performed on Bispo dos Santos (2015, 2018, 2019) and Krenak (2019, 2020). Furthermore, key contributions by Mãe Beata de Yemonjá (Costa, 2000, 2002, 2017), Steiner (1962), Buber (1923), Kumar (2017), Osho (Jain, 2012), Lovelock (2014, 2020) and Margulis (2014) are summarised below. We identify three more components of spirituality in their thoughts: organicity (the circularity, the spin, the circle), matriarchy and the feminine.

- **Beatriz Moreira Costa (Mãe Beata de Yemonjá)** – Spirituality lived in her life through myths, dreams, poetry, imagination, intuition, wisdom, and connections with nature and ancestry, grounded in *Candomblé* (Batiste, 1961; Santos, 1988), in the matriarchal and feminine care that promotes affection and love with ourselves, our fellow human beings, and communi-

ty action. Costa nurtures the concepts of plurality in worlds, environment, and cultures, promoting human rights, health, education, and the fight against sexism and racism (Costa, 2000, 2002, 2017; Silva, 2008; Costa, Ilê Axé Omiojuaro, n.d.; Costa, Criola, n.d.).

- **Rudolf Steiner** – Spirituality based on the trinity *Think, Sense, Act/Action*, corresponding to the triads *Head, Heart, Hands; Culture, Legal/Political, Economic; and Freedom, Equality, Fraternity*; it advocates the preservation of the environment, the protection of human rights, socio-economic transformation, and promotion of education for freedom (Carlgren & Kilingborg, 2006; Lanz, 1983; Steiner, 2008).
- **Martin Mordechai Buber** - Spirituality is witnessed in life experience, in community, in the openness to listening and dialogue through relationships, in experiencing and caring for the present other, and in encounters devoid of prejudice (Bartholo Jr., 2001, 1994: 7; Buber, 2003).
- **Satish Kumar** - Spirituality based on the promotion of social justice, local and community life, non-violence, wellbeing, kindness, relationships with nature, poetry and art, preservation of the environment, and care for social relationships (Kumar, 2017).
- **Rajneesh Chandra Mohan Jain (Osho)** – Spirituality is based on life experience, connected to intuition/deep consciousness, dreams, wisdom, myths, love and imagination. It uses the right hemisphere of the brain (the feminine side), which speaks through stories, anecdotes and parables, devoid of theories and doctrines. It is connected with the here and now, with the poetics of life, with the fluidity of thinking beyond logic (Jain, 2012).
- **James Ephraim Lovelock and Lynn Margulis** – Spirituality translated through the experience of life, of the human being in interaction with Earth as a living organism, on interrelations and interdependence between everything that exists, and the changing dynamics of the natural world (Lovelock, 2014, 2020; Margulis, 2014; Kumar, 2017: 23).

From this work we identified 69 components of spirituality; these were employed as research indicators to guide, interpret and prove the field work observations. We have named them as *Components of Spirituality to Safeguard Life*, and propose a map of connections and inter-dependencies (Table 1).

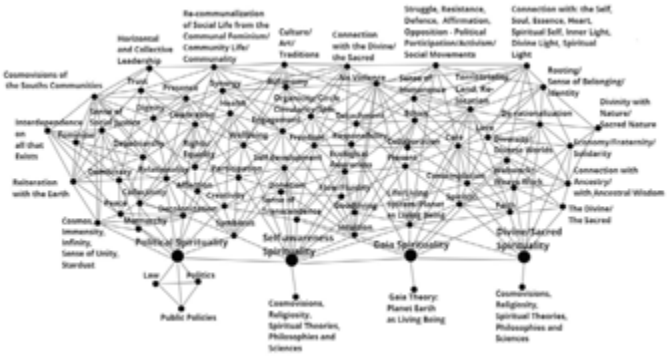

Table 1. Components of spirituality to safeguard life, created by the authors, 2022.

The Souths

The focus of the research has been on learning from the *Souths*, as presented by Gutierrez (2015b; 2021). The term *"South"*, or *"the Souths"*, does not refer exclusively to the geographic south, includes *"the silenced"*, the peripherals: people, communities and groups that have been *"excluded, denied, ignored"*, considered *"defective, backward, underdeveloped, and in need of progress"*, due to a dominance of Western, Anglo-Eurocentric values and practices. Gutierrez expounds on the concept of designing the world from the vision and practices of the different worlds that permeate these *Souths*, equally proposed by Escobar's *"pluriverse"* (2018). Gutierrez states that *"the South, the Souths, the Others* and *by Other NameS* (DESSOBONS - DEsigns of the South, of the Souths, Others, By Other NameS)" should be considered as central references of wisdom, knowledge and worldview in a concept that involves collective, communal, ethical, ecological, human, social, cultural and justice values and praxes. These are considered useful as a way out of totalitarianism, unsustainability, uniformity and massification of the industry and development projects proposed by the Western Anglo Eurocentric capitalist world (Gutierrez, 2015b; 2021). We observe that, inspired by Freire's libertarian philosophy and pedagogy (1987, 1992), Gutiérrez, Escobar, Bonsiepe and Santos question western domination along with the hegemony of the North, while signaling the need for the decolonisation of knowledge - focusing on looking, listening and learning from the voices and wisdoms of the *Souths* that experience social practices (Gutierrez, 2015b, 2021; Escobar, 2018; Bonsiepe, 1985, 2011, 2012; Santos, 2009; Santos and Meneses, 2009). We consider the *Souths* as learning references in that they convey ancestrality, wisdom and knowledge towards recovery and flourishment and continuity of life. Within this scope, we posit that design has the possibility of finding informative clues to promote transformative processes.

Methodology

Fieldwork has taken place in online and in-person, ethnographic and autoethnographic formats, through participatory experience. The qualitative methodology of inductive and deductive nature implied a proximity to the studied communities; moreover, complex data collection was performed among direct and participant observations, along with conversations, and exploratory and semi-structured interviews. We identified *Souths* communities from Portugal and Brazil that reveal implicit spirituality-driven design management approaches, as selection criteria for the learning objects of our research. They are:

i) Association of Women Farmers of Castelões (Associação das Mulheres Agricultoras de Castelões - AMA Castelões, Tondela, Portugal);
ii) Quilombola Association of Conceição das Crioulas (Associação Quilombola de Conceição das Crioulas – AQCC, Salgueiro, Pernambuco, Brasil), and
iii) CRIOLA NGO (CRIOLA, Rio de Janeiro, Brasil).

An added factor in the choice of communities in Brazil was proximity based on collaborative work previously carried out between the years 2002-2004 and 2006-2008. The community in Portugal was identified contextually, in a leather craft workshop held in the village of Castelões in September 2020.

They are comparable due to the presence of a *Souths*, ontology, as presented above. A brief presentation of the three learning cases and associated methodologies follows bellow.

Learning cases and the fieldwork development process

- **AMA Castelões** is a Portuguese association formed by a group of women artisans over 65 years old, who for more than 20 years has ensured the viability of the linen cycle tradition in the region of Castelões, Tondela, Portugal. They meet weekly to produce linen fabric pieces with embroidery and crochet, perpetuating ancestral wisdom and knowledge contained in local linen cycles (AMA Castelões, n.d.). Field work began on 29 September 2020, and ended on 8 March 2021: it consisted of 21 face-to-face meetings (approximately 3 hours and 30 minutes each), totalling 69 hours and 30 minutes of participatory experience; 52 pages of field diary; 795 photographs; 221 videos, a sum of 3 hours and 11 minutes of recorded images and speeches; and 40 audio recordings, a total to 14 hours and 23 minutes of recorded audio material.
- **AQQC** is a Brazilian association created in 2001 to promote the development of the community of Conceição das Crioulas along with its ethnic and cultural identity, as well as the fight for the *quilombola* cause (AQCC, n.d.). Field work began on 30 May 2020 and ended on 15 July 2022. 12 meetings were held: 3 face-to-face meetings with the community, 1 via WhatsApp and 8 online via Google Meet: 56 hours, 12 minutes and 15 seconds of participatory experience; 18 pages of field diary; 204 photos; 36 videos, totalling 1 hour, 11 minutes and 10 seconds of recorded images and speeches; and 16 audio recordings totalling of 5 hours and 57 minutes of recorded audio material.
- **CRIOLA** is a Brazilian civic organization created in 1992 in the defense and promotion of Black Women's rights within social values of justice, equity and solidarity. Its mission is to empower black women in face of racism, sexism, lesbophobia and transphobia, acting as agents of transformation in public spaces (Criola, n.d.). Field work began on 26 April 2020 and ended on 22 September 2022. We held 7 meetings, 6 online via Google Meet, 1 face-to-face in Rio de Janeiro: 9 hours, 23 minutes and 30 seconds of participatory experience; 8 pages of field diary; 46 photos; and 5 audio recordings, a total of 6 hours, 23 minutes and 30 seconds of recorded audio material.

Experience through direct and participant observations, together with conversations, exploratory and semi-structured interviews, provided us with the awareness of implicit, potential spirituality-driven design project management components in the activities of studies communities. The outcome is a set of 13 main and common components of spirituality: present (the here and now), presence, organicity (the circularity, the spin, the circle), interdependence on all that exists, relationality, the feminine, matriarchy, love, affection, care, ethics, intuition and ancestry.

We came to realise that the communities' representatives, teams and artisans plan, create and implement their projects in synchrony with the needs that are being experienced in the present, as well as in an organic and circular format. Project planning, creation and implementation are anchored in ancestral wisdom philosophies of the *quilombola* and traditional African matrix peoples, as well as women linen artisans. These are empirically experienced in lived life, and rooted in the aforementioned *quilombolas* (Santos, 2015, 2018, 2019), *Candomblé* (Batiste, 1961; Santos, 1988) and Portuguese linen cycle traditions (Oliveira, et al., 1991). Thus tangible actions become transformative towards cultural sustainability, environmental preservation, health, socio-economic transformation, territoriality, as well as creative, circular and organic economies and communities. Especially in the scope of the CRIOLA and the AQCC, we also observed actions towards protection of human rights and promotion of education, citizenship, diversity, respect and good living of the black people.

Preliminary conclusions and grounded theory developments

Based on the aforementioned 13 spirituality components, empirically grounded on developed field work and literature review, we posit the *Pulse Approach*. As an ongoing formulation, the *Pulse Approach* is currently founded on the ancestral wisdom philosophies of the *Souths* communities from Portugal and Brazil. We present it as a head (think) - heart (sense) - hands (act) *integral design project management* approach towards the empowerment of transformative processes. It may facilitate strategic planning, project management, group and team development, self-development, and complement other design project management and/or management tools for the above purposes.

The *Pulse Approach* operates as follows: with a relaxed and open mind set, sensory receptivity and active processes; in the here and now; in authentic presence; in connection with relationality (with humans, non-humans, forces of nature, the cosmos); in interdependence with all that exists (terrestrial beings and life energies); in organic and circular forms; sensing intensely at the core: matriarchal and the feminine love,

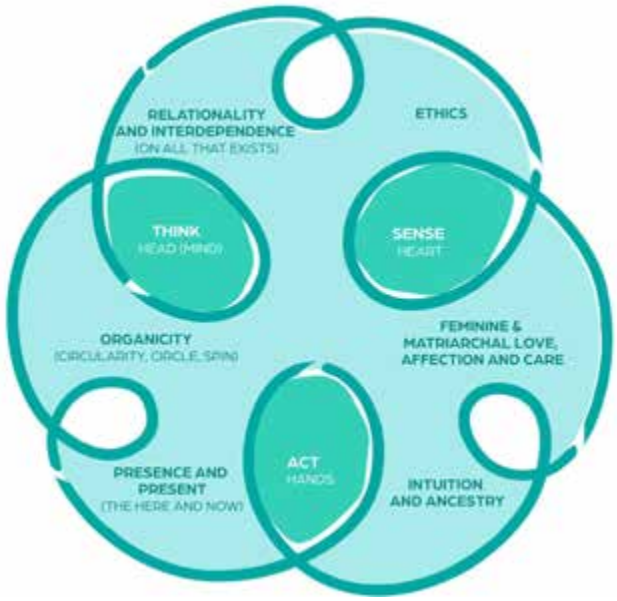

Table 2. Pulse Approach, created by the authors, 2022.

affection and care, ethics rooted in the intuition and ancestry (intelligence, consciousness, wisdom, deep confidence).

We propose the application of the *Pulse Approach* at this developmental stage in precariousness and turbulent times. Further research will be performed regarding its implementation. In addition, elaborated design will include the knowledge acquired in two sensory experiences that have meanwhile been developed with Conceição das Crioulas and Castelões.

Research on design sketch from different disciplines: overview and directions

Zhenyu Ma

Graduate School of Creative Thinking for Social Innovation, Musashino Art University, Japan

dcct21005bs@ct.musabi.ac.jp

Abstract

The sketch plays an essential role in different disciplines and industries, not only to visualize the ideas of designers and professionals but also to promote innovation and increase opportunities for reflection. The sketch is also a widely researched approach or tool that stimulates the generation of design thinking using representation, which is different from rational thinking and can facilitate effective communication between different disciplines. However, with the fragmentation of the traditional design disciplines, the boundaries of the traditional design disciplines have gradually become blurred.

In this context, the gaps and conflicts that have always existed in the design disciplines have been exacerbated, such as the huge gap between the traditional educational model with clear disciplinary boundaries in the design disciplines and the rapidly evolving design market, and the increasing conflict between the designers trained in this traditional educational model and the design talent required by the current market. And these conflicts characterize the current state of development of design disciplines, including conflicts between disciplines, within disciplines, and between design tools. Therefore, to improve the situation where these gaps and conflicts are intensifying, this study takes the sketch, a design representation method used in almost all design disciplines, as the object of study.

This study conducts a literature review of taxonomies of sketch in traditional design disciplines and design tools associated with sketch in contemporary design disciplines. Traditional and contemporary design are then categorized according to several empirical classification criteria proposed in this study, followed by a qualitative analysis around the use of sketch in different design disciplines in terms of stage, form, complexity of processing, fidelity, and other parameters. Consequently, differences in the habits, variations, and role of sketch in the context of traditional and contemporary design disciplines were identified.

The study provides recommendations for future models of design education and specific questions about the skills required by future designers, suggesting ways to mitigate and improve existing conflicts between design disciplines and suggesting possible new directions for future research to connect the different design disciplines.

Author keywords

Design sketch, multidisciplinary, traditional design, contemporary design, literature review.

Introduction

In a context where the boundaries of what was once recognized as discrete design disciplines, such as architecture, product, graphics, and fashion design, have been and continue to dissolve (Rodgers, 2008), education and practice in the design disciplines have been experimenting with [the cultivation of knowledge and collaboration across disciplines] (Irizarry, et al., 2016; Elżbieta, 2016), and the split between different disciplines in the field of design has led to a shift in creative practice from being 'discipline based' to 'issue or project based' (Heppell, 2006). We propose that this shift is related to the shift between traditional and contemporary design disciplines in terms of designers, design objects, constantly developing design environments, etc.

We present that traditional academic research-oriented education programs can no longer meet the need for interdisciplinary practical talents in contemporary design disciplines. As educators are asked to be more innovative in today's commercial environment, it becomes critical to weigh in on design thinking (Dym, et al., 2005; Mabogunje et al., 2020), design doing (Sanders and Stappers, 2013), and trans-disciplinary domains (Leavy,2016; Fawcett, 2013). With social development and economic growth, the world continues to promote innovative design, and interdisciplinary disciplines are becoming popular (Norman, 2004).

In the above context, we argue that the field of design research and its investigation methods continue to change and extend beyond the boundaries of the traditional design discipline while also noting the uneven development of the various parts within the design discipline. Therefore, this study argues that several important gaps and conflicts currently characterize the current state of development of the design discipline: (1) conflicts between disciplines (macro level: ambiguous disciplinary boundaries); (2) conflicts within disciplines (meso level: education and business environment); and (3) conflicts between specific tools (micro level: changes in the skills required for design). Therefore, to clarify the above-mentioned gaps and conflicts, this study confines itself to the micro-level of (3), i.e., the gap between the professional skills required by traditional design tools and contemporary design tools as boundary objects. By conducting a multifaceted comparative analysis of sketch-related tools in several typical design disciplines, we expect to contribute to identifying (1) and (2) from the side. Design sketch was chosen for this study because it plays an important role as a method specific to the design discipline, not only in design education and design practice

but also permeates almost all design disciplines. As current research on sketch in the design disciplines is discrete, and contributions are always from different disciplines, research contributions on sketch are mostly scattered in cognition (Tovey, 1989; Schön and Wiggins, 1992), creativity (Hua, 2019; Goldschmidt and Smolkov, 2006), reflective activity (Schön and Wiggins, 1992; Bilda and Demirkan, 2003; Wu, et al., 2012), visual thinking and visual communication (Goldschmidt,1991; Goldschmidt, 1994; Vistisen,2015), human-computer interaction (Buxton, 2007), and digital technology.

For understanding and analysis, we propose to divide the design disciplines into two categories - traditional and contemporary - according to certain criteria, and to analyze the role and use of the sketch in the different design disciplines and design tools from this new perspective. Through this new perspective, the role and use of sketch in the different categories of design disciplines and design tools are analyzed. The review and analysis suggest more specific conflicts and gaps in the design disciplines and a series of issues that need further research. Finally, it is expected that the results of this study will contribute, directly or indirectly, to the resolution of the wider conflicts of (1) and (2).

This paper is structured as follows.

Firstly, the history of the design disciplines is briefly reviewed, and the disciplines are broadly divided into two categories based on the empirical classification criteria provided in this study, and their relationships and trends are discussed.

Secondly, an overview of the taxonomy and related tools for sketch in traditional and contemporary design disciplines based on the same set of parametric criteria is discussed.

Finally, through a qualitative analysis of the use and trends of the sketch in the context of the same set of parameters in both traditional and modern design disciplines, some results are derived and summarized in terms of the respective developmental strengths of the two classifications, as well as attributes and experiences worthy of mutual reference between them.

The transition between Design principles

The disciplines of design and design research are rapidly transforming. The definition of design disciplines with a history is constantly changing and expanding in the scope of application. For example, industrial design has traditionally been seen as an applied art and science that seeks to improve a product's aesthetics, ergonomics, functionality, and usability (Noblet, 1993). Moody and Stanley defined industrial design in 1984: 'Industrial design seeks to relate hardware to the dimensions, instinctive responses and emotional needs of the user, where these are relevant requirements' (cited in Design Council of India, 2016). However, this definition seems to limit the potential impact and influence of the creative skills and methods taught to designers.

A moderately expanded version comes from the Industrial Design Society of America (IDSA, 2013), which currently defines industrial design as 'the professional service of creating products and systems that optimize function, value, and appearance for the mutual benefit of users and manufacturers'. This definition encompasses an increasing inclusion of industrial design and shows the expanding boundaries of the traditional design disciplines and the growing importance of multi-scientific and interdisciplinary design. The work of design firms and designers such as Ronan and Erwan Bouroullec (2003) Marti Guixe (2002) and IDEO (2005) now routinely transcends historical disciplinary frameworks such as interior design, fine art, product design and graphic design. In particular, the boundaries between product and service design (SD) are becoming increasingly blurred. Furthermore, because of the increasing relationship between IT engineering and design disciplines, there is a certain overlap and mutual inclusion between the education and practice of Interaction Design (IxD), UX Design (UXD), and SD.

In summary, it can be observed that the relationships and boundaries between the design disciplines of different eras are still blurred. Therefore, this study argues that before summarizing and analyzing sketch-related methods in different design disciplines, it is necessary to make a general categorization of the changing design disciplines. We refer to those disciplines that have clear boundaries between them as 'traditional design disciplines' and those that are inherently intersectional and inclusive as "contemporary design disciplines". A classification principle with several parameters is given for this (Table 1).

Table 1. Classification principle between traditional and contemporary disciplines.

Aspect	Traditional	Contemporary
Historical	Relatively long history	Relatively short history
Educational	The theory is quite well established a full range of courses at the univer-sity	Theoretical research is evolving Gradual integration into curricu-lum
Practical	Examples of practice are abundant	Fewer actual cases but increasing
Boundary	Once clear boundaries between disciplines are beginning to blur	The discipline itself was created with a multidisciplinary background

As the problems that design can address become increasingly complex (Latour, 2008), design research shifts towards a user-centered approach to problem-solving. The emergence of integrated design based on a wide range of disciplines has prompted discussion and exploration among participants. Collaboration and communication between various fields and professions have become more frequent and complex.

In addition, interdisciplinary collaboration has been emphasized in traditional design disciplines. For example, Pierre (2003) argues that integrating interdisciplinarity into the industrial design process can solve the problem of establishing sustainable design and consumerism. And according to Doerry, et al. (2001), in the 21st century, modern engineering design is approached as an interdisciplinary endeavor, which requires each engineer to work as part of a team that includes a range of specialists. We consider that the contemporary design discipline's ongoing value on multidisciplinary, interdisciplinary, and even trans-disciplinary collaboration is a major reason for this trend. There are also overlapping fields between their disciplines, such as theory and design process, as is recognized by the overlap between fields such as UX and service design (Forlizzi, 2010). Furthermore, excellence in experience creation and customer value in contemporary design projects requires 'design team members' to bring in expertise from their disciplines, such as service management, UX design, SD, and technology, among others (Khambete, 2011). Don Norman (2016) is critical of traditional design courses when discussing design education because they focus on craft skills rather than requiring a broader systems view, i.e., involving social or scientific competencies.

Parameter	Definition	Detailed Explanation For Criteria				
Dimension	The dimensions used in sketch, which are classified according to Gillian Smith	1D	2D	3D	4D	
		thoughts, words	paper sketches, images, journey maps, scenarios	modeling, rapid prototypes, mock-ups, object theater	enactments, video, animation	
Complexity	The complexity of handling sketch in the design process	Level 1	Level 2	Level 3	Level 4	Level 5
		just collect	just select and print/ create	devise for ease of understanding	categorize and prioritize what you create	identify relationships between selected outputs
Fidelity	This parameter only considers the extent to which the sketch reflects the design of the final product, not the proximity to the final design	Design	Low	Middle	High	
		Traditional	ideal to quickly solidify ideas, to estimate effort on concepts and to test navigation	ideal to show a high functional version of the concept, while still quick to design and cheap to discard	ideal to get feedback on visuals, estimate effort on interactions (e.g., animations) and to help as guide for implementation	
		Contemporary	simple in form and function but can be represented to some tent by imagination	simple in form, but reasonably represents the form and structure of the final deliverable	except for function, the form or structure may be fairly close to the final deliverable	

Figure 1. Certain criterias for dimension, complexity, and fidelity of sketch proposed by this study.

The direction of contemporary design education and research has shifted from artifact-based design and production to integrating different knowledge and disciplines at each stage. Thus, both traditional and contemporary design disciplines, from the focus on the cultivation of multidisciplinary and interdisciplinary models in design education and the increase in inter- and trans-disciplinary design projects in design practice, show a consistent trend towards the dissolution of boundaries between design disciplines.

Sketch as a universal method in design disciplines

Sketch, one of the most important conceptual design tools, is the most widely used in design practice and is the design representation most often associated with designer activity (Bar- Eli, 2013; Goel, 1995). It is generally accepted that design representation through sketch is fundamental to conceptual design activity (Cross, 1990; Lawson, 2006). Most designers have adopted freehand sketching as a valuable part of the design process (Lawson, 1994; Pipes, 1990). This study aims to use the role and use of sketch in different design disciplines as an entry point to further observe the similarities and differences between design disciplines born in different eras, as well as the design patterns and directions worth learning from each other from an unusual, microscopic perspective.

To fully understand the purpose and changing history of the use of sketches in the design discipline, we begin by reviewing and analyzing the sketch taxonomy that has evolved from the traditional design disciplines. This is done by identifying the different sketch taxonomies in terms of design phases and design purposes, including the role and use scenarios in the traditional design disciplines. In 3.2 we present an overview and analysis of design tools in contemporary design disciplines that use the sketch method according to the same criteria as in 3.1.

Domain	Authors	Sektch taxonomy	Investigation phase	Ideation phase	Prototyping Phase	Dimension	Complexity	Fidelity

		Persuasive Sketch			○	1, 2d	4	Middle

Figure 2. Review and analysis of sketch taxonomies in traditional design disciplines.

Sketch used in traditional design disciplines

The design sketch originated in the academic discourse of architecture and industrial design (Schön, 1992). As different applications of the sketch taxonomy have been proposed and discussed in the traditional design disciplines, it is considered necessary to compare the different taxonomies to understand the role and use of sketch in the traditional design disciplines. Therefore, this chapter begins with a review of the role and use of sketch at different stages of the three traditional design disciplines - architectural, engineering, and industrial design.

In this study we have categorized the design process into 3 general phases. The RESEARCH PHASE includes investigation and problem definition, the IDEATION PHASE includes ideation and developmental design, and the PROTOTYPING PHASE includes detailed design and prototyping. We then summarized the phases in which each sketch taxonomy would work and classified them according to certain criteria for dimension, complexity, and fidelity (see Figure 1 for criteria).

For each of the three traditional design disciplines that are the subject of this study, we selected the most representative sketch taxonomies as the object of analysis. Two of these taxonomies are from the field of architecture (Fraser & Henmi, 1994; Lawson, 2012). There are also two taxonomies from the field of engineering design, one of which was first proposed by Ferguson (1994) to classify sketches according to their function in the design process, while Lugt (2005) builds on this by adding " storing sketch ". Another taxonomy was proposed by Pei (2009), based on the needs and intentions of designers when sketching. Finally, there are taxonomies from industrial design, one of which is Tovey (1989) classified sketches according to their functions and corresponding forms, while another, like Pei's, is based on Olofsson & Sjolen (2005) classified sketches according to the designer's needs or intentions when sketching.

Sketch adopted in contemporary design disciplines

As the contemporary design discipline represented in this study, UXD is about shaping the experience of using a product. Much of this experience involves some interaction between the user and the product. Although these contemporary design disciplines all have different origins, there is a mutual inclusion between their respective fields. Given that IxD is generally considered to be contained within UXD and UXD within SD, we follow this hierarchical classification to review and analyze the design tools that include sketch. The analysis results are then compared with the results of the traditional design sketch.

Here, this study follows Buxton's (2007) suggestion that sketch is not just an archetypal way of using paper and pen to support what Kolko (2009) and Brown (2009) and Martin (2009) call the 'reductive feeling' of design but can be used as a much broader way of thinking. As such, this study decided to adopt the approach proposed by Vistisen (2015) from the perspective of the spatial and temporal dimensions involved in the sketch, using Gillian Smith's (Smith in Moggridge 2006) classification of dimensions in IxD, between 1D-4D, as a suggestion for what designers can call 'sketching' of dimensions (1D: thoughts, words; 2D: paper sketches, images, scenarios; 3D: modelling, rapid prototypes, object theatre; 4D: enactments, videos, animations). In addition, UX designers usually create content such as wireframes, personas, and prototypes. Service designers end up creating service blueprints, customer journey maps and service ecosystem maps, but many of the tools they use are the same.

Considering that the definitions and descriptions of these design tools involving sketch vary somewhat from publication to publication, for the sake of consistency we will focus on the following two highly recognized publications as references for the analysis of sketch-related tools in contemporary design: a guide to service design practices by Marc Stickdorn et al. -- "This Is Service Design Doing: Applying Service Design Thinking in the Real World"; and the workbook by Buxton et al. – "Sketching User Experiences: Getting the Design Right and the Right

Domain	Authors	Design Tool	Investigation Phase	Ideation Phase	Prototyping Phase	Dimension	Complexity	Fidelity
Contem--porary Design (e.g., IxD, UXD, SD)	Research data	Research wall	○			All	3	Low

Figure 3. Review and analysis of sketch-related design tools in contemporary design disciplines.

Design", which introduces how sketching can be considered as a concept and used flexibly in UX design.

The result of the analysis between traditional and contemporary design

This chapter compared and discussed the results of the analysis in Figures 2 and 3. Relatively deep insights are gained into the transformation and differences in the roles and functions of the sketch in different design disciplines, and a contribution is made to improving and resolving possible gaps and conflicts in all design disciplines.

Firstly, no clear trends or differences were observed in the use of sketch in the different design phases. This may be due to the fact that designers have developed a sufficient number and variety of sketch taxonomies and sketch-related tools to suit the different design scenarios and phases.

However, there are some patterns and according to Smith's classification of dimensions in IxD, most sketch dimensions in the different taxonomies and design tools are concentrated in 2D and 1D. Traditional and contemporary design disciplines are similar in terms of dimensions. However, with the development of various smart devices and design software, the use of sketches in the ideation and prototyping phases of contemporary design has expanded to include 3D and 4D.

Secondly, in terms of sketch complexity, the taxonomy in traditional design disciplines tends to focus on 2,3,4 (with 3 being the most common). In contrast, contemporary design disciplines tend to focus on 4,5. The taxonomy of the sketch is therefore thought to favor the visualization of individual ideas about physical products and the facilitation of innovation, iteration, and communication through such easily understood visualizations. In the contemporary design discipline of design tools, however, the sketch is more oriented towards visualizing the overall structure of the system, the set of interactions of the service being provided, and so on. This makes it easier for designers and stakeholders to understand the complex relationship between the intangible service/system and the tangible product/interface in the design process. In addition, although the average of contemporary design disciplines is higher than traditional design in terms of sketch complexity, traditional design may require more sketch skills than contemporary design.

Thirdly, the contemporary and traditional designs of this paper are judged differently in terms of fidelity. Traditionally, fidelity is judged by how close it is to the final design in terms of appearance and function. Contemporary design, however, considers whether the sketch represents a system diagram or storyboard that is close to the intended composition of the final design, the expected interaction, the experience, and so on. In other words, traditionally the sketch represents the construction and form of a specific design (micro level). In contrast, in contemporary design, the sketch is used to describe the system framework of the design (macro level), the specific experience to be realized (meso level) through storyboards, etc., and the interaction required to realize that experience (micro level).

Because of the fast and rough nature of the sketch, the analysis of sketch taxonomies and design tools that use the sketch method in relation to fidelity is concentrated in the low and middle levels, with the high level rarely occurring. The reason for the high level is the application of the sketch method to the final prototype or finished product, and the reason for the middle level is the application of sketch to prototyping. In general, however, both the sketch taxonomy and the sketch-related design tool take advantage of sketch's ability to simply represent ideas or concepts and its ability to quickly externalize them. Also, as digital technology develops, sketch's property of being vague and allowing for reinterpretation and the ability to offer designers new solutions may enable sketch to be used in fields of high fidelity in the traditional design disciplines.

Whereas in the contemporary design discipline, although the design objects include specific products, most of the design tools analyzed in this study are used in the context of UX or the frameworks that make up the service. Even though the threshold for sketch use has been lowered by the addition of new technologies, it is observed that sketch fidelity is at the middle level in most tools, besides the general low level, according to our definition in table1. Despite the differences in design objects in different design disciplines, the ability of sketch to support efficient and rapid visual representation of objects that become more complex. The ability to represent and convey a degree of fidelity (2d) may still be difficult to replace by other simpler (1d) or more complex approaches (3, 4d).

Discussion and future work

This study has explored the changes and differences in the role and function of the sketch in traditional and contemporary design. It provides some preliminary findings and insights into how to address and improve some of the current gaps and conflicts between design disciplines. It also gives some ideas about changes in design education and the professional skills or knowledge that designers will need in the future.
Regarding the dimensional expansion of the sketch. For traditional design, the techniques to be learned and the knowledge of design theory from interdisciplinary sources has increased. And for modern design, the understanding of sketch characteristics may need to be improved to save time and cost in the design process.

Based on the analysis of the complexity of sketch, some possible gaps can be identified, i.e., traditional design disciplines can be educated more towards the development of design representation skills, while contemporary design disciplines are educated more towards the development of logical thinking and the training of design tools with a fixed framework and practical team exercises. Therefore, a mutual learning process between the contemporary design disciplines, with their emphasis on logical and systematic thinking, and the traditional design disciplines, with their emphasis on practical training, could help to mitigate the conflicts within the disciplines (i.e., the gap between the slowly changing design disciplines and the rapidly changing business environment that demands design talent).

This study argues that the difference in criteria for judging sketch fidelity is largely due to the difference in design objects between traditional and contemporary design. The contemporary design discipline is more concerned with designing services to meet a range of customer needs and incorporating products that enhance customer satisfaction. In contrast, traditional design is concerned with designing products to solve customer problems, focusing on practicality, design, durability, etc. While each has a strong focus on interdisciplinary collaboration, modern design is more likely to integrate the experience and knowledge of different disciplines than traditional design, which once had clear disciplinary boundaries.

Therefore, a more inclusive and open-minded approach to the traditional design education model, such as the development of courses in modern design disciplines (e.g., Service Design, Transformative Design), may open more opportunities for future designers in traditional design disciplines and contribute to the resolution of (2) conflicts within disciplines or even (1) conflicts between disciplines.

In summary, based on the review and analysis of sketch in various design disciplines from the perspective of (3) conflicts between specific tools, this study argues that traditional design education and practice need to introduce the attributes and experiences of contemporary design disciplines that focus on multidisciplinary collaboration. And in contemporary design education and practice, there is a need to focus on developing a certain level of theory and knowledge of traditional disciplines to help build a foundation of knowledge systems in multidisciplinary collaboration.

In the future, the disciplinary boundaries between traditional and contemporary design will become increasingly blurred. The unique theories and tools of each discipline may become increasingly uncertain, ineffective, or even conflicting in their educational and practical applications. To effectively address the potential confusion and conflict of theories and design models that may arise in the future because of the dissolution of design disciplinary boundaries, this paper provides a more general review and analysis of design disciplines from different fields and origins by offering a new perspective on specific tools at a micro level. More detailed studies exploring (i) future models of design education and (ii) the skills required by designers will require more comparative studies with examples of overlaps and gaps between specific disciplines (e.g., Industrial and UX Design).

Abstract

Information Architecture (IA) is a digital design process constituting the structural design of shared information environments (originally websites and databases) through organising, labelling, and navigation systems. However, due to the complexities of cross-channel, pervasive and ubiquitous computing, IA has shifted its approach to consider the design of information spaces in larger social, cultural and technological contexts. In practice, values of universality and certainty have given place to plurality and complexity. The practice of IA can be explained as an (inter)play between the science and the art of shaping information to support usability and facilitate findability. Design Thinking (DT) is a commonplace approach in IA, and both are means to interconnected problem (re)solutions at their core. Ultimately, IA presents a method of intelligibility design which is no longer constrained to digital practice.

Censoring information and visuals by and within sub-communities and digital interactive information technologies sets a dangerous precedent and disseminates strategies of what does and does not 'matter'. The stigmatisation of lesbians often results in violent hate crimes, which are emblematic of social violence against sexual embodied diversity outside the imperial, (hu)man-, phallo-, hetero-, cisgender-norm. The vis-à-vis between the epistemic violence of communication technologies and the real-life brutality of lesbian actualities points to an expansive system of visual 'knowledge management', which needs to be addressed in discourse, technology, and technique.

A more extensive research project explored how un/intelligible lesbian representational practices recursively shape and are shaped by their interactions with the informatic architectures of Instagram's censorship mechanisms. The research argued that the search and retrieval techniques of Instagram's Explore Tab act as an agent of intelligible (dis)allowance. More so, Instagram's shadowbanning, and its predecessor, soft-banning, cannot be separated from policies that inform it and the foundation of its algorithmic architecture. However, as participants' invisibilities and concealed architectures informed the research project, particular methodological challenges became apparent. This paper responds to the methodological challenges faced when researching indeterminate problems, opaque participants, and covert knowledge management of vulnerable materialities and their representations.

Comparable to research design, DT can be seen as a strategy, a method, or even an epistemology. IA and DT are inherently interdisciplinary, and the collision between traditional approaches with novel techniques offers the potential to overcome normative conventions in both fields and present alternative assemblages of support. The conceptualised methodology recursively positions conventional qualitative research practices against DT and IA-informed phases and their corresponding activities. Specifically, the research compares data collection methods to synthetic conceptualization; data analysis approaches to understanding and defining design problems; interpretation of findings to ideation; and evaluation of findings to prototyping. Lastly, the research troubles both qualitative methods of validation and solution-led approaches within DT and IA praxis.

Introduction

The stigmatisation of lesbians often results in violent hate crimes, which are emblematic of social violence against non-normative sexual embodied diversity. Unescapable homophobia in traditional patriarchal cultures of the global south, which makes up more than 80% of Instagram's user base outside of the United States, requires lesbians to negotiate layers of visibility due to social factors, interpersonal relationships, and economic implications (Duggan et al., 2015; Msibi, 2011; Waterhouse, 2019; Smuts, 2011). The fear of stigmatisation and prosecution often leads queer bodies to seek (visual) information and validation elsewhere rather than in mainstream media (Aslinger, 2010; Molabocus, 2010). The trouble is that this 'elsewhere' is not always there. Instagram has a legacy of censoring queer content. However, #lesbian has faced far more stringent 'management' from removing of all tagged content predating 2015 to the imposed 'soft' censorship up to 2017 and, finally, the more covert techniques of

shadow banning from 2018 onward. Censoring information and visuals by and within sub-communities and digital interactive information technologies sets a dangerous precedent and disseminates strategies of invisibility and unintelligibility. The *vis-à-vis* between the epistemic violence of communication technologies and the real-life brutality faced by lesbian actualities points to an expansive *'knowledge management system'* that needs to be addressed in discourse, technology, and technique.

The discipline of Information Architecture (IA) concerns the structural design of shared information environments to facilitate findability-come-usability. Although initially applied to the web and large databases, the practice of IA has shifted due to the cross-channel, physical and digital complexities of web 2.0 technologies. IA's fundamental interest now considers the design of information spaces in larger social, cultural and technological contexts; in other words, values of universality and certainty have given place to plurality and complexity (Lacerda & Lima-Marques, 2014). Likewise, Resemi (2014) affirms that practice-led issues of labelling, website conventions and hierarchy structures have been replaced by sense and place-making, design, cross-media, complexity and embodied cognition. Design Thinking (DT) is a commonplace approach in IA, and both are means to interconnected problem (re)solutions at their core. Ultimately, DT and IA present methods of intelligibility design, which is no longer constrained to digital practice. More so, contemporary DT and IA offer techniques to address (societal) 'knowledge management' problems.

IA solutions are not immediately clear to the end user, presenting disadvantages and challenges but also resilience and opportunity. For users, the product's interface, functionality and content constitute its user experience, and the IA is only tacitly understood. Fenn and Hobbs (2014) argue that the disconnect between IA deliverables and user perception poses an opportunity for the discipline to extend beyond its current practical application. Conversely, the opaqueness of information domains' structural components obscures the representational logic behind a design but also raises methodological challenges when researching the complexities of information domains and technologies.

When indeterminate problems present themselves, they do so as a struggle to determine where a problem-centre lie, and as with most wicket problems, the problem itself is but a symptom of a much larger and more systemic problematic (Buchanan, 1992). As such, it was essential for the research to move beyond the determinate phenomena of censorship on Instagram to identify the indeterminate problem-centre of the technological disallow through information technologies and the actors therein. The study at large explored how un/intelligible lesbian representational practices recursively shape and are shaped by their interactions with Instagram's information architecture, censorship mechanisms and value-laden, complex and contradicting terms of use. However, as participants' invisibilities and concealed architectures informed the research project, particular methodological challenges became apparent and necessitated a systemic and strategic approach to problem-solving.

Like research practice, DT can be seen as a strategy, a method, and even an epistemology in its own right (IDEO, 2018). In short, DT is a way of solving problems using a designer's toolkit, and because design, like IA, is fundamentally and foundationally interdisciplinary, it can be applied to qualitative research approaches of 'problem-solution'. Be that a way of overcoming field and methodology issues or grappling with 'problems' embedded in research questions or purpose statements. For this reason, rather than considering conventional research concepts, the research turned to an intra-disciplinary approach by interweaving the principles and processes of DT and IA with conventional qualitative research practices. In response to the methodological field issues raised above, this paper critically reframes what *can*, does and should be considered research data by employing synthetic conceptualisation. Further, through recursive feedback between DT, IA and qualitative research designs, the research compares data analysis approaches to understanding and defining design problems, interpretation of findings to ideation, and evaluation of findings to prototyping. Lastly, the research troubles both qualitative methods of validation and solution-led approaches within DT and IA praxis.

Synthetic Solutions for Qualitative Data Collection

By comparing various design thinking frameworks, Fenn and Hobbs (2014) illustrate an aggregated design thinking model with three phases: *research, ideation* and *prototyping*. Each phase frames specific but overlapping conceptual activities, and the continuum of the phases are iterative and self-regulating. Equivalently, an IA project is outlined as iterations of *research, strategy, design*, and *implementation*. IA methodologies are transient, iterative, and evolving due to temporal changes, emerging phenomena, and advanced understanding of the referential context that frames user needs (Fenn & Hobbs, 2014; Rosenfeld et al., 2015; Resmini & Rosati, 2011). Congruent to the iterative and recursive methodologies of DT and IA, Creswell and Poth (2016) posit that qualitative research activities of data collection and analysis as interrelated and frequently super-imposed.

The entry point of data collection is identifying a site or individual (Creswell & Poth, 2016). The larger study motivated both thresholds, but it is valuable to unpack how the individuals that occupy the problem domain were identified and how their 'data' was gathered. Plummer (2011) proposes a *Purposeful Identification of Persons* approach with three typologies of 'persons' to demarcate a research milieu. According to Plummer (2011), *great persons* fundamentally impact their epoch, community or discourse, *marginal persons* are embedded in conflicting cultures, and *ordinary persons* exemplify the larger culture of the research milieu. By such consideration, the research acknowledges seminal authors in the field of IA as great persons. Access to these great persons is granted through reviewing their literature and consulting their instructional texts. Identifying individuals who occupy the conflicting culture of censorship or stand as an exemplar of technological disallows is more challenging as they refer to predominantly silent and almost exclusively invisible users of a social media platform. What the research *could* do was uncover traces and utterances of marginal and ordinary persons. Published user accounts reflecting on personal experiences of Instagram's censorship mechanisms contextualised

these users as research participants. Moreso, this maneuver frames 'participant voices' in the form of their blog and Instagram posts, news articles and references in academic literature. It is worth noting that this reframing moves beyond traditional accounts of field observation, interviews and focus groups. Still, what constitutes participants and their voices in this account is no less mediated than they would be through primary data collection methods, as data generated by research activities can only ever be interpretive (Bourdieu cited in Fenn & Hobbs, 2014).

Creswell and Poth (2016, p.156) urges researchers to consider a multi-phased approach to data collection and recognise that each phase extends "beyond the typical reference point of conducting interviews or making observations." Once the research site is selected, a researcher must evaluate the most appropriate data collection approach, and due to the exponential growth enabled by (information) technologies, a researcher will have to collect multiple data from multiple sources. More so, considering the ethical representation of volumes of data across information channels, a researcher must develop a systematic but flexible protocol for capturing data. (Creswell & Poth, 2016, Ellingson 2011, Jackson & Mazzei, 2012). Rosenfeld et al. (2015) recommend a *Noah's Ark* approach when undertaking content analysis. A Noah's Ark approach aims to capture a 'couple of each species' data types. The range of formats, in turn, must span textual, audio-visual, interactive materials and resources to represent 'surrogate' records of the environment. Rosenfeld et al. (2015) locate that what you may find in a content analysis may not match the vision, techniques and technologies, strategy or quality of information put forward by an organisation. By undertaking a content analysis, a researcher can "identify and address the gaps between top-down vision and bottom-up realities" (Rosenfeld et al., 2015, p.323).

The research mapped the navigation flow of Instagram's *Community Guidelines Portal* and *Help Centre* to represent a surrogate record of Instagram's top-down vision. Additionally, the research iteratively engaged the 'voice of Instagram', *Instagram Blog*, as a representative of Instagram's organisational culture and politics. The bottom-up realities were captured by recording four biannual episodes of #lesbian content on Instagram's Explore Tab feed through screenshots and vocabulary mapping. In reference to Creswell and Poth's (2016, p.159) *Compendium of Data Collection*, the collection of audio-visual material includes "examining physical trace evidence" and "examining favourite possessions or ritual objects". Although the *Explore Tab* feed may not be considered physical trace evidence, it is nonetheless trace evidence of material representation. Additionally, #lesbian can be considered a ritual object of identification and identity representation (Palmer, 2015). Therefore, the user accounts detailed above also indicate the bottom-down realities of queer users on the platform.

While the research offered recommendations to address data collection concerns, primarily informed by IA's approach to content analysis, what to do with this data is still to be discerned. To follow is the account of how - through qualitative approaches, DT principles and IA processes - data becomes information.

(In)Forming Qualitative Methods of Data Analysis through DT and IA Research

The *research phase* in DT concerns understanding the 'societal world' within which the final design solution will exist and intervene. The user-centric approach of DT and IA maintains that meaningful solutions must acknowledge and address user needs and desires as they emerge (and evolve) from their cultural, social, economic and political contexts. Correspondingly, Fenn and Hobbs (2014) advocate that more than understanding a user's phenomenological context, a designer must consider the user's epistemological framework or how they think and justify their actions. DT research can, as a result, conceptualise the interpretation of the context from which the problem emerges and the "relational social logic" of a meaningful solution (Fenn & Hobbs, 2014, p. 14).

Alike the iterative nature of DT and IA phases and processes and the series of interrelated activities required in data collection, Creswell and Poth (2016, p.150) argues that the course of analysis and data visualisation are "interrelated and often go on simultaneously". Consequently, qualitative research conceptualises the practice of data analysis as a spiral. The entry point to the *Data Analysis Spiral* is data, or rather volumes of data produced through rigorous research exploring the complex social reality of a design or research problem. The data 'as is' is a messy and unruly collection of 'stuff' and therefore requires a sort of 'management' which constitutes the first loop on the Data Analysis Spiral (Creswell & Poth, 2016, p.185). According to Creswell and Poth (2016), a researcher typically organises data into (computer) files, followed by converting files into "appropriate text units" in preparation for analysis. It is worth noting that the preliminary stage of data analysis constitutes adding data to data. More than creating a meta-data schema for easy information retrieval as an information architect would do, adding data to data also appends meaning to the data set.

The research phase of IA entails gathering and reviewing background materials and current strategies. Put differently, IA research establishes the existing structural framework of the information site. The high-level framework, or contextual understanding of an information environment and the user's needs and behaviours, sets the foundation upon which an IA strategy builds. Similarly, once the unruly collection of data is managed in qualitative research, the data is set to be 'read'. Reading and memo-ing present the second loop in the Data Analysis Spiral. In this phase, the researcher immerses themselves in the data set to develop a holistic understanding of the information before abstracting it (Creswell & Poth, 2016).

At "the heart of qualitative data analyses" is the third loop of the data analyses spiral, where a researcher describes, classifies, and interprets data into codes and themes (Creswell & Poth, 2016, p.186). Detailed description entails recounting what the research 'sees', but of particular importance is that the detailing is provided within the context of the persons, places or events. Between analysis and interpretation, the designer, information architect and researcher stand as a conduit. The tension of data becoming information through the conceptual activities of the designer or researcher is best described in DT and IA's ideation phase. Furthermore, ideation, as framed by DT and IA, is comparable to the interpretation of qualitative research findings.

(In)Forming Qualitative Interpretation of Findings through DT and IA Ideation

A key characteristic of the *ideation phase* in DT and IA is that activities of constructing, understanding and creating a design connect in a mutual relationship. In the seminal text, *Dilemmas in A General Theory of Planning* (1973), Rittel and Webber argue that one cannot understand and then solve. To this account, a researcher, a designer and an information architect cannot understand a problem without first understanding its relational context. Moreover, these actors cannot meaningfully find information without a form of orientation. Rittel and Webber define the pivot that enacts useful information gathering as a "solution concept" (Cited in Fenn & Hobbs, 2014, p.14). By placing the context of a problem and the potential solutions in an iterative loop that cyclically and reciprocally edits the understanding of both fields, an artificial solution transforms into a problem/solution conjecture. Through multiple cycles of recursive feedback, a corresponding problem-solution pair become apparent. Fenn and Hobbs (2014, p.15) elaborate that the conceptual process of formulating matching problem-solutions allows solutions to emerge from a "designer's analysis, categorisation, structuring, organisation, prioritisation and consideration of the rich data.". The evolving solution, or best-matched problem-solution pair, reciprocally reduces the range of relevant data. In this way, only the data that will impact a more advanced understanding of the problem-solution conjectures amalgamate to form new meanings and develop better possible solutions.

Haverty (2002) presents a corresponding interconnected and iterative process in the practice of IA, known as Constructive Induction (CI). CI employs two intertwined searches to generate a design solution. The first search requires identifying the most adequate representational framework for the problem. The second search involves locating the best design solution within the representational framework. The intertwining is how the synthetic design solution translates back to the problem now situated in a representational framework (Haverty, 2002). In the context of CI, a representational framework signifies the constraint on user interactions through information platforms, technologies, and policies. This research argues that the concept of a representational framework can extend to qualitative research approaches (such as ethnography, narrative, phenomenological, grounded theory, and case study designs) or theoretical lenses (such as post-classical discourses) employed by the researcher, as they frame both the research question and approaches necessary to address the research question.

The interpretation of qualitative research requires abstraction beyond codes and themes into more amassed meanings or better problem-solution pairs. To demonstrate, Creswell and Poth (2016) posit that the information is further abstracted once thematically coded by organising and categorising them into larger 'meaning units'. In qualitative research, what reifies the interpretation of data is representing or visualising the data-now-information in text, tabular or figure form (Creswell & Poth, 2016). In the practice of IA, the data gathered and interpreted as (relevant) information is developed into a high-level strategy. The high-level strategy, in turn, informs IA design. In the design phase, an information architect creates detailed visual representations of the high-level strategy through conventions such as sitemaps, wireframes and metadata schemas (Rosenfeld et al., 2015). What follows ideation in DT and design in IA is prototyping and implementation. Similar to qualitative research's evaluation of findings, prototyping is not a concluding action or phase. These conceptual activities rather stand as a trigger for further iteration until a meaningful problem-solution pair emerges or solid hypotheses are crafted in response to a research question.

(In)Forming Qualitative Evaluations of Findings through DT and IA Prototyping

The iterative conceptual repositioning of problems and solutions informs the generation of design outputs. Generating becomes generative, and the feedback between the research and ideation phases develops into the *prototyping phase*. Equivalently, the *implementation phase* prescribed by IA is where information architecture is built, tested, and launched through organising and tagging content, improving processes, and developing policies. The implementation phase ensures that the information architecture can be maintained and improved over time as prototypes are iteratively validated against context, content, and users' needs and behaviours (Rosenfeld et al., 2015; Harverty, 2002). Haverty (2002) argues that this process ensures the quality of an IA solution as it avoids reductionism which manifest through a series of abstractions.

Criteria that evaluate qualitative research findings are replete with strain, not because the concept of quality is subjective but because it is contextual. Therefore, Howe and Eisenhardt (cited in Creswell & Poth, 2016) suggest that broad, abstract standards are the only way quality can be assessed. Conversely, evaluating quality in DT and IA is antithetical to broad, abstract terms because the synthetic concept is reified in each iteration to be the most appropriate, but not necessarily the only, solution within the conceptual framework of the problem. Moreso, evaluating the quality or appropriateness of a design solution by broad abstract standards proposes that the design solutions respond to broad abstract problems rather than contextual and often systemic problematics.

According to Fenn and Hobbs (2014), DT and IA are oddly framed in product-led fields, and systemic design problems are often obscured as product problems in briefs drafted by stakeholders. If products, as opposed to 'appropriate' solutions, are automatically applied in response to a design problem, they fail to engage with the complexities that emerge from design research and early ideation. Applying a generic product as a solution further implies that design problems share the same data and research setting. Consequently, a generic product effectively erases the design and research concerns which emerge from particular histories, cultures, knowledge systems and narratives. What is obscured is often tied into socio-political actualities, and more than undermining cultural values, generic responses to contextual and systemic problems may be ecologically and economically unsustainable (Fenn & Hobbs, 2014).

Truisms of universality and generality also encumber qualitative research. Referential to product-led disciplines, hard sciences often question the reliability and validity of qualitative enquiry, and in response, some qualitative research designs will adopt positivist and constructivist terminology

to facilitate acceptance by the harder sciences (Creswell & Poth, 2016). Conversely, other qualitative enquiries aim to recontextualize the universal underpinnings of validation by substituting the criteria with more naturalistic research terms such as credibility, authenticity, transferability, dependability, consensual validation and referential adequacy (Creswell & Poth, 2016; Lincon & Guba, 2011; Eisner, 2017). Two things are worth noting. Firstly, the substitution of generic universality through qualitative criteria, as listed above, draws parallels to the conceptual activities of ideation, where representational frameworks are evaluated against problem-solution conjectures. Secondly, supported by the critical repositioning of solution-led design instead of product-led approaches, DT and IA strategies can reframe qualitative 'assessment' away from abstract *criteria* to iterative validation *strategies* such as prolonged engagement and persistent observation, triangulation, and thick description.

Conclusion

In summation, the research required to understand a design or societal problem produces vast amounts of information, and understanding the complexities of design research data through synthesis can be considered the critical act of problem resolution. The conceptual process of formulating matching problem-solutions allows design solutions to emerge through analysis, categorisation and prioritisation of rich research data. In this way, information architects and designers *research to discover* and *organise information to be understood* by others in a meaningful way (Fenn & Hobbs, 2014). Therefore, the tools and techniques employed by DT and IA mediate complexity in a way in which vast and varied accounts of information can be discovered, understood and resolved.

This paper aimed to offer workable solutions to the methodological challenges faced when researching indeterminate problems, opaque participants, and covert knowledge management of marginal and vulnerable identities and their representations. In closing, introducing the technique of formulating problem-solution conjectures firstly acknowledges that 'indeterminate' design and research problems present themselves as a symptom of a larger and often more systemic problematic. More so, the conceptual activities required to generate appropriate problem-solution conjectures make clear that problems do not disappear in the advent of a solution but persist in the overlay. Therefore, employing approaches that mediate systemic problems, such as DT and IA, allows for a better understanding of the relational social logic of a societal design or research problem. Lastly, embedding design thinking and information architecture in systemic problems (re)solution allow culturally sensitive, ecologically, and economically sustainable solutions to emerge from their relational context.

T+ designers: a case for transdisciplinarity in design higher education by way of a South African case study

Fatima Cassim, Kyle Rath

University of Pretoria, School of the Arts, Information Design division, South Africa
fatima.cassim@up.ac.za, kyle.rath@up.ac.za

Abstract

In recent years, the term 'transdisciplinarity' has been widely applied to a range of collaborative design approaches ranging from inter- to multi-disciplinary co-production. While each of these forms of co-production have their place, many of these approaches are branded, tokenistically, as transdisciplinary. According to Toomey et al. (2015), a transdisciplinary mode of collaboration is one that looks beyond bridging divides within academia, to engage directly with the co-production and use of knowledge from within and outside of the academy. Within the context of design specifically, the term 'T-shaped designers', championed by IDEO's Tim Brown, is often used when promoting design thinking to tackle complex problems, which comprises multiple stakeholders and typically occurs within a team setting. The vertical leg of the 'T' represents disciplinary depth (such as the various skills in design) and the horizontal bar suggests the application of these skills across a breadth of other contexts.

For this paper, we extend the interdisciplinary nature of the T to a transdisciplinary one. That is, we move from the traditional T-shape as a base, and propose how transdisciplinarity can be used not only to foster a heightened sense of social awareness in students, but to inculcate civic values that will be transferable beyond the academy, ultimately in their professional practice. In this way, as the vertical stem deepens, civic graduate competencies are nurtured and the T transforms into a plus. We illustrate this transformation by presenting an exit-level BA Information Design curriculum-related project. As a collaboration between the University of Pretoria (UP), South Africa (SA), and the University of Roehampton (UR), United Kingdom, the project was delivered in a meaningful transdisciplinary way, whereby students co-produced a series of accessible and engaging infomotions (information visualisations in motion) - a visual toolkit of sorts. The infomotions, which disseminate strategies for effective partnership, are aimed at early childhood intervention practitioners in South Africa. Specifically, the infomotions serve a communicative and mediative role between therapists and health practitioners, early childhood educators and family and or caregivers as they collaborate on various early childhood interventions that help young South African children (0 to 6) who may have or be at risk of developing special educational needs, disabilities and/or developmental challenges; challenges that were highlighted at the height of the Covid-19 pandemic. At its core, the project serves to highlight the value in transdisciplinarity as an effective model for collaboration in ECI in South Africa and indeed across the globe.

Design education; transdisciplinarity; information visualisation; South African design; design for development; early childhood intervention.

Introduction

As a reflective practice (Schön, 1983) that's adept at tackling humanity's wicked problems – such as climate change, education, equality, health, and wellbeing – design is inherently collaborative and social in nature. Now more than ever, Herbert Simon's (1969, p. 129) seminal definition of design that "[e]veryone designs who devises courses of action aimed at changing existing situations into preferred ones" speaks to the transformative potential of design. For example, in contemporary design practice, cross-disciplinary partnerships are evident across a myriad of design practices; co-, participatory-, social-, transformative- and service- are just some adjectives that are used nowadays to denote that design approaches transcend predefined, historical silos of working independently.

Cross-disciplinary partnerships have also increased, given the popularisation of design thinking as a problem-solving methodology. While design and designers increasingly occupy a space in the front-end of innovation, the application of a design thinking approach is sometimes more of a fad to drive innovation (Johansson-Sköldberg et al., 2013). As such, collaborative design approaches are sometimes conflated with being inter-disciplinary and multi-disciplinary, and are thus labelled as being transdisciplinary. Using this critique as a springboard for investigation, we aim to elucidate a transdisciplinary approach specifically from a South African design education perspective. To this end, the paper presents a triangular interest in contemporary design practice, transdisciplinarity and design higher education. The paper begins by outlining the history and nature of T-shaped professionals as it appears in extant literature. Next, we provide a working definition of transdisciplinarity before presenting a curricu-

lum-related BA Information Design (ID) project. Ultimately, the analogy of shifting from a T-shape to a T+ guides the discussion for transdisciplinarity in design higher education.

Doing things to a T

According to Ing (2008), the term "T-shaped skills" is credited to David Guest in an article that appeared in London's The Independent newspaper in 1991. This was followed by its use by Marco Iansiti (1993) in an article titled Real-World R&D: Jumping the Product Generation Gap. Citing Iansiti, the term was subsequently used at length by Leonard-Barton (1995); the context was a study "of R&D groups in system-focused companies, emphasising skills within a team as a whole" (Ing, 2008). The term was also related broadly to problem-solving instances. During the 1990s, the focus on T-shaped professionals shifted towards a more specific role, namely T-shaped managers. This shift was informed by a move away from a more linear form of management style during the industrial age (Ing, 2008). It became necessary for professionals to not only have depth of knowledge of their discipline or area of specialisation but increasingly a breadth of knowledge or understanding of other disciplines too. Hence, this dual need informs the pictorial representation of the T-shape where the stem of the T represents disciplinary or functional skills, and the crossbar of the T connotes application of knowledge across a broader range of contexts, and end-users.

Owing to the scope of skills required to address wicked social and cultural problems, the general concept of T-shaped professionals has since been adopted in design, management and innovation discourse. In particular, the term gained popularity by Brown (2010) who championed the notion of designers as T-shaped people when promoting design thinking, the nature of optimal work teams (which alludes to co-creation) as well as organisational culture and hiring employees. Peter's (2012, p. 65) explanation of Brown is that "the T-shaped designer possesses a principal skill of, let's say, industrial design (vertical), as well as an empathic or inquisitive nature that encourages branching out into other skills, such as anthropology (lateral)".

What's significant with regard to T-shaped designers is Brown's argument that the horizontal crossbar of the T is composed of empathy "... because it allows people to imagine the problem from another perspective - to stand in somebody else's shoes" (Brown in Hansen, 2010). Furthermore, Brown highlights "active listening" as a form of empathy. Active listening is a trait that is seminal to our argument, and we return to it in more detail in the case study section.

The concept of T-shaped individuals is also evident in education-related discourse, which traverses different disciplines. For example, it can be found in design (Peters, 2012), medical (Donofrio et al., 2010), STEM (Conley et al., 2017), and engineering education (Tranquillo, 2017). The recurring theme in educating T-shaped students across different disciplines concerns nurturing students who will become graduates with attributes that will not only support them in advancing professionally, but also personally as critical citizens.

Transdisciplinarity and the higher education landscape

Transdisciplinarity in education is not always a categorically distinct term; it is often used interchangeably with inter- and multi-disciplinary practices. However, in a recent literature review study titled "Higher education, the arts, and transdisciplinarity" van Baalen et al. (2021, p. 24) present a continuum "moving from buzzwords to a theoretically delineated usage – to make sense of the use and conceptualization of transdisciplinarity". While it is not our intention to unpack this continuum, we align our research with an intentional theoretical usage of the term and not merely as a tokenistic adjective to describe our case study. Moreover, we show how design did not occupy an "instrumentalized position" where design approaches were used by other disciplines. Instead, a transdisciplinary approach was adopted whereby a new space of interaction was created beyond the traditional disciplinary bounds. Thus, the following understanding of transdisciplinarity, ineducation, serves as our working definition: "Trans-disciplinary work moves beyond the bridging of divides within academia to engaging directly with the production and use of knowledge outside of the academy" (Toomey et al., 2015, p. 1). A visual comparison by Jensenius (2012), as seen in Figure 1, makes explicit the differences between the broad range of disciplinarities.

Figure 1. Visualisation of the nature of different disciplinarities (Jensenius, 2012).

Transdisciplinarity is fast gaining ground in institutions of higher education both globally and locally. This is not surprising as higher education is also expected to evolve and adapt to changes to prepare graduates when applying their skills in the real world. Consequently, there is a universal move to outline graduate attributes, which aim to strengthen the links between what is taught and what skills are necessary not only for graduate employment but also in context of the socio-economic-political needs. At our home institution, "[t]ransdisciplinary research has long been part of the University of Pretoria's [UP] key strategic vision" (Kupe, 2022). It is also clearly noted by UP's Department of Institutional planning that graduate attributes "are aligned with the human capital needs of the economy and society, need to encapsulate both universal and particularly South African demands and develop in students critical citizenship" (University of Pretoria, 2023).

Case study: infomotion

Following this imperative, we introduced transdisciplinarity in our undergraduate ID programme. The ID course appreciates that design does not exist in a social vacuum; rather, it affects and is affected by larger social concerns and consequently, students are encouraged to appreciate the outcome of their work within a broad socio-cultural environment.[1] This means

1 One of a kind in South Africa in terms of its broad-based approach, the BA ID programme promotes design thinking through the exposure to and integration of various communication design disciplines. The philosophy in ID is to consider teaching and learning strategies that centre on learning by doing, hermeneutic enquiry, experiential learning, balancing theory with practice, and encouraging both individuality and civic responsibility

that the pedagogical strategy aims to prepare students to work within the expansive domain of humanist or socially-oriented design.

Keeping the social underpinnings of the course in mind, the following section provides an intimate overview of a fourth (and final) year student animation project conducted in 2022. It was delivered by a team of lecturers, led by the authors and Alexander Melck (Phlogiston). The project serves to highlight the value in transdisciplinarity as an effective model for collaboration in early childhood intervention (ECI) in SA and across the globe. As we demonstrate, the practice-lead project, whereby students engaged with and gained valuable field insights from ECI practitioners as well as the project team, is fundamentally transdisciplinary in its conception and execution. That is, it is not merely an interdisciplinary project in which students engage with different fields of expertise at different points in the project. At its core, the stages of the project are led by two principal lecturers, who not only provide a sense of continuity in facilitating these ongoing interactions, but also help students to filter and leverage the diverse perspectives and focus their project outcomes in order to create innovative and impactful design solutions. Moreover, although our focus is on this practical project, it is worthwhile pointing out that it formed part of a larger ECI research initiative. That is, in its broader conception, the design contribution lies in distilling complex, dynamic and interconnected ideas gleaned from the research.

The research initiative, led by Dr Susana Castro-Kemp (UR), sought to identify current practices and challenges faced by ECI teams in delivering interdisciplinary provision for young, vulnerable children. In collaboration with Prof Shakila Dada (UP) and Dr Alecia Samuels (UP), the initiative looked specifically at ECI in SA. A national survey with ECI practitioners across disciplines was conducted, followed by more in depth virtual focus groups and telephone interviews .

The team identified a range of challenges specific to the local ECI context. Notably, the researchers found that owing to the high level of poverty, 30-50% of households are not able to meet basic nutritional needs, let alone consider any sort of specialised medical treatment for children with significant developmental needs (May et al., 2020). Moreover, the study notes a significant shortage of ECI practitioners available to the public health sector. At least two million children in SA live with disability. Unfortunately, as of 2019, 70-80% of children with disabilities (CWD) are reliant on the public healthcare sector, which accounts for less than 20% of the registered ECI practitioner workforce (Kathard et al., 2020). To respond to these challenges, the research outlines three overarching strategies. Firstly, the researchers address the efficacy and resource intensity of different modes of collaboration in ECI and suggest that a transdisciplinary model is more sustainable in terms of manpower and continuity in treatment. Secondly, in order to achieve effective transdisciplinary collaboration, the research promotes various modes of open and constructive communication involving active listening and joint decision-making as a way of building trust between practitioners and reaching consensus about the child's needs. Finally, the researchers found that collaborative ECI is most effective when it is family-centred, whereby families are considered as part of the team of experts and are empowered in the decision-making process with regard to care for their children so that intervention is more likely to continue at home.

With these strategies in mind, the researchers collaborated with our ID division, to develop a series of motion graphics that unpack these strategies in a meaningful and accessible way. The aim was to produce a series of infomotions (information in motion) - a toolkit of sorts - that serve a communicative and meditative role between therapists and health practitioners, early childhood educators and caregivers as they collaborate on various interventions that help children (ages 0 to 6) who may have or be at risk of developing special educational needs, disabilities and/or developmental delays.[2] As a set-up for the practice-based project, students were divided into nine groups of five. The research and findings gathered in the first phase of the project were distilled into nine abstracts (divided into three categories) each subsequently informing the respective student groups as they progressed into the research and conceptualisation phase of the project.

During the conceptualisation phase of the project, students were encouraged to conduct supplementary research in a variety of ways. To start with, students took part in a story-building workshop, where they unpicked the key elements of good storytelling. The idea of the workshop was to develop a sense of narrative thinking; to gain insight into the way we internalise information so that students produce meaningful stories, as opposed to stale, instructional videos. From there, groups worked through and pitched several ideas, each revolving in some way around metaphorical analogy; comparing the core problem statement in their research to an accessible or relatable phenomenon.

The next phase was scriptwriting, where students began to translate their concepts into a workable, tangible structure. While still exploratory in nature, groups untangled structural concerns such as logical flow, repetition, abbreviation and integrating case study examples. Students were also given further classes on script-writing practice, again with an emphasis on narrative storytelling. The focus here was to develop a story arc, through writing and structure, the rhetorical nuances in narrative writing and lessons on the value of micro-editing to inject voice and texture to a piece. For example, the first group was tasked with describing not only what the concept of collaboration is in theoretical terms, but also *show* in a meaningful way, how this concept has practical and immediate value to their practice. [3] In order to do so, the group used inversion as a rhetorical strategy to contrast the practice of 'do-it-yourself' (D.I.Y.) versus collaboration. In the script, the designers flesh out statistics that describe, with some whimsy, the follies of D.I.Y. in day-to-day home improvement; construction gone awry, broken bones and missing appendages. At the halfway point in the script, these 'mishaps' are described as reasonably 'fixable' since one is always able to "rebuild, repaint and reattach."

3 To view the infomotion entitled *Why collaboration matters in early childhood intervention*, visit https://youtu.be/p81buijyxPI (Information Design, 2022).

In contrast, the script concludes that this is *not* the case when it comes to ECI, since the first six years of a child's life are developmentally fundamental and are not as easily 'redone' if a mistake is made. Hence, ECI is not a do-it-yourself project, but requires timely collaboration.

Importantly, at this point in the project, the groups were put in touch with ECI practitioners, via an online chat platform, Slack. This proved to be helpful to the script-writing process, since students were able to use the insights and real life stories they gleaned, to help ground some of the more abstract research concepts they were dealing with and that had to be distilled in an accessible way. A good example of this is in the case of one group who tackled the topic of 'why families are important to ECI.'[4] The students' research exposed them to a myriad of occupational and physical therapy intervention techniques that can be continued at home. In order to avoid simply negotiating different viewpoints by listing an overwhelming array of techniques in the script, students depict a simple scene that mimics an actual scenario of an occupational therapist teaching parents of a CWD a mirroring technique to help with physical and mental coordination. Interestingly, in recalling the experience to the students, the practitioner also happened to mention that owing to the particular child's difficulty with maintaining eye-contact, it was the child's mother who suggested that the activity be modified to where they do it without facing each other. After months of initially stalled treatment, this slight modification had a substantial impact on the child's uptake of successive techniques.

Working with various ECI practitioners also brought to light an incongruence in the initial narratives across the first four research themes. Initially the second and third infomotions were meant to be summaries of three models of collaboration (multi-, inter and transdisciplinary collaboration) with the fourth as a conclusion that transdisciplinarity is the preferred model. What became clear however, was that there was an assumption that transdisciplinarity may be viewed as the preferred model simply because it is listed as the third mode. Therefore, in the interest of accessibility for knowledge dissemination, it was important to first unpack the strengths and weaknesses of the former models, but specifically as a point of *contrast*. And so, in discussion with the groups, the disciplines came together to find a consistent, overarching metaphor, of modes of water-dissemination, as forms of collaboration that occur in nature.[5]

After several iterations of the scripts, students recorded a rough edit as a prototype to present to the project lecturers, researchers and ECI practitioners.. The prototyping was used to gain a bird-eye view over continuity between the nine scripts as a whole. That is, how certain concepts described in earlier infomotions are ultimately clarified, picked up on or circulated without unnecessary repetition in later ones. Secondly, the researchers and practitioners were particularly helpful in identifying incongruencies in use and application of terminology. Upon finalisation of the scripts, students collaborated with sound producers and a voice over artist from UP's local radio station to record the scripts. At this point, students were taught how to direct the voice over artist in terms of tone, texture, mood and pronunciation to ensure that the target audience receives the message in an accessible and engaging way.

Next, students begin to consider and develop a visual style for their infomotions that is not only conceptually appropriate to the research theme, script and narrative, but appropriate for the intended audience. At the same time, students are required to consider scene-to-scene animation by way of a storyboard. Storyboarding, as a type of visual shorthand, helps students to work through and prototype the relevance and meaning of several narrative ideas fairly quickly, without committing to hours of work that goes into just a few seconds of animation.

Students then moved onto the audio-mixing phase. This is arguably the most important technical aspect to an infomotion since, in most cases, the audio guides the pacing and rhythm of the animation for the viewer. Where syncing to the voice-over most obviously guides the pacing of a motion piece, students are taught to pick up on, enhance and add audible changes in the backing track to help create drama through climax and anticipation. Moreover, backing tracks and sound effects were also employed to help shape the atmosphere for a piece.

Students then begin to animate. As a form of animation, infomotion affords the designer time and sequencing as tools to unfold a meaningful narrative. Motion graphics need to evoke rhetorically powerful signs and symbols quickly in order to effectively and intelligently communicate complex concepts. Therefore, they should communicate singular, accessible concepts. In other words, in promoting accessibility in the production and dissemination of knowledge, students were encouraged to simplify the scene-for-scene depictions to produce focused ideas, one at a time. If more than one idea is communicated per scene, there is a chance that the animation may confuse or overwhelm the viewer.

As part of the ID degree, there is a strong emphasis on the value of reflection as an analytical and developmental tool. For this reason, students were briefed, at the onset of the project, to document their research, critical thinking and design processes; from concept, storyboarding and animation to working with and across disciplines. Students had to consider moving from their initial insights to developing a more robust and thoughtful concept. Students had to consider, for example, what they might have originally assumed would be an appropriate conceptual solution compared to what was ultimately gathered from the transdisciplinary interactions . Ultimately, owing to the transdisciplinary focus, students reflected on how, if at all, consultation with fellow group members, project leaders, the client and ECI practitioners helped to evolve their thinking and design approach.

Developing T+ designers

The aim of the transdisciplinary project was both pedagogic and practical. The project facilitated epistemological development of design students. More significantly, they learnt about

the co-production of knowledge as it relates to the idea of design as a relational practice, comprising reflective as well as reflexive processes. Students engaged with research for design from a different perspective, to script a 'new' narrative.

Although the project constitutes various research phases, the reason we focussed on the practical component specifically is twofold; as design is a field invested in critical thinking and problem-solving it is typically the case that designers are required to develop a deep understanding of the problem at hand in order to thoughtfully consider the research initiative and its initial findings and strategies, but then also to communicate these findings to the end user in an accessible, intelligible and meaningful way. Through a real-world project, students experienced first-hand that design serves as a throughway between the research and end users, and is able to distil possible communicative gaps in both the acquisition, dissemination and uptake of research.

With regard to the traditional T-shape, the design education context of the project facilitated areas of professional design practice; students were expected to apply disciplinary depth by synthesising and building on their design skills, scaffolded over their former years of study (the vertical leg of the T). Perpendicular to this, the complex nature of ECI in SA introduced different contexts, stakeholders - including research and end-users - and disciplines to the students (the horizontal bar). The breadth of engagement required students to broaden their worldviews; it highlighted that their design decisions need to be informed through cooperation, collaboration, prototyping, and dissemination and not only imagined by their preconceptions.

Social change is at the heart of knowledge creation – not only within the bounds of this project, but also in terms of fostering a sense of social and ethical design citizenship that is maintained, paid forward and extended further as design graduates enter their chosen professional field. What this project showed us was how to nurture "citizen designers" (Resnick, 2016). Through facilitation of the project, we recognised a transformation in the students' problem-solving approach; an empathic outlook was evident, which from a civic point of view, gives them a sense of agency in making socially impactful messages heard. This conscious approach to transdisciplinarity was also carried over in subsequent ID projects. More importantly, the deep social awareness and civic responsibility that students gained will hopefully extend beyond the classroom, like the stem of the T extending upwards to shape a plus (+); a T+ shaped designer. This is not to say that social awareness and civic responsibility is not part of the traditional T-shape. Instead, it is our position that (1) more attention on *strengthening* the link between design education and design practice, and (2) on encouraging the design student to strive for civic responsibility beyond the classroom, might strategically extend the core tenet of the traditional T. Over time the experience of transdisciplinary design practice may become transferable graduate attributes that designers embody not only in their professional trajectories but also social, cognitive and basic values that contribute to a more socially-just world. Given SA's apartheid past, the socio-economic inequalities that still plague the country will indeed benefit from solutions developed from within and for a local context.

In transition: material knowledge, commons, and design education

Meret Ernst

Institute of Contemporary Design Practices, Academy of Art and Design, Basel, Switzerland

meret.ernst@fhnw.ch

Abstract

In reflecting on two teaching units, this paper analyses the relation of design to environmental awareness, thus gaining arguments to combine speculative approaches with designerly material knowledge and the social practice of commoning in design education. Criticising the linear paradigm of existing design programmes, it argues for redefining design education as an agent for change furthering transformation in the design field.

Starting from the perception of the current socio-ecological crises, condensed in the disputable term Anthropocene, the paper discusses how to open new ways of conceptualising design education through redescribing the situation, adapting a critical notion of design history, and reevaluating the speculative heuristics of design in a MA Design programme.

The second part discusses combining circular design strategies with 'designerly material knowledge' in the same educative setting. As an explorative approach, designerly material knowledge is based on the findings of material sciences integrating a historical and cultural understanding of materiality. Assuming design unlocks and redefines materiality through experimental, creative, and prototyping approaches, the question arises of how to validate this knowledge in the design process and pass it down to future students. Inscribed with the urgent need to counter «de-futuring» practices of unsustainable design (Fry, 2020), we should speculate about «futuring» design education. Thus, conceiving a material-based design methodology of circular design practices and processes could lead to a revision of design education and practice and a deeper understanding of the role of materiality in the design process.

The third part builds on the assumption that design education should heighten the experience of the social embeddedness of each design task in place and time. Instead of designing discrete objects, design students learn to conceive relationships, interactions, and experiences for and within complex social systems to achieve potential systems-level change (Irwin, 2015). Therefore, design is best described and trained as a co-design activity involving various actors (Manzini, 2015). Understanding any short and long-term ramifications of using resources could benefit from a closer reading of commoning as a social practice, as discussed in a Bachelor's teaching unit. Commons are historically contingent (Ostrom, 1990). How Commons are organised signifies how societies understand their embeddedness in any (natural, social, planetary) environment. Thus, a historical perspective on commoning as a social practice could help students acknowledge that environmental issues and eco-conscious practices always form part of socially regulated and therefore designed systems.

In conclusion, the paper discusses the ramifications of those two specific teaching experiences on their potential to transform design education into a more circular practice of educating.

Transition design; Design education; Materiality; Commoning

Introduction

The human-caused altering of the chemical composition of the Earth's atmosphere, the unfolding climate change, the dramatic loss of biodiversity, melting glaciers, or continuing acidification of the oceans is threatening the critical zone, i.e., the thin layer allowing all life forms to live on the planet (Latour, 2018). These crises threaten societies and environments, mainly caused by the Global North (United Nations, 2015). As an inextricable part of the history of industrialisation, design finds itself in the middle of the debate and, with it, the crucial role of design education.

Witnessing such crises is no longer just a matter of scientists. 'Eco-anxiety', the chronic fear of environmental doom, despite not yet being considered a diagnosable condition, gained recognition, as was its disproportionate impact on children and young people (Rao & Powell, 2021). Fueled by debates in mass media and illustrated by memes on social media, the feeling of loss hits people from all backgrounds. Teenagers and young adults brought the fight against climate change to the streets in Western societies and into the highest governmental institutions in the late 2010s thanks to social movements like Fridays for Future or, on a more desperate urge, Extinction Rebellion, Last Generation, or Renovate. Design students are particularly concerned by this. According to a traditional understanding that still widely grounds design education, its methodology remains defined by the linear approaches of industrial production and consumption patterns. Therefore, design holds responsible for the damage caused, as Victor Papanek summed up famously when he decried designers as "creating whole new species of permanent garbage to clutter up the landscape, and choosing materials and processes that pollute the air we breathe." (1971, p. XXI) Hence, design does not create the future, according to its distorted but cherished self-image; it takes our future away, as Tony Fry (et al., 2015, p. 9) denounced: "In particular, industrial society has brought these, and a myriad other defuturing things and forces, into being."

How can we, as design educators react to this situation? Even more so, we are affected by the same feeling of profound loss and confronted with losing credibility as part of an older generation that could have known better, at least since the 1980ies. Transforming design education entails a thorough self-assessment of educators, questioning the intensely linear paradigm of prevailing design programmes and coming up with alternatives. Thus, in reflecting on the debates with students during two teaching units on BA and MA levels at Basel Academy of Art and Design, this paper argues for combining speculative approaches with designerly material knowledge and the social practice of commoning in design education.

Starting from the perception of the all-encompassing socio-ecological crises, condensed in the disputable term Anthropocene, the first part of the paper discusses how to open new ways of conceptualising design education in a project-based teaching unit at MA levels. The need for this is twofold: First, as educators, we are often confronted by students asking about design's social and environmental responsibility. Such questions gain acuteness at the end of their basic studies when they have learned designing skills and methodological principles. Thus, their unease relates to the foundations of the professional field for which they are being trained. How can design education help to transform a professional field perceived as not future-proof? Second, if we define design as mediating technology, resources, and policies, our practice indirectly affects existing and creates new environments. Therefore, design is deeply integrated into sustainable and unsustainable everyday living, defining behaviour, access, or norms defining design as always political (Mazé et al., 2013). Given this entanglement, the question arises if and how the policies of design education can contribute to resolving the crisis.

The second part discusses how the same MA students combined circular design strategies with 'designerly material knowledge' in the project-based teaching unit. Conceiving a material-based design methodology could lead to a revision of design education and practice and a deeper understanding of the role of materiality in the design process.

The third part of the paper builds on the assumption that design education should heighten the experience of the social embeddedness of each design task in place and time. Understanding any short and long-term ramifications of using resources could benefit from a closer reading of commoning as a social practice, as discussed in an interdisciplinary theoretical BA teaching unit. In conclusion, the paper discusses the ramifications of those two specific teaching experiences on their potential to transform design education into a more circular practice of educating.

Positioning design education in relation to environmental crises

As Latour (2018) reflected, it is high time to define our situation in what he considers a fundamental crisis of modernity detached from its material constraints. Beyond the much-needed political activism (in which design educators could take a much more active part), the crises urge us to redefine where we are in temporal and spatial terms. To discuss the situation on a planetary level without nurturing deeply disturbing perspectives and prevailing feelings of helplessness and doom, Latour's notion of *atterissage* is of great help. If included at the beginning of a teaching unit, this opens an ongoing debate about making meaning in times of uncertainty.

We thus collectively developed a project-based teaching unit at the master's level led by Evelyne Roth, Jörg Wiesel, and the author. The interdisciplinary teaching unit 'Thinking and acting in circles' collaborated with a Swiss outdoor sports company to develop circular design propositions in the Autumn Semester of 2022. The 15 master students with an international background and BAs in Industrial Design, Textile Design, Fashion Design or Scenography worked in groups. They aimed to research on how design propositions can help transform a linear methodology into circular processes and practices. Together, we structured the teaching unit according to a standard design process and integrated theoretical inputs on debating definitions, historical perspectives, and the heuristics of speculation. We started with an explorative investigation of the company's products and objects. We immediately integrated practical design experiences and reading, open questions and knowledge gaps into the discourse. Not all students were familiar with the debate on the Anthropocene or had read the founding texts on circularity. Nonetheless, they reacted positively to the opportunity to ask wide-ranging questions about the current crises, the difficulties in describing them, and how this affects their positioning in design.

It is no easy task to subject the canon of designing to critical revision, i.e. to solve or address in a still very linear way clearly defined problems. The underlying rationale of design education is still governed by the belief that creation is exclusive to humans and a means of self-expression for the better of other humans. Reworking such definitions by learning to describe the planetary situation otherwise and looking back to find inspiration in counter-narratives of design history presupposes a cognitive level only reached in the MA programme. Here, it is no longer about understanding design-related terms, methodologies and theories but about critically examining the underlying notions, even if this may deconstruct long-held beliefs.

What words? Relearning to describe the current situation

Perceiving a crisis calls for new terms describing the situation in its singularity. From a geological perspective, there are good reasons to rename the current epoch in which significant changes to the structure and functioning of the Earth System, including the climate system, are to be observed. Naming this still disputed new geological epoch 'Anthropocene' refers to the realisation that human beings have become a global geophysical force.

Besides terminology, beginnings are much debated in historiography, even more so in geological time frames. The ratification process is still ongoing, and thus the beginning of this epoch remains to be decided definitively by the experts. Of higher interest, though, is the fact that in the meantime, the term Anthropocene has become an environmental buzzword coined by the late atmospheric chemist and Nobel laureate Paul Crutzen in 2000. In his view, the outcompeting of natural processes started "about two centuries ago, coinciding with James Watt's design of the steam engine in 1784", linking the beginning of the Anthropocene with the industrial revolution. (Crutzen, 2006). In an equally influential later publication, he and his co-authors proposed dividing the Anthropocene into three stages. The Industrial Age 1800-1945, the Great Acceleration since 1945, followed by a future phase to gain joint responsibility for the Earth's system by the global community in 2015 (Steffen et al., 2007).

Alternatively, the beginnings of the Anthropocene are traced back to the Great Acceleration period after the Second World War and the advent of the nuclear age (McNeill & Engelke, 2014). This hypothesis will probably prevail as the stratigraphic and Earth System approaches assess this period as crucial. Since then, geologists have detected the increasing worldwide use of synthesised fertilisers in strata, as well as aluminium, heavy metals and techno-fossils. Microplastics, which pollute regional waters and oceans, are entering the food chain and will probably still be detectable in sediments thousands of years from now (Waters et al., 2016)

Altering the Earth's system will inadvertently affect us with all other living species and non-living entities. Thus, 'Anthropocene' has vast philosophical and historiographical implications beyond its geological significance. It designates a shift of perspective from living in the "new world" and being dependent on it (Holocene) to adopting an active role in (re-)designing or even creating a "human-made new world" (Anthropocene).

Thus, reflecting critically on the term Anthropocene with the MA students entailed two propositions, as we collectively worked out in one of the theoretical inputs during the project-based teaching unit. First, the hubris engraved in the term forcibly leads – especially Western thinking – to a turning point in the definition and perception of the relation between the environment and human beings, acknowledging that humans are more deeply entangled with it on a factual and epistemological level. Therefore, as Donna Haraway points out, alternatives to describe the situation are much needed. She proposed another definition for this new age and coined the term 'Chthulucene' (from the Greek *chthonos*, meaning "of the earth"), describing it as an age "made up of ongoing multi-species stories and practices of becoming-with in times", an age in which we must decenter humans from their adopted central place: "We are at stake to each other." (Haraway, 2016). It is urgent to deconstruct the historiographical implications of the term Anthropocene, suggesting that human beings are still moving forward in their conquest of space and (geological) times, according to Crist (2013, p. 132). More so, the term wrongly suggests that humans are controlled by fundamental biological and geological processes or even creating them.

Second, we need to understand better how the present crises are related to their political and historical causes. We live amidst a full-fledged ecological and socio-political crisis unfolding unfolding as massive global inequity. Such inequity forcibly leads to reflecting on the discursive aspects of the rather generic term 'Anthropocene' as it tends to blur causes and effects. Sociologists, therefore, oppose it, arguing that the current environmental crises derive from overshooting the capitalist economy rather than the mere fact of being human. (Malm & Hornborg, 2014). The term wrongly reduces "the mosaic of human activity in the web of life" to an abstract "homogeneous acting unit", essentially removing "inequality, commodification, imperialism, patriarchy, racial formations, and much more" from consideration, as Jason W. Moore criticised (2015, p. 170). Thus, using the term 'Anthropocene' in non-geological contexts bears the potential to de-politicising the ongoing crises. Therefore, Latour (2018) urges us to redefine how and with whom we can sustainably live in what he describes as the 'critical zone', i.e. the fragile layer allowing all life forms to live on the planet. He suggests that we must shift our focus to sustain this critical zone and become 'terrestrial', a status he explicitly links to a fundamental critique of modernity, its underlying paradigm of progress, and contemporary politics. He further extends this notion to a critical, participatory relationship to our living world in unprecedented danger, defining the worldwide situation as the 'new climate regime'. This regime is not limited to ecological crises but touches on questions of politics, cultural history, and ethical and epistemological perspective changes. Scrutinising design's role in this process is vital to reformulating a new ontology of design (Fry, 2020). Design gained critical attention through the sense of hubris in the term Anthropocene's meaning and its oppressed question of liability.

Counter-narratives of design and its history

The debate on the Anthropocene was further contextualized during theoretical inputs by a thorough reflection on the historical roots and the canonized, predominantly western understanding of 'design'. As an inextricable part of industrialisation, design – defined as an 'interface' to make technology available (Bonsiepe, 1999) – finds itself in the middle of the debate. Crutzen's reference to James Watt's invention of the steam engine in 1784 underlines the crucial role of technology at the root of the current environmental crises. With the invention of steam power, the change from agrarian to industrial societies in Europe and North America soon made itself visible in many areas, including the landscape. Before industrialisation, people used natural forces – wind, running water, or gravity. With the steam engine, the releasing of chemically bound energy began, and the new machines were driven from within, for which they needed fuel, be it wood, coal, or coke. Energy consumption massively increased starting the era of extractive industries intricately connected to colonialism, which today puts the primary responsibility of urgent decarbonisation on the Global North.

The need to protect the forests through sustainable silviculture concerned not only foresters but broader sections of the public (Radkau, 2011). A hitherto unprecedented burden of pollutants on the environment became apparent in the 19th century. In the big cities, people could hardly breathe; the air was full of smoke, and toxic sulphur dioxide compounds led to forest dieback on a larger scale. However, as in the Middle Ages, technical and legal protective measures were still limited to containing visible and malodorous substances. The belief in the almost unlimited self-purifying power of nature continued to dominate. Thus, according to a traditional understanding that still widely grounds design education, 'design' is seen as primarily defined by the processes of industrialisation and therefore held co-responsible for the damage caused by it.

Still, there is a counter-narrative to the role of industrialisation in design. Besides debating the role of design history in design education, such alternatives open a different grasp on the potentialities of design in the current situation. The social and environmental costs of mass production did not go unnoticed by design itself, from William Morris's utopia News from Nowhere, published in 1890 (Morris & Kumar, 1995), critical systemic thinking (Fuller, 1969); (Rittel & Webber, 1973) to socially integrative (Papanek, 1971), feminist (Buckley, 1986), or decolonial (Escobar, 2018) approaches that all define alternative design methodologies considering environments of all sorts. In the last two decades, criticism of design in the service of an industry that externalises environmental damage and privatises profits intensified, lately propagating approaches like Transition Design (Irwin, 2015).

The role of the prototype: Making potentialities tangible

It turned out to be crucial embedding both discursive undertakings – redescribing where we are and re-writing the history of design on the model of existing counter-narratives – in non-linear, openly discursive didactical settings integrating them in the ongoing practical explorations of circular design practices in a predefined and real situation. In this setting, the MA students were invited to activate their design skills in reformulating longtime undisputed design practices and thus free themselves of the negative and unproductive feelings of 'being ashamed' as designers.

On a theoretical level, this led to rethinking the defining problem-solving paradigm. Design entails the promise not only to create solutions to existing problems but to undo or redo the effects of decisions taken in the past. Thus, the current and much debated hopes for technical approaches like geoengineering to deal with the devastating effects of Global North's overconsumption on the climate. In a crisis, however, the problem-solving paradigm of design concedes to designers the invidious role of coming after the shock: They seem obliged to repair the debris and thus save the world. Should we, therefore, compare design to the Red Cross, treating but "a few wounds that capitalism inflicts" and therefore "prolongs capitalism like the Red Cross prolongs war", as German sociologist Wolfgang Fritz Haug (1970) criticised design as serving the needs of a capitalist society. His unfair and blatantly wrong comparison is just one of many criticisms of design-as-embellishment of capitalist interests in the 1970ies. The most salient aspect is the basic notion of timing that undergirds Haug's critique: If we limit the scope of action for design to mending what has gone wrong, we miss one of the central heuristics of design of opening possible futures. We should better conceive of design as a vital resource for transformation. Such a notion relies on attributing design with an intrinsically speculative potential.

Speculative methodologies extend to multiple disciplines linking art, design, technology, or strategic thinking. An epistemological axis of the unconstrained connects them to the constrained (Montgomery, n.d.). Speculative design makes potential futures tangible and, therefore, negotiable, shown amongst others in the work of Anthony Dunne and Fiona Raby. Their impact in the early 2000s was liberating for designers, even if the approach was rightfully criticised as binary and too biased on western notions of design (Bardzell & Bardzell, 2013). Opposed to affirmative design as problem-solving reinforcing the status quo in the industry's service, Dunne & Raby (2013) characterise speculative design as problem-finding in the service of society, asking how the world could be.

'Proto-typing' is a means of trying out solutions beforehand. In contrast to other critical practices, it mainly uses prototyping to gain knowledge. Iterative processes go on until stakeholders agree on the result. Thus, prototypes are not only futuristic but deeply discursive objects. They bring a proposal to the table, as preliminary as it may be. Embracing such a heuristic instead of dismissing design once and for all because of its undisputedly capitalist and colonialist heritage could help overcome future crises.

In the one-term MA teaching unit setting, speculative design approaches helped the students greatly free themselves from the burden of delivering ready-to-implement propositions. In activating their exploratory and observational skills, they nonetheless gave valuable inputs to the company regarding their repair processes or managing their leftovers, amongst others. At the same time, the students achieved a practical understanding of the difficulties of transforming linear into circular production and consumption processes in real life.

Hands-on: Understanding materiality in project-based teaching units

Circular economy formulates another promise for design which plays a central role in the upcoming transformation of society and production systems (Irwin, 2015). This role also implies 'repairing' instead of inventing 'the new' with its modernistic notion of starting from scratch on a white sheet of paper, but at the same time, subscribes to design to adopt a much more active and integrative role along production and consumption cycles.

The drawbacks of the Circular economy on the systemic level, i.e. the real danger of keeping an unsustainable system of overconsumption in action, were easily discerned by the MA students particularly critical of greenwashing. Therefore, focusing on the crucial role of design decisions to make a service, a product, or a system more 'circular' – in any of the different circles drawn by, i.e. Ellen Mac Arthur (Ellen MacArthur Foundation, 2013), Braungart McDonough (2002), or others – entails a better understanding of both systemic flaws like rebound effects that also affect design decisions about materials or production processes. Design educators, therefore, are called upon to reconceptualise the temporal dimension of designing from a linear to a circular understanding.

Parallel to designing proposals for the specific company, the students began to reflect on what does it need to be able to anticipate practices of usage and beyond in designing? How does this broaden definitions of stakeholders? Do we have to redefine co-designing, considering the environment on a planetary level at stake? Do we have to redesign 'design' as a whole? Such questions lead to a thorough redefinition of material's role plays in everyday life.

Designerly material knowledge forms part of the long-lasting entanglement of design and environment(Fallan, 2019). Knowing of and about materials is based on the findings of material sciences integrating a historical and cultural perspective on materiality. As a transdisciplinary practice, design needs a deeper understanding of materiality to expose hidden meanings and historically rooted use and misuse of materials. Combined with a speculative design approach, this leads to a broader understanding of materials-in-use meanings. Assuming design unlocks and redefines materiality through experimental, creative, and prototyping approaches, the question arises of how to validate material knowledge in the design process and pass it down to future generations. Thus, conceiving a material-based design methodology could lead to a revision of design education. The demand for sustainable design based on material knowledge and acknowledging where materials-as-resources come from is anything but new. Given the foreseeable depletion of resources, the report 'The Limits to Growth' (Meadows & Club of Rome, 1972, p. 177) called on designers to create easily repairable and durable products to minimise resource consumption despite higher (design) costs. To "improve the functioning of a society in a state of equilibrium", the report called for, among other things, efficient recycling techniques to reduce resource depletion, a better design to extend product life and promote repairability so that capital depreciation rates are minimised. The methodologies need-

ed to achieve this have since been differentiated with Green design (Burall, 1991), Circularity (Stahel, 1996); Ecodesign (Braungart & McDonough, 2002); (Charter & Tischner, 2017); Co-Creation (Meroni, 2007), (Manzini, 2015); Circular Economy (Ellen Macarthur Foundation 2013) and Transition Design (Irwin, 2015). Not all of them extend material knowledge in historical and cultural dimensions.

Materials are central role in circular design methods (Oberhuber & Rau, o. J.). Therefore, the teaching unit with the MA students began by exploring the outdoor sports company's textile leftovers and used and damaged products. The students realised how time-consuming it is to undo consumer goods like highly functional sports apparel, high-end rucksacks, or jackets and how many different textiles are combined in just one product. At this moment, they experienced hands-on how crucial the conceptual phase is for assessing the life cycles of artefacts and processes.

Theoretically, this perspective called for a redefinition of the design process. Instead of conceiving a project and searching for the most sustainable materials and production processes, students learned to focus first on materials and then on their design tasks. It required researching materials and their origins, perceived cultural values and entanglements in colonial discourses. Finding out how to keep materials in circulation led the students to a different understanding of materiality. If their design project should keep materials in circles, it only 'borrows' materials for a limited time before transforming into something else. Such a metaphor can reverse the design process upside down with lasting effects on design education.

One potential outcome for future project-based teaching units on the MA level is reevaluating of material libraries and project archives. Assuming the informed choice of sustainable materials and production processes is crucial for designing sustainably, using such archives becomes an integrated part of practice-based teaching units. Material samples and artefacts from design processes convey applied know-how. They are usually stored in material and sample collections or project archives. To use them fruitfully, students must reflect upon them critically, as they, too, have a complicated history of their own.

Model and pattern collections were an integral part of arts and crafts schools at the end of the 19th century, from which art and design education developed. They were considered an effective means of enforcing design standards. As the core of the emerging arts and crafts museums, they served to educate general taste. (Pazaurek, 1919) We must critically evaluate archives' canon and existing structures to build up a designerly material knowledge. Archival systems should extend to materials and the implicit knowledge gained in design processes. Material collections combine cognitive information with haptic experience conveying material, technical and cultural knowledge through samples and descriptions of processes. Materials and their use are culturally coded. As such, they form part of discourses that need to be re-read from the perspective of decolonisation and sustainability. Therefore, archives could lead us to a historically and culturally informed mode of dealing with materials as a prerequisite for creating a more circular design.

The theory of the Commons in design education at the BA level

Undergraduate design students learn to base their design process on thorough research to determine its speculative potential. In doing so, they acknowledge the embeddedness of any design proposal in a pre-existing world. Thus, they lead their practice-oriented projects on mostly given briefs. In the process, they rely on generic descriptions of design processes as a work frame. However, questioning the base of such practice needs other settings or moments in a predominantly project-based education. Usually, theory classes seem to allow reflecting on methodology, but in doing so, we push the unfortunate division between theory and practice even further. To overcome such divisions at least partially, an interdisciplinary teaching unit at BA levels allowed developing a broader definition of acting as designers using the commons theory.

Commoning sense: Acting as being part of something bigger

Instead of designing discrete objects, designers should drive systems-level change in conceiving relationships, interactions, and experiences for and within complex social systems (Irwin 2015). Therefore, we can best describe design as a co-design activity involving various actors (Manzini 2015). In the view of the all-encompassing ecological crises, the 'actors' involved are not only human beings but all living beings and non-living entities of the critical zone, entailing a multi-species vision. Speculating about a sustainable future includes all entities now and in the future. Understanding any short and long-term ramifications of sustaining through using limited resources could profit from a close reading of commoning as a social practice.

Commoning reflects a social practice within limited resources, maintaining long-term use of Common pool resources. Historically, the discourse about common goods had a revival at the time of the Great Acceleration, coinciding with the Peak Oil theory first presented by Marion King Hubbert at a meeting of a branch of the American Petroleum Institute in 1956 (Gosh & Prelas, 2009). Hubbert predicted that global crude-oil production would peak in about 2000, decline quickly, and eventually disappear in the 22nd century. Such outlooks were perceived as disturbing in an economy heavily relying on fossil fuels. In his widely debated article 'The Tragedy of the commons', Hardin (1968) combined political economy with neo-liberal "life-boat-ethics" (Oakes, 2016, p. 238). Furthermore, an irritating lack of historical accuracy determined Hardin's notion of the commons (Cox, 1985). On the other side of the political spectrum, the need to discuss systems and rules was pervasive when the environmental movement was emerging, and the need to limit the damage of industrialisation was broadly recognised (Radkau, 2011, p. 124ff)

If resources are limited, we need consensually established rules for their use. Rules to preserve the commons and the ways of breaching and sanctioning such misbehaviour are historically contingent. They have always been formulated as coexistence systems and religiously or morally based intentions. Elinor Ostrom famously scrutinised them in her comprehensive study of the underlying principles of Common pool resources (Ostrom, 1990). The survey that posthumous got her the Nobel Prize in Economy in 2009 aimed to show how essential actors are in determining the regulations of sustainable use to prevent the debatable notion of the "tragedy of the commons". Based on many case studies, Ostrom analysed long-enduring Common-Pool resources (CPR). Her study shows why some sustained and others deplete over time and how self-organised systems help to solve two of the significant real dilem-

mas of the commons, namely "the problem of commitment and the problem of mutual monitoring." (Ostrom 1990, p. 59)

As a social practice, commons are historically contingent; they are negotiated, structured, and embedded in rituals, virtually present in the minds of their participants and life-changing for them. They can be read as the changing notions of the lived embeddedness of societies in their natural environment. Therefore, the history of the commons explains how the conception of the intricate connection between the environment and societies is established and how it changes over time. As such, commons are comparable to systems design (Ernst, 2021). Understanding how they were designed and what policies – that historically also led to the exclusion of the have-nots and the socially vulnerable — had to be put in place for their long-term functioning shows the deeply collective task of designing sustainable environments. Thus, a historical perspective helped the BA students understand how environmental issues and eco-conscious practices always form part of socially regulated and therefore designed systems. In hindsight, one of the most efficient ways to teach the difficulties of designing a sustainable environment was to let students experience and discuss the value of cooperation with the help of the prisoners' dilemma formulated in the form of a short detective story by the American mathematician Albert W. Tucker (Mérő, 1998).

While the BA students were activated in debating the theory of the Commons in reading a syllabus of foundational texts, exploring game theory and the prisoner's dilemma, amongst others; the whole teaching unit was acutely lacking a practical exploration of commoning as a social practice in design. Nonetheless, the students appreciated debating an approach heightening the understanding of designing as a collaborative practice that questions the still widely uncontested creative paradigm of the (mostly male) designer-as-author.

Conclusion

While critically reflecting on traditional design education based on a linear understanding of designing, we should not refrain from design's potential to bring past, present, and future together. Based on its heuristics, design entails the promise not only to create solutions to existing problems but to undo or redo the effects of decisions taken in the past. Similarly, the current debate hopes for technical approaches to deal with the multiple crises due to rampant CO2 emissions; geoengineering is the latest resource. They inscribe themselves in Herbert Simon's definition of design as devising "courses of action aimed at changing existing situations into preferred ones." (Simon, 1988) Still, we must be aware that design is profoundly and methodologically entangled in the problem leading us into an unsustainable state. Therefore, it cannot offer quick solutions. Nevertheless, we could start redefining design by considering the embeddedness of design in the critical zone. Then, it would no longer be defined as a linear practice of framing a single problem and iteratively coming up with the best possible solution, as singular as it may be.

Designing may help us to reimagine and conceptualise the way of living together in the 'critical zone'. Therefore, due to its heuristic qualities, we should not refrain from design's potential to bring the past, present, and future together. To be grounded entails knowledge of situatedness and how to preserve it in the future. In other words, designing helps us to project possible futures without losing ground.

In criticising traditional design education based on linear notions of designing, we should try to develop easy-to-grasp metaphors of a different understanding. So instead of using a simple geometric operation that rounds a linear structure of iteration in a circle as in Circular design methods (and aptly performed by Tim Brown in his video on Circular Design), we should better use a spiral as inspiration. This form clarifies that we will have to rework what is already there on different levels. Replacing a linear representation with a spiral may sound meagre as a result. However, behind this insight lies a thorough and collective examination of the often disguised, unaddressed assumptions that shape undergraduate design studies, whether in the curricula, semester projects, or mentoring. Breaking through these underlying figurations seems to be a first step towards perceiving design education and practice differently.

Although designing is by no means limited to conceiving tangible material objects, design students on both BA and MA levels must learn to come up with discursive objects that may stand the test of a debate, anticipating possible futures. Prototyping, therefore, is a central aspect of design, relying significantly on designerly material knowledge. Such knowledge allows designers to act embedded and more conscious of one of the essential aspects of sustainable design processes and practices: Materiality. Unless materials are to be conceived of as Common pool resources, design education risks perpetuating unsustainable design practices even if they teach Circular design methods. Materials are always sourced in the critical zone; they are always considered precious and limited. Therefore, designerly material knowledge correlates with the theory of the Commons. 'Material Commoning' may serve as a further model for transition design, bringing together social issues, embeddedness in the critical zone, and a futuring prospect.

Acknowledgments

I would like to thank the BA students participating in the teaching unit 'Meins, deins, unser aller.

Design für das Gemeinwohl', Spring 2021, Programme Ästhetische Praxis /Critical Media Studies, and MA students taking part in the project-based teaching unit 'Thinking and acting in circles', Masterstudio Design, Autumn 2022, both at Basel Academy of Art and Design.

Abstract

We live in a time of accumulating economic, environmental, social, political, and cultural crises. The current systemic crisis demands various transitions: from linear to circular, destructive to regenerative, and individual to collective. As we face uncertain times, we must consider new and diverse perspectives about how the future may look and feel. These possible futures help us better understand their potential and make decisions about the futures we wish to embrace. In this paper, we will highlight context-specific art and design practices to create regenerative imaginaries and prototypes for the future. This context-specific approach fundamentally builds on comprehensive fieldwork and participation to interact profoundly with the environment and its actors. In particular, the paper focuses on how we embed these practices from our research in higher art and design education. We will discuss two practice-based master-level courses that introduced art and design students to specific societal challenges. Both courses engaged students in representing and shaping regenerative futures by learning to connect with specific local manifestations of global issues. The sensibility of real-world locality allowed them to develop skills in exploring, collaborating, and reimagining contextual issues through art and design methods and artifacts. Our ambition as researchers and educators working in this context is to develop an educational system that is locally embedded but globally connected. Our agenda is focused on developing methods, strategies, and tools focussing on challenges that are close to us but simultaneously reflect and resonate globally about wicked problems.

Introduction

Our society finds itself in a turbulent and complex transition period characterized by friction and failing economic, political, social, environmental, educational, and cultural systems (Rotmans, 2017). The accumulation of these crises can be characterized as *wicked problems* (Rittel & Webber, 1977) that create uncertainty about the future and lead to conflict and social resistance to change (Latour & Weibel, 2020; Morton, 2018; Adam et al., 2019). The wicked nature of accumulating crises are symptoms of a system that no longer provides sustainable prospects for the future. This system, which is organized on a global scale, risks neglecting its impact on local people and their living environment. Rather than withdrawing to a closed-off localism, focusing our efforts on the concreteness of locality will allow us to open horizons to the complexity of the global (Latour, 2018).

To facilitate the transition towards a regenerative future, we focus on a context-specific approach to address wicked problems on a local scale to develop diverse perspectives on regenerating regional ecosystems (Gibbons, 2020). Wicked problems require an approach that goes beyond the traditional problem-solving process, as we see, for instance, in industrial design where marketable solutions are created from the single perspective of a client (Cross, 2000). Rather, Haraway describes a mission to "generate problems, elicit powerful responses to devastating events, calm troubled waters and rebuild calm places" (2016, p.19)

We argue that art and design practitioners can represent and shape regenerative futures and thereby contribute to the development of desirable futures. To represent these diverse and inclusive futures, a context-specific approach is required that includes the viewpoints of various actors embedded in these contexts. Art and design languages allow us to make complex challenges tangible and give us tools to engage with these actors. Moreover, including different points of view is a way of embracing the uncertainties and complexities of the situation and obtaining a holistic perspective.

Art and design education plays a central role in this discourse, as it will shape the ideas, objects, and narratives that can shape the future. Therefore, it is important that we ask ourselves the following questions: How can we teach students

to think, act, and design in uncertain contexts? How can we unlearn commonplace paradigms that prove insufficient to deal with the complex challenges of contemporary crises? And how can we prepare new generations of students to take on a role in imagining and creating regenerative futures? (Whitehouse et al., 2020) As educators focused on artistic and design research, we feel it is our responsibility to ask these questions and to co-develop diverse perspectives on education and strategies to deal with wicked problems.

Context-specific education

In this paper, we elaborate on two case studies where we engaged with this context-specific role in art and design education. The courses were organized in and around our college campus which is located on a former coal mining site in Genk, Belgium. The city has had to reinvent itself several times over the last hundred years due to the combination of local and global crises. Genk transformed from a small village with vast heathlands around 1900 to a highly industrialized mining town in the sixties. The coal mining industry's demise in the late 1980s and the closure of a large Ford car manufacturing plant in 2014 forced the city of Genk and its residents once again to transform. Today, Genk is still the third largest industrial city in Flanders, and the surroundings of our campus transformed from an abandoned mining site to a creative and cultural hub. Nevertheless, the city is still struggling with complex issues such as pollution, biodiversity loss, high unemployment rates, poverty, global pandemics, and resource depletion. Our ambition as researchers and educators working in this context is to develop an educational system that is locally embedded and globally connected. Therefore, the art and design academy should not be an island but instead act within and with the communities in which it is spatially located while making global connections.

By integrating critical and profound context-specific learning in our educational system, we aim to educate a new generation of students who can contribute to the transformation towards a regenerative future (Hagenaars & Hendriks, 2021). Our approach is a way to unlearn and deconstruct mechanisms in art and design education that perpetuate the paradigms that prove insufficient to deal with the complex challenges of contemporary crises (Morton, 2018; Latour, 2020). When solutions are detached from the cultural and ecological context in which they are implemented, they can impact the local ecosystem in unforeseen ways and timescales (Fry, 1999). When human-centered design processes focus explicitly on problem-solving for generic personas, they result in generic solutions that neglect the social and natural ecosystem in which they are implemented. (Morton, 2018; Schwartz & Krabbendam, 2013) These insights, emerging from our art and design research practice, helped us develop two practice-based educational courses—*Post Ford Genk* (case 1) and *Shifting Grounds* (case 2)—focusing on working and learning in specific contexts. Their goal was not to teach in a linear top-down form but to explore and research collectively with our students and other actors in a specific context. This way of collaborative inquiry-based learning creates an inspiring, dynamic, and participatory learning environment of our living environment. (Ingold, 2019)

Case study 1: Post Ford Genk

The Post Ford Genk course focused on the industrial heritage of the car manufacturing facility of Ford in Genk. The company started producing cars in Genk In 1964. At its peak in 1994, Ford Genk employed over 14.000 people living in and around the city of Genk—which had a total population of 60.000 at the time. In 2014, the production was relocated to Valencia, and Ford Genk was forced to close permanently, resulting in a major social crisis and mass unemployment. Today, Genk is a Post-Fordist environment where residents, policymakers, and local industries collaborate to reimagine its future. The city invested in an r&d campus focused on the development of renewable energy systems to attract new types of industry. The city policymakers also aspire to transform the recycling industry into a circular manufacturing industry.

Left: **Figure 1.** Newspaper: *The Post Ford Genk* designed by participating students. / Middle: **Figure 2.** Robotic metal shaping inspired by traditional crafts by Cas Reynders. / Right: **Figure 3.** Flax fibers as a natural alternative to carbon fiber by Kato Herbots.

In this context, we challenged a team of master-level product design students to create regenerative futures for the city of Genk, local industries and its residents. The course was organized during one semester and divided into a collective and individual assignments. The collective assignment was focused on the development of a fictional newspaper, *The Post Ford Genk* (see Figure 1). The purpose of this collective assignment was to immerse the students in the local context and history. They interviewed several local actors to write articles from cultural, political, economic, and technical perspectives. While the interview conducted with the mayor was oriented to the future of Genk as a decentralized and circular economy, the former factory workers reminisced about the past and explained their struggles to find a new job.

The starting point of the individual assignment was an op-ed that was a personal answer to the research question: What type of products, services, and systems can be designed based on the remaining resources post-Ford Genk? The op-ed was translated into several prototypes suggesting several future scenarios based on the industrial heritage of Ford Genk (see Figure 2-3). The role of these future prototypes is not to solve a specific problem but to create new possibilities that can kickstart new connections in the local ecosystem. To facilitate the debate the newspaper was published by the city of Genk and presented to a union for industrial manufacturers located in Genk. Through this public process, we aimed to set up new collaborations between local citizens, policy, and industry.

Case study 2: Shifting Grounds

In the interdisciplinary course *Shifting Grounds*, we challenged master-level art and design students to engage the issue of the invasive plant species Japanese knotweed within their practice. Originally from East Asia and brought to Europe as a highly desirable ornamental plant for gardens, Japanese

knotweed has quickly become perceived as a significant invasive ecological and economic threat. Through its rapid spread, the plant is not only straining our local biodiversity, but the issue also extends globally. Although *Shifting Grounds* mainly focused on the context of Genk and its surroundings, we collaborated with other organizations such as Trajna (Ljubljana, Slovenia) and Timelab (Ghent, Belgium), and researchers such as Antia Iglesias (Vigo, Spain) who are working with Japanese knotweed in their local context. This way of working exposed the opportunities between local action and global thinking for our students.

The course started with an intensive three-day immersion to introduce students to the context of Japanese knotweed and the many perspectives on this issue. The first day consisted of presentations on the general context of Japanese knotweed by (international) experts and a guided tour of a nature reserve in Genk by members of a nature preservation group. We also did a walk through the city to observe knotweed's presence in the built environment. On the second day, we introduced students to the potential of art and design practices in these kinds of contexts. A curator gave a lecture and held a group discussion on how contemporary art deals with topics like nature and the Anthropocene. Afterward, we shared our own research into the domain of Japanese knotweed and how we approached certain topics through art and design. This consisted of theoretical conceptualizations (including Anthropocene, rewilding, and vernacular design) and practical knowledge. We shared the latter through a workshop on dye extraction to gain familiarity with the materiality of the Japanese knotweed. All these activities were ways to have continuous conversations on the assumptions and ideas of the students and their relation to the natural environment and knotweed in particular. During the third day of immersion, we formalized these conversations during group discussions (sometimes in the field) and coaching sessions. From this point, the students started conceptualizing their own point of view through the eyes of their discipline and practice. Group-coaching sessions guided them to develop work over the following five weeks, culminating in a group exhibition.

Left: **Figure 5.** Speculative knotweed biolab scenario by Esmeralda Mertens and Alexsandro Celea. / Middle: **Figure 6.** Photograms on knotweed paper by Kevin Vaesen. / Right: **Figure 7.** Lamp object with knotweed stems by Tijl Custers.

The student work of *Shifting Grounds* was diverse and ranged from visualizing speculative scenarios (see Figure 5) to projects focusing on plant material research (see Figure 6), architectural interventions in the landscape, and knotweed-based products (see Figure 7). Other projects had less tangible outcomes such as a knotweed weaving co-creation workshop, a generative game model study on the plant's growth, and a knotweed tea ceremony. As a summary, we made the 'Not in my backyard' publication, where color analysis, conceptual background, matter research, photography and graphic design experimentation are presented through different voices that help us better understand our vegetal partner. (Vrancken and Kosten, 2021)

Discussion

In this discussion, we compare the methods used in our case studies that apply a context-specific approach to art and design education, and discuss the challenges we encountered. Both cases are characterized by fieldwork; researching the ecosystem of local actors. In both cases, fieldwork was essential for understanding the complexities related to a specific context and translating them into regenerative futures. The methods for including the ecosystem of local actors differ because of the nature of the actors that were involved in the two cases. In case 1, diverse perspectives of local actors were mapped by interviewing former workers, the local mayor, industry leaders, and the team of product design students. Actors here are people representing different viewpoints on the topic *Post Ford Genk*. In case 2, the term "actor" is expanded to more-than-human actors in line with the conceptualizations of Latour (2018). The lead actor in the case 2 scenario is the plant species Japanese Knotweed. As plants can't be interviewed in a traditional method, including the perspective of the Japanese Knotweed required a tailored method inspired by anthropology, such as participative observation (Ingold, 2013).

Representing the diverse perspectives of humans and more-than-human actors required methods tailored to the specific nature of the actor. In case 1, this was done through articles, pictures, drawings, and prototypes bundled in a newspaper. A format that could represent the political, economic, social, and environmental layers of the Post Ford Genk context. In case 2, this was assembled in a publication that showed the research process and the various futures it represented. Although case 1 was organized within the curriculum of one specific discipline and case 2 was organized across the curricula of various disciplines, both cases benefited largely from a multidisciplinary approach to represent and shape diverse perspectives. The role of the art and design students in this process clearly diverts from the traditional problem-solving perspective. Our context-specific design approach is more focused on problem framing, understating the ecosystem of which they are part before proposing solutions. The added value of the art and design students in the process was the representation of the complex issue at hand in visual and tangible ways.

The challenges for developing a context-specific art and design practice relate to temporality and locality. The context-specific nature requires a tailor-made approach and preparation, as these challenges can vary greatly from context to context. Identifying these challenges can be a labor- and time-intensive process for both lecturers and students. Because much time has to be spent on exploring the context and dealing with uncertainties in the research and design process, less time can be put into the outcome of the final project that students develop within the timeframe of the course. In addition to providing a realistic timeframe, a process evaluation is more appropriate for assessing context-specific assignments. Engaging local participants requires students to connect with people, which can be particularly challenging for international students who do not speak the language. But even students

who speak the language require the right social skills to connect and attune with human and non-human actors that represent the local ecosystem.

Conclusion

This paper highlighted the potential and importance of context-specific practices in arts and design education to create regenerative futures. This context-specific approach fundamentally builds on comprehensive fieldwork to interact profoundly with the environment and its human and more-than-human actors. By immersing our students in context-specific situations and confronting them with wicked global problems on a local scale, we aim to develop their skills in representing and shaping regenerative futures.

We are convinced that the future of art and design education should be organized around contexts and collectives rather than disciplines that promote unembedded and individual artists and designers. Teaching generic processes—part of globalized systems—disconnects future art and design practitioners from the real-world contexts in which they live and work.

Although it is still too soon to prove that both cases lead to regenerated futures, these context-specific research, learning, and design approaches create more conditions for qualitative collaborations between artists, designers, citizens, and other actors in our environment.

Abstract

The paper discusses the role of learning spaces as an integral part of the larger educational ecosystem. Covid-19 pandemic accelerated the trends of digital transformation in education by liberating educational content in time and space and radically reformulating the process of teaching and learning. However, the current spatial archetype of the learning environment still features traditional plans with segregated classrooms and auditoriums. This model is obsolete and does not meet the new requirements of the 21 century education which is student-centred, knowledge and skill-oriented, technology-enabled, collaboration-based and personalized. The role of the teacher is also profoundly changed from transmitting knowledge towards facilitating the educational process that predetermines the wide variety of activities performed in the classroom.

The main objective of the paper is to explore how interior design can be aligned to the new learning theories and technological advances, and to propose strategies for the re-design of the traditional learning spaces. Based on the data obtained in a survey conducted with students to gain insight on their specific learning styles and needs, and a survey conducted with university lecturers to understand their teaching approaches and spatial necessities, six types of spaces were proposed. The study followed the principles of grounded theory to construct a hypothesis on the spatial qualities of each space and relate it to the pedagogical and technological requirements.

Author keywords

Learning spaces; learning environment; future-oriented spatial design; learning experience; educational ecosystem

Introduction

The implications of the social, economic and technological changes in the twenty-first century require rethinking education as an ecosystem. The educational ecosystem is defined as a network of people, educational resources, pedagogical tools and abiotic factors/components which interact to seamlessly work together (Railean, 2019). Derived from evolutionary biology, the term of ecosystem can be applied in the field of education to allude aspects such as diversity, maximum productivity, dynamic adaptability and scalability (Luksha et al. 2018). This notion not only transforms our understanding of learning but also considers how education can evolve and prepare learners for the increasing complexity and challenges of the future. The concept of the educational ecosystem takes into account the context in which learning occurs, responds to the fluctuations of the environment, withstands the treads and embraces the learning opportunities to align them to the current and emergent needs of the new generations of learners.

Learning today is no longer confined to the physical space of the classroom, it involves various learning providers who deliver both face-to-face and technology-mediated learning experiences in the physical, immersive and digital learning environment. Covid-19 pandemic played a critical role in accelerating the trends of digital transformation in education by liberating educational content in time and space and radically reformulating the process of teaching and learning. The diversification of the learning environment stimulated the development and application of varied learning methodologies to engage learners, boost their creativity and enhance the learning outcomes. However, while technology and pedagogy advance, one of the components of the ecosystem, the physical environment, has been neglected. The current spatial archetype of the environment still features traditional plans with segregated classrooms and auditoriums which support lecture-based learning and emphasize the hierarchical relationships between educator and learner. This model is obsolete and does not meet the new requirements of the student-centred, knowledge and skill-oriented, technology-enabled, collaboration-based and personalized 21-century education. The role of the teacher, which is profoundly changed from transmitting knowledge towards facilitating the educational process, encourages flexibility in teaching and predetermines the wide variety of activities performed in the classroom. Though the physical environment has been recognized as the third teacher (Edwards, 2011) and its impact on students' engagement and performance has been widely researched (Fisher, 2004; Oblinger, 2005, Jankowska and Atlay, 2008), the rigid design of the classroom conceived for traditional direct instruction remains the same since the Industrial Revolution. This not only does not respond to the educational needs but also constrains current teaching and learning practices.

The main objective of the paper is to explore how interior design as a component of the educational ecosystem can be aligned to the new learning theories and technological advances. We propose strategies for the re-design of the traditional learning spaces, based on the data obtained in a survey conducted with students at the University of Monterrey (Mexico) to gain insight on their specific learning styles and needs, and a survey conducted with university lecturers to understand their teaching approaches and spatial necessities. The study followed the principles of grounded theory (Glaser and Strauss, 1967) to construct a hypothesis on the spatial qualities of each one of the proposed spaces and relate it to the pedagogical and technological requirements.

Pedagogy in the 21st century and its spatial needs

Education in the 21 century is predetermined by the necessity to prepare students for the social reality of a volatile, uncertain, complex and ambiguous future (Fadel and Groff, 2019). In the context of a rapidly transforming world, the main goal of education is to train students to be adaptable and versatile to be able to succeed and thrive in any unpredictable upcoming situation. This requires focusing not only on the knowledge gained but on acquiring the skills of how this knowledge can be used, developing character qualities how to behave and engage in the world, and mastering meta-learning strategies how to reflect on oneself and adapt one's learning to achieve one's goals (Fadel et al., 2015). To include all these four dimensions in teaching requires innovative pedagogical practices that can ensure effective learning and active engagement of the students in the learning experiences. Scott affirms that to rethink pedagogy is as crucial as identifying the new competencies learners need to acquire (Scott, 2015). Pedagogies which support the development of higher order skills, the four Cs – creativity, critical thinking, communication and collaboration (OECD, 2012), should be based on three Ps – personalization, participation and productivity (McLoughlin & Lee, 2008). The application of approaches that give learners the opportunity of making choices driven by their own needs, creative knowledge production and interactive sharing has been afforded by digital technologies. Bringing a radical shift in education, "[k]nowledge technologies shape what is learned by changing how it is learned" (Laurillard, 2012). Being easily accessible and independent of time and space, technology promoted varied interactions with the content, the instructor and the other learners. The transition from a lecture-focused to a learner-centred education involves students in a process of doing and reflecting on what has been done, or the so-called active learning. "Active learning practices may range from simple methods such as interactive lectures and class discussion to case study analysis, role-playing, experiential learning, peer teaching, and flipped lessons. Active learning may involve problem-based, visual-based, collaborative, project-based, or game-based learning" (Misseyanni et al., 2018). It is recognized that the application of these practices needs an adequately designed physical space, adapted to the diversified needs (Baepler et al., 2014; Oblinger, 2006; Fisher, 2005).

The innovative learning environments defined by Mahat et al. as "the product of innovative space designs and innovative teaching and learning practices" can act as change-maker by stimulating educators effectively and efficiently apply active learning pedagogies (Mahat, 2018). Innovative learning environment's focus on the dynamics and interactions between the learner, the teacher, the content, the facilities and technologies (Dumont and Istance, 2010a) which once again emphasizes the systematic character of education and acknowledges the importance of the design of the physical space to achieve the goals of education. Dumont and Istance outline the core principles for designing an effective learning environment – learners are the core participants and their active engagement is encouraged; the social nature of learning is recognized and organized co-operative learning is encouraged; learning results as a dynamic interplay of emotions, motivation and cognition; the environment is acutely sensitive to individual differences and preferences and adapts in a sustainable way to both the individual and the group as a whole; each learner is appropriately challenged and pushed constantly to excel; the learning environment clearly states expectations and uses assessment consistent with the aims; horizontal connectedness is promoted across areas of knowledge and subjects in- and out-of-school (Dumont and Istance, 2010b).

Based on these premises, we as designers were interested in the design implications and how the potential of interior design can be harnessed to support the implementation of the innovative teaching and learning practices. Borri et al. identify five multipurpose spaces for the new generation of schools – group space, exploration lab, agora, individual area and informal area. The group space is given priority as the heart of the school where students build and maintain their identity. Its layout should enable flexible setting to accommodate various learning activities as collaboration and work in groups, creation of artefacts and multimedia objects, individual work, and presentation. The exploration lab is the space for learning by doing, with dedicated tools to observe, experience, explore, experiment. The agora is a community meeting space, where groups of students can gather for creative activities or discussions. The individual space is dedicated to focused work, requiring concentration and reflection, it should be equipped with pods, caves with reading and writing tools. The informal space is a recreation area with comfortable furniture for individual retreat or informal group meetings (Borri et al., 2016; Borri, 2021). Oblinger describes the elements which the spaces intentionally designed to respond to the new learning theories and student's needs should possess: flexible layout to provide ease of re-configuration to support immediate change of activities; comfortable furniture to support different body sizes and avoid distraction from learning; environment offering sensory stimulation and seamless integration of technology; decentredness and consideration of the campus as a whole with spaces conveying co-learning and co-construction of knowledge. In addition to these functional aspects, the cognitive dimension of the space and the relations between the spatial elements and the creation of a meaningful learning experience have to be considered. Strange and Banning discuss the symbolic aspects of the space which convey powerful message and subconsciously influence the behaviour and the creation of a sense of place. They propose ten features of the spaces which support the inclusion, security, engagement and community experience. To carry this into effect the space needs to be: welcoming (creating sense of belonging), inclusive (affirming identities and expression of self and others), functional (supporting key tasks and activities), sociopetal (encouraging interaction and

encounters), flexible (adapting to multiple purposes), aesthetic (inspiring creativity and uplifting the spirit), reflective (encouraging imagining and meaning making), regenerative (restoring energy and motivating persistence), distinctive (creating memorable impressions) and sustainable (supporting human experience) (Strange and Banning, 2015).

Learning spaces design – the case of the University of Monterrey

Context of the study

The current study was motivated by the urgent need to re-design the leaning spaces of the University of Monterrey (UDEM), Mexico. The strategic development plan of the university which is centred in the development of the person and his transcendence in the construction of a sustainable society, results in the adoption of a pedagogical model characterised by active learning practices, application of cutting edge technology, development of disciplinary and transversal competences, creating a warm and safe environment for the students, encouraging work on interdisciplinary projects (fig. 1).

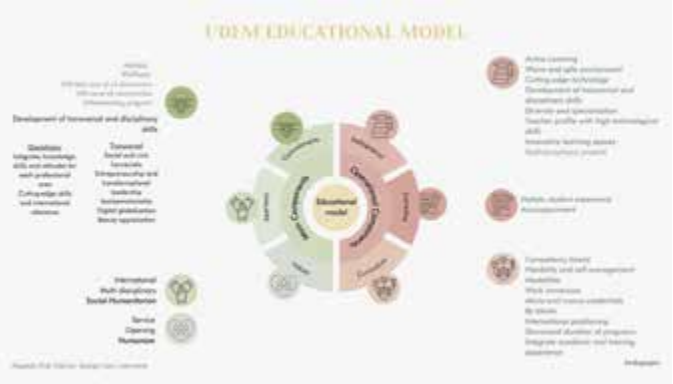

Figure 1. UDEM educational model

However, the physical environment does not support achieving the aims of the strategy. Despite the management's efforts to modernize the campus, the academic buildings where classes are given have not been substantially changed since their inauguration in 1984. The architectural project has been elaborated by the US firm Caudill Rowlett Scott – renowned at that time for their expertise in school design. William Caudill was researching educational spaces and authored the book "Space for Teaching" (1941) and John Rowlett had degrees in both architecture and education. The project they proposed met the needs of the growing student population while taking into account the specifics of the local context. The building consists of four interconnected volumes, featuring open circulation areas adapted to the hot climatic conditions of the region. The façade is treated with vertical concrete panels which function as sun screens blocking the sun from penetrating directly into the classrooms. Nevertheless, the layout is based on standardized cellular classrooms which responded to the lecture-based teaching practices of the past but in the current context hinder the implementation of the aligned to the digital age educational model adopted by the university.

Research method and data collection

To propose spatial solutions for the re-design of the current learning spaces which will be relevant to the pedagogical model and the strategic development plan, a more holistic understanding of the mindset, behaviour and the specific necessities of the UDEM community was necessary. As we aimed to propose strategies for the design of the learning spaces as an inductive process based on the identified gaps between the current and the desired learning experience, grounded theory was selected as a research methodology. The first phase of the research included user surveys and observations, followed by data coding, categorization and scenario mapping and ultimately, development of hypothesis on the spatial qualities of the learning spaces of the future. To gain insight on what kind of learning spaces will best meet the needs and to inform the development of design strategies providing a more meaningful learning experience, two questionnaires were distributed among students and teachers. The purpose of the student survey was to acquire deeper understanding of their specific learning styles and spatial preferences. The teacher survey intended to collect data about the most commonly used teaching approaches and learning activities and the respective spatial needs. In addition, a workshop was conducted with students in the creative field (architecture, industrial design and interior design) with the aim to create scenarios for the future use of the learning spaces and to identify opportunities for future-oriented innovation.

The surveys were implemented in the 2022-2023 autumn semester when 70 % of the classes were delivered face to face and the remaining 30 % were offered online. Responses were obtained from 93 students and 25 teachers. Each questionnaire was designed to collect both qualitative and quantitative information. The questions were predominantly open-ended to encourage the respondents to reflect on the spatial aspects which have a positive or negative impact on the learning experience. Students were asked to describe situations and spaces where they have acted in a very creative way, have concentrated successfully, and where they have been fully immersed into collaboration with others, so that the desirable features of the spaces supporting these activities are revealed. Another important question we were interested in was how a sense of community is fostered so we asked students to speculate on the spatial elements which create a sense of belonging. Teachers' questionnaire focused on their current pedagogical practices, the frequency with which activities are changed during a typical class, which spatial elements of the current environment support or hinder the implementation of these activities and which are the desirable spatial characteristics to freely implement their teaching approach. The technological tools which they usually use or would like to use in the future were also required to be listed.

Mapping the learning experience

Survey results indisputably indicated that the physical space has a great impact on the learning process. Respondents pointed that it influences concentration, creativity, the emotional and physical well-being and the dynamics of the interaction during the class. When comparing which activities are preferred to be performed face-to-face, interaction with the teacher and peers, hands-on activities and presentations are predominant, while listening to a lecture and individual work are preferred to be done online. Among the mandatory re-

quirements towards the space were mentioned the connection with the outdoors, smart technologies, availability of silent areas, comfortable furniture, good lighting and flexibility of the environment.

To triangulate the data obtained from the survey, we organized an intensive workshop where 11 students were challenged to define the needs of the student in 2030 and to envision a better learning experience for the future. By applying design thinking methodology the participants were pushed to generate a wide variety of ideas about learning spaces which meet the future needs of the students. After several critique rounds they were encouraged to visualize the most prominent ideas by giving them a distinct shape by translating the goals and motivations of the users into specific spaces and contexts. The scenario of the future learning experience was visualized into two collages representing the experience in the physical space and in the digital space (Figure 2). The collage technique was selected because of its possibility to provide insight on what students will do, think and feel while pursuing their learning goals.

Figure 2. Collage of the physical and digital learning experience of the future (Developed by B. Elizondo & D. Gamboa)

Conceptualizing the learning spaces of the future

The empirical analysis of the survey data was done together with consideration of the related literature advising that the learning space should support creativity, critical thinking, communication and collaboration (the 4 C's) and allow personalization, participation and productivity (the 3 P's). The development of the spatial typologies of the future learning spaces and the definition of the preliminary design principles for each type was informed by mapping the problematic points of the current physical environment and its comparison with the identified desired future state. Six different spatial types were suggested (Figure 3):

Formal Learning Spaces: Dedicated to scheduled instructor-led classes, where students are encouraged to move and use the different settings, which are most suitable for the various activities performed and always supported by integrated technology.

Individual Area: Informal learning space dedicated to individual focused work and self-directed learning in both open and closed spaces to ensure the student will concentrate undisturbed.

Group Area: Informal learning space dedicated to the collaborative work of small groups of students both in open and closed spaces to encourage dialogue and the individual participation in the group activities.

Webinar / 360°: Formal learning space dedicated to presentations and webinars, designed with a circular layout and flexible LED screens so that the presenter can be seen from all angles of the space.

Arcade / E-learning: Formal/informal learning space dedicated to collaboration. Designed hand in hand with technology, with a LED floor, interactive screens, tables for augmented reality and virtual reality pods, so that students can take their learning to the next level with the aid of technology.

Encounter Area: Informal learning areas activating the transition areas with additional functions, dedicated to the coexistence and interaction between students, designed with comfortable and flexible furniture to support relaxation and well-being. Integrated interactive screens ensure students will be always connected to the community.

Figure 3. Spatial typologies: Formal learning space; Individual area; Group area; Webinar / 3600; Arcade / e-learning; Encounter area (Developed by B. Elizondo & D. Gamboa))

Conclusion

Technological advances and the change in current pedagogical practices are drivers for the change of the physical space where learning takes place. As teaching methods continue to evolve, spatial design also needs to remain open for changes and empower their implementation. Furthermore, design can play a transformative role enabling changes in the educational ecosystem. The proposed spaces break away from the rigid teaching model of the past and encourage the dialogue between teachers and learners, turning them into co-participants in the educational process and co-creators of knowledge. Such radical transformation is needed to initiate a process of liberation and awakening of students as critical thinkers and creators. The design aims to make students immerse into the environment, to activate the participation in the performed activity, to challenge the imagination, to arise curiosity, to inspire new ideas, to create a sense of security and inclusion in the campus life. Though the floorplan is not fully opened and the enclosed rooms are still preserved, their uniformity is broken as various sizes and various functional areas are proposed to provide optimal conditions for learning. The conventional classroom is converted into a new configuration of flexible spaces which satisfy the current needs but are opened to experimentation so that they easily adapt to the needs of the future. Both teachers and students are stimulated to explore the space and find new ways to interact and establish new relationships. By identifying opportunities for future-oriented spatial design innovation we expect to support the self-directed learning, promote the active participation of the students in the educational process and provide a more meaningful learning experience.

Abstract

How can universities in the field of product design anchor a sustainable, future-oriented approach in their curricula? How can they do it in a long-term way that goes beyond individual current topics and can be communicated well both internally and externally? How is a sustainable attitude compatible with a discipline born out of industrialisation?

In the context of a curriculum development in the years 2020 to 2022 at the Lucerne School of Art and Design, the opportunity arose to include the Sustainable Development Goals (United Nations Department of Economic and Social Affairs 2015) in every single module description of our product design bachelor's degree course. The project discussed in this paper served as an important reference in this development, as it succeeded to combine a structural attitude based on the SDGs with the most diverse aspects of product design education, such as design goals, manufacturing techniques and external partners.

This paper has been written to gain an overview of how other schools and programmes in the field of design and art deal with the demand for sustainable and future-proof education and to learn from the methods they use. The aim is to exchange experiences and discuss collaborations for exchange programmes or collaborations, but as well to find out how independent the path we have chosen is.

How to include sustainability into a product design education?

Product design surrounds us everywhere - almost everything we touch during our daily routines has been designed as a serial product.

As a discipline, product design emerged with industrialisation and is closely linked to it. Currently, product design needs to emancipate itself from industrialisation: how can we define our attitude and values in such a way that the side effects of industrialisation do not stand in the way of a future worth living? Nowadays, there is probably no product design education at Bachelor or Master level that does not talk about sustainability. Sustainability, however, is an extremely elastic term – is there a structure that we can follow without losing sight of our core competence of product design?

Our department at the Lucerne School of Art and Design currently offers 13 courses at Bachelor level. Over the past two years, the department has been engaged in curriculum development across the entire Bachelor level (Holzer 2023a), starting with the new curricula in September 2022. While this curriculum development aimed at facilitating new transdisciplinary modules and transdisciplinary skills by aligning structures, it provided an opportunity for the individual programmes to revise their offerings. We, as a bachelor programme in Object Design, wanted to use the curriculum development to anchor sustainability in all modules - but how could we do this beyond lip service, without losing our focus on product development?

In the search for a guiding structure for our programme, the following factors were important:

- a broad establishment and recognition
- an understanding of sustainability that includes social, ecological and economic aspects
- the coordination within the various product design programmes at the Lucerne School of Art and Design as well as with the sustainability lecturers at our department.

We decided to orientate ourselves according to the Sustainable Development Goals (SDG), which the United Nations General Assembly published in 2015 as political goals to be achieved by the year 2030: from the autumn semester 2022 onwards, each module of the Object Design curriculum will focus on one or more SDGs, which will be communicated at the beginning of the module. For the basic modules in the first semester, the SDGs are the same in each year; for the advanced modules, the SDGs are chosen according to the respective design tasks. (Fig. 1) For the Bachelor thesis, the students themselves specify the SDGs for their self-chosen topic (Fig.2).

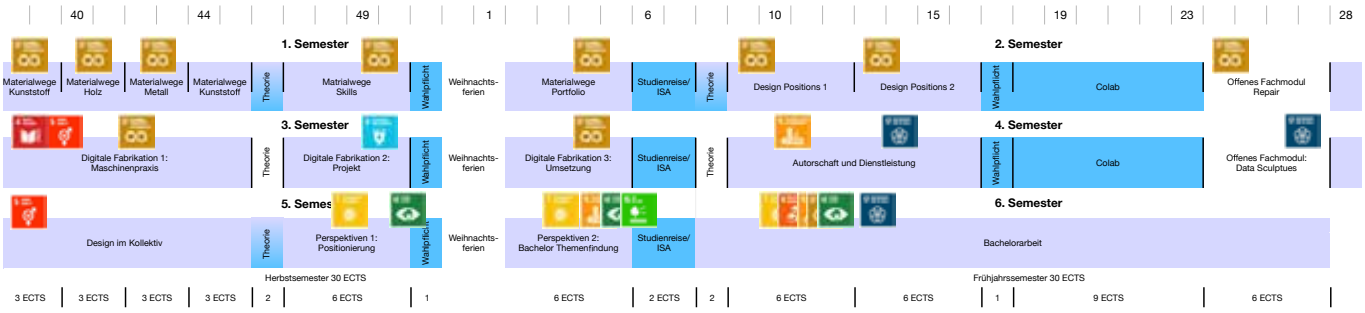

Figure 1. The Object Design Curriculum of the academic year 2022/23 with the SDGs (colored squares) year with the SDGs assigned to the respective modules: Basic modules in the first year (upper line) focus on SDG 12 "Responsible Consumption and Production", while in the modules in the 2nd and 3rd year the range grows and changes annually depending on the chosen topic. Bachelor students in the sixth semester choose the SDGs of their final project themselves.

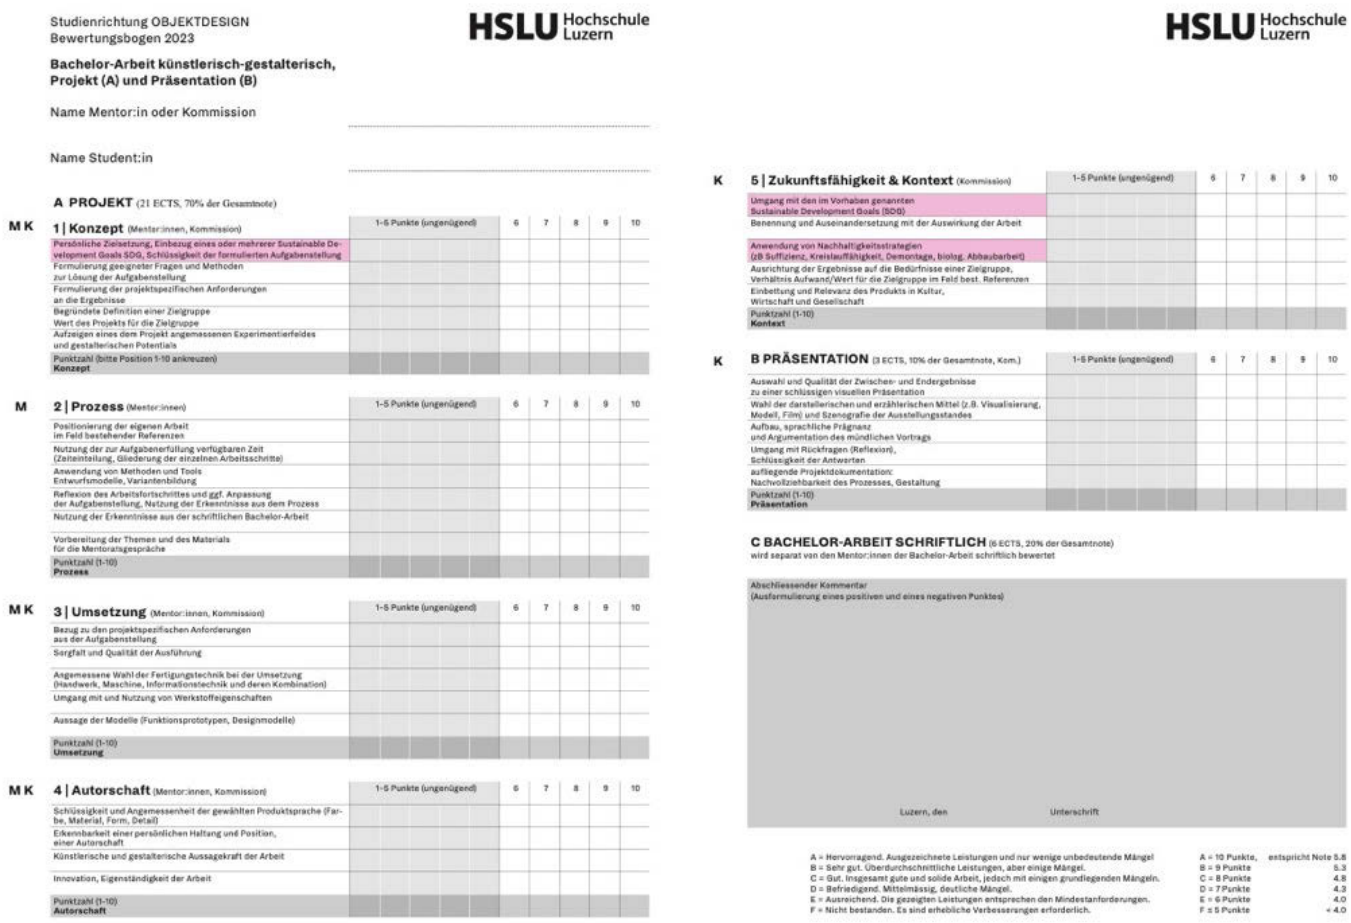

Figure 2. The SDGs are an integral part of the Bachelor's thesis without being the main focus: The SDGs are carefully but unmistakably integrated into the evaluation form of the Bachelor thesis at the points marked in pink. At the top left of the assessment criterion "Concept", the students select a "Personal objective, inclusion of one or more Sustainable Development Goals SDGs, conclusiveness of the formulated task". In the assessment criterion "Sustainability & Context", the "Handling of the Sustainable Development Goals (SDG) as mentioned in the draft" is assessed as well as the "application of sustainability strategies (e.g. sufficiency, recyclability, dismantling, biodegradability)" in general.

In parallel, the SDGs were integrated into the Textile Design programme, who had initiated the discourse about integrating SDGs into the new curricula (Holzer 2023b). This, in turn, built on a strategy of the department's Products & Textiles Research Group, which has been embedding the SDGs in its research proposals since 2017, referring to the Swiss Federal Department of Foreign Affairs "2030 Agenda for Sustainable Development" (Agenda 2030). Back in 2019, Object Design and Textile Design had already developed together the voluntary training "Sustainability for Lecturers in Design and Art" (Perret and Zimmermann 2020).

Since November 2022, the reference to the SDGs is stated on our website: "All modules in the Object Design programme focus on one or more goals of the United Nations Sustainable Development Goals (SDG). For their Bachelor's thesis, Object Design students define one or more of these goals." (HSLU Objektdesign SDG 2022).

An essential quality of a paper is to situate one's own teaching in the context of other universities. We investigated the integration into other product design programmes on four levels:

ChatGTP

This is 2023, and initially we started with ChatGTP: "Which Bachelor's or Master's programme in product design integrates the United Nations Sustainable Development Goals (SDGs) into its curriculum?" To which ChatGTP replied the following on 31/01/2023: "I'm not aware of a specific Bachelor's or Master's program in product design that integrates the United Nations Sustainable Development Goals (SDGs) exclusively into its curriculum. But many universities and institutions offer courses and programs that cover sustainability and the SDGs as part of their product design curriculum. You may want to check with specific universities or institutions for more information on their offerings."

SDGsUNi

While the SDGsUNi initiative (WASD 2023) lists a few schools in the arts, only a few of them address SDG 12 'Sustainable Consumption and Production', none of them related to product design: the Sibelius Academy in Finland (a music school), the University of The Holy Qur'an and Islamic Sciences in Sudan, and the Ghana Institute of Journalism. However, as we are not listed there ourselves, we must not assume completeness of these lists.

she ji Study

One of the reviewers of this paper kindly drew my attention to a comparative study on "Sustainable Product Design Education" published in she ji (Watkins 2021). It compares curricula from six universities in different countries. All of them teach sustainability, e.g. in studio projects, final projects, elective and compulsory modules, some of them refer in these modules to the SDGs (Nottingham Trent University, Technical University of Denmark, TU Delft). However, the study does not give any indication of a continuous implementation of the SDGs in one of their curricula.

Internal Study HSLU

Thanks to an internal, unpublished and therefore non-quotable comparative study carried out in our department last year, we got an up-to-date overview of design and art courses offered worldwide at design and art colleges in the field of eco-social innovation at BA, MA and PhD level, as well as in the field of further education. Of the 26 Bachelor's programmes, 15 could be assigned to the field of "Design", eight to the field of "Fashion and Textiles" and three to the field of "Art and Liberal Arts". Of the 15 programmes in the area of "Design", one specialises in visual communication, six focus on product design and two have a very open curriculum. For the purposes of this paper, I have only examined the six universities in the field of product design in more detail. A browser research with ChatGTP and Google brought the results in Table 1, see links in the references at the bottom of this paper.

Table 1. Overview of product design schools related to the SDGs based on internal study

Product design school	use of SDGs	reference
Universidade de Trasos-Montes e Alto Douro	lists the school's activities related to SDGs on its website since 2019	UTAD SDG 2019
Hochschule für angewandte Wissenschaften Coburg	lists the SDGs as a focus of the "ERIC - Entrepreneurship Track for Regional Impact on Global Challenges" programme	HS Coburg SDG 2022
Ecosign	no specific mention of the SDGs	
Häme University of Applied Sciences	lists SDGs as part of their "Sustainable Development Programme"	Häme SDG 2017
Falmouth University	claims to be ranked as a Top 10 Institution by the 2021 and 2022 SDG Teach In	Falmouth SDG 2021
Linnæus University	lists publications from Linnæus University that are connected to the SDGs	Linnæus SDG 2022

Even by contacting these schools directly via email and explaining the purpose of this paper, none of the six schools answered to the request. Until the moment of the publication of this paper, we could not find evidence of a structural integration of the SDGs into a product design education in any of them. Despite today's possibilities of an investigation, we are far from making a claim to its completeness and thus to a unique selling point of our curriculum. Nevertheless, seven years after the presentation of the SDGs in 2015, this is a surprising interim result for an education that has such a big impact on our use of resources.

Figure 3. Glass blowing at the Open Glass Studio with help of a digitally milled mould

Case Study: 'Value of Tap Water' Project

Institutions that use the SDGs in their corporate communication are required to substantiate these goals with concrete measures if they do not want to be accused of greenwashing. In the case of our curriculum, we would like to show what role the SDGs play in a specific module. Our case study is the module "Digital Fabrication" from the 3rd semester of Object Design:

In a country like Switzerland, we take it for granted that water of the best quality is available free of charge. Switzerland is a country of wells. Globally, this is an exception. Nevertheless, Swiss people afford themselves the luxury of buying bottled water; in 2021, for example, sales amounted to 903.5 million litres (Statista 2021). This behaviour leads to a burden on the environment, through transport, packaging and production. What does a glass container have to look like to make tap water seem more valuable than a bottle of San Pellegrino? Within four weeks, 3rd semester students designed fourteen counter-position to the culture of branded water. This resulted in fourteen glass vessels for an event of experimental gastronomy in interaction with digital tools and a

glass blower – see four examples in a project video on https://vimeo.com/771902070. The project 'The Value of Tap Water' aims to bring together five different perspectives:

1. We envisaged the appreciation of tap water as a design objective and sustainable meta-theme, closely linked to the SDGs 6 Clean Water and Sanitation, but also SDG 3 Good Health and Well-Being and the obligatory SDG 12 Responsible Consumption and Production.
2. For alumni, it is important that as many school projects as possible achieve a visual quality that can be presented in a portfolio. In case of this project the design aim was to explore the formal, narrative and functional aspects of glass carafes and vessels for water.
3. The project was developed in the module 'Digital Fabrication' in the curriculum of our programme. Students learned about three-dimensional drawing, the creation of data for the CNC milling machine as well as its handling by means of mould making for glass blowing.
4. The linking of digital woodworking with archaic glass blowing at the professional Open Glass Studio exemplified the diverse and unexpected areas of applying of digital fabrication. The contextualisation with the SDGs, as well as the application of Digital Fabrication goes beyond earlier examples of glassblowing in product design, see for instance Glanzmann L. (2012) and Scott de Martinville, A. (2015).
5. With its experimental gastronomy, our Dutch project partner steinbeisser.org offers an expressive platform for presentation, discussion and sale of the objects. Steinbeisser scheduled a prominent event with Vegan Michelin-cook Zizi Hattab and Karime Lopez in September of 2023 at the Merian Gardens in Basel (Steinbeisser 2023), where the submitted objects will be used as part of an experimental gastronomy. Following the event, the glass objects will be offered as individual pieces at their online store on www.jouwstore.com.

While the material experience of glassblowing and the collaboration with the partner steinbeisser.org were enormously appreciated by the students, there was hardly any feedback for the establishment of the SDGs in the curriculum.

Lessons we learned

As we considered the implementation of the SDGs a major step for our curriculum and perception, we started a digital survey of all object design students on the following questions:

- Has anything changed for you since we embeddd the SDGs in the Object Design curriculum - and if so, what?
- Did the SDGs mentioned at the beginning of the modules influence your design decisions - and if not, why not?
- Do you have any advice for us regarding the introduction and embedding of the SDGs in the following academic year?)

First of all, it should be mentioned that despite repeated requests, there was only little feedback from the students. Participating students of all study years stated that sustainability would have been a priority in their lives even before they started their studies. Nevertheless, they were not or only little aware of the SDGs and they would like to have a more profound, also critical examination of the SDGs. One person wrote that projects could also be based on the SDGs, instead of a later classification. Another person stated that her project research had to do with drinking water and was therefore connected to the SDGs, but rather in an unconscious way.

For the first time in 2023, the fifteen Bachelor candidates in Object Design were asked to refer to one or more SDGs in their outline of their Bachelor project (cf. Fig. 2). Although this was only done marginally in their project drafts, we noticed a considerably deeper engagement with sustainability in the topics chosen by the students.

The most concrete student feedback we received during the presentation of the SDGs in the first year, while introducing a text by Rutger Bregman on moral ambition: we had not been consistent with the gender-inclusive word endings in the German translation, and thus students told us that the presentation did not meet our own requirements of SDG 5 "Gender Equality". As a consequence, we organised a discussion on gender-inclusive language with all the lecturers of the first year and reviewed our use of language.

A little surprised, we note that the effects of the SDGs in the curriculum are only indirectly experienced by the students. At the same time, we as a study programme - as lecturers –

Figure 4. Connecting vessels with a tube: Zita Fahrländer's project illustrates the interrelations of drinking water resources
Movie still: Raisa Durandi

Figure 5. The variety of different moulds produced at the wood workshop of Lucerne School of Art and Design: most of them on the CNC milling machine in massive beech, others in plaster or even sand
Image: Andri Stadler

are aware that this step helped us enormously to integrate a sustainable attitude consistently and in all its diversity into our teaching.

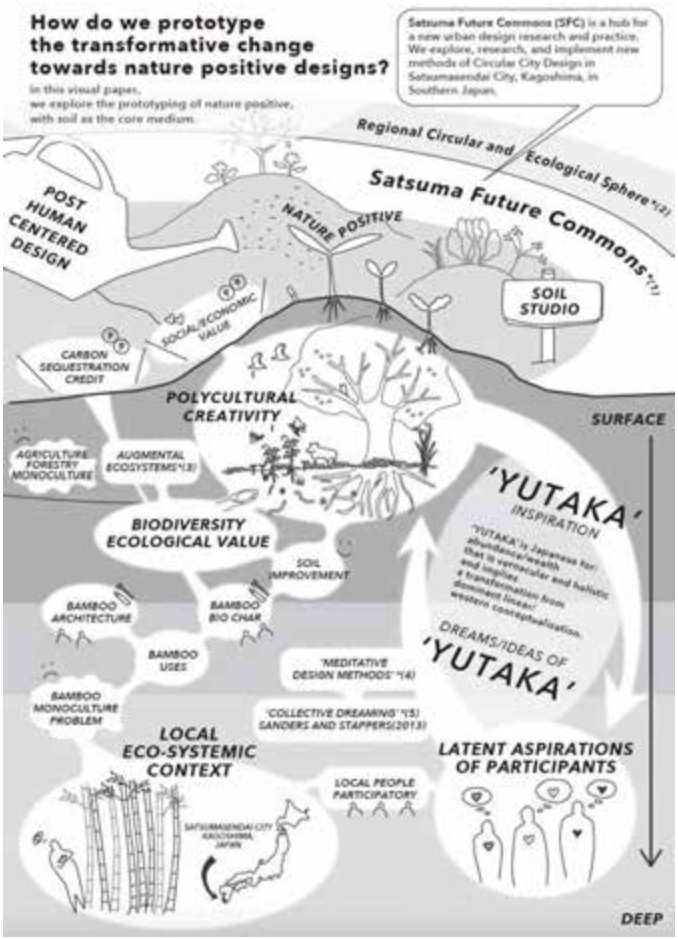
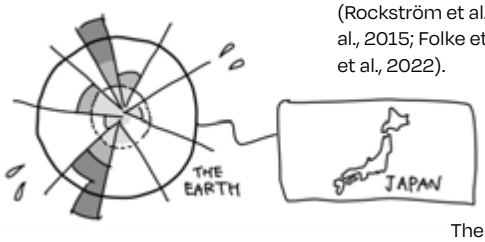
Abstract



Author keywords

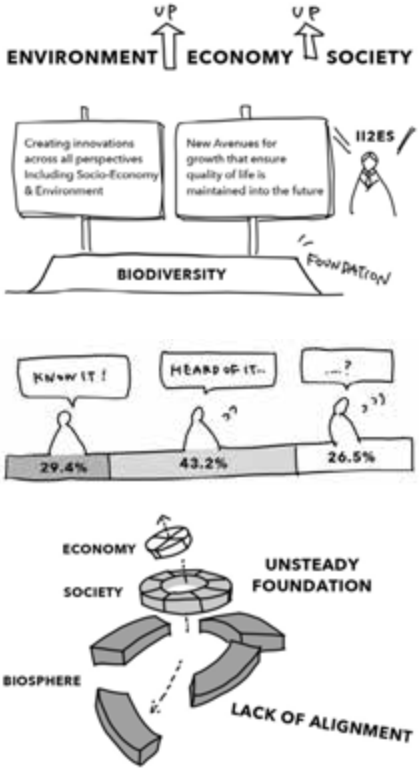
nature positive; circular design; polycultural creativity; meditative design methods

Introduction



(Rockström et al., 2009; Steffen et al., 2015; Folke et al., 2016; Persson et al., 2022).

Global biodiversity and Ecosystems threatened! We need planetary health! (Horton, et al., 2014)



Transformative change is needed! (IPBES, 2019)

The Japan Biodiversity outlook 3 issued by the Working Group for Comprehensive Assessment of Biodiversity and Ecosystem Services), Ministry of the Environment Japan (WGfCAoBaES, MoEJ), also echo's the IPBES report and urges action. In response to Japan's challenges the Ministry has launched the Circular Ecological Economy, proposed by the government in 2018 in the 5th Basic Environment Plan.

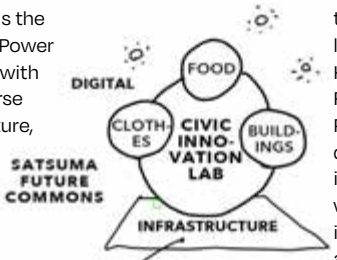
'Integrated Improvements on Environment, Economy and Society' (II2ES).
(Cabinet Office, Government of Japan ,2022) The plan aims to achieve the SDG's (United Nations, 2015).

Combining II2ES plan with sustainable use of regional resources and creating partnerships, is synthesized in the Circular Ecological Economy vision (MoEJ, 2021).

Satsuma Future Commons (SFC) Launched by the city to realize its vision of a circular city. In the background all of this initiative lies in the macro population decline in Japan as well as aging population (MoEJ, 2021).

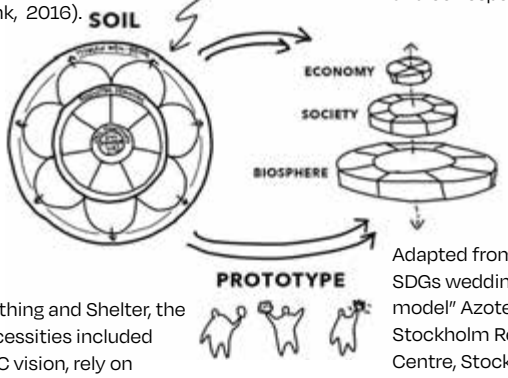
Circular economy with innovation hub located at the 240,000m² area of former unused farmland in proximity to the SNPS (Kamio, 2022).

The major economic driver however is the Sendai Nuclear Power Station (SNPS), with ongoing discourse regarding its future, alternative.



The city developed the plan with collaboration between Kyushu University, and Re:Public inc. Plans and vision were developed with expert input (incl. Inamura) with citizen dialogue including face to face, and correspondence.

Soil properties. (Adhikari & Hartemink, 2016).

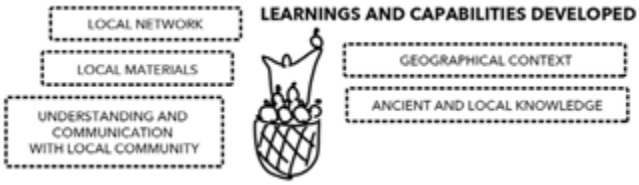


Adapted from "the SDGs wedding cake model" Azote for Stockholm Resilience Centre, Stockholm University

Wy Soil?
Food, clothing and Shelter, the basic necessities included in the SFC vision, rely on nature, such as rice, natural fibers (e.g. silk, cotton, linen) and wood. Such provisioning services are examples of ecosystem services provided by nature. Agroecological (agriculture plus ecology) practices reported to generally positively link with ecosystem services (Palamo-Campesino, et al. 2018). All such provisions rely on soil as the fundamental enabling infrastructure. Soil is the hidden nexus of food, water and energy (Hatfield et.al, 2017)

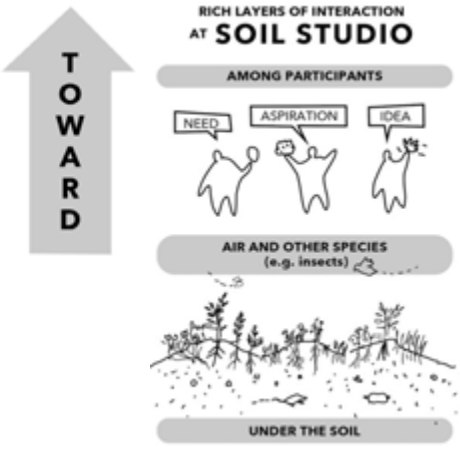
OBJECTIVE
This visual paper explores how to prototype this change from a design standpoint and introduces the Soil Studio as a means to prototype transformative change from the ground level. The Soil Studio aims to explore what is *Yutaka* in relation to soil, where *Yutaka* is a holistic and regional conception of wealth, abundance, and harvest.

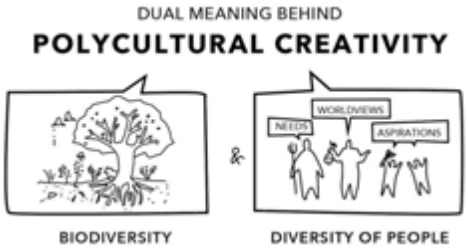
The authors conducted desk research in Augmented Ecology (Funabashi, 2016; 2018), and prominent models of agroecology.



The Soil Studio launched in September 2022, is a format where participants each plant a polyculture in adjacent plots which reflects their own needs, wants, aspirations and world views. This format has been piloted through a test bed in the outskirts of Satsumasendai city, on property provided by local citizens involved in previous projects.

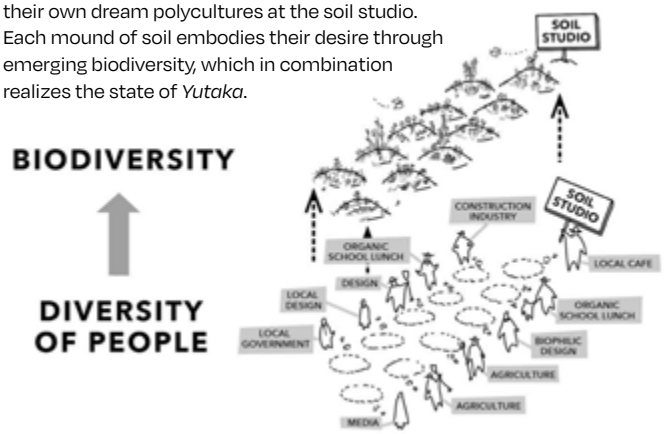
Yutaka is drawn from traditional Japanese thought and defined here as a holistic and regional conception of biodiverse wealth and abundance.



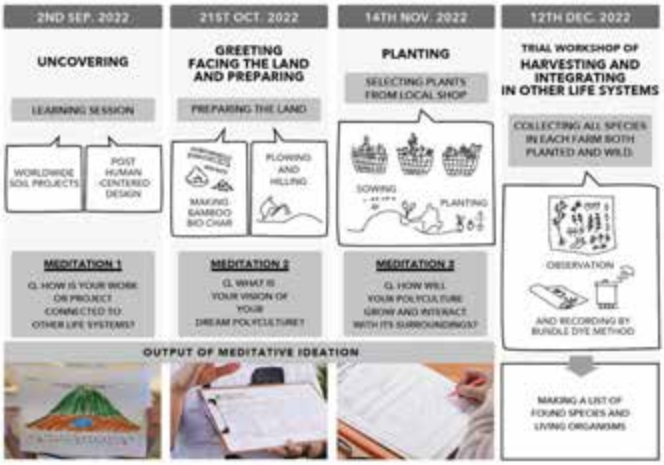


Typically Polyculture is used to denote agricultural species mixtures (Weißhuhn, 2017).

Pilot Soil Studio Overview
People from various backgrounds tried to realize their own dream polycultures at the soil studio. Each mound of soil embodies their desire through emerging biodiversity, which in combination realizes the state of *Yutaka*.



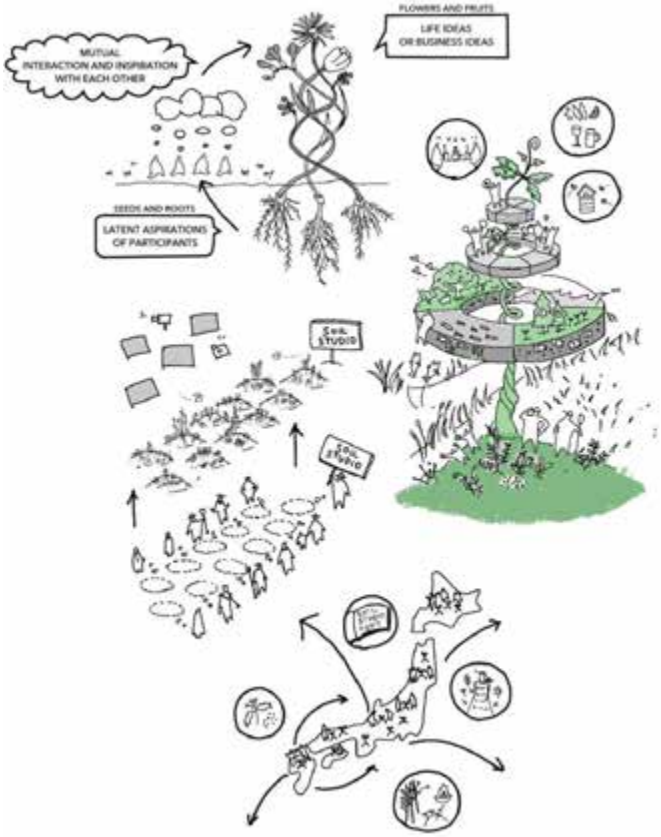
The meditative methods developed by Inamura (Ito, 2021) was combined with co-dreaming of Sanders and Stappers (2012, 2014). With recent shifts in design research toward more-than-human conceptions (Sznel, 2020; Inamura 2022), co-dreaming has been expanded.



Results

matches the research on feelings of connection to nature. (Mayer & Frantz, 2004).

What are te characteristics of the Soil Studio



1: Polycultural creativity
The key difference is to foster the individual human aspirations/desires/needs of the participants through polyculture.

2: Design Studio Concept
The Studio concept: 'what is Yutaka in relation to the soil?'. This is a provocation to learn and develop new ideas for how to connect biodiversity to value. Design approaches have shown many possibilities of innovative use of natural materials (Solanki & Corbin 2018).

3: *Yutaka* Concept
Invoking the concept of *Yutaka*, abundance and wealth based on ancient and holistic world views, is a unique point of the Studio.

4: Methods
Some key methods conducted during Studio praxis included, co-dreaming, meditative design methods, prototyping, and learning sessions.

5: Agroecological technique

Funabashi has presented a no tilling method (though hilling is allowed), minimum soil improvements and no external fertilization (2016). Here, Bamboo bio-char (a local monoculture issue) was used to improve soil conditions and be eligible for carbon credits. As for species of plants, commercial species were chosen, however the Studio format is open to local/heritage varieties and seeds.

6: SLOC scenario

Soil that is Small, Local, Open and Connected.
In line SLOC scenario proposed by Manzini (2011).

7: Societal Context

The soil studio is part of a joint research project between industry and academia and built on a memorandum of cooperation between the city municipal government and university faculty. The city's vision reflects citizen feedback, national policy, and intergovernmental goals. As such the studio pilot is interlinked with layers of regional societal systems, connecting policy to individual.

Conclusion

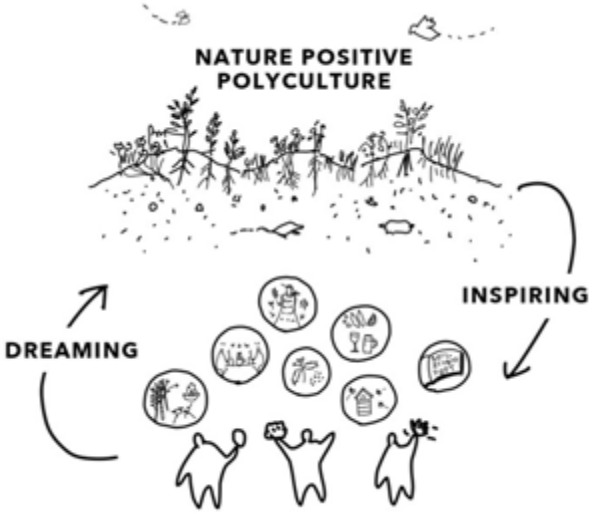
A studio model was established based on Funabashi's work on Augmented Ecosystems through desk research and a site visit. Agroecological methods were combined with the 'collective dreaming' of Sanders and Stappers, utilizing Meditative Design Methods developed by Inamura to explore latent aspirations of human participants to envision a thriving polyculture. The participants then engaged in prototyping and making based on the polyculture. The preliminary results and feedback were recorded. Participant feedback provided highly encouraging anecdotes on the success of the pilot. These results were shown in a public exhibition in the city. The documented interactions of the participants indicate a sense of connection to nature and drive a virtuous cycle of dreams and inspirational learning from the emerging nature positive polyculture. The studio empowers participants with a potent means to explore what is *Yutaka* in relation to soil.

Relevance to readers

The concept of *Yutaka* is relevant as an example of vernacular/local worldviews to drive design development in the nature positive space.

Readers in the Societal, or design for government space, can be informed about how individuals might be engaged in large scale societal transformations on the ground level, with alignment to layers of policy.

Those who are researching mindfulness, meditation and related concepts will find novel applications reported through the case to add to the overall literature of meditative design processes.



Future Research

Though the project is still early in its pilot stage, it has demonstrated potential as a transformative model towards agroecological states of *Yutaka*. Next steps will be to develop the existing Soil Studio, enabling participants, as well as quantitative and digital approaches. The Soil Studio presents aspects that more than the sum of their parts, though based in local worldviews and ecological contexts, have clear structural, methodological, and societal aspects that can be adapted to other localities, beyond Japan and the Asia-Pacific region. Testing the studio format to see how it applies to other sites are also an important trajectory, considering the global spread of circular, participatory and nature positive approaches, it can be hypothesized that the soil studio format will be relevant in many places, and the adaptations necessary also need to be clarified.

Material experience: the future of material selection for product design

Emma Kirjavainen, Milla Johanssons, Jonna Häkkilä

Universityof Lapland, Finland
emma.kirjavainen@ulapland.fi
milla.johansson@ulapland.fi
jonna.hakkila@ulapland.fi

Abstract

It has become more and more important to consider the future material selections in product design. The material choices influence on the user perception and hedonic experience qualities, but they affect also product qualities such as recyclability and durability. Understanding the user experience with materials can help us to design for more sustainable transformations. In this paper, we address the topic of material experiences through user research. In our research, we focus on four characteristics in the material experience: arctic, classic, expensive and cheap, and present two user studies investigating the user experience with materials in products. The first study utilized the material probes method, and included a user test in which the participants could explore and feel different materials: glass, metal, leather, plastic, concrete, and wood. The second study consisted of individual interviews of eight (8) people. As salient findings, we report that wood, glass, and leather were perceived to represent classic and arctic, whereas plastic provoked negative reactions. With plastics, an interesting contradiction was found when people still often used plastic products to describe an expensive product category.

Author keywords

Design materials; material probes; user experience; user studies.

Introduction

Designers' work can be said to focus around creating new products and solutions for people to use, and their work is visible in every sector of life with different consumer products. However, it is recognized that today we live in a world where the population grows and consumption is constantly increasing, creating problems with the over consumption of natural resources, pollution, and waste, and an urgent pressure to change this development. As a result, we are more focused on the environment and sustainability. According to Maleque & Salit (2013), the environment and factors affecting it are featured increasingly in design; this shows in how materials are chosen, manufacturing processes, life cycle thinking and in material development. Environmental values and sustainable growth are also significant factors in marketing of these products (Maleque & Salit, 2013, 70), and drive for design for transformation and nature friendly solutions.

Product designers and industrial designers work integrally with different physical materials. Materials are an essential part of the user experience with tangible products, and their selection influences on the product's outlook, durability, usability, price, and recyclability. Material choices are thus an important part to consider in the design phase, and understanding how people perceive the materials provides useful background information for these choices.

We investigated the user experience with product design materials with two different user study methods. The first study utilized the material probes method, and included a user test in which the participants could explore and feel different materials: glass, metal, leather, plastic, concrete, and wood. In the second study, interviews were conducted with eight (8) people, who also presented product examples of their choices. Our work contributes in understanding the user perceptions of material qualities and user experience, and can provide insight and inspiration for product designers and researchers who are interested in materiality as part of the user experience.

Material Experience

User Experience with Materials

User experience (UX) is a central concept when designs are assessed, and it goes beyond the definition of usability - efficiency, effectiveness and user satisfaction - which has traditionally been the key concept when user interface design goals are set (Law et al. 2008). User experience design does not consider only the instrumental value of the interactive artifact. It highlights also hedonic aspects, and that emotion and affect have important roles in the holistic perception. These include factors such as aesthetics, emotional engagement and stimulation (Hassenzahl & Tractinsky, 2006). User experience is studied with user-centered design methods, which can be applied in design and evaluation phases (Hassenzahl & Tractinsky, 2006; Häkkilä, J. 2020, p. 68).

Even though design education is changing, and the methods and tools in the field have generally moved to fast modeling methods such as 3D printing and laser cutting, design stu-

dents still need a good knowledge of materials and practical experiences (Johansson & Konttinen, 2021, 90). The skill of producing successful and insightful design requires knowledge of previous solutions from a contextual and historical level (Falin, 2011, p. 122). Only with sufficient understanding of the effects of material selection, can we have an impact on the future of product design.

Also, successful product development requires a deep understanding of users' preferences. Design is one way to concretize users' needs and make products easier to use, more functional and sustainable. Today, a designer is expected to have good empathy skills, so that they understand user needs and at the same time can push their own opinions aside (Huotari, Laitakari-Svärd, Laakko & Koskinen, 2003, pp. 9-25). Understanding user experiences with materials can be a tool for change and transformations.

According to Karana (2010), the material is a very essential part of the product and the material experience created through the product is multifactorial. When people interact with products, their senses are in contact with the product's materials, which mainly provide visual and tactile stimuli. The environment and previous experiences also have their own influence on how materials are perceived (Karana, 2010, p. 23.) Designers need to be aware of the overall picture affecting users' experience with physical products and materials. Materiality plays a central role also with tangible user interfaces, since materials can be experienced thru touching and haptic feedback. Nevertheless, according to Häkkilä & Johansson (2018) materials also affect the visual design and the style of the products. Therefore, the designer can promote values and create associations with material selections (Häkkilä & Johansson, 2018, p. 36).

Materials and Designing for Nature Positive Transformation

Design educators are creating a foundation for the future by teaching tomorrow's designers. Preparing design students with knowledge about the importance of material selections for product design can make a difference towards a nature positive transformation. Nature positive transformation is an essential requirement in the future design. This is simply because a turn towards more sustainable solutions must happen in order to give Earth as the living planet a chance to flourish also in the future. The future of the entire planet is greatly affected by the ongoing development trends, which are of great concern. These include the overuse of natural resources, global warming, increasing population, urbanization and the socio-economic challenges of consumer society. Different measures and campaigns have been developed to increase the awareness of the issues. As one illustrious example, Earth Overshoot Day has been announced as a measure to describe the overuse of natural resources and the planet's capability to recover from the toll the humans are putting on the biocapacity. It is calculated for each year by Global Footprint Network, and marks the day when Earth's biocapacity suffices to provide for the Ecological Footprint of humankind. In 2022, the Earth Overshoot Day was on the 28th of July. Sustainability needs to be addressed with a wide spectrum of solutions across the society, since it has been recognized as a key challenge. According to Ljungberg (2007), developing more sustainable products can be affected in part by the material selections. However, the material selection process today is complicated and challenging, since there are virtually countless options available. Designing products for a sustainable future gives the material selection and the designer even more significant role.

Study I – Material Probes

Method

In the first phase of our research, material probes were used as a qualitative data gathering method. Material probes method in the context of interaction design has been described by Jung and Stolterman (2010), who addressed the topic of materiality related to digital artifacts. The method was developed to provide understanding on how people perceive different material qualities, and to feed to the discussion on how these observations and desires could be incorporated into the design. Jung and Stolterman employed a three-step procedure, which included asking the study participants to tell stories of memories related to physical artifacts, playing with material samples while speculating on their preferences, and comparing the physical and digital artifact experiences (Jung & Stolterman, 2010). The material probes method was later adapted by Häkkilä et al. (Häkkilä, He & Colley, 2015), who studied the experience with natural materials by providing tangible samples and assessing them with product reaction cards based on the Microsoft PRC set (Benedek & Miner, 2002). Here, product reaction cards provided a set of predefined words, from which the participant could choose the terms best matching their experience with the physical material probe.

In our study, we adopted the material probes method by concentrating on the second step of the original procedure by Jung and Stolterman (2010). Here, we introduced study participants the material samples as tangible, physical bits they could touch.

Study Set-up

The material probe method used in our first study consisted of seven material probes and the questionnaire which had three questions for each material sample (probe). We chose seven hard materials, and decided to name and label the material samples (probes) in the test situation alphabetically (a, b, c, d, e, f, and g) to minimize pre-existing opinions related to different materials. The material probes are presented in Figure 1 and consisted of the following materials: glass, metal, leather, plastic, concrete, cardboard, and wood.

Figure 1. Material probes in the Study I:
A. glass, B. metal, C. leather, D. plastic, E. concrete, F. cardboard, and G. wood

Each study session lasted for approximately 40 min, and included the following steps:

- Completing a background questionnaire.
- Interacting with each material probe in turn.
- Following a Product Reaction Cards (PRC) based methodology (Benedek & Miner, 2002), for each material, selecting three (3) terms from a list of 14 that best described what the material 1) felt like and 2) looked like.

» Rating the materials on a 5-point Likert scale against the categories: arctic, classic, expensive, and cheap.

A total of 22 participants (15 female, 7 male; aged 20–41, with the average of 27 years) took part in the study. Participants were predominantly university design students and staff.

Results

The tactile and visual sensations evoked by the material samples are presented in Figure 2, which summarizes the answers for the questions posed with the material probes: "How does the material feel?", and "What does the material look like?". Figure 2 presents the three most common PRC terms selected for each material.

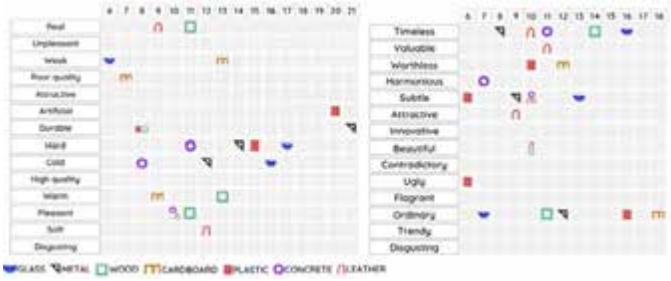

Figure 2. Three the most frequently chosen PRC terms for each material to describe 1) how the material felt like (left), and 2) how the material looked like (right).

The test participants' associations between the materials and categories arctic, classic, expensive, and cheap are present in Figure 3. Wood, glass, and leather were perceived to represent classic and arctic, while concrete, plastic, metal, and cardboard did not fit these categories so well. Wood, glass, and leather were perceived almost equally as classic and arctic materials. Leather was perceived as the most expensive material. Plastic and cardboard were perceived as the cheapest materials compared to the others used in the material probes.

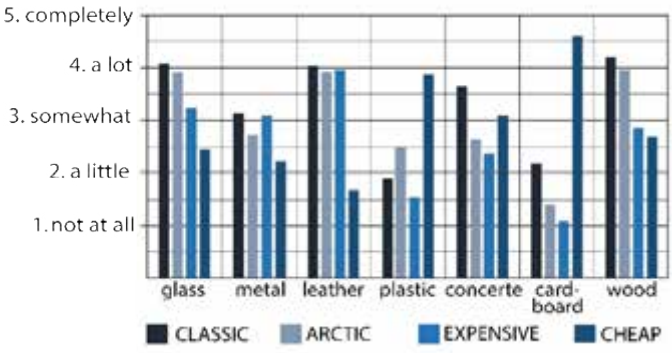

Figure 3. The average of the results of how participants combine materials with the categories arctic, classic, expensive, and cheap.

Study II – Interviews

Method

The second phase of the data collection consisted of interviews. The interviews were run as a separate study, with different participants as the first, material probes study. The interview method is suitable for situations where the answers are relatively unknown, and where the researchers are interested in bringing out comprehensively different viewpoints (Millar & Tracey, 2009, p. 80). Different kinds of probes can be used as an integral part of an interview in order to provoke memories and to stimulate the interviewee to speak more (De Leon & Cohen, 2005). De Leon and Cohen (2005) call non-verbal, tangible probes as object probes. Object probes are artifacts which are used explicitly to generate verbal responses, and they can be selected by the researcher or the study participant him/herself. Object probes can be for instance photographs, which can help participants to verbalize their memories and observations. For instance, Collier and Collier (1986) have pointed out how photography can support ethnographers in conducting interviews and thus in collecting richer data from field studies. Our interview study took inspiration from the material probes method by Jung and Stolterman (2010), who asked people to tell memories related to different materials. In our study procedure, we utilized objects and photos selected by the participants as part of the interview.

Study Set-up

The interviews were supplemented with product examples chosen by the participants, and the material experience was observed through the selected products. Prior to the interview, the participant had to choose one product from their home for each category: Classical, Cheep, Expensive, and Arctic. We also instructed that the examples should not be any clothing or anything eatable.

T study included the following steps: The pre-task, a background questionnaire, and nine ready-made questions, which the participants received before the interview situation. Each interview lasted 30–40 minutes and was conducted via video calls. Altogether eight participants (7 female, 1 male, 27-61 years, average 40 years) took part in the study. All persons interviewed had some kind of connection to the Finnish Lapland.

Figure 4. Pictures of the products which participants had chosen for the categories arctic, classic, expensive, and cheap.

Results

All the product examples are shown in the Figure 4. there found also the products main materials. In the "arctic" category, the products included many sports equipment that are used in the (sub)arctic region. The products chosen to fit the definition of "classic" consisted mainly of products related to home and living, excluding musical instruments. The products chosen to fit the definition "expensive" consisted mainly of electronics products. The product choices defined as "cheap" were justified by the affordability of the purchase price. Two products of this group were self-made.

Discussion

About the Findings

Material experience is a very wide and subjective matter, influenced by a large number of factors, such as the user's values, cultural background, previous experiences, age, gender and senses. Also, the user's financial situation affects how materials are experienced, especially when defining them as either expensive or cheap. Therefore, designers need to take the target group into account when choosing the product materials.

Based on the research regarding expensive materials, it can be concluded that people consider technical products expensive, because of their cost and for not being long-lasting in respect to their price. This is a well-known problem, and the principles of sustainable development are nowadays not implemented in all technical devices. It is especially interesting to discuss the "arctic" qualities of product design based on this study. The material and product choices of the arctic category showed a clear connection to natural materials. The functionality of the materials and the match with the use cases in the arctic region came to the fore. Of the categories used in the study, arctic was the only one that was a region-related category. It may be that the functionality of a material is easier to understand if it can be linked to a certain area or conditions. This would provide an interesting line for further research.

Plastic is a material that divides people's opinions, as noticed also in this study. Participants experienced plastics very negatively, both through physical experience and mental images. In interviews, however, a result contradicting this observation emerged, as many of the objects in the "expensive" category were, to our surprise, plastic.

The findings indicated that design has a rather large importance in how users experience the material and how they see and feel about it through the products. Plastics as a material is not perceived as expensive, rather the opposite, but it is used in many products that are expensive. The designer's choices affect how the user is experiencing different products and materials. The designer should take the target user group into account already when choosing the materials for the design, as the perceptions on different material qualities may differ between user groups. However, these factors are not fully controlled by the designer alone.

About the Theme Transformation for Nature Positive

The development of new materials has an important role in the future in replacing the existing harmful ones. Designers should be educated about new, more sustainable materials to be able to make better choices for product design, as they do have a role in transforming the physical artifacts to be more nature positive. Consideration of nature comes in quite seamlessly in arctic design, since the design is strongly influenced by the surrounding environment (Häkkilä & Johansson, 2018). Also the effects of climate change are specifically apparent in the arctic areas. For the nature positive transformations, it is promising to note that plastics, which have gained a lot of negative publicity for the waste problem it has created, also provoked negative results from the participants in this study.

Limitations and Future Work

We acknowledge that our study is limited by the sample the participants. The results might have differed somewhat if the same users would have selected to do both of the studies -material probes as well as interviews, or if the study had been conducted in different culture. However, as the research addressing the perception of design materials is at the core of product design, we believe our study provides some interesting insights to the topic. For future research, the observed contradictions e.g. with plastic as design material would be an interesting topic for future research.

Conclusions

In this paper, we have presented a two-phased qualitative research investigating the user experience with design materials. As salient findings, we report that wood, glass, and leather were perceived to represent classic and arctic, whereas plastic provoked negative reactions. With plastics, an interesting contradiction was found when people still often used plastic products to describe an expensive product category.

Based on the research results it can be concluded that some materials provoke a more nature positive user experience. Especially in the arctic category, natural materials such as leather and wood emerged. In the study, the product choices of the arctic category were combined with the conditions of the (sub)arctic region. In the selection of materials, wood, leather, and glass were chosen as arctic materials, which was also observed in the arctic product choices regarding leather and wood.

Discerning modes of design in ecological restoration

Madeline Sides

School of Design, Carnegie Mellon University, USA

msides@andrew.cmu.edu

Abstract

Ecological restoration is an art and science that offers a practical approach to repairing and caring for relationships in living systems. Restorationists, a community of multiple epistemic cultures, most often frame their work as a practice of ecology. Ecology provides a systems-oriented approach to natural and life sciences that can be applied to restore and repair. Yet, the word design also frequently appears in the work of ecological restoration. What do restorationists mean when they refer to design?

In this paper, I introduce ecological restoration to a design audience and frame restoration as a repair practice that advances designed interventions in socio-ecological systems. Through three case studies from the United States context, I identify three different ways that design appears in the work of ecological restoration: planning, technology, and transitions. As these case studies show, approaching restoration as designing can make restoration processes more transformative, more inclusive of multiple worldviews, and more critical of environmental injustices. Yet, design approaches can also depoliticize ecological restoration by oversimplifying it, or by normalizing an overly technological approach that seeks quick fixes to complex problems. By bringing ecological restoration and design into deeper conversation, this piece highlights the impacts of various design postures that are brought to the work of restoring ecosystems.

ecological restoration; earth repair; socio-ecological systems; transition design

Introduction

Worldwide, communities and governments are responding to environmental degradation by taking up the work of ecological restoration. The term restoration describes the work done by people to return ecological structure and function to sites like wetlands, coastlines, forests, meadows, and rivers after they have been harmfully disturbed. Examples of large-scale anthropogenic disturbances that restoration responds to include some types of agriculture, aquatic eutrophication, hydrologic disruption, logging, mining and oil spills (Jones et al., 2018). Restoration may also be used to address disturbances that are not directly anthropogenic, like wildfire and flooding, or to re-introduce beneficial disturbances that promote ecosystem flourishing. Restoration is widely accepted and recognized as a useful tool for ecological repair, and features in two key United Nations frameworks. One, to restore 350 million hectares as part of the UN Decade of Restoration and the other, to preserve biodiversity through restoration of 15% of earth's degraded ecosystems by 2020, an Aichi Biodiversity target that has not yet been realized (Unit, 2020). While restoration activities receive billions in funding (USD) annually, success in ecological restoration work is a complex and elusive process of changemaking that often requires modifications in policy and human activities, in addition to ecological parameters (Christian-Smith & Merenlender, 2010). In this paper, I introduce restoration to a design audience by asserting that restoration is a design practice, illustrating the ways that design practices and postures appear in restoration, and suggesting how those ways of designing relate to the potential for a restoration initiative to effect systemic change.

The practice of restoration affirms that humans have necessary, active and beneficial roles to play in repairing and maintaining earth's ecological functions (Egan et al., 2011; Higgs, 2003; Jones et al., 2018). This stance distinguishes restoration from practices of rewilding, conservation and preservation, where people are intentionally kept out of or away from protected lands. The restoration community comprises a vast amalgam of people, institutions and local communities who practice restoration with distinct methods, motivations and visions of success (Higgs, 2003; Kimmerer, 2011; Tomblin, 2009). The practice is most broadly defined as "the process of assisting the recovery of an ecosystem that has been degraded, damaged, or destroyed." (2023). Early definitions of ecological restoration emphasize the replication of historic conditions (Higgs, 2003). However, most contemporary restoration approaches frame the work as a way to create desired ecological conditions that, while deviating from a historic baseline, are ecologically sound and culturally relevant (Coleman et al., 2020).

Restoration as Repair

Restoration can be understood as a practice of repair. In fact, it is often referred to colloquially as "earth repair" (M. Hall, 2005). Restoration has also been described as an act of "relational repair" between groups of people, as well as between people and various non-humans, for injustices past and present (Almassi, 2017). This framing reminds us that social injustice is often intertwined with ecosystem degradation, as is the case with the removal of many Indigenous people and groups from their lands in the North American context (M. M. Hall et al., 2021; Kimmerer, 2011). Holistic and durable repair of ecosystems

must also consider these social contexts. Writing about repair, scholars Markus Berger and Kate Irvin theorize that repair can be either "first-order" or "second-order". First-order repair is about "a continuation of what occurred before (i.e., a car mechanic replacing a standardized part)" (2022, p. 2), whereas second order repair requires "enacting thinking and practices that challenge the status quo" and leads to "a complete transformation of the thing, system, and relationship itself" (ibid). With this framing, repair can be evaluated by the extent to which it is a systemic intervention, or simply a symptomatic fix. Restoration reflects this tension, as many projects are limited to first-order repair, prioritizing cleaning up an environmental mess without addressing its systemic root causes. Both kinds of repair are necessary, yet scholar Laura Martin argues that restoration "will offer no more than a temporary repair" (2022, p. 230) if systemic causes of degradation remain unexamined. To conceive of restoration projects as systems interventions, we must conceptualize ecosystems as socio-ecological systems that include human social dynamics and concerns (Perring et al., 2015).

Restoration as Design

Restorationists create material interventions in living systems ranging from earth moving to plant propagation in order to bring about better future conditions. Restoration is thus a practice of not only repair, but also, designing. Ecologist Eric Higgs draws the connection, noting, "Restoration is fundamentally about design, and the challenge ahead is to enlarge our capacity for good ecological design." (2003, p. 95). Discussing restoration in relation to design is inherently important because of restoration's significant contributions to a thriving and living future for both humans and non-humans. Further, despite the recognition by restorationists that design is relevant to their work, a robust dialogue is mostly absent between the fields of design and restoration, to the detriment of both. Higgs observes that, "as restorationists, we are involved in the design of ecosystems and places whether we like it or not" (271). Noting some ecologists' hesitancy to engage with design, he further argues that, *"we need to acknowledge that restoration is fundamentally a design practice [emphasis original]"* (274).

Scholars Mang and Reed (2013) and Du Plessis (2012) connect the dots between design and living systems by advancing frameworks for what they call regenerative design and development. These frameworks and tools support "design and construction of mutually beneficial and life-supporting relationships between built and natural environments" (2012, p. 15). As these proposals originate from a design and architectural posture, they emphasize changes to how the built environment is designed to benefit and regenerate natural systems. Restoration, on the other hand, primarily originates from ecological sciences, a field which has historically omitted the built environment from its study and consideration. Thus, with the exception of scholarship from designers of the built environment, design and restoration ecology mostly lack theory and frameworks to explain how their work interacts. Here, I bridge this gap and respond to Higgs' call for explicit recognition of design in restoration. I do so by identifying and discussing three ways that design is currently used to create interventions in socio-ecological systems through restoration and earth repair activities in contemporary cases from the United States context. I additionally suggest that the way we design restoration and repair will determine if the repair will catalyze beneficial systems transformations toward more sustainable and ecologically sound futures.

Design and Restoration: Three Cases

Here, I present three cases to discern and critique the roles that designing plays in restoration, so that restoration activities may yield more durable and transformative outcomes. These examples come from the American context, with start dates ranging from 2010 to 2022. They were selected because they are contemporary, self-identify as restoration projects, and illustrate three distinct modes of how design appears in restoration. As they are all ongoing projects, their ecological and social outcomes are not fully realized or understood. Restoration projects are typically evaluated in terms of recovery completeness and recovery rate based on indicators from ecological sciences (Jones et al., 2018). Instead of grading or scoring these project outcomes, my review identifies and critiques how design appears in the processes used to plan or carry out the restoration projects. I also locate the interventions in terms of their positioning as systemic leverage points using the "Places to Intervene in a System" framework by Donella Meadows (1997). This framework ranks leverage points in order of their likelihood to produce meaningful systems change, which Meadows calls "effectiveness". In this framework, a leverage point in the 12th spot is the least effective, with effectiveness increasing as the ranking proceeds from 12 up to one.

Institutional Restoration: Upper Truckee River

Design frequently appears by name in what Tomblin (2009) calls institutional restoration projects. These are projects led by state and local government agencies, or other institutions who may own or manage land, such as land trusts. Design is often considered a distinct stage in these projects, taking place between the establishment of goals and reference conditions and project implementation. In these contexts, designing is the process of solving a specific, singular problem of spatial configuration of ecosystem features (Holl, 2020).

This use of design appears in the case of the Upper Truckee River, a restoration project in the works since 2010 in the Lake Valley State Recreation Area (LVSRA) in South Lake Tahoe, California. This project aims to reduce sediment flows into Lake Tahoe from the Upper Truckee river by slowing or stopping streambank erosion in a particular river section. Erosion control measures include bank stabilizing work and re-introduction of historic river meanders, which slow down the flow of water. In addition to the river, the other significant feature of the LVSRA is an 18-hole public golf course on the river's banks. Restoration goals, which are set and managed by the California State Parks, also include creating a larger buffer zone between the river and the golf course, so that the river is less affected by the golf course and vice versa.

Restorationists in the Upper Truckee currently face a daunting task. Their design must simultaneously re-establish river meanders, move the golf course holes further from the river bank, keep the golf course at 18 holes, and do all of the above within the current footprint of the LVSRA. Project backers have hired professional golf course designers to solve this restoration problem by producing a golf course design that checks all of these boxes. In the socio-ecological system of the Upper Truckee river, design is being used to change the "structure of

material stocks and flows (such as transport networks, population age structures)" which Meadows (1997) rates as the 10th most effective place to intervene in a system, out of 12.

Work on this restoration project has not moved beyond the design phase in almost 10 years of deliberation due to a lack of public support and conflict amongst stakeholder groups. Despite the seemingly impossible constraints to satisfy, project backers continue to believe that a design solution exists for the LVSRA that will check all of the boxes. In a case like this, considering design as a distinct phase with pre-prescribed activities may be preventing restorationists from fully engaging with all that design has to offer to their work, as well as limiting how much learning and emergence can influence their processes.

In this case and in many other institutional projects, design serves an additional purpose of being the means for communicating and recording a plan of action for regulatory purposes. Regulators and the public may need to give approval to a specific restoration design, often communicated through 2-D schematic drawings as seen in Figure 1. In this way, design serves as a unifying vision of restoration success, yet restorationists must avoid framing ecological degradation as a purely logistical problem that a restoration design plan alone can solve. In the LVSRA case, project leaders maintain their emphasis on golf course design as the way forward, with a new course design and environmental impact statement expected in early 2023.

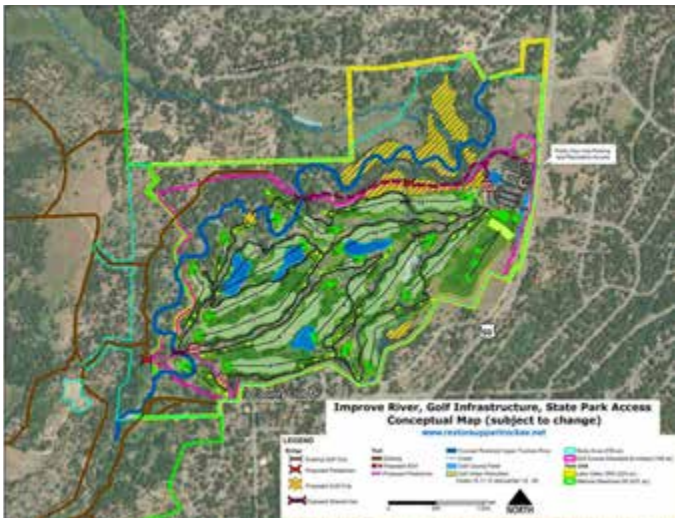

Figure 1. A proposed restoration design for the LVSRA (Source: CA State Parks)

Designing Technology for Restoration: RIBITs Interface Redesign

Design has long been associated with planning in institutional settings. Increasingly, design also interacts with restoration through technology. A 2022 collaboration between the non-profit Environmental Policy Innovation Center (EPIC) and the US Digital Service (USDS) illustrates this dynamic. In this project, an interdisciplinary team of designers and programmers worked to re-design the website interface (Figure 2) of a restoration tracking database managed by the US Army Corps of Engineers, called the Regulatory In lieu fee and Bank Information Tracking System (RIBITs). RIBITs is used to organize and track mitigation banking, a form of ecological offsetting for wetlands that shares some similarities with the practice of carbon offset trading.

The USDS and EPIC project is an example of "designing for restoration", which differs from the "designing restoration" example on the Upper Truckee River. In this case, a design process was used to update the human interface for a technological system that organizes restoration efforts. In a blog post about the effort, design project members explained that the current RIBITs system (Figure 2) was known to be difficult to use, and that a human-centered design approach was selected as a methodology for improving usability (Mahr, 2022). Over the course of several months, the project used tools like affinity diagrams, user journey maps and digital prototypes to design proposed changes to the system interface.

These redesign efforts for RIBITs will likely make a positive contribution to the system interface and perhaps make the system easier to use for those who engage with it. Yet, this project, in designing technology for restoration, exemplifies a common pattern in the way that design engages with wicked problems. This pattern appears when designers acknowledge wicked problems in designing, even citing them as a primary motivation, but focus their efforts on updating or creating technologies to mitigate the effects of the wicked problem, rather than interrogating the root causes of the problem itself.

Project briefs that make a call to, for example, "design for mental health" or "design for sustainability" show this same pattern. The problem with this way of working is that a website or technology design can be made highly usable and reflect the results of a human-centered process while doing little to address or change the dynamics of broken systems that produce these wicked problems. This kind of designing produces only first-order repair. In this case, the broken system is the market-based wetlands offset governance system that RIBITs reports on. Mitigation banking is meant to ensure "no net loss" of wetlands. Yet, in practice, the system incentivizes novel wetland construction or wetland consolidation in exchange for the destruction of healthy, functioning wetlands. What's more, the wetlands that mitigation banking produces are often less ecologically functional and offer fewer ecosystem services than the ones they replace (Steinhoff, 2008).

Figure 2. The RIBITs interface before the redesign effort (Source: US Army Corps of Engineers)

Design's engagements with wicked problems like wetlands protection and river restoration must produce more than first-order repair. Eric Higgs notes that "Design offers the prospect of reorienting our typical relations in a technological culture" (2003, p. 280). From a systems perspective, the proposed website redesign of RIBITs for greater usability aims to change the structure of information flows in the socio-ecological system of United States wetlands mitigation banking. This type of intervention ranks as leverage point number six of 12 in the Meadows framework. This leverage point is com-

monly engaged through digital technology design projects. While this particular design intervention may make the work of wetlands mitigation banking more transparent and efficient through RIBITs, this approach also normalizes a technological restoration culture. Here, rather than being used to "attune us to critical responsibilities" (ibid), such as stopping wetlands destruction in the first place, or finding creative ways to preserve them, design has been used to make the RIBITs system more navigable. These two examples show that design can be used for restoration in ways that ignore or even normalize the root causes of degradation. Instead, design must be used for more substantive change to catalyze the transformations that true earth repair requires.

Designing Transitions by Restoring: Fire Mimicry in California Oak Woodlands

In this final example, design appears in a restoration project without being explicitly named. This example illustrates the ways that restoration, as a design practice, creates meaning and culture while also solving a problem. In this case, restoration is a designed transition emerging from a community group. In contrast to the previous examples, in which design was used as a way of conceptualizing ideal spatial plans in restoration, or in advancing technological approaches, this final example shows how a designed intervention for restoration can create transformative learning and relationships to catalyze broader change.

Oak woodlands are ecologically and culturally significant features of the landscape in coastal California. Prior to Euro-American colonization, Native Californians managed oak woodlands with fire as well as hand tending (Klinger, 2006). Today, these beneficial disturbance regimes (Anderson, 2013) have largely disappeared, due to ongoing Native land dispossession. As a result, forest health has declined and these woodlands are more susceptible to disease, drought and catastrophic wildfire. Oak forests need regular episodes of low-intensity "good fire" to restore health, but many forest sites are too unhealthy or too close to human settlements for this kind of burning to be possible.

Fire Mimicry is a transitional restoration process that bridges this divide between current conditions of unhealthy, fire-prone oak forests, and a future where healthy oak trees can be tended with fire (Klinger, 2008). Fire serves many purposes in an ecosystem such as making soils more alkaline, killing pathogens, hardening oak tree bark and lowering overall fuel loads. Fire mimicry offers these benefits without direct application of fire. Phases of fire mimicry are sequenced, beginning with a stage of clearing and thinning of unhealthy or overgrown woody materials. Then, mosses and lichens are removed from the tree trunks with a mineral wash applied. Finally, the tree soil is treated with alkaline minerals, and any infection sites are surgically removed and covered with more mineral wash. The trees can be treated multiple times over several years, and observation over time is a key part of the process. Fire mimicry is generally quite safe and, with the exception of tree felling, can be easily practiced by non-experts. The method is primarily disseminated through community workshops and work weekends to non-expert and aspiring land stewards, and is not explicitly named as a design practice.

How is fire mimicry designing, and what might it teach about other ways of designing? Fire mimicry relates to design in several ways. One, it is an important example of a transitional design practice taking place at the household and community scale, what Manzini calls "diffuse and competent designing" (2015). Through gradually redesigning a landscape, fire mimicry interventions restore forests such that good fire can be returned to the landscape, transitioning forests and human communities away from the legacy of fire suppression. If those who practice fire mimicry are successful, the practice will become largely obsolete. This characteristic indicates an effective transitional practice. Those who practice fire mimicry do not explicitly self-identify as practicing design or Transition Design. Yet, the way that this practice simultaneously makes change across material and immaterial dimensions exemplifies the approach to changemaking that Transition Design proposes (Irwin, 2019; Sides et al., 2022).

Through landscape and designed transition, fire mimicry may produce second-order repair. The processes of learning and practicing fire mimicry produce what might be called "relational encounters" (Manzini, 2015) within groups of people, as well as between people and trees. These kinds of relational encounters support the kinds of transformative, systems-level change that comprise second-order repair (Dorn & Dickman, 2022). Locating these interventions in the Meadows framework, Fire Mimicry appears to act at two different levels. One, the landscape design activities change the size of buffers and stabilizing stocks (leverage point 11 of 12), such as the soil pH and the local fuel loads. At a higher level, by empowering community members to see nature as a socio-ecological system in which humans can positively contribute, fire mimicry also engages leverage point four, "the power to add, change, evolve, or self-organize system structure" (Meadows, 1997, p. 14). Fire mimicry work and the relational encounters it produces can effect change by fostering cultures of land stewardship and tree care, educating the public about the links between fire suppression and cultural suppression of native people, and ultimately, facilitating the return of indigenous land to indigenous stewardship along with the associated practices of cultural burning.

Table 1. Summary of restoration cases reviewed

Case	Location	What interventions are being designed?	Leverage Points Engaged	Design mode case exemplifies
Upper Truckee River	Lake Tahoe, USA	River and golf course layout	The structure of material stocks and flows (10)	• Designing as Planning • Professional Design
RIBITs Interface Design	Cloud Data-base, USA	Wetlands data-base interface	The structure of information flows (6)	• Designing Technology • Human-Centered Design
Fire Mimicry	Coastal California, USA	Oak forest composition over time	• The power to change system structure (4) • The size of buffers and stocks (11)	• Diffuse designing • Designing Transitions

Conclusion

The previous three examples illustrate three different ways that design appears in the work of ecological restoration: through planning, technology, and transitions. In the exam-

ple of the Upper Truckee River restoration project, design is employed in an expert-driven, problem-oriented way to serve as an official plan of record for a restoration project. This example shows how restoration is designed in institutional settings and its tendency to produce first-order repair only. The RIBITs interface design example shows how design interacts with restoration through technology, illustrating the pattern of designing "for" wicked problems through technological means. In this case, human-centered design was used to redesign the interface of a system for governing wetlands mitigation banking. While the project likely met system usability goals, it did not show evidence of deep engagement with or attempt to change the dynamics of mitigation banking. Finally, the example of fire mimicry shows how, through producing meaning and culture while also solving a problem, restoration practices can serve as designed transitional interventions. While all of these cases come from the United States context, their lessons may be relevant to other geographies. In particular, the planning and technological modes of designing identified here are likely to appear in other landscapes of ongoing settler colonialism, as these modes reflect a way of relating to land based on abstraction and control.

Together, these examples paint a picture of how design already appears in restoration. By analyzing them together, we can begin to imagine additional or modified design postures that will more consistently produce durable and holistic ecological repair. Restorationists, acting as or collaborating with designers, must bring the best version of their craft as well as critical attunement to the meaning of "nature-positive" to this challenge. In the context of restoration, designers should aim to: acknowledge and address the root causes of environmental harms, recognize that a particular design is just a snapshot in an ever-chanting system, remain open and transparent in their processes, seek out ways to engage non-experts in the design process of restoration, and center the wishes and needs of Indigenous people, local communities and the beings whose lives are most affected by environmental harms. Design postures that reflect the above suggestions have a great deal to contribute to the challenges of restoring living systems. The way that ecological repair work is done matters deeply. Through engagement in this work, design and those who practice it may also be positively transformed.

From visual to multisensory: how does intangible cultural heritage of traditional costume self-remodel in digital interactive environment?

Abstract

With the rapid development of digital technologies such as artificial intelligence, virtual reality, augmented reality, and 3D imaging, digitalization has become one of the primary cultural heritage protection and dissemination methods. Compared with other cultural relics, traditional costumes are vulnerable to environmental factors in storage. Therefore, protecting them in the digital environment and stimulating visitors' senses effectively is still an important project. Especially under the upsurge of the "digital future", avant-garde and artistic virtual products and technological innovations such as virtual fashion, 3D simulation displays, and virtual exhibition halls have brought new cognition and provided abundant means for the digital protection of traditional costumes. However, researchers have not paid enough attention to summarizing their narratives and expressions in the context of digital technology from a methodological perspective.

First, this paper analyses the concept of intangible cultural heritage and its digitalization from a documentation perspective, investigating research themes, technical means, and display modes in the digital production of traditional costume heritages. This part is a review and summary of the early stage of the research. Second, this study combined 5 typical practical cases in China, from the aspects of multimedia interactive participation, mobile interactive applications, digital museum display(virtual tour), gamification(skins) and digital costume collection to explore how organizations, museums and professionals can use digital technology to map information transmission with the audience's multi-senses, which will better authentic experience of traditional costumes. Finally, taking the life etiquette costume of the Ming and Qing Dynasties as the research object, this study discusses the technical path and development strategy of digital protection and constructs the overall framework of the database.

The results show that as a cross-disciplinary field, emerging digital technologies have broad application potential in protecting traditional costume cultural heritages, conducive to reproducing the new form of these finite objects and delivering rich intrinsic value. Meanwhile, in the interaction process, visitors have more opportunities to perceive the more profound charm of cultural heritages. The conclusion in theoretical and practical value can be used as a reference for other related cultural heritage fields in the digital background.

digitalization of intangible cultural heritage; traditional costume; digital technology; multi-dimensional construction; innovative application; case studies

Introduction

With the rapid innovation and application of digital technology, it has become an obvious trend to use computer graphics, virtual reality (VR), augmented reality (AR), computer animation and other technological means to present national intangible culture through digital storage, retrieval and display (Ch'ng, Cai, Leow, & Zhang, 2019; Yu & Cui, 2021). The protection and effective development of intangible cultural heritage, realizing all-round and three-dimensional digital information transmission, as well as multi-sensory interactive experiences such as sight, hearing, and touch, effectively broadens the path for inheritance and enhances social influence (Zhuang, 2021).

Costumes are an intuitive expression of national self-cultivation and spiritual outlook. Their unique beauty is also essential to sharing pleasure and artistic inspiration for creativity(Kang, Cassidy, Cassidy, & Li, 2015). Visitors can only view the restricted and protected collection of valuable old costumes and textiles through the windows using the old exhibition methods. With the popularity of human-computer interaction technology, three-dimensional virtual presentation, and the new mode of clothing culture propagation through mobile clients, more comprehensive sensory experiences are provided to the public (Jiang, Guo, & Ma, 2017; Martin & Mauriello, 2013). This has become an effective way to inherit and recreate costume culture. Scholars pay attention to the technical aspects of digital costumes and explore the possibility of virtual simulation in reproducing historical costumes(Jiang et al., 2017; Villarreal, 2020). Some studies have applied two-dimensional and three-dimensional software to create digital replicas of costumes from historical sources and to assess the similarity between historical prototypes and their replicas(Kang et al., 2015; Moskvin, Kuzmichev, & Moskvina, 2019). Liu's latest research results, with the help of CLO3D software to complete

the costume archaeology and digital restoration of the figures in the Tang Dynasty's paintings(Liu, Lu, et al., 2022; Liu, Wu, et al., 2022; C. Zhu et al., 2022). In conclusion, digitalizing historical costumes is a contemporary multidisciplinary research field combining cultural studies, science-based reconstruction methods, and virtual reality(Moskvin et al., 2019).

A unisensory interface stimulates only one sense, while a multi-sensory interface involves multiple senses (e.g., sight, hearing, touch) (Mishra, Shukla, Rana, & Dwivedi, 2021). Immersive technologies such as VR and AR are cutting-edge in providing users with unique multi-sensory digital experiences(Spence, Puccinelli, Grewal, & Roggeveen, 2014). China has carried out the digital transformation of cultural products based on the digitalization of museums but there is still a gap between the practice and exploration of digital fashion for traditional costumes and other collections (such as porcelain and bronze ware). The content of this paper is organized as follows. First, this study reviewed relevant concepts through literature reviews, such as the realization process and technical means of intangible cultural heritage digitization, and the contents and methods of digital protection for traditional costumes. Secondly, combined with five typical cases in China, we summarized the specific methods of reshaping traditional costume cultural heritage with digital means to improve users' sensory cognition. The third part introduced one of our ongoing research and its digital protection ideas and development strategies. Finally, the academic and practical implications are discussed.

Intangible cultural heritage, traditional costume and digital protection

The digitization of intangible cultural heritage (ICH)

UNESCO's 2003 Convention defines the concept of Intangible Cultural Heritage (ICH) and divides it into five categories (UNESCO, 2003). China has further divided ICH into ten categories(Chinese Cultural Studies Center, 2008). Some scholars have integrated and concluded according to the research needs. For example, Lv *et al.* proposed that ICH can be divided into three major modules: traditional performance, traditional skills and culture(Lv & Zhang, 2016). It is unreasonable to use the dualism of tangible and intangible as the criterion for dividing the material and intangible cultural heritage(Carboni & De Luca, 2016). Because ICH contains both tangible and intangible material and behavioral meanings.

Digitalization has become one of the main ways to protect and spread ICH. The digitalization of ICH is to transform, reproduce and restore the contents of ICH into a shareable and renewable form by using digital collection, storage, processing, display and dissemination technologies (Ma, Tu, & Xu, 2019; Wang, 2009). The ICH's digitalization in China has experienced three historical stages of " in database " (2005-2012), " being online " (2013-2016), and " in presence " (2017-present), and has formed digital feature forms, communication and user experiences(Quan, 2022; Wen & Zhao, 2022). According to the characteristic of dynamic and static, the digitalization of ICH can divide into three categories: dynamic art (oral tradition and performing art), static art (craft skill), and space-time art (festival ceremony)(Ma et al., 2019). An analytical framework should account for the range of visible and invisible objects under the constraint of a context-dependent action in a universe of symbolical and collective representations and enable the digital processing of physical and immaterial levels (Fig. 1)(Carboni & De Luca, 2016; Ma et al., 2019; Staab & Studer, 2010).

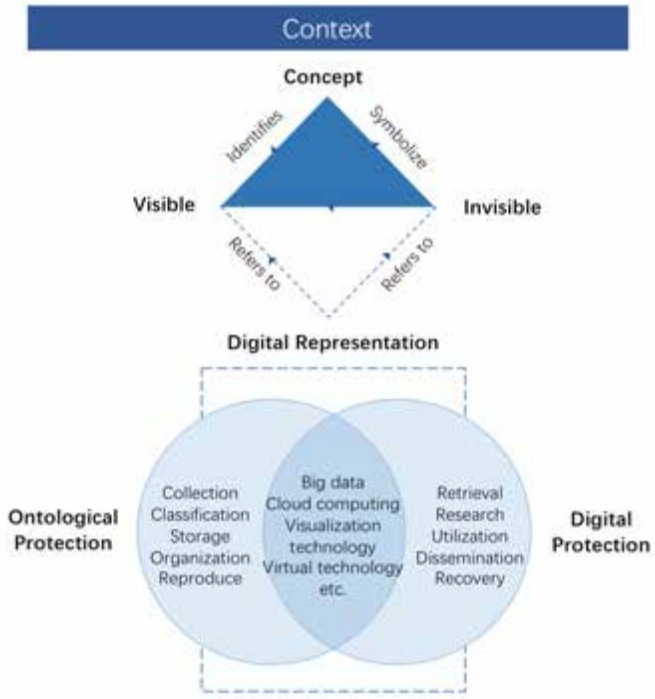

Figure 1. The process analysis and coding system construction of the digitization of ICH.

The technical means and presentation methods of digital protection of ICH

Integrating cultural heritage and digital technologies has produced many concepts. Ma *et al.* (Ma *et al.*, 2019) differentiated ICH digital technologies between basic e.g., pictures, text, video, and audio, and emerging e.g., the application of 3D scanning, VR, AR, and motion capture technology, the latter providing more technical means to digitalizing ICH. Both technologies utilize various new media carriers to digitally display ICH. Some researchers have summarized and classified the exhibition types of ICH. For example, Huang *et al.*(Y. Huang & Tan, 2012) believed there are five presentations: traditional information type, mechanically controlled type, interactive touchscreen type, sensor-based interactive type and virtual-reality-based experiential type. In terms of the digital communication mode of ICH, mass media, digital collection, and Internet-based are the main modes of communication at present, with immersion communication as a supplement to the previous three(Tan & He, 2021). ICH encompasses a variety of types, cultural connotations, and categories. Therefore, digital displays need to adopt appropriate and varied media technologies in order to accurately display information about cultural relics and convey their intangible elements such as value and spiritual connotation (Ma *et al.*, 2019).

The contents and presentation of digital protection of traditional costumes

Traditional costume collections found in handicraft and folk art are an important ICH and reflect a culture's social life. Cui et al. (Cui, Niu, & Wang, 2019) pointed out that traditional costume as a cultural expression can be seen in three contexts: material, social, and spiritual. Based on these contexts, our research constructed an overall framework of digital display

design of traditional costumes (Fig. 2). The flexible use of digital technology improves the effectiveness of the transmission of information about traditional costumes and enhances the audience's knowledge, viewing experience, and sensory perception of that interaction.

The traditional costume should focus on the organic combination of ontological and digital protection. To date, the ontological protection has been quite adequate. The digital protection of traditional costumes should focus on the dynamic presentation of invisible factors, such as traditional skills, the production process, and various attributes of cultural value and spiritual connotation. The display media for digital protection of traditional costumes are based mainly on public culture platforms, PC network platforms, mobile intelligent devices, and social networks (X. Zhang, 2015). For example, digital museums and digital databases, as necessary digital operating forms, are also introduced into the clothing field. Research has been conducted on making and restoring traditional Chinese clothing with 3D virtual technology, such as CLO3D, Style 3D and Style Fabric (Liu, Lu, et al., 2022; Tong & Li, 2021; W. Zhang & Ma, 2021). VR technology is essential for both revitalizing intangible values of ICH and comprehending those intangible values. It also allows for the understanding and reproduction of the relationship between tangible and intangible values in each context (Karakul, 2022).

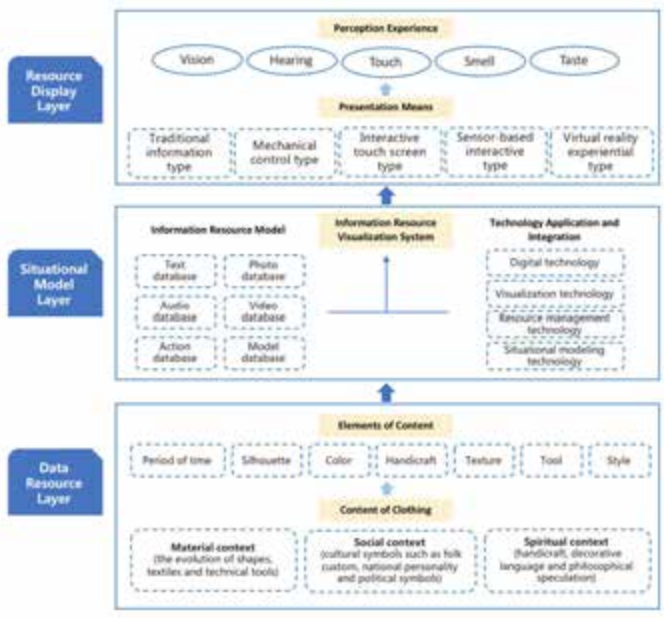

Figure 2. The model of digital display design of traditional costumes.

Innovative application of digital protection of traditional costumes: Methods and case studies

Case 1: "Palace Embroidery and Costume" project in the Palace Museum

In addition to using traditional media to display intangible cultural heritage, museums, art galleries, and other public cultural platforms integrate digital means for display(X. Zhang, 2015). The Duanmen Digital Pavilion is composed of the virtual digital form of the Palace Museum's cultural relics, including paintings, interior furnishings, costumes, embroideries, ancient architecture and so forth(M. Huang, 2016). Using the interactive display of "Digital Court Costumes" with human posture recognition technology and Kinect motion-sensing control technology, visitors can virtually try on Qing Dynasty court costumes through interactive equipment (Fig. 3). This interactive feature allows users to appreciate and understand their artistic features and institutional norms, thus deepening their knowledge of traditional costume culture. In the "Digital Palace Embroidery Paintings" project, visitors can use touch screen linkage Ventuz technology to gain an understanding of the imperial embroidery painting process and to observe traditional skills such as embroidery. In conclusion, interactive multimedia, with its sensory participation experience, is the platform whereby visitors more easily understand the historical aspects of cultural relics collections.

Case 2: Ethnic Costumes Museum of Beijing Institute of Fashion Technology

Major comprehensive museums or museums focusing on costume collections have realized the importance of building a web-based digital museum with the Internet and digital technology for online communication, dissemination and protection of intangible cultural heritage(Wu, Jiang, Liang, & Ni, 2022). The Ethnic Costumes Museum of the Beijing Institute of Fashion Technology holds more than 10,000 pieces of traditional cultural relics, such as national costumes, fabrics, embroideries and silver ornaments(Beijing Institute of Fashion Technology). The Museum has a digital database of ethnic costumes based on design and application, thus providing an opportunity for researchers and lovers of costume culture to gain a greater understanding of the subject. The Museum's Ethnic Costume database displays the clothing of 36 ethnic groups in China. Among these, the Han costume section includes 291 pieces of short jackets, long gowns, single trousers, horse-face skirts (Fig. 4), and cloud shoulders. Each collection piece has detailed descriptions (basic properties, collection information, material technology) and pictures (overall silhouettes, details, cutting drawings). Using short videos and animations, the Museum's three other databases display 32 pieces from ancient collections, introduce 91 typical costume materials and techniques, and show the

Figure 3. The digital project of the Palace Costumes.

Figure 4. The display online of digital database for ethnic costumes.

production details and wearing process. The digitalization of the Ethnic Costume Museum has broadened online access to valuable resources, thus enabling historical costume lovers and researchers to further their learning and stimulate their positive attitude toward cultural heritage.

Case 3: The art visualization network platform of Guizhou ethnic minorities

Taking the excellent traditional culture and art of 17 ethnic minorities in Guizhou who have lived for generations as the research object, this project classified and displayed them in digital ways by integrating internet information technology and big data(Guizhou Minzu University). Four mobile apps have been built with AR interactive displays and interactive wearable experiences to allow users to view ethnic costumes, silver jewellery, architecture and opera. When opening the "Guizhou costume" program (Fig. 5), users can select the representative costume through the left and right arrows and understand its basic shape and patterns by rotating the 3D model. In addition, app users can learn the cultural connotation of the traditional costume by reading the accompanying text description when they click the model. Interestingly, AR technology can be used to create a virtual scene with interactive characteristics by first scanning the ground and then combining costumes, characters, and scenes in a self-selected background. This, too, is available just with a click, on the circular icon in the upper left corner of the home page. This process helps users obtain a more comprehensive sensory experience of traditional costumes (Fig. 5). This project also built a virtual simulation platform of Miao embroidery, where visitors can learn Miao embroidery skills at any time by following an on-screen step-by-step animation simulation. Therefore, the interactive experience of the AR interface can help users better imagine what these historical costumes may have looked like, thus increasing their enthusiasm for learning traditional costumes.

Figure 5. 3D model and AR experience of the Miao nationality's costume for the festival.

Figure 6. The design of the traditional costume game skin in The Magic Blade.

Case 4: The series of digital costume design in Liangyuan Hanfu and Huaxia Nishang

Digital costumes are commonly known as skins in the game industry. Skins are one of the tools used by players to decorate their avatar to achieve a unique and personalized aesthetic expression of the player, rather than just a simple graphic symbol(Makryniotis, 2018). Louis Vuitton, Burberry, and other luxury brands have cooperated with game companies to design costumes for game characters and produce gamified digital marketing. Currently, historical costume elements are also introduced into digital fashion to promote the sustainable development of traditional costume culture. In 2021, the TV program "Dress China" cooperated with the designer, Guo Pei, and the game "The Magic Blade", leading to the design of a series of Chinese-style costumes in the theme, "Floral Scrolls with Mandarin Duck". This pattern represents the beauty of good marriage (Fig. 6). These costumes are reproduced by digital art, so young people can enhance their perception of the beauty of Chinese-style costumes when playing games. Gamification is a design strategy that improves users' experience. Fu *et.al*(Fu & Liang, 2022) said traditional costume skins could build emotional bonds between game users and game characters, stimulating players' curiosity, imagination and exploration and enhancing their cultural identity in the real world and well-being in the virtual world. Museums and costume-oriented cultural organizations have also formed a new creative mode that can be shared(Wen & Zhao, 2022). In 2022, the magazine, Chinese fashion, and the digital collection platform, Changong, launched a series of digital traditional costume collections of "HuaXia Nishang" from the Tang, Song, Ming, and Qing Dynasties in which users can virtually try on costumes(Qing, 2022). Overall, the combination of online games and traditional costumes can be seen as an attempt to lead modern fashion consumption and the sustainable development of traditional Chinese costumes in a digital way.

Figure 7. Costume interactive program through a visitor touch screen.

Figure 8. The virtual exhibition hall of the "Yiguan Dacheng: The Costume Culture Exhibition of Ming Dynasty" and 3D virtual costume models.

Case 5: Digital preservation and utilization project of relics collected by Shandong Museum

Clothing from the Confucius Mansion is the symbol of the Ming Dynasty costume culture and, as a result, is rich in information about the Dynasty's intangible elements and hierarchy regulations. In 2022, one important part of the "Digital preservation and utilization project of relics collected by Shandong Museum" was "Yiguan Dacheng: The Costume Culture Exhibition of Ming Dynasty". This undertaking digitally protected more than 40 pieces or sets of historical costumes which have been collected by Shandong Museum, spanning a range of silhouettes, details, and textiles. This project consists of three steps: high-definition photo shooting; three-dimensional data acquisition and processing; and, pattern extraction(Z. Zhu & Zhou, 2020). Information mapping, the most crucial aspect of digital protection, maps the detailed structure and color texture collected by the HD camera in the first step to the modeling results from the second step. The result is a three-dimensional model with complete information. This project differs from the other project's noted above because its displays are comprehensive and use a variety of technical means and display media for representation and communication. For example, the large-screen interactive program set up in the physical museum (Fig. 7) can present costume information through a visitor touch screen. The exhibition also designed a touch screen version of silk fabric to enhance tactile perception(An & Chen, 2022). Additionally, there is an animated display showing when and how traditional costumes were worn by those living in the Confucius Family Mansion. The animation enhances the audience's visual and auditory senses, leading to a deeper understanding of the meaning of each traditional costume. Elsewhere, visitors can experience a virtual tour of the virtual exhibition hall(Fig. 8). More interestingly, visitors can click the costume picture to watch the high-definition 3D virtual costume model and learn about the costume's pattern, wearing rules, and meaning. In summary, this project uses digital deduction and engaging interactive experiences to entertain visitors and advance their aesthetic perception and knowledge.

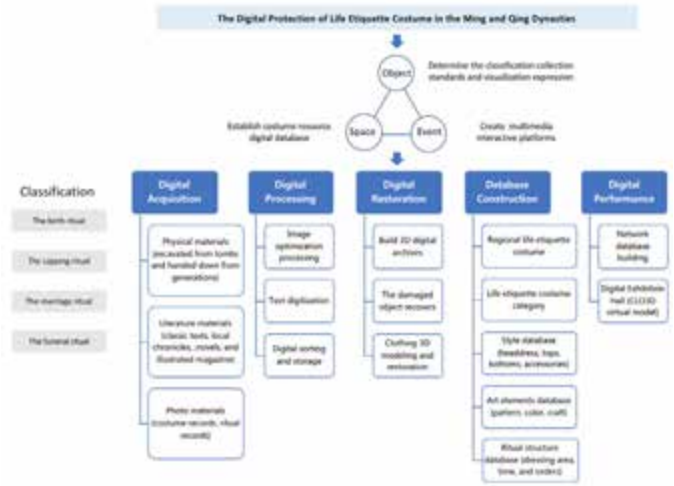

Figure 9. Digital protection countermeasures of life etiquette costume in the Ming and Qing dynasties

Exploration on the path of the digital protection of traditional costumes: Taking the Life Etiquette Costume in Ming and Qing Dynasties as an example

Life etiquette is a vital yet intangible part of folk culture heritage, constituting a symbolic cultural space created from folk costumes, rites, rituals, and beliefs. It is generally believed that the four transitional rites held at the critical point of life stage of birth, adulthood, marriage and death are called "life etiquette", which is an important "rites of passage"(from Arnold van Gennep(Gennep, Vizedon, & Caffee, 1961), French ethnographer and folklorist). A person's life etiquette costume is the clothes they wear during the four critical stages of life (birth, adulthood, marriage and death). As carriers of ritual activities, life etiquette costumes play an important cultural intermediary role. They contain rich artistic aesthetics, folk connotations and cultural characteristics. Changes in social environments, norms, and rituals, have led to the disappearance of the rituals and costumes that represent traditional life etiquette. In the complex and multiple modern context, especially the era background when the government emphasizes the importance of strengthening national etiquette education in China, the contemporary inheritance and practical transformation of traditional life etiquette costumes have attracted the attention of many aspects. The use of digital technology in the information age may give life etiquette costume "new life" and provide strong support for the dissemination, protection and development of traditional clothing cultural resources. Therefore, this study proposes a path for the digital protection of life etiquette and costume culture in the Ming and Qing Dynasties through the use of "object (costume)", "event (narration)", and "space (experience)" (Fig. 9). Before building the database, digital acquisition (e.g., literature and images), digital processing (e.g., image optimization) and digital restoration (virtual restoration and multidimensional display) are necessary for life etiquette costumes. The overall framework of the database classifies and sorts the corresponding life etiquette costumes according to the life etiquette categories and ritual structure and then summarizes the primary sorts, typical styles and collocation ways in the dressing lines. Hopefully, this approach of presenting the results of both the literature review and research on life etiquette costumes will provide a model for contemporary dress codes and design guidelines.

Discussion and conclusion

A field of research is currently exploring how best to effectively combine intangible cultural heritage with emerging digital technologies so that user interactions are optimized. A summary of the results are as follows:

1 This study contributes to the literature on the application of digital technology in the digital conservation of ICH and traditional costume relics and the role of providing a multisensory user experience. This study summarized the basic concepts, primary technical means, and presentation media of intangible cultural heritage digitization through literature reviews. Compared with unisensory interfaces, multisensory interfaces provide vividness and interactivity for users in a sensory-rich environment(Flavián, Ibáñez-Sánchez, & Orús, 2019). Based on this, from the perspective of costume culture communication, this study built an overall framework for the digital display design of traditional costumes. The application of digital technologies (such as AR, VR and 3D virtual) expands traditional displays. It visualizes the projection of the real world and the physical environment, promoting information search and reducing the cognitive burden of users.

Table 1. Overview of innovative application cases of digital protection of traditional costumes.

NO.	Title of the case	Display media	Display mode
Case 1	"Palace Embroidery and Costume" pro-ject in the Palace Museum	Public culture platforms	Multimedia interactive application
Case 2	Ethnic Costumes Museum of Beijing Institute of Fashion Technology	PC network platforms	Digital image presentation
Case 3	The art visualization network platform of Guizhou ethnic minorities	Mobile intelligent de-vices	AR interaction scene construction
Case 4	The series of digital costume design in Liangyuan Hanfu and Huaxia Nishang	Social networks	Gamification design and development, network media display
Case 5	Digital preservation and utilization project of relics collected by Shandong Museum	Public culture plat-forms, PC network platforms, mobile intelligent devices and social networks	Network media display, 3D virtual simulation, multimedia interactive application, digital animation innovation

2 This study selects 5 typical cases to explore methods of traditional costume relics' digital protection and their adapted digital media and modes (Table 1). The research shows that the digital communication mode based on public culture and PC network platforms is the most common way to promote knowledge learning and sensory attraction. Creating AR interactive scenes changed the costume display for users, effectively improving users' interest and visual perception. Integrating traditional costume elements into gamification design and digital collections will become new tools for museums and cultural institutions to expand the spread of costume culture. Case 5 shows a relatively comprehensive digital communication system for the intangible cultural heritage of a costume. Dynamic forms of multiple senses can create higher visual and emotional attraction to enhance the interactive experience and improve users' cognition and understanding of costume culture.

3 Taking the life etiquette costume of the Ming and Qing Dynasties as the research object, this study discusses the technical path and development strategy of digital protection and constructs the overall framework of the database from the direction of "object-event-space". The communication of traditional costumes needs to include the activity field matching them. Computer graphics technology and 3D clothing software provide the opportunity to realize the image, product and space virtualization of traditional costumes and improve users' perceived visual and emotional attraction to a greater extent. More importantly, digital practice is beneficial to the protection and promotion of life etiquette costume, such as promoting understanding and acceptance of traditional culture or fostering national pride in younger generations and providing inspiration for relevant designers or enterprises in product design.

Digital design content is regarded as the expression of technology, but it is worth paying attention to how to use technology to design and establish effective information dissemination channels. Through the analysis of typical cases, the results of this study aim to help museum managers, organizers and designers better understand the application status of intangible cultural heritage digitization and provide valuable strategic insights into the development, application and promotion of the multisensory interface experience of traditional costumes extended by digital technology. Further studies should adopt quantitative research to compare users' responses to the digitalization of costumes between haptic and multisensory interfaces. Additionally, the role of different levels of users' attitudes and behavioral intentions in a multisensory environment should be explored.

Designing sustainable furniture: guidelines to promote furniture life cycle design

Dongfang Yang, Carlo Vezzoli

Politecnico di Milano, Design Department, Italy
dongfang.yang@polimi.it
carlo.vezzoli@polimi.it

Abstract

Given the serious environmental impact of the furniture system, the role of design in innovating furniture products toward sustainability is increasingly recognized as a key leverage, as acknowledged by the European Union's Circular Economy Action Plan in 2020. The need for sustainable design knowledge to address environmental issues caused by the life cycle of furniture products – a fundamental part of the furniture system – has now been prioritized. Despite the fact that Life Cycle Design (LCD) is widely studied as a systematic approach that considers all life cycle stages and engages the objectives of reducing environmental impacts, its application within the furniture system is still very limited. Within this framework, the paper presents furniture-specific LCD guidelines to guide sustainable furniture design. These guidelines were developed through an established methodology involving scholars and specialists on both Design for Sustainability and Furniture Design, and were the results of a research project funded by the Italian Ministry of Education (MIUR), aimed at developing and disseminating innovative design strategies and guidelines to foster a sustainable and circular economy within the furniture industry. In this sense, these guidelines will promote long-term open innovation and technological transformation of furniture products, allowing designers and organizations to support the implementation of sustainable options from the beginning of the design process.

Author keywords

furniture design; Life Cycle Design; design guidelines; sustainable design.

Introduction

Furniture has recently been identified as one of the key sectors that should be addressed and improved to achieve more sustainable development (European Commission, 2020). Estimated by the Centre for Industrial Study (CSIL), total global furniture production in 2019 was US$490 billion, exportation was US$160 billion, and consumption was US$477 billion (CSIL & CNFA, 2020), resulting in huge resource consumption, harmful emissions and waste generation. Each year, 10.5 million tons of furniture are produced in the European Union, with 10 million tons of furniture waste generated, accounting for more than 4% of municipal solid waste in the European Union (EU) (Forrest et al., 2017). These impacts could also be seen throughout the life cycle of furniture, including pre-production, production, distribution, use and disposal (González-García et al., 2019).

The role of design

The importance of design in innovating furniture products for sustainability is becoming more widely recognized. Up to 80% of a product's environmental impacts are determined during the design phase (European Commission, 2020), emphasizing the importance of sustainable design knowledge in addressing major environmental issues associated with the furniture life cycle. Indeed, addressing environmental concerns early in the design process is more efficient than retroactive actions, as it avoids costly and dangerous operations to reverse or limit the damage. Looking at the overall design scene, although disciplines like environmentally sustainable product design or LCD are widely studied, their application within the furniture sector is still quite limited. Furniture LCD is the design of the furniture life cycle stages that aims to minimize the overall environmental impact of all life cycle processes concerning the functional unit (Vezzoli, 2018). Two major approaches, in particular, must be introduced. The first is the life cycle thinking approach, which means shifting from furniture design to the design of furniture life cycle stages, i.e. considering all processes required to produce, distribute, use and dispose of materials and furniture. The second approach is the functional unit approach, i.e., considering the function of the furniture rather than the physical furniture itself during design and impact evaluation.

The development of furniture-specific LCD guidelines

In this scenario, the paper presents innovative furniture-specific LCD guidelines. The development of furniture-specific guidelines was carried out as part of more than two decades of research of LeNSlab Polimi, a research group within the Design Department of Politecnico di Milano, working on Design and system Innovation for Sustainability (DIS).

In particular, the current contribution is based on the results of the research project_The Circular Economy for the competitiveness of Made in Italy industry - GIOTTO, which was funded by the Italian Ministry of Education and Research (MIUR) in collaboration with eleven national organizations. The project aimed at developing and disseminating innovative design

guidelines and tools to promote and implement a sustainable and circular economy within competitive value chains of Made in Italy, i.e. furniture, food and fashion. Through a multidisciplinary and complementary research consortium, GIOTTO contributed to empowering small and medium enterprises with innovative approaches to minimizing the environmental impact of their products throughout their entire life cycle. Within this context, , LeNSlab Polimi led research activities aimed at defining specific Life Cycle Design strategies and guidelines to guide the development of environmentally sustainable furniture products.

Method: from general to furniture-specific LCD guidelines

The approaches and processes for developing specific LCD guidelines from general ones have well-established roots. Over two decades of research and consultancy activities carried out by LeNS lab Polimi gradually led to the definition of a structured and validated methodology (Vezzoli & Sciama, 2006). This study was carried out with the method as illustrated in figure 1.

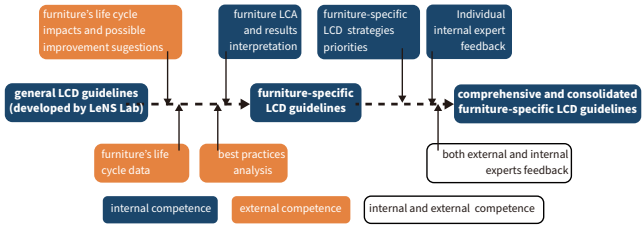

Figure 1. Prior knowledge and steps to develop furniture-specific LCD strategies/ sub-strategies/guidelines, adapted from (Vezzoli & Sciama, 2006).

The project started with a preliminary phase of desk research to uncover the most updated knowledge about the environmental impact of the furniture life cycle. On one side, a critical review of available literature was conducted to analyze previous evaluations of furniture's environmental impact, i.e. Life Cycle Assessment.

On the other hand, a detailed analysis of best practices from an environmental standpoint was conducted to provide inspiration for subsequent collaborative sessions when elaborating on furniture-specific LCD guidelines. The first stage produced an overview of the environmental impact of furniture's life cycle stages and best practices representing promising designs. Results from these research actions represented the framework to facilitate the successive step within the GIOTTO project, aimed at moving from general LCD strategies and guidelines toward the definition of furniture-specific version to reduce the overall environmental impact along furniture's life cycle.

The specification process was carried out through a collaborative workshop that involved scholars and experts on Design for Sustainability and Furniture Design, with the goal of generating a preliminary draft of furniture-specific LCD guidelines. The findings of the literature review and case study were presented as a context introduction. The workshop's main activity, the guidelines specification, was then completed. During this phase, a structured process was implemented for each general guideline, allowing participants to perform a variety of specification actions such as: integrating a general guideline related to particular furniture products or typology; adding a new guideline that deals with a certain environmental impact related to particular furniture products or typology; adding notes related to particular furniture product or typology; and erasing a guideline if irrelevant. The outcome of the workshop was a draft of furniture-specific guidelines, which was further reviewed and refined to integrate final improvements. Please see table 1 for a more specific example of the shift from general to furniture-specific Life Cycle Design guidelines.

Table 1. An example of generating furniture-specific strategy, sub-strategy and guideline from general ones

General strategy, sub-strategy and guideline	Furniture-specific strategy, sub-strategy and guide-line
Strategy: Product lifespan optimization	**Specific strategy:** Furniture use extension and intensification
Sub-strategy: Facilitate repairs	**Specific sub-strategy:** Facilitate/enable furniture re-use and remanufacturing
Guideline: Arrange and facili-tate disassembly and re-attachment of easily damageable components.	**Specific guideline:** Facilitate disassembly, especial-ly for parts that are easy to wear out, such as task chair wheels and back, up-holstery and desk surfac-es, using reversible connections or a two-way snap-fits system.

Furthermore, proper identification of LCD strategy priorities (the degree of relevance of various strategies) that take function into account is crucial for guiding design efforts. It is assumed that some strategies have greater priorities than others for each product, whether a car, a piece of furniture or something else. For furniture, for example, extending the lifespan is more important than reducing resource consumption, whereas reducing the resource consumption is more important for a car which consumes energy while in use. As a next step, a priority indicator was defined for each of the 6 design strategies based on their potential for environmental improvement (compared to the other strategies), based on the life cycle environmental impact of furniture defined in the first stage.

Results

Furniture's environmental impact along the life cycle

The **Pre-production** stage incorporates the impact associated with the acquisition of resources, delivery to the production area and raw materials preparation. If take wooden furniture, which has a significant proportion of total furniture consumption (Forrest et al., 2017), as an example, an average production of 1 m3 particle board consumes a total of 759 kg of materials and 507 MJ energy (González-García et al. 2019). The overuse of resources may cause resource depletion or deforestation. Chemical use is a critical source of hazardous emissions. For example, formaldehyde is a sensory irritant that, depending on the concentration in the environment and exposure time, can cause health problems for workers and users, such as eye, skin and respiratory allergic reactions (Liu et al., 2012). The **Production** stage includes all activities such as raw materials processing, components and package production, furniture assembly and other finishing processes, like polishing and painting of solid wood-made furniture. The cutting, punching and sanding processes generate solid waste such as sawdust, metal and plastic residues. The assembly, finishing and coating processes use adhesives and coatings which consist of resins, pigments, sol-

vents, additives and diluents, may emit Volatile Organic Compounds (VOCs) such as alcohols, olefins, ethers, alkanes and aldehydes, as well as wastewater containing sulfide, chlorine, alcohols, olefins, alkane (Cheung et al., 2017). VOCs will harm the environment and human health (Berrios et al., 2005). The **distribution** stage is concerned with furniture packaging and transportation to a warehouse or end users' location via truck, train, ship or even plane. These activities necessitate not only the use of energy for transportation but also the use of resources to manufacture and store the means of transportation. The **use** phase, which may consume water, detergent and electricity, has low environmental impacts (Donatello et al., 2017). However, it is still an important stage that must be considered because it has the potential to extend the lifespan, reducing the environmental impacts per functional unit in the long term. The **Disposal** stage includes different scenarios. In the EU, 80-90% of furniture waste is incinerated or disposed of in landfills, with 10% recycled (Donatello et al., 2014). Many furniture products become obsolete before the actual end of their functional lifetime. This is due to various factors such as relocation, furniture inadequacy after renovation, expansion of premises or new staff, and changes in the interior or corporate design – the latter resulting in perfectly functional furniture being disposed of for aesthetic reasons. Frequent office furniture replacement contributes to increased solid waste production, requiring more landfill space (Besch, 2005). Landfill disposal may generate methane and groundwater pollutants, while incineration generates toxic ash and causes air pollution (Ulrich & Eppinger, 2012).

Last but not least, consumption of non-renewable fossil fuels such as coal, natural gas and diesel oil occurs throughout furniture's life cycle for raw materials production, transportation or electricity generation releases CO2, CH4, CF4, C2F6, SO2, HF, NOx, CO, particulate matter, etc., may contribute to Global Warming (CO2, CH4, CF4, C2F6), Acidification (SO2, HF, NOx), Photochemical Ozone Creation (SO2, CO, NOx), human toxicity (NOx).

Many furniture LCAs (scientific papers and company Environmental Product Declarations) compares the environmental impact of furniture's life cycle stages (Wenker et al., 2018; Babarenda Gamage et al., 2008; Plaschke, 2019). Results indicate that the highest environmental impacts occur during the pre-production stage; The production stage is the second one, followed by the distribution, disposal and use stages; the pre-production stage has more significant impacts than all the other stages.

Furniture best practice analysis

Sustainable furniture best practices were investigated to discover innovative design interventions and long-term sustainable benefits and characteristics. 41 case cards (from 32 brands) were created. These case cards were used directly for brainstorming or as examples of design guidelines developed in the following stages. See an example in figure 2.

Furniture-specific LCD strategies (with priority), sub-strategies and guidelines

As a result of the research, furniture-specific LCD guidelines were developed, which include 6 strategies, 21 sub-strategies and 141 guidelines to stimulate and guide the generation of environmentally sustainable ideas. Table 2 shows an example of the hierarchical structure of each strategy, which contains several sub-strategies and additional specific guidelines.

Each of these 6 strategies was assigned a priority indicator – very high, high, medium, low and very low – which refers to the potential environmental burden reduction associated with each LCD strategy. ***Furniture use extension/intensification*** (very high priority) is to reduce the environmental impact of furniture and components by extending or intensifying the lifespan. ***Reduce material consumption of furniture*** (high priority) aims to reduce material use throughout the life cycle by avoiding extraction, processing, transportation and disposal. ***Furniture materials life extension*** (middle priority) seeks to extend the lifespan of furniture materials through recycling or composting. ***Resources conservation/bio-compatibility*** (low priority) aims to use renewable or inexhaustible resources (energy and materials). ***Reduce toxicity of the furniture system*** (very low priority) aims to choose materials or processes that minimize harmful substances emissions throughout the life cycle. ***Reduce energy consumption of the furniture system*** (very low priority) means reducing energy use throughout the life cycle.

Table 2. A furniture-specific strategy with sub-strategies and guidelines.

Strategy: 1. furniture use extension/intensification

Figure 2. A case card of sustainable furniture product (own elaboration)

Sub-strategies
1.1 Facilitate furniture maintenance;
1.2 Facilitate furniture upgrading and adaptation;
1.3 Design furniture for reliability;
1.4 Facilitate/enable furniture re-use and remanufacturing
1.5 Intensify furniture use

Guidelines: 1.2 Facilitate furniture upgrading and adaptation
1.2.1 Design reconfigurable furniture that is able to adapt to different spaces/situations, such as modular desks and storage structures that can be used for both the transformation of a given space or for a new function.
1.2.2 Design a family of products instead of single ones, with different properties and functions that enable adaptation.
1.2.3 Include add-on parts to transform and/or upgrade functions and properties.
1.2.4 Avoid premature aesthetic obsolescence by designing furniture that can be customized (e.g. exchangeable seat covers).
1.2.5 Consider designing multi-functional products that can adapt to the user's development (physical and cultural).
1.2.6 Design modular and on-site upgradable furniture, allowing the user to substitute with standard tools, for example, fixed feet with wheels or fixed components to adjustable ones.
1.2.7 Include multiple connection possibilities on tables and storages, e.g. electricity cables, joints to combine table surfaces, etc.
... a total of 13 sub-guidelines...

All furniture-specific LCD guidelines were eventually integrated into one of the main outcomes of the GIOTTO project - the MIUR manual "Handbook for sustainable furniture system design", which was conceived as an operative tool to enhance the application of the furniture Life Cycle Design, specifically aimed at guiding designers and companies toward environmentally sustainable furniture design and innovation. The handbook is available and open access on LeNS International's 'tools' section (http://www.lens-international.org/).

Conclusion: furniture-specific LCD strategies and open innovation

The primary contribution of this research is a set of furniture-specific product LCD strategies, sub-strategies and guidelines with best practices. The main innovation are the development of 21 furniture-specific sub-strategies and 141 guidelines that will significantly contribute to reducing environmental impact along the furniture's life cycle.

A second innovation lies in the priority assigned to each strategy, i.e. i.e. the level of environmental impact reduction achieved by implementing the strategy, which is crucial to improve the efficiency during the design process.

A handbook that integrates all these outcomes is currently being distributed worldwide through the Learning Network on Sustainability (LeNS), an international network that connects over 150 higher education institutions and organizations, with the goal of developing and disseminating the Design for Sustainability (DfS) discipline in worldwide curricula with a multipolar, open and copyleft ethos. Moreover, the handbook is being used in international master courses, as well as subjected to implementations and improvements to foster a collaborative and open innovation logic in the furniture sector. Indeed, even though the phenomenon of open innovation is now well-established and widespread in several disciplines (Gassmann, Enkel, & Chesbrough, 2010), the same cannot be said for the majority of sustainable furniture knowledge innovation. The handbook can represent a key resource for designers and organizations to support the implementation of sustainable choices at the early stages of the design process.

Reflection

These strategies, sub-strategies and guidelines have been developed for general furniture, but specific guidelines tailored to each type of furniture may be necessary for optimal effectiveness in real design practice. Since the outcomes of this research are open access, other groups of researchers and companies can develop more specific guidelines for individual furniture types.

The research contributes to 'Design for transformation' in the scope of the furniture sector. The design guidelines facilitate 'systemic & strategic problem solving' by supporting the furniture LCD at early stages to reduce the environmental impact throughout the life cycle.

Abstract

In our post-industrial society, although the remarkable technological advancement allows us endless possibilities, the maturity of the debate on environmental sustainability requires new design, production and consumption strategies, and a radical revision of the concept of development. Our lifestyles increasingly lead us to spend much of our time indoors, and this condition, exacerbated by conflicts and pandemic, has turned the spotlight on the importance of accessibility to the natural environment, put in risk by growing urbanization and global urban population, the upscaling of environmental degradation and the challenges posed by climate change. In this context, Designers are challenged to question new ways of establishing connections with nature that will contribute to mitigate, cope, and adapt to environmental and societal challenges while at the same time helping people to develop new capabilities in their given contexts. Biophilic Design emphasizes the need to maintain, enhance and restore the beneficial experience of nature in the built environment. Even if it's based on scientific evidence from several studies in the fields of psychology, medicine and social sciences, which demonstrate that exposure to natural environments or related elements has a positive impact on human health, further reflections are needed on how these inputs can be embodied in environments and artifacts by the Design disciplines. Based on these assumptions, the theme of the Psychology and Cognitive Ergonomics course within the bachelor's degree program in Industrial Design at Sapienza University of Rome was developed. Through an interdisciplinary approach Human-Centred Design and Environmental Psychology were combined to enquire about the use of biophilic elements within remote studying environments, a widely used practice following the closures of schools and universities caused by the Covid-19 pandemic. A combination of methods and tools from both disciplines were used to test Biophilic Design hypotheses that, on the one hand, ensure optimal ergonomic usability and, on the other hand, through their regenerative qualities, promote psychological well-being and reduce stress symptoms related to remote study activities and social isolation. The analysis of these case studies allowed us to reflect on Biophilic Product Design and their role in remote studying environments. We conclude by advocating the use of interdisciplinary practices in which Design, combined with Environmental Psychology becomes a promoter of more desirable domestic environments and of a future in which a symbiotic relationship with nature is established.

Introduction

The growing urbanization and the continuous increase of the world's urban population have led to a direct and indirect (McDonald et al., 2020) impact on biodiversity (Turner et al., 2004). Environmental degradation and the challenges of climate change make access to greenery and nature a restricted privilege. In today's 'indoor generation,' most human activities occur within an enclosed space (Kelly & Fussel, 2019). This condition has been further exacerbated by the conflicts our society is experiencing and the global pandemic. Following the drastic incidence of Covid-19 since March 2020, the Italian government has implemented strict measures to stem the pandemic spread through rigid lockdowns. Since the pandemic, the world of work has radically changed, with a massive reliance on remote working for all those activities that did not require an unavoidable work presence. However, one of the areas most affected by the implementation of restrictive measures was the educational sector. All Italian schools and universities were forced to implement distance learning (e-learning or remote learning) throughout the most acute phase of the emergency. This forced transition has entailed not only a restructuring of teaching methods, now characterized by the unavoidable use of digital technologies

and means of communication (such as Zoom, Teams, Meet, etc.) but to a complete restructuring of home environments, now dedicated to the activity of studying or working remotely. In addition to this, of course, one of the main consequences of lockdowns has been the inability to leave except for stringent reasons (Corley et al., 2021; Dzhambov et al., 2021), thus limiting people's ability to have contact with natural environments (e.g., Garrido-Cumbrera et al., 2022; Mintz et al., 2021). Therefore, finding strategies to implement natural elements within the home environment became necessary.

The biophilia theory and biophilic design

The term "biophilia" can be summarized as "the innately emotional affiliation of human beings to other living organisms" (Wilson, 1993, p. 31). The concept was introduced by Erich Fromm (1964/1976) and has been popularised in the work of Kellert & Wilson (1993), who affirm that human evolutionary history has produced "the innate tendency to focus on life and lifelike processes" and the need to "affiliate with other forms of life". Biophilia has been conceptualized as a sign of mental and physical health, with supporting evidence showing that natural settings (compared to built settings) are preferred and lead to positive health outcomes, such as restoration from mental fatigue and stress. Building on the theory of biophilia, the biophilic design seeks to use nature in the design of indoor and outdoor environments (as well as in the design of artifacts) to promote people's health and well-being. Biophilic Design stresses the need to maintain, improve and restore the beneficial experience of nature in the built environment. It represents a sustainable approach with financial advantages across healthcare, education, retail, workplace, and community environments (Browning et al., 2012). Kellert & Calabrese (2015) have proposed design strategies for successfully applying biophilic design in diverse contexts, such as educational settings (Alves, Betrabet Gulwadi & Nilsson, 2022). The basic components of the biophilic design framework are: direct (e.g., having indoor plants), indirect experience of nature (e.g., watching nature), and the experience of space and place (e.g., prospect and refuge). Drawing from empirical evidence, biophilic design patterns are not formulas; they are hypotheses to be tested and should be thought of as another tool in the designer's toolkit - meant to inform, guide, and assist in the design process (Ryan et al., 2014).

The psychological impact of biophilic design

Biophilia is one of the aspects most touched upon in the study of this predisposition concerns the natural elements directly or indirectly experienced by the individual. The positive effect of exposure to natural environments and stimuli in promoting psychological well-being has been widely studied (Bratman et al., 2019). The term restoration refers to the recovery or regeneration of mental resources used in daily activities (Harting, 2004). The two main theories concerning restorativeness are the attention restoration theory (ART; Kaplan & Kaplan, 1989), according to which natural environments do not require direct attentional effort, thus allowing for a reduction in the use of cognitive resources (Jiang et al., 2020), and the stress recovery theory (SRT; Urlich, 1983), which draws on a psycho-evolutionary perspective, and postulates that the natural environment allows for a reduction in arousal and stress levels (Chang et al., 2021). Direct experience in natural environments is not the only strategy to activate the regenerative process. Implementing natural elements (real or reproduced) in indoor environments through biophilic design can allow one to experience effects similar to those activated by immersion in natural environments. Natural or artificial light with similar characteristics, implementation of natural materials such as wood or stone, natural sounds, and implementation of indoor plants or other reproductions of natural environments are just some of the elements most frequently found in the literature (Bolten & Barbiero, 2020; Browing et al., 2014; Kellert, 2008; 2018; Sturgeon, 2017). Research based on the implementation of biophilic design has reported results consistent with the literature on restorativeness in natural environments (Aristizabal et al., 2021; Cole et al., 2021; Determan et al., 2019; Jiang et al., 2021; Yin et al., 2020), thus confirming the possibility of being able to effectively integrate these types of elements into built and indoor environments as well, with positive effects on psychological well-being.

Aim of the study

Based on these assumptions, this paper intends to report an empirical study promoted during the Psychology and Cognitive Ergonomics course within the bachelor's degree program in Industrial Design at Sapienza University of Rome. Through an interdisciplinary approach, Human-Centred Design and Environmental Psychology set out to promote the use of Biophilic Design to improve remote studying environments, a widely used practice following the closures of schools and universities caused by the pandemic by Covid-19. The aim is to illustrate a possible methodology within Design education and to bring to greater maturity the reflections on Biophilic Product Design to extend our scientific community's knowledge and promote interdisciplinary practices.

Method

Participants

The research sample comprised 521 college students from different Italian universities who voluntarily completed the questionnaire. They were aged 18 to 38 (M = 20.93; SD = 2.20); 232 were men (44.5%), 282 were women (54.1%), and 7 preferred not to answer (1.4%). 466 students were enrolled in a bachelor's or single-cycle degree program (89.4%) and 55 in a master's degree program (10.6%).

Tools and procedure

The research was conducted in full compliance with the Ethical Principles of Psychologists and Code of Conduct of the American Psychological Association (APA) and was authorized by the Ethics Committee of the Sapienza University of Rome. The study was conducted in April 2022, when Italian universities, due to the Covid-19 pandemic, continued implementing a hybrid teaching mode with in-person and remote lectures. During an initial administration, participants were asked to think about the home environment where they performed their remote study activities (didactic or self-study) and to complete a self-report questionnaire. The first instrument was the Perceived biophilic qualities in remote studying (ad hoc): the measure includes 19 items referred to the main sources of Biophilia found in the literature (e.g., Bolten & Barbiero, 2020; Browning et al. 2014; Kellert, 2008; Kellert 2018; Sturgeon, 2017) divided into the 3 categories identified by Kellert and Calabrese (2015), namely direct experience with na-

Table 1. escriptive statistics, bivariate correlations and Alpha in diagonal.

Variable	N	M	SD	S	K	1	2	3	4	5	6	7
1. General Perceived Biophilia	521	3.20	.61	-.03	-.01	.81						
2. Direct Experience	521	3.65	.69	-.36	-.01	.89***	.81

4. Prospect and Refuge	521	3.19	1.23	-.02	-.86	.73***	.60***	.15***	.72			
5.Restorativeness	521	3.27	.72	-.18	.12	.41***	.36***	.25***	.25***	.72		
6. Engagement	521	4.43	.95	-.39	.17	.18***	.15***	.12**	.12**	.26***	.88	
7. Stress	521	2.35	.41	.16	.36	-.08*	-.10*	-.04	-.02	-.18***	-.08	.75

Note: * = p < .05; ** = p < .01; *** = p < .001; M = Mean; SD = Standard deviation; S = Skewness; K = Kurtosis.

ture (10 items; Alpha = .81), indirect experience (6 items; Alpha = .68), and the experience of space and place (3 items; Alpha = .88). Also, an overall perceived Biophilia score was calculated (Alpha: .82). The psychological variables concernedPerceived restorativeness (5 items; Alpha: .72; Korpela et al. 2008),Student Engagement (UWES-9; 9 items; Alpha: .88; Schaufeli & Bakker, 2003; 2004),and Student Stress - Effort-Reward Imbalance student questionnaire (12 items; Alpha: .75; Wege et al., 2017) For all these measures, the response scales consist of a 5-step Likert scale (from 1 = "Completely disagree" to 7 = "Fully agree"), except for the Engagement rating scale, for which a 7-step Likert from "never" to "always" was used. Socio-demographic data (gender, age, and degree course level) were also collected. The same participants were asked to fill out a second questionnaire containing an ergonomic checklist for objectively assessing all the biophilic elements with which they relate, directly or indirectly, during remote studying activity and that, therefore, could contribute to their satisfaction and requirements needs related to certain needs classes such as Safety, Well-being, Usability, Appearance, Management (UNI 8289:1981). For each requirements class, the requirements classes have been identified (UNI 8290-2:1983) to which the items of the Checklist refer by proposing questions for the verification of the qualitative and quantitative characteristics of the elements observed, starting from minimum inclusive safety performance (Villani et al., 2021) thresholds defined by regulatory references related to health and safety at work agile (L. n. 81/2017, art. 18-23), to the usability (D.M. 236/89) and from "good technique" criteria correlated with people anthropometric data.

Results

Relationship between perceived biophilic qualities and psychological variables

Jamovi v.2.2.5 statistical software was used to analyze frequencies, descriptive statistics, and correlations among psychological variables. The mean scores, univariate normality, and bivariate correlations between the variables under research are shown in Table 1. According to the skewness and kurtosis values, which are all between -1 and +1, the normality assumption was not violated. From the correlation analysis, the overall indicator of perceived Biophilia was found to be correlated with perceived restorativeness (r = 0.41; p < .001), engagement (r = 0.18; p < .001), and stress (r = -0.08; p < .05), demonstrating how the perception of natural elements can help regenerate students' cognitive resources, promoting their engagement in the educational activity, by reducing stress-related symptoms. Regarding the specific sources of Biophilia, direct experience of natural elements, whether internal or external to the study environment, reported the highest correlation indices, correlating positively with restorativeness (r = 0.36; p < .001) and engagement (r = 0.15; p < .001) and negatively with stress (r = -0.10 < .05). Indirect experience with nature, prospect, and refuge reported same correlation indices with restorativeness (r = 0.25; p < .001) and engagement (r = 0.12; p < .01). Unexpectedly these two sources of perceived biophilia did not correlate with perceived stress (r = -0.04; p = n.s.) (r = -0.02; p = n.s.).

Objective perception of biophilic-related elements

The ergonomic checklist results about biophilic elements have been analyzed on three levels: biophilic elements in general (one general index), level of individual needs classes (6 indices), and level of individual requirement classes (15 indices). Each of these three refers to the individual elements of the checklist that, aggregated, return these summary indices. Generally, it has emerged that inside the remote study sites/

workstations, there are no biophilic elements in 40% of cases inside the remote study sites/workstations. The results of the other two levels are shown in Table 2.

Examples of biophilic design

The psychological and ergonomic results were subsequently considered as a basis for developing the design proposals. The ergonomic approach to the project, with its ability to evaluate the multiplicity of variables that define the interaction between people and what they relate to (Tosi, 2018), has been combined with the philosophy of Human Centered Design. The biophilic design solutions presented by students vary in the use of materials, shapes, and textures in their aim to stimulate sensory perception, improve well-being and meet ergonomic requirements. Moreover, to prevent the solutions of these new designers from being replaced by superficial imitations, a more holistic and sustainable approach has been stimulated (Stevens et al., 2020), promoting the use of solutions respectful of Nature and also from the point of view of materials and production processes.

The data collected by the Ame group showed that as the appearance variable increases, the level of perceived stress decreases while the person's interest increases. On the other hand, an increase in olfactory well-being, linked to air quality, leads to a psychological reduction in stress. Finally, good usability within the smart studying workplace positively influences the subject's performance, increases well-being and engagement, and reduces stress and burnout. They proposed a cactus-shaped desk module that performs several functions, including tidying up cables, pen holders, and air freshener. This product is intended to improve classes of needs such as Safety, Wellness, Usability, and Management, stimulating the perception of natural elements on different sensory levels. The material they use for production is Ecoallene, derived from the processing and recycling of poly-bonded waste, which is colorable, versatile, infinitely recyclable, and suitable for various types of molding.

Instead, the Palma group, in order to improve their situation, worked on the correlation of ergonomic well-being on mental and physical health and on how colors and materials reminiscent of nature increase the sense of belonging to a place and, consequently, the desire to spend more time there. So they designed Ceppo, a footrest whose materials and shapes recall a tree trunk. In particular, it improves the ergonomics of the study station and stimulates sight and touch during the remote study activity through natural materials such as wood and stabilized lawns.

The Cinquis group started from the point of view of implementing acoustic well-being, usability, appearance, and safety, which were found to be lacking in the questionnaire, and from the psychological point of view, improved direct experience with nature, in particular through sound, because of the direct effects they have on restorativeness and engagement. They worked on evoking nature at a sound level, designing a speaker that recalls the organic shapes of a shell, also associating on a semantic level the act of bringing the shell to the ear to listen to the sea. In addition to reminding marine environments, the speaker emits white noises that stimulate concentration during one's study time.

In the last case, however, the ergonomics checklist showed that visual comfort, usability, accessibility, and flexibility were lacking, so they implemented them in their remote studying station. From a psychological point of view, they instead worked on enhancing the indirect experience with nature through shapes and colors, as it increases the organizational potential of the user, the positive relationship between the user and the room, and a general sense of security. So, with the *Jungle-IT* (Figure 1), Marmotas group brings the jungle into the remote study station. The system, consisting of simple elements such as wooden profiles, rope, cork leaves, and S-shaped steel hooks, offers the possibility of a support/shelf where to place books and also serves as a bulletin board, allowing to reorder sheets and notes.

Conclusion

In conclusion, this study shows the positive impact of using natural elements in promoting ergonomic and psychological well-being in remote studying settings. Design, with its ability to act both on a micro- and macro-scale, can encourage the implementation of biophilic elements, particularly in those contexts where direct contact with green spaces has been diminished, such as in large cities or metropolises, but also extreme context like the Fourth Environment. It can help to cope with traumatic and unpredictable events, such as the Covid-19 pandemic and conflicts, that makes immersion in green spaces difficult. The collaboration between two different perspectives, such as Psychology and Design, shows how Biophilic Design can be put into practice: it allows both the analysis of objective requirements for design and the consideration of students' subjective needs and perceptions. The benefit of this interaction is that it allows the construction of more desirable remote studying environments centered on humans and their real needs and a symbiotic relationship with nature. Biophilia alone is not enough to generate automatically sustainable solutions in this context. It is therefore important to provide constant input to students on how to make this reconnection with nature not only aesthetic but the result of a conscious practice at every level. To face today's challenges, using the green "as a sole legitimization of an otherwise unsustainable project is not enough," as Celine Baumann states (Block, 2019). There is, therefore, a need to find more holistic and enlightening solutions by broadening the scope and examining the challenge in a wider context and at different scales (Scalisi & Ness, 2022). Developing a new unity with nature is necessary, a paradigm shift from "human on nature" to "human and nature".

Abstract

The emerging field of Biodesign sees living organisms as embedded in the design process to create bio-generated materials and artefacts. To support the growth and maintenance of these organisms, designers can adopt a Bioreceptive Design (BD) approach, recently defined as a design approach occurring every time materials or artefacts are intentionally designed to be colonized by life forms. Through this approach, the inert counterpart undergoes specific studies to reach the best bioreceptive potential for the designated life form, also considering the environment in which the artifact will be placed. In urban environments, BD examples tackle vegetation to create greener spaces and provide phytoremediation for better air quality and biodiversity in the built environment, in the wider view of nature-based solutions and climatic transitions of cities.

This study addresses the possibility of developing bioreceptive interfaces for mosses and lichens to respond to biophilic and regenerative sustainability needs in urban contexts. These organisms have contributed as pioneers, during the evolution of life on our Planet, in the formation and regulation of soil and atmosphere; moreover, they are currently used in biomonitoring actions, also contributing to the environmental awareness of the built environment. The paper proposes BD as a design approach of mutual interest, aiming at responding to the host needs and preferable environmental conditions, serving multiple species that act as co-authors of an open-ended design, increasing urban biodiversity, and providing resilient, restorative, and regenerative environments.

In particular, we present some of the results of an interdisciplinary research through design, born from the collaboration between design and biology, aiming both to bring sustainable and innovative solutions for the Biodesign and architecture sectors, but also to positively affect biological activities of biomonitoring and citizen awareness. From the design perspective, BD is applied for the selection of those material features that match the needs of the selected organism (e.g., porosity, color). Moreover, the use of Computational Design has played a crucial role in designing and prototyping bioinspired, organic shapes and textures. From a biological perspective, the research compares different methodologies for the bio-colonization of artefacts to obtain the best results for the timing and survival of the organisms. The prototypes were therefore exposed open-air with no protection or superficial treatments in a highly colonized area (from mosses and lichens), favoring the attachment of spores and propagules on the surfaces. On the other hand, some prototypes were used to test the transplant of the organisms as an alternative and faster possibility, also suitable for interior design.

This study points out how BD can be applicable when designing for the living, making clear the designer's possibilities for adopting this approach: ranging from material design to biomimicry, designing for not-only-human users, considering the host's needs and preferable growth conditions, adopting a multispecies design approach while suggesting new relationships among biotic and abiotic agents. The paper highlights how BD can provide sustainable, low-maintenance, and regenerative nature-based solutions to foster resilient urban environments.

Introduction

The design field is increasingly aware of the limits of the current models of production and consumption, therefore looking to contribute to the transitions by proposing sustainable solutions. In particular, designers are rediscovering the material side of the projects, hybridizing their practice with materials science, chemistry, and biology, opening up a new era of interdisciplinarity driven by the research for radically sustainable materiality (Oxman, 2016). In this regard, Biodesign arises from an entanglement of design and biology as a new approach based on the involvement of living organisms in the design process (Myers, 2012). The biological origin of biodesigned materials and artefacts can lead to an organic aesthetic and a more significant presence of living organisms in the built environment. Livingness has already been recognized as a material quality in design (Elvin Karana et al., 2020). This feature leads to design systems relying on organisms' abilities to create bio-augment-

ed products and multispecies environments. From the low to the high level of biological organization, the quality and quantity of interactions between humans and other natural agents can positively affect human wellbeing (MacKerron and Mourato, 2009). On a "microscale", recent studies recognize the importance of microbiota in the built environment for human health (Flandroy et al., 2018; Mills et al., 2019). To restore urban microbial biodiversity, Watkins and colleagues (2020) propose a framework for microbiome-inspired green infrastructures, by explicitly recognizing the microbiota's role in the functionality of an urban ecosystem (Watkins et al., 2020). Also on a "macroscale", the presence and abundance of natural/green areas is demonstrated to positively affect human health, habits, and work (Wargocki et al., 2000). Many organisms can have bioremediation effect, they can contribute in microclimate improvement, carbon storage and sequestration, noise reduction, and phytoremediation; these are just some of the benefits of plants and vegetation in urban areas (Dadea et al., 2017). Cryptogamic covers (which include cyanobacteria, algae, fungi, lichens, and bryophytes) have a significant role in the fixation of carbon dioxide and nitrogen from the atmosphere (Elbert et al., 2012), as well as reducing the runoff during the increasingly frequent phenomena of heavy rains, and providing food and shelter for other organisms, thus enhancing urban biodiversity. Many of these species, especially lichens and mosses, can also be used for environmental biomonitoring, defined as "the use of biological systems (organisms and organism communities) to monitor environmental change over space and/or time" (UNE EN 16413:2014). Lichens and mosses are currently used as bio-indicators of air quality changes in urban and non-urban environments (Contardo et al., 2020): being sensitive to air pollution, the physiological alterations occurring in polluted environments are manifested at individual and community levels. Furthermore, many species are able to bio-accumulate a large number of contaminants, providing a reliable estimate of the presence and the biological effects of those substances on the biota (Bargagli & Mikhailova, 2002). Still, natural elements also have a psychologically positive effect, addressing "biophilia", a concept introduced by the psychoanalyst Erich Fromm and, to date, highly appreciated in design and architecture (Söderlund, 2019; Soderlund & Newman, 2015). E.O. Wilson defined biophilia as "the innate tendency to focus on life and lifelike processes" (Wilson, 1984). Wilson argues that exploring life, and understanding how we are part of it, can be a profound and complex process in human mental evolution. Humans' benefits in response to a natural environment are based on our co-evolution with the natural World, and today biophilic urban design is claimed for its beneficial effects on humans' mental health and life quality (Andreucci et al., 2021). However, our current cities are far from a biophilic approach: they embed the modern aesthetic of sanitation as a value system (Pasquero & Poletto, 2020), and are planned for the confinement more than the proliferation of other species. To foster biodiversity and biophilia, urban environments should be designed to support the spontaneous growth and regeneration of living organisms, improving multispecies relationships and self-regulating and regenerative environments. Such coexistence with other organisms should be accommodated through proper design, addressing materials, surfaces, textures, spaces, and habitats. Here, the role of the inert counterpart as life-supporting material is fundamental and can be designed to better meet the organisms' requirements. In this respect, Bioreceptive Design (BD) is an approach that occurs *every time a material or artefact is intentionally designed to be colonized by one or several groups of living organisms* (Pollini & Rognoli, 2021), aimed at supporting self-regulating biotic and abiotic assemblages, designed to foster biodiversity and green spaces. This study aims to enhance the presence of lichens and mosses in urban environments through BD, by testing both material features and biological treatments suitable for an effective bio-colonization of the built environment. The selection of the organisms for this project was based on their tolerance to highly urbanized environments. The cryptogamic cover, in general, can positively affect air quality, augmenting green spaces and fastening cities' rewilding and biophilia exposure. Moreover, a significant objective of the study is the possibility of using bioreceptive materials and objects for biomonitoring activities to foster human awareness of the environmental quality of urban spaces intended as multispecies environments.

In the last years, the emphasis on improving the resilience of cities in the face of urbanization and climate change has led to the adoption of the (not still clearly defined) expression of "urban resilience" (Meerow et al., 2016). Many scholars have already related this concept to the importance of biodiversity and ecological networks (Ahern, 2013; Jansson & Polasky, 2010; Schewenius et al., 2014). Although these actions are primarily human-oriented, the dimensions of urban resilience need to tackle cities ecosystems as a whole, designing for restorative and regenerative nature-based solutions (Mang et al., 2016; Seddon et al., 2021).

Methods

This study relies on a transdisciplinary, mixed-method research approach, including design and biological methods. From a design perspective, the project relies on three main approaches: (i) Bioreceptive Design for the selection of those material features that match the organism's needs (e.g. texture, composition, porosity, color); (ii) Computational Design for the creation of special textures and shapes, followed by additive manufacturing for prototyping; (iii) Biomimicry for gathering inspiration from the natural shapes and textures increasing water absorption and spatial distribution on the surface to increase the self-regulatory ability of the system. Once the prototypes were created, the second part of the study focused on the observation of changes, by exposing the prototypes open air to evaluate the colonization status of biofilm, lichens and mosses over time.

Bioreceptive Design: bioreceptivity has been defined as "the aptitude of a material (or any other inanimate object) to be colonized by one or several groups of living organisms without necessarily undergoing any biodeterioration" (Guillitte, 1995). Pollini & Rognoli (2021) proposed to broaden the original definition, for design purposes, outlining a methodology for the design of bioreceptive materials and artefacts. This study mainly relies on this methodology, with the aim of identifying those bioreceptive material features that can facilitate the colonization by lichens and mosses. The Bioreceptive Design traditionally follows 3 steps: (i) the design of the material composition, (ii) the design of the physical characteristics of the surface, and (iii) the design of the shape of the material or artefact (Pollini&Rognoli, 2021).

Computational Design: The shift from imitation of natural forms to the imitation of the constitutive logic through which

nature creates its forms appears today as one of the emerging patterns in the relationship between computational design and additive manufacturing. Layering production allows objects with material systems of extreme formal complexity. In this direction, generative design and additive manufacturing integrated with a bioinspired approach can contribute to the development of new types of products with high form, function and performance in relation to the context (Pollini et al., 2020). The computational approach plays a leading role in this context, directing the formal as well as the material conception process (Romero, 2014). Computational Design was crucial for prototyping during the 3D modelling phase, assisting the conceptual phase. Generative modelling software (Rhino and Grasshopper) was used to develop and test different textures and shapes, while additive manufacturing was employed to create the prototypes and moulds.

Biomimicry: among the biological informed disciplines, biomimicry works at the interface between physical and biological sciences (Iouguina et al., 2014). In this research, we looked for natural models for water management, from the ability of a texture to capture nocturnal humidity, to dendritic shapes to avoid excessive water stagnation. Moreover, we took inspiration from some natural patterns that distributed empty and full spaces for greater bioreceptivity.

Bio-colonization evaluation: materials' bio-colonization is a complex mechanism that occurs since the moment an object is exposed open air. The weathering, creates micro-fractures and deposit a large amount of water and nutrients other than spores and microorganisms in general on the surfaces (de los Rios et al., 2004). Biocolonization has traditionally been seen as a threaten for materials, (de la Fuente et al., 2013); however, the biofilm cover can actually play a protective role in some cases, thus the debate about the removal or not of biofilm is case-specific (Pinna, 2014). To evaluate the biocolonization stages, prototypes were exposed open air in a highly colonized location by mosses and lichens. Some tiles were previously treated by transplanting in the grooves parts or the entire body of the selected organisms, others were exposed with no treatments.

Project description

As outlined in the BD procedural thinking (Pollini & Rognoli, 2021), at first it is necessary to acknowledge the life cycle and preferred living conditions of the organisms, to create suitable bioreceptive materials and artefacts. To do so, we selected two cosmopolitan species, widespread in heavily urbanized environments: the lichen *Xanthoria parietina* and the moss *Bryum argenteum*, and we created an ID cards for both of them (Figure 1).

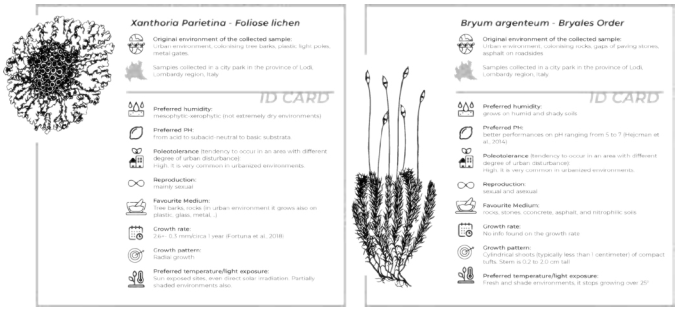

Figure 1. ID cards of the lichen Xanthoria parietina and the moss Bryum argenteum

In BD there are three levels of intervention: the material composition, the surface texture and the whole system, including the overall shape of the artifact (Pollini&Rognoli, 2021). All these variables are being tested, however the slow growth rate of the organisms is a limiting factor (Fortuna & Tretiach, 2018). Besides, we carried few other experiments as possible proof of concept for a further hypothesis of bio-colonization pattern.

To date, we have had two prototypes exposure cycles, the first since April 2022 and the second since December 2022; The project is following a reiterative investigation workflow which can therefore be subdivided in three main phases: (i) the creation of support prototypes with different bioreceptive features; (ii) the prototypes' exposure in an open environment (rooftops and similar), characterized by high lichen and mosses colonization or transplant actions (iii) the comparison between tiles with different analysis tools (e.g. microscopy) to address the degree (and success) of colonization based on the characteristics of the material and texture.

The phase of design and prototyping carried several research questions. Some emerged from the early literature in the field, which already reported about 3D printing techniques for biological colonization observing the role of microgrooves (derived by the layer-by-layer printing texture) and planned geometries (Huang et al., 2018; Mustafa et al., 2021). Other questions addressed the best integration model between biology and design, mainly focusing on creating physical samples idoneous for lichen and mosses colonization. Willing to test the bioreceptive material properties we developed different sets of tiles on which to study the bioreceptivity of the different design options by avoiding other variables; here, the tile can be considered the minimum unit of measurement to study the influence of a texture or material in terms of bioreceptivity. The design of textures was drawn through 3D modeling and parametric design (Figure 2). Parametric 3D modeling has been performed using the software Rhino and Grasshopper, particularly Grasshopper's plugin Parakeet, which provides a collection of components focusing on bioinspired and geometric algorithmic pattern generation (Parakeet, 2018).

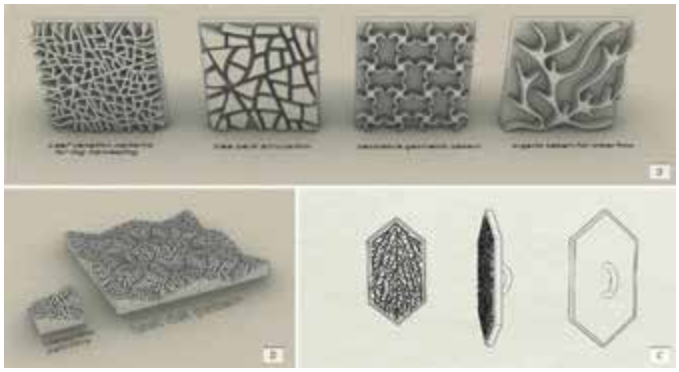

Figure 2. Computational modeling of different patterns (a. Stamps with different patterns - computational modeling; b. Tile pattern virtual testing - computational modeling; c. Stamp with pattern - computational modeling)

In the concept phase, planning the water flow has been fundamental, in fact, both lichens and mosses require high humidity but no water stagnation, meaning that the ideal substrate needs to drain water and possibly harvest air humidity without having parts of the surface where water can stagnate for a long time. Textures have been mainly bioinspired; in particular, four of them took inspiration from dendritic patterns,

an archetype for growth patterns in nature (Miguel, 2014), which characterizes many natural surfaces (e.g., leaf patterns), and they can easily aid in water channeling. To better test the hypothesis that bioinspired forms could more easily be bioreceptive, two textures with purely decorative motifs have also been tested, which, however, could still channel the water without excessive stagnation. Biomimicry has been considered for the realization of textures simulating the unevenness of tree barks and leaf venation patterns, in fact, leaf venation has been tested successfully as a model for bioinspired fog harvesting (Qasemi et al., 2020), which might be ideal given the high humidity requirement that bot lichen and mosses have. Another type of tile was conceived with a dendritic pattern, but this time designed also taking into consideration a minimum hint of shape, thus approaching the third level of BD which also considers the shape. Assembling side by side several tiles, a wavy surface is obtained, with more internal movement where, in addition to the grooves that inscribe the pattern, there is a concave and convex movement of the entire surface (Figure 2 a, b, f). We choose to limit the movement of the objects in order to avoid strong differences of exposure and shading, which could influence the effectiveness of bio-colonization. The physical creation of the tiles followed using advanced machinery for 3D printing. Here, a series of prototypes in self-hardening clay, PLA, and resin were made. The PLA and resin prototypes served as models to create moulds, which were subsequently used to make clay and concrete tiles (e.g., Figure 3, c, d). Moreover, a few other samples were 3D printed in clay and suddenly fired.

Among the planned variables we had, we decided to analyze traditional building materials first, indicating further DIY-Material experimentation (Rognoli et al., 2015) for subsequent and future steps. Among the materials analyzed we have terracotta, white and red clay, mortar and concrete. Testing different materials also allows us to test the effect of different colors, material porosity and composition. Surface color is a neglected aspect in the study of cyanobacterial biofilm formation, however, color appears to influence the growth of cyanobacteria, which few study shows prefer red and white (Gambino et al., 2019; Sanmartín et al., 2020). Porosity and roughness instead are very well known and important parameters for this field of study (D'Orazio et al., 2014; Manso, 2014;

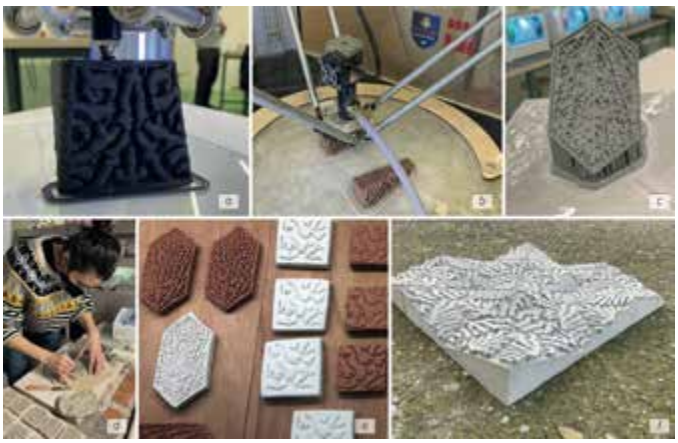

Figure 3. Prototyping process (a. 3D printed dark grey clay; b. 3D printing red clay; c. 3D printed stamp; d. Usage of 3D printed tiles as stamps; e. Clay tiles; f. Concrete tiles)

Miller et al., 2012), as well as pH levels (Manso et al., 2014). The selected set of prototypes differing in colors, shape, material and superficial pattern are described in Table 1.

Table 1. Prototypes description

Material	Shape and size	Shape and size	Color
Hand molded clay	5x5 cm., flat	6 patterns – 6 tiles each	Red and white
3D print-ed clay	10x10cm., concave	1 pattern	Red
3D print-ed clay	10x10cm., concave	1 pattern	Dark grey
Concrete	10x10cm., concave	1 pattern	Pale grey
Mortar	10x10cm., concave	1 pattern	Light grey to white

From a biological perspective, the study compares the performance of different treatments of the materials for the bio-colonization, with the aim to obtain the best timing and treatments for our final goals. The artefacts were exposed to open air in a highly colonized environment by mosses and lichens with three different treatments. The first one is "no treatment" to see the effective bioreceptivity of the artefact per se and the textures both for lichens and mosses (and biofilm in general). The second is the "transplant" treatment, for which entire organisms (the moss Bryum argenteum and the lichen Xanthoria parietina) were transplanted on the artefacts, by exploiting their grooves to put a part of the soil and the moss, or natural glue on the prominences for the attachment of the lichen thallus. The third treatment is a different kind of transplant, since using the same technique of the method above, just the reproductive parts of the lichens and the mosses were transplanted on the artefacts. Except for the "no treatment" samples, the other two treatments were carried out separately for mosses and lichens to avoid the substratum competition between the two organisms. To test the influence of the material per se without the textures, some samples with no texture were exposed in the same environment. The different treatments aim to test the timing of bio-colonization in different "scenarios"; i.e., the absence of nutrients, the presence of adult individuals and the presence of young or potential individuals (experiments still in progress). The 5x5cm. tiles, instead, were sorted by pattern, glued to wooden supports and exposed with no treatment in natural environment (Figure 4).

First investigation from April 22: the first cycle of exposure took place a little late in the winter season due to the restrictions on access to the facilities caused by the pandemic. In any case, since April 2022, the first ceramic prototypes have been on display (and still are). Regular checks are performed to avoid excessive coverage from extraneous material (e.g., leaves) and assess the tiles' integrity. Currently, no evidence of colonization is visible to the naked eye. As time progress, we will study effective colonization and to which extent it occurs, comparing the degree of colonization between colors, patterns, materials, and shapes.

During the same period, parallel material experiments were made: (i) lichens were transplanted onto self-hardening ceramic tiles using a DIY bioplastic as glue, and (ii) silicone molds were created for making tiles testing different combinations of

Figure 4. Tile exposure (a. b. d. Siena Botanical Garden; c. e. mosses and lichen transplant; f. Tiles exposure and first colonization by green algae)

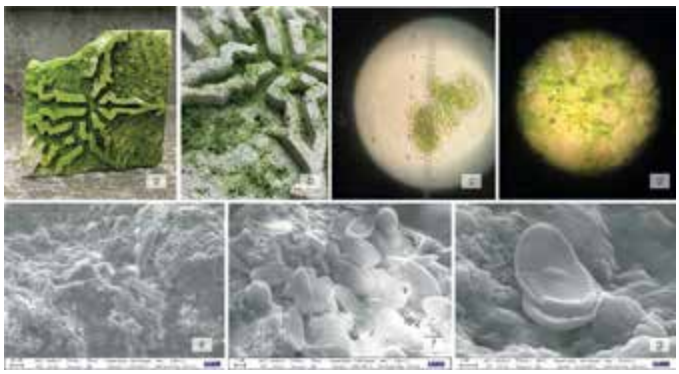

Figure 5. Analysis of green algae colonization of concrete tile (a. b. Colonized concrete tile; c. d. 40x visualization of green algae species; e. f. g. SEM observation of the green alga species "Cocconeis placentula")

cement and mortar; the latter were used for moss transplant and spontaneous colonization tests.

Second investigation from December 22: the second cycle of exposure made use of cement tiles for a more inclusive experimentation with the moss component as well. A set of 16 tiles were exposed of which 3 without treatment, 6 treated with transplants (3 for lichens and 3 for mosses), 6 with transplant of reproductive portions (as before), 1 flat tile as a control sample. Other side experiments in this second cycle were a moss colonization test by rubbing and the testing of materials with different cement and mortar gradients aimed at moss transplantation.

Early findings

Given the slow growth of these organisms, at the moment, no visible results were obtained, as expected. However, some early findings emerged from the parallel and DIY-oriented experiments: the first exposed concrete and mortar tiles in 2022 were colonized by green algae and mosses protonemata (early stages of development of mosses), considered a good sign as a pioneer species. Through SEM observation it was possible to identify the species of the green algae, that could be *Cocconeis placentula*, pioneer species of inorganic substrata (Figure 5). Such colonization corroborates the importance of the porous substrate and microgrooves pattern, typical of 3D printing, for the bio-colonization.

Moreover, the moss transplanted in January 2022 onto a cement tile is still alive, exposed outdoors. On this basis the authors decided to set up the second cycle of experiments in 2023. Also, the lichen transplant that took place in January 2022 was successful, maintaining its vitality even after a year of indoor exposure. This also paves the way for the possibility of using these bioreceptive solutions indoors, with applications for biophilic design and bioremediation (and biomonitoring) of indoor air. Our findings regarding the bio-colonization are in line with those reported by Rely et al. (2019), who tested the installation of plants on concrete mixtures for green walls, observing the persistent vitality and development of the organisms. Moreover, regarding the effectiveness of the pattern and the material's features, our findings confirm what hypothesized by Manso et al. (2014) and Mustafa et al. (2021), by working with concrete features. With this study, we aim also at highlight how BD can provide materials experiences (Karana et al., 2015), that might become significant for more-than-human users too. Living organisms cannot report considerations on the sensory, emotional, significant and performative aspects, but these levels could be evaluated based on their living response and the quality of their growth. Considering the human perspective, the material experience arises also from the relationship between the material and the organism grown on it. In this case, the significant aspect compared to traditional materials is the change over time and the perception of the living material. The proposal is to insert a transversal temporal level in the materials experience framework, which can report information on how sensoriality, emotion, performance and meaning can change over time.

Next steps – Conclusion

Thanks to this multidisciplinary collaboration, the possible outcomes of the project can be broad, contributing to biophilic urban resilience, and positively affecting design, architecture, lichenology, bryology and citizen science. The first goal of the project was the design of multiple bioreceptive surfaces to serve as support within the biomonitoring activities with lichens and mosses. The project foresees reiterative research cycles, and it is currently still in progress, oriented to understand which materials and textures are more pleasant for lichens and mosses to proliferate on. On the basis of the obtained results, we will investigate (i) a more suitable design of the tiles (ii) Different treatments before exposure, focusing on using natural medium to favor transplant (especially for lichens), (iii) material design experimentations, that can still lead to new insight, also adopting a DIY approach, offering the possibility to play with materials properties such as pH or porosity. (iv) Following the first results, new prototypes will be made for further tests, and different measurements and analyses will be possible over time concerning both lichenology, bryology, and material design (e.g., thermal insulation, oxygen production, air bioremediation, and expressive-sensorial qualities of the artefacts in terms of design opportunities).

Acknowledgments

We thank the laboratory LaborA (Politecnico di Milano) and the laboratory saadlab Prototype (Scuola di Ateneo Architettura e Design "E. Vittoria", Unicam) for the support in the creation of the prototypes, the Botanical Garden of Siena (Italy) for providing space for their exposure, and Professor Lorenza Draghi, Department of Chemistry, Materials and Chemical Engineering "G. Natta" for the SEM images.

Artificial nature: possibilities for mycelial composite material design

Haorui Tian, Li Zhang, Meng Zhang

Abstract

Although the trend of interdisciplinary and non-disciplinary boundaries is becoming increasingly vigorous, due to the lack of knowledge related to biomaterials, in the process of using them for design practice, designers have developed a knowledge gap between design and material disciplines. Thus, they cannot integrate biological materials into product innovation to form artificial natural objects that are more ecological and life-like. This paper experimentally explores the way mycelium composites are used in product design in an attempt to incorporate the unique growth and rich sensory experience of mycelium materials into the design process. A design method oriented to biomaterial innovation is proposed, and a prosthetic protective cover is designed using this method. By developing agricultural waste into biological mycelium materials, products are re-endowed with a time-sense compound experience and a rich sensory experience, thereby creating artificial natural objects with the ability to repair nature.

Author keywords

Mycelial materials; Material experience; Biomaterial design; Artificial nature.

Introduction

Materials, as an important innovative element in design activities, unsustainable materials, and their product applications are constantly pressing the limits of Earth's ecosystem. Biomaterial design, as a typical interdisciplinary discipline, presents strong potential for innovation, mainly in that biomaterials provide a variety of alternative production methods, such as biomanufacturing and natural growth, for current production activities. For example, the representative mycelium composite material in biomaterials, with the help of the automatic force of fungal growth, helps designers change the traditional role of passive application of material properties; however, forward thinking utilizes the properties of biomaterials and introduces them into design activities throughout the entire process.

This paper will use mycelium composite material as an example of a prosthetic protective cover material and employ methods such as material experiments and the innovative design of biological materials to study the objective and subjective characteristics of mycelium materials. Through the new design method and experiment, this research has preliminarily obtained a new experience quality for the material. Due to its non-toxic and harmless natural growth method, it can not only replace the traditional industrial production method but also reduce its incidental pollution problems. The above results will provide theoretical and practical references for the design of emerging materials and their application areas in the future. A design approach based on material innovation will simultaneously change the designer's role of passively selecting materials to one of actively and experimentally creating new materials and promoting the rapid application of new materials in design activities.

Research on the Characteristics of Mycelium Composite Materials

Mycelium is the vegetative part of fungi, such as Ganoderma and mushrooms, and it is also called "the root of mushrooms." Mycelium is composed of many microscopic mycelial long-line fiber structures that use the enzymes secreted by themselves to decompose the polymers in the matrix and produce the nutrients needed for growth (Appels et al., 2019). In addition, mycelium functions as a "natural glue" that penetrates the gaps of the matrix material by the growth of mycelium and eventually forms interlocking structures to produce biocomposites (Elsacker et al., 2020). Combining the objectives and experimental materials of this research, the author will focus on the design method and application research of mycelial composites to reveal the potential future application and development value of the material through an experimental exploration of the subjective and objective design characteristics of mycelial composites.

Subjective properties of mycelium composite materials

Humans carry the environmental influences of society and culture to perceive the unique qualities of materials through the five sensory organs of the body. The subjective properties of materials are the characteristics with which humans form perceptions with the help of multiple senses, such as touch, which contains emotions, a sense of experience, etc. (Sun, 2016). It is often more akin to a sensory interaction between

materials and people that occurs through the human sensory organs to perceive and stimulate psychological and physiological response attributes (Zuo, 2010). This research will focus on mycelium composites, which have a flowing "time" quality and material texture due to their unique biological properties. To obtain people's subjective characteristic evaluations of new biomaterials, the author used a focus group method to collect qualitative data on the subjective characteristics of mycelium materials and summarized them in a table. A table of the subjective characteristics of the mycelium composite material was established (Table 1).

Table 1. Sensory properties of mycelium composite materials.

Sensory	Properties
Tactility	Sometimes delicate and sometimes rough; the delicate part is like soft skin
Texture	Bumpy natural fiber texture with some irregular signs of use
Color	Scattered pale yellow small spots among large areas of white
Form	Non-fixed organic looking form, twisted and squeezed into a shape at will
Odor	Has a special natural odor; the smell is reminiscent of a haystack after rain

By experiencing the quality of materials first-hand, designers and users avoid being limited to capturing the objective characteristics of materials, thereby ignoring the relationship between new materials and external factors (Yin, 2017). According to the table of the subjective properties of the material, this biomaterial, characterized by growth and dynamics, develops an imperfect experience of the passage of time.

Objective properties of mycelium composite materials

Through queries and combing literature related to the properties of mycelium materials, the three dimensions of material composition, physical properties, and chemical properties were explained in detail.

1. Composition of mycelial composites. Mycelium grows by sticking to the substrate matrix to form biocomposites. Different types of fungus seeds and substrates ultimately affect the properties and growth conditions of the material. At present, it is common to inoculate substrates with species of Basidiomycota, which have two important characteristics: septum and anastomosis (Alemu et al., 2022). In the selection of substrate materials, agricultural waste, such as straw, sawdust, wheat bran, corn cobs, straw, fallen leaves, etc., can be used, as well as tea leaves, fruit and vegetable peels, coffee grounds, nut shells, etc. that are discarded in daily life, giving the material the ability to degrade quickly and naturally.
2. Physical properties of mycelial composite materials. After the mycelium material has finished growing, it presents an open porous structure similar to sponges and bones. The combination of the three-dimensional structure and chitin in fungal cells makes the material extremely light yet strong (Haneef et al., 2017). This unique porous structure enables it to absorb sound waves in the frequency range of 350 Hz to 4 kHz (Pelletier et al., 2019). It is a potential sound-absorbing and sound-insulating material. A related study tested the physical and mechanical properties of two groups of mycelial materials with different substrates made of wood, sawdust, and a combination of sugarcane and cassava roots. The final results of the tests showed that the density of the first group of materials reached 420 (kg/m^3), while the density of the second group of materials was 440 (kg/m^3); the average modulus of elasticity was 3.97 (MPa) for the first group of materials and 22.7 (MPa) for the second group; and the average compressive stress at 5% deformation was 0.17 (MPa) for the first group of materials and 0.61 (MPa) for the second group of materials (Heisel et al., 2017). Clearly, different combinations of substrates and their processing methods affect the density and tensile and compressive strength of mycelial materials.
3. Chemical characterization of mycelial composite materials. Fire resistance and non-allergenicity are two chemical properties that mycelium materials possess. In terms of fire resistance, chitin produced by fungi is a natural polymer whose combustion requires high heat (Silverman et al., 2020). The substrate covered by the growth of chitin in the hyphae has high fire resistance properties; thus, this material is also called a natural fire retardant. Its non-allergenic nature is due to the substrate it uses being a natural and environmentally friendly material. The mycelium forms a soft white covering after it finishes growing on the substrate. Finally, the material is sterilized at high temperatures for up to several hours to effectively remove bacteria and other microorganisms.

Application of Mycelium Composite Material in the Design of a Prosthetic Protective Cover

Creating product goals

This paper takes the material-driven design method (MDD) proposed by Karana as the basic process (Karana et al., 2015) and fine-tunes it with the application scope of mycelial composites and prosthetic protectors cover. Eight steps of the biomaterial design approach are proposed. Design a protective cover product for the disabled that provides calf prosthetic protection and decoration functions and constructs an innovative design process for mycelium composite materials. The prosthetic protective cover can provide a collision protection function for prosthetic parts and realize beautification and waterproof functions by covering the prosthetic parts. Studies on users with physical disabilities have shown that people with disabilities not only need tools to assist them physiologically but also have a strong sense of inferiority and rejection psychologically. The addition of mycelium materials can reconstruct the visual, tactile, and other multisensory interaction modes of rehabilitation aids (Zhao et al., 2020), bringing more emotional care to the disabled.

Material property matchingj

Based on the analysis of objective and subjective characteristics of mycelium material above, match the material characteristics with the product objectives. Query whether the material characteristics can meet the user requirements and product development objectives. This design successfully

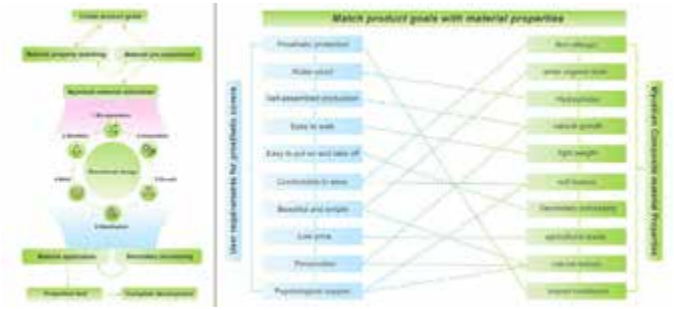

Figure 1. Left: Mycelium composite material design flow chart ; right: Matching of product requirements and material properties.

Figure 2. Left: Mycelium protective cover cultivation process: (a) substrate disinfecting; (b) inoculation; (c) adding material into the mold; (d) mycelium grows naturally; (e) drying material ; right: mycelium prosthesis protection cover wearing effects.

matches the user requirements and material properties (Figure 1), the prosthetic cover will be designed in depth.

Mycelium material pre-experiment and cultivation

After comparing the color, odor, form, touch, and texture between the six mycelium material samples and the impact resistance test, the sample with the material formulation of Ganoderma, wood chips, wheat bran, and glucose was selected because the subjective and objective characteristics of this sample met the product development needs.

To begin, the chopped sawdust and wheat bran were mixed according to 70% and 30% of the total mass of the material, respectively, placed into a sealed bag, and sterilized in a high-temperature environment of 100 °C for 2 hours to prevent the substrate from being contaminated by bacteria. After the inoculation was completed, the substrate was placed in a sealed bag with a breathing valve, and the mycelium was left to colonize and grow in the substrate for one week. The colonized mycelium composite material was then placed into the mold, and pressure was applied to limit the growth space of the material and to generate the shape to be molded. After eight days of growth in the mold, the shaped mycelium composite was removed. It was placed into a sealed bag and grown again for seven days, allowing the mycelium to completely cover the substrate and increasing the strength and density of the material. During the cultivation process, the mycelium growth environment temperature should be controlled at 25°C–30°C, and the relative humidity should be 80%–90%. Finally, after growth, the mycelium composite material was placed into an oven and baked under convection at 100 °C for 2 hours to remove the fungal activity and moisture in the mycelium. The mycelium protective cover cultivation process is shown in.

Secondary processing and material application

To realize the convenience of wearing the prosthetic protective cover, secondary processing is required. To date, a calf prosthetic cover based on mycelium biomaterial has been fabricated. The steps for wearing the mycelium prosthetic cover are shown in, and the effects are shown in (Figure 2).

Material properties test

A material testing machine was used to test the mechanical properties of the prosthetic material The mechanical properties of the complete mycelium prosthetic cover were tested. The test was divided into a vertical cross-section and a transverse cross-section of the protective cover, test process, and results (Figures 3). A series of material performance tests proved that the performance of mycelium material is between that of rigid polymer foam and polyethylene, and the prosthetic protective cover made of mycelium material can provide corresponding protection functions and meet its basic performance requirements.

As an emerging biological material, mycelium's biophilic properties can help designers create a more ecological and natural artificial nature and integrate it with nature to form a "living" artificial natural object. Designers also have the opportunity to be the subject of life-shaping, blurring the boundaries between living and non-living, and presenting a cooperative model of mutual integration and symbiosis between human and non-human species. Based on the exploration of the implicit and explicit characteristics of mycelium materials, this study provides designers with a biomaterial-driven innovative design approach through the experimental application of biomaterials in the design of rehabilitation assistive devices. It is worth noting that the physical properties of the material will be affected by product function, manufacturing technology, and the use environment. Therefore, designers need to further investigate the application of the material in diverse products, in addition to testing the mycelial prosthetic cover through international standards to verify the usability of the product. The innovative application of biomaterials expands designers' imaginations and gives products a new sensory experience. In addition, mycelium materials use new biomanufacturing models to naturally "grow" carbon-negative products with low energy consumption, and they can be combined with different agricultural wastes to produce unique material textures to meet the individual needs of users. The experimental application research of mycelium material also builds many possibilities for the future application development of biomaterials in design and can even rebuild the artificial new order of nature with the help of its biological elements.

Abstract

Although far away, the pandemic of 2019 has given rise to many thoughts towards people's lifestyles and attitudes. More and more people are getting used to working and studying at home, which has given rise to many inspirations for the development of technology related to the lifestyle. Studies have previously demonstrated that incorporating botanical decorations into living scenes can benefit people's mental and physical health. There are also many artists and scientists on this basis to explore the integration of plants and machinery development, trying to use the characteristics of plants to achieve the purpose of convenient people's life. "Biophilia" advocates the human instinct to be close to the natural world and defines the innate emotional connection between humans and other living things as 'pro-life'.

By parametrically controlling the growth of plants to create furniture forms for people to use, this article tries to push the boundaries between living and non-living, natural and artificial, and computational and biological intelligence. The experimental method is adopted to precisely control the exposure of experimental plants to indoor environmental qualities such as water, sunlight, air movement, gravity, touch and media to produce tolerant porous shapes in their growth forms and then shape into furniture form. This has also been verified by previous studies that show the effectiveness and possibility of creating self-standing 3D structures by integrating computational design tools in designing with plant roots.

In addition, this case also combines knowledge from disciplines such as biology and materials science to parametrically predict trends in the survival of plants as intelligent organisms and to explore the use of plant ecosystems in the construction of man-made landscapes by presenting the possibility of plant roots as sustainable materials and transport carriers. Products created so far include chairs and tables using plant roots. The paper details the process of designing parametric plant furniture and the product's effect pictures. The second half of the paper highlights the potential implications of this design technique. At the end of the article, the research explores the future direction of parametric plant design, i.e. the use as furniture while preserving the natural properties of plant growth, thus creating a new ecological cycle in future use. Overall, this study has been carried out with important implications for biological, sustainable, and environmental design. In addition to the current research, which is mainly concerned with the simple planting of space, this study goes further and explores the plasticity of plants themselves as controllable biomorphs. With the current trend of sustainable design, it is also worth looking at how ecologically sustainable and circular living spaces can be constructed. Finally, this research will also enrich the diversity of human living spaces with tactile sensory and interactive properties that can be further developed and applied to the health and education sectors in the future, aiming to improve the well-being of the inhabitants.

Introduction

Design practice is affected by a growing understanding of the ecological footprints caused by humans. In design practice, there is a growing understanding of the ecological footprint caused by humans (Sahoo & Sethi, 2021). With the increasing awareness of environmental pollution, searching for new materials and solutions has become a major trend in recent years. As a result, eco-design, or "sustainable product development", has come to the fore. Wimmer et al. (2010) define eco-design as an approach that takes into consideration the environmental impacts of products during their whole lifecycle. Design practices also vary in terms of their CO2 emission (Kim et al., 2013), energy efficiency (Favi et al., 2012), recycling (Gallagher et al., 2019) etc. In addition to the aspects listed above, other studies explore design from the perspective of the whole, with great attention now focusing on the "cradle to cradle" design framework, initially proposed in 2002 by architect William McDonough and chemist Michael Braungart. Representing a continuation of a sustainable approach that takes into consideration multiple forms of life and future generations, "cradle to cradle" design is a biomimetic way of designing products and systems that models human industry on nature's processes, where materials are viewed as nutrients circulating in healthy, safe metabolisms (McDonough & Braungart, 2017).

This research explores an awareness of sustainability that aims to push the research for new materials and solutions as a branch of botanical design. It is also an approach of "sustainable product development" (Wimmer, Lee, Kun-Mo & Po-

lak, 2010) designed to improve the environmental impacts and the quality of human life.

Even though some research exists, it is a new area and is still in its infancy. Especially research on parameterisation in plant design (Song et al., 2019). Thus, this research takes the approach—Growing Design (Camere & Karana, 2017; Ciuffi, 2013; Montalti, 2010) as the main concept, trying to take the growing materials from living organisms (plant roots) to achieve unique material functions, expressions and sustainable design solutions. In Growing Design, designers collaborate with biological organisms, guiding their growth and forging the conditions in which a material/product is created. Such a creative process may generate novel materials, exploring the range of properties by controlling the growth of the organism or by experimenting with different shape possibilities by directly growing materials into a desired product idea (Camere & Karana, 2017).

In early 2020, during the COVID pandemic lockdowns in many countries, the idea for this practice arose. Limited access to outdoor activities prompted a reevaluation of the relationship between humans and nature, and the potential for incorporating plants in furniture design. Given that plants have existed on Earth much longer than humans, this research explores the intersection of the two. Despite the pandemic's waning impact, mobility issues still prevent some, such as the elderly and disabled, from experiencing nature still common. Thus, this research results in the cultivation and design of furniture utilising the Bougainvillea glabra's roots as the primary focus for conducting furniture design. The current collection includes a chair and table. The research aims to contribute to a sustainable environmental design by offering unique insights into parametric design and plant growth control.

Theoretical basis

Sustainability and parametric approaches can be used together to create innovative and sustainable solutions. Inspired by the natural forms of plant roots and a desire to maintain organic shapes and patterns, this research seeks to create more intuitive and user-friendly products that feel more connected to the natural world. This offers a means of keeping the most original feel and inspiring the use of more sustainable materials and manufacturing processes, as natural systems often use minimal resources and generate little waste. Such considerations provided the initial inspiration for this research and its ultimate objectives.

Sustainable design focuses on reducing the environmental impact of products and spaces, considering the entire lifecycle of a product from its design to its disposal. This approach can include using sustainable materials, minimising waste and energy consumption during manufacturing and transportation, and designing products for disassembly and recycling. Sustainable design can also incorporate the principles of biomorphic and parametric design by optimising the use of materials and reducing the environmental impact of the design process. In this research, there are clear sustainable advantages to harnessing the environmentally friendly nature of plant roots, the low level of industrial intervention in the creation process, the natural form of the finished product, and the subsequent recycling, treatment, and reclamation.

The parametric design uses algorithms and digital tools to create complex, non-linear shapes that respond to specific design parameters, such as structural integrity, environmental conditions, or user preferences. This approach can help to create more efficient and optimised designs that use materials and resources more effectively. Parametric design can also be combined with biomorphic and sustainable design to optimise the use of materials and reduce the environmental impact of the design process. In this research, the main objectives are (1) to explore the reason of adopting parametric tech in design practice, (2) to achieve tailored plants, and (3) to explore their adoption in furniture design.

Together, these two design approaches can create sustainable, innovative, and beautiful designs that respond to the natural environment (Eren, Düzenli & Akyol, 2018; Yoo et al., 2020).

Table 1. Two primary materials horizontal comparison.

Plant types	Length of stem	Technical support/advantages	Weakness for furniture design
Bougainvillea glabra	Single stem up to 6m; Example: In the sixth lane of Liantang Village, Luohu District, Shenzhen City, bougainvillea glabra climbed along the building from the underground to the 8th floor, occupying most of the wall surface and forming a "flower waterfall" with a height of about 20 meters.	There are many research bases in China and other areas; Many cities in China regard it as the city flower, like Shenzhen, where also has a plant-research center; In Chaoshan region of China, craftsmen specializing in the cultivation of bougainvillea species for root carving; life time is long; Evergreen woody large vine, water, fertilizer, adequate sunlight; When it has enough water and fertilizer, it grows as fast as it can; Non-perishable and durable, it can still be used for sculpture after being transformed into a dead body.	Slow growth, need to optimise cultivation approaches; There are many kinds of species and more experiments need.
Fungi	After the operation of crushing, various shapes can be generated; There is no diverse manipulation of features.	There have been successful cases, and the products can be smooth, waterproof, sustainable cycle; There are related research centres in Netherlands, Germany, the United Kingdom, China etc.	Cell polarity and growth rate affect mycelium morphogenesis; As furniture material is easily affected by room temperature, humidity and other environmental factors; Different fungus need to be selected for experiments; Most experimenters still need to mix it with wood, waste or other materials.

Drawing inspiration from natural systems and using advanced digital tools, designers can create products and spaces that are both functional and aesthetic while minimising their environmental impact. Integrating these design approaches can lead to more efficient and sustainable designs, benefiting both people and the planet.

Methods

The research is based on taking advantage of computer vision and sensing improvements. The key is determining which rhizomes can be controlled by effective parameterisation. The transverse comparison was conducted on three raw materials of bougainvillea glabra and fungi as the primary analysis objects. The focus is mainly on the physical characteristics of the two materials, the advantages of application, and the weakness of furniture design. There are two reasons for the materials chosen: firstly, the accessibility of the material was a key consideration. Bougainvillea glabra is widely grown in the southern regions of China and fungi are well-researched for cultivation. Secondly, the team included sustainability and low carbon as core objectives in the initial design planning. In other words, we wanted to eliminate unnecessary industrial processes throughout the design. Ensuring the original growth of the plants was another key factor considered. Therefore, combining these two considerations led to the selection of trillium and fungi as the two alternative raw materials.

It is clear from Table 1 that the biological characteristics of bougainvillea glabra - its ability to survive for long periods, the width and length of the plant's roots, and the fact that it is grown over a large area in southern China - make it very suitable as a raw material for plant furniture. Although fungi are also extremely plastic. The use of fungi as a raw material for furniture may require the production of appropriate abrasives for the targeted cultivation of colonies and a series of tests on the load-bearing capacity of the furniture once it has been shaped. Thus, bougainvillea glabra was chosen as the main object of study. However, it is not the perfect raw material in its original form. The biggest problem is its slow growth rate. Therefore, various nutrient solutions (to promote growth) were used for testing during the design process. In the end, coconut water and tetracycline-based growth hormone were used in this study as the main nutrient solution to stimulate the growth of bougainvillea glabra.

Results

The study is currently in its experimental phase and is set in a factory located in Wuhan, China, where the root of the bougainvillea plant is being extensively researched. It should be noted that this is a conceptual investigation. The entire process can be divided into two parts: cultivating the roots to produce raw material for furniture design and using a parametric model to control the plant's secondary growth and shape it into plant furniture.

Cultivating process

The project is still in the experimental stage and should be considered an investigation on a conceptual level. Thus, a bougainvillea glabra design is taken as an example to explain in detail. First, selecting a container with a large basin mouth and mixing a large amount of river sand with culture soil is necessary to maintain bonsai. It is important to note that when planting the stump into the mixed culture soil, the bonsai stump should be raised above the mouth of the basin. River sand curing bonsai has good drainage permeability and is a better choice. Another point worth noting is that after adding a large amount of river sand, the soil's fertiliser protection performance is weakened, and water and fertiliser management should be paid attention to in the later maintenance to ensure the normal growth of plants. Let the roots sink deep into the soil. Then consider whether to transplant. The detailed steps include six, from root extraction to gravel cultivating root.

Table 3. Six steps of cultivating the root.

1 Root extraction	Coil up most of the root system and curl it into a certain shape. During transplanting, the root system of the plant should be lifted upward, preferably beyond the height of the pelvic mouth, and most of the coiled roots should be fixed with tools and wrapped in sand. In the normal maintenance process, under the influence of external factors such as wind, sun, rain, etc., most of the coiled roots will be slowly exposed, and the improved roots will be slightly shaped and processed. Expose the root system in a regular time and remove the soil from the roots of the plant, leaving some of the roots bare.
2 Developing root	Fill a deep cylinder pot with a layer of soil (nutrients added with growth hormones) at the bottom and sand at the top. Plant the prepared plants in the pot. In order for a plant to grow, its roots will keep spreading down to absorb nutrients. What we need to do is, every once in a while, remove some of the sand from the top of the pot, so that the root system will slowly come out. Finally, the roots of the plant have sunk deep into the nutrient soil at the pelvic floor. After the upper layer of sand is removed, the plants are replanted in the pot together with the nutrient soil, and the exposed roots can be artificially fixed with tools after shaping. After a period of time, it can be set, and this time can be exposed to the natural wind and sun, which can naturally promote the aging of the exposed roots.
3 Revealing the roots	Plant the plants in shallow POTS. Due to the limited height of the pot, the root system of the root part of the plant will definitely be exposed to the soil of the pot. The root system can be gradually fixed, and finally shaped.
4 Desoiling	If breeder want to create the effect of hanging roots and exposing claws, you need to expose the roots on the surface of the soil. You need to spray water, and you need to flush the soil away from the surface and expose the roots.
5 Choking	Plant into the pot, pile soil at the roots so that the base of the plant is above the pot but not completely exposed. Wait until the plants are alive in the pot, slowly from high to low remove the backsoil, after a long time of maintenance and shaping, can be replanted on the pot.
6 Gravel cultivating	Use plastic to roll up and make a cylindrical drum without a bottom, or use a wooden bucket or bamboo basket without a bottom to surround the plant and fill it with sand, a few pebbles, water and fertilizer. Once the plant is alive and the roots have penetrated into the soil beneath the sand, remove the sand from the top several times, preferably at different intervals with the help of growth hormones. Finally, remove the roll and reserve the finished product.

Parametric growth

The main branches were intentionally bundled and different environmental stimuli, including water, gravity, touch, and media, can guide plant roots. With artificial manipulation, plant roots can be shaped to grow in various directions and either stay on the surface or penetrate obstacles they encounter. In

materials science and engineering, the porous structure of parameterization allows plant roots to form a network structure with bearing capacity. By placing obstacles in the direction of growth, the roots can be shaped, and the hierarchical drive of botanical roots can be combined with parametric porous structures. After experimenting with AGAR medium and 3D porous barriers, small and large porous pla structures were 3D printed to design appropriate barriers for the roots and complete the "parameter porous bead experiment." The "bonding ability" of the roots associated with the porous structure enables them to combine into 3D blocky patterns with high compressive strength, verifying that the porous structure of the 3D printed plant can produce a certain tolerance in root formation.

The process of parameterizing plants can be divided into eight steps. Firstly, record the growth of the plant roots, including growth rate and time. Next, an algorithm is generated, which may be integrated within the GH modelling software. Thirdly, the initial furniture design model is set to roam freely. Fourthly, record the user's body data in detail. Fifth, determine the rhizome (starting point), which involves combining personal data with the user's usage habits, distribution of force points, and common postures. Sixthly, using this data, deepen the model and set the "obstacles" and "collisions" in the GH parametric modelling software. Seventh, use a Boolean Toggle to control the reset operator. Eighth, the rootstock grows gradually according to the obstacle position, creating a stable path network. Extract the trajectory lines and use the Weaverbird plug-in to smooth the surface (which can be set to subdivide the structure). Finally, a furniture model with a support structure is created.

There are several recommendations for this whole process. The main branches should be kept bundled and guided. Plant roots can be shaped gradually in different environments by water, gravity, touch, and other media. Plant roots can be artificially guided to grow in all directions and can stay on the surface of obstacles or penetrate them when encountered. In the porous structure of parameterisation, the plant roots can form a network structure and develop bearing capacity, because the porous structure allows the plant roots to grow into a denser network structure with a higher degree of fit that ensures a stronger network structure.

Figure 1. The grinding picture of the production process.

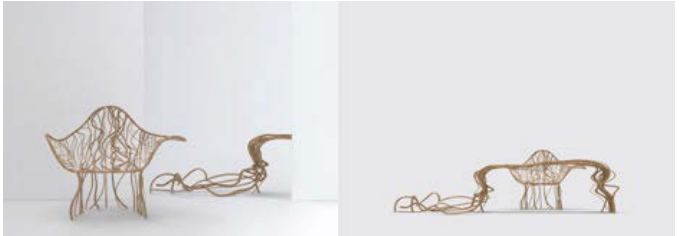

Figure 2. Effect pictures of the two items.

The project initially planned to include a wide range of furniture products, such as tables, baskets, chairs, lamps, etc..However, there was a shortage of funds during the project. The final products therefore consisted of a chair and a table (see Figures 1&2).

Conclusion

Sustainable design is the global challenge and goal of humankind. Sustainable product design and production driven by technology can reconstruct human and environmental relationships. As the embodiment of this concept, plant furniture design is important. Taking the tree house as an example, it can effectively withstand nature's storms. After an earthquake or tsunami, the only structure that can guarantee human survival is a treehouse. This design is also significant for improving the urban environment and solving the housing problems of low-income and homeless people.

In addition, plant furniture is of great significance for establishing a biological regenerative life support system. Bioregenerative life support system is the core technology of long-term manned space activities in the future. It has the advantage of continuously regenerating oxygen, water and food, the necessities of life for human beings, in a closed system. Plant is an important part of the biological regenerative life support system. Plant furniture can complete its metabolism and regulate indoor and outdoor temperature and air quality, significantly benefiting disease patients, medical places, urban planning, etc.

There are drawbacks to such studies. The first is the high cost of input. Suppose the related techniques are to be promoted on a large scale. In that case, further experimental studies on the rhizosphere growth of Bougainvillea are needed, such as experiments on guided growth in different environments. Later user testing, as well as the cost of promotion, are significant expenses. Secondly, the maintenance of the product also needs a series of experiments to test its usability, such as whether it will grow mouldy in the supermarket environment, how to maintain it and so on.

Creating a meaningful product application concept, i.e., designing for material experiences, takes much work. It requires a critical understanding of what the material offers in terms of function/utility and overall experience: *how it gratifies or disturbs our senses, what meanings, associations, and emotions it evokes, and what it makes us do* (Giaccardi & Karana, While a material with endless combinations of its ingredients, would excite and inspire designers in exploring its possibilities for design, this may also give a sense of uncertainty (Daalhuizen, Badke-Schaub, & Batill, 2009; Krishnan & Bhattacharya, 2002), as the *boundaries of the material* would not be known in an early stage of a material-driven design project (Barati, Karana, & Hekkert, 2015).

In a word, this research uses this case to analyse the characteristics of the growing design process, which aligns with the notion of WHO 2022 sustainable development goals. The creative thinking and design of material and product concurrently expand the boundaries of design toward new territories asking for new tools and methods, which also is one of our future research endeavours.

Systemic Design Oriented Leadership (SDOL) – a co-created play for eco-social leadership development with the methods of systems thinking

Pelin Celik

School of Culture and Design / System Design, University of Applied Sciences HTW Berlin, Germany

pelin.celik@htw-berlin.de

Abstract

The global economy is at a turning point, having reached its limit long ago after many decades of fossil fuel economy and growth thinking. Moreover, the world is becoming increasingly complex, accompanied by social, political, climate and technological challenges. The global COVID-19 pandemic has highlighted the interdependence and interconnectedness of different systems. Organizations that have to constantly adapt and reinvent themselves to changing situations require leaders who have learned to think in a connected way, to experiment, to endure uncertainty and, above all, to change their mental models.

In recent years, organizations invested considerable effort and resources to developing and enhancing the leadership skills of managers through various forms of Design Thinking tools and Design methods. Nevertheless the complexity for human and ecological problems asks for a further education of leadership actors, towards a new leadership mindset – beyond Design Thinking methods. Current leadership training programs aim to develop individual skills and growth of leadership without considering this in a systemic context and promoting the systemic perspective. How can a Systemic Design Oriented Leadership (SDOL) play kit - developed in co-creation - enable tomorrow's leaders to see the whole picture and to make systemic decisions that are sustainable and social?

In order to train leaders in an eco-social thinking and behavior a Systemic Design Oriented Leadership (SDOL) play kit was developed. The method framework was set to Grounded Theory (Glaser, 1967) and Systemic Action Research (Burns, 2014), where playful, experimental interventions were designed, methodically recorded and evaluated together with the managers in regular co-creative workshops.

Through SDOL play kit, leaders are able to understand complexity and at the same time the play kit can serve as a compass, that influences the strategic competence of leaders to make eco-social decisions. SDOL as a play and co-creation trains the new skills for eco-social management in organizations. It allows leaders as players to experiment, speculate and react to behavior in play by the infinite game of synthesis, critique and redesign.

Leadership, Systemic Design, Systems Thinking, Play, Co-Creation

Introduction

In the context of digitalization, climate change and overlapping crisis, many companies are facing a huge complexity in the world. More than ever, companies and their leaders are challenged to think and act in a systemic way. In recent years, organizations invested considerable effort and resources to developing and enhancing the leadership skills of managers through various forms of Design Thinking tools and methods. Managers in middle and higher management positions have clearly realized the business values of design methods, especially Design Thinking (Badjoko, 2018) and User Experience, that have have been at the forefront of supporting digital transformation in companies (Magistretti et al., 2021). The leadership of tomorrow might has to experiment and needs new design strategies beyond Design Thinking. Authors such as Beehner (2019) argue that leadership has to enter into new relationships with nature, society and individuals in order to be able to make a sustainable, trust-based impact on solving problems. The new approach for leadership develops towards an ethical approach as Beerel (2020) formulated in her book "Ethical Leadership and Global Capitalism: A Guide to Good Practice". She argues that "(...) ethically sensitive managers need to engage in self-examination and developing their own self-awareness. They need to reflect on the kinds of people they are, their value system and the types of decisions they make. They need to be open to self-development and change and should seek out for opportunities for personal growth and challenge". Also Mugadza et al. (2019) explain how leadership has changed since the Pre-Industrial Age - from the born leader in industrial times towards innovative leadership with a Systemic Design perspective.

It seems that traditional innovation methods such as Design Thinking or UX Management might not be sufficient anymore for an eco-social leadership development. Habicher et al. (2021) conclude in their research on transformation of leadership in SMEs, that Design Thinking plays only a marginal role in the firms, if it comes to socio-ecological transformation. Current leadership training programs aim to develop individual skills and growth of leadership without considering this in a systemic context and promoting the systemic perspective. If organizations are looking for new leadership or eco-social leadership development, managers might first be trained in Systems Thinking, in analyzing relationships between stakeholders and finding patterns in behavior. How a ludic Systems Thinking in

leadership development can change a mindset from growth to a more sensitive one into the direction of social and ecological decision making, has not been extensively researched. There are almost no tools in leadership development that focus on a change management by Systems Thinking play and game dynamics beyond design thinking methods.

The central objective of the ongoing research project is the question to which extent Systems Thinking as a ludic intervention embodied in a serious play kit can influence the personality development of managers to act in a socially sustainable way in order to transform corporate structures.

How can a Systemic Design Oriented Leadership (SDOL) play kit, developed in co-creation, enable tomorrow's leaders to understand complexity and to influence the strategic competence of leaders to make systemic decisions that are sustainable and social?

This paper shows the first results of the author's ongoing research project SDOL and the co-created ludic intervention.

Theoretical concept of play

Play seems to be a serious opportunity to make the reality of work more motivating and meaningful - not only for leaders. Because play seems to enable people to reflect themselves, to question behavioral patterns, to test and explore interactions in a group. Also play might enable people taking over risks and bearing uncertainty, which is often the case in design processes. Brown et. al for example claim, that play is a catalyst, like design methods, for being productive and creative (Brown et al., 2019).

There seem to be various definitions in literature of what play is and it might depend on its nature, purpose and manifestation. Three famous examples might be the definitions of authors such as Huizinga, Vygotsky and Rubin. According to Huizinga (1955), play is a free activity standing quite consciously outside 'ordinary' life as being 'not serious', but at the same time absorbing the player intensely and utterly. In psychology Vygotsky (1978) for example characterized children's play as an activity that is "desired" by the child, "always involves an imaginary situation" and "always involves rules" (which are in the minds of the players and may or may not be laid down in advance). Rubin et al. (1983) characterized play as a behavior that is intrinsically motivated, focused on means rather than ends, distinct from exploratory behavior, nonliteral, free from externally imposed rules and actively engaged in by the players.

As Gray (2013) e.g. concluded that essentially all of the descriptions of human play can be boiled down to the five characteristics: Play is an activity that is self-chosen and self-directed, intrinsically motivated, guided by mental rules, imaginative and conducted in an active, alert, but relatively non-stressed frame of mind. Gray's conclusion seems to describe the qualities of creative thinking in design processes and seems to have similar arguments to Mainemelis et al. (2006), who proposed that play facilitates five creativity-relevant cognitive processes: problem framing, divergent thinking, mental transformations, practice with alternative solutions and evaluative ability.

Figure 1. Shows the comparable framework of the author and Mainemelis.

The SDOL research project follows the definition of play according to Mainemelis, because of the comparable System Design teaching process that was developed by the author at the HTW Berlin: Synthesis, Critique and Redesign (fig. 1, see below).

Table 1. Shows the comparable framework of the author and Mainemelis.

System Design teaching process	Mainemelis et al. play process
1. Synthesis – exploring the system	Problem framing and divergent thinking
2. Critique – identify the leverage points	Mental transformation
3. Redesign – create the system interven-tion	Practice with alternative solutions and evaluative ability.

Methodology

The methodology is inspired by Grounded Theory and Systemic Action Research where playful, experimental interventions were designed, methodically recorded and evaluated together with the managers in the co-creative workshops. The process in the ongoing research project SDOL took place both horizontally in the leadership teams and vertically in the individual areas.

Organization of the workshops

Together with the participating leaders (finance and consumer goods industry) three consecutive workshops, based on the Systemic Design process mentioned before, were organized. Each workshop duration was up to four hours, twelve leaders from different departments participated. For the first workshop on *"Synthesis – Explore the System"* the leaders got information by forehand in form of articles on Systems Thinking, Systemic Design process and the goal of the workshops. Each of the three workshops started with a playful warm-up. The task in the first workshop was to define the personal definition of leadership. The guiding questions in the first workshop were:

What personal competences distinguish you as a leader? What is your eco-social perspective in your context (team, company, organization, etc.)? How would you describe your leadership style? What challenges do you face in your leadership position? After this, each group had to present and discuss their personal challenges and definition on leadership in their current status in the whole group.

The aim of the second workshop *"Critique – Identify the Leverage Points"* was to reflect on the re-enactment of leadership and the causality in order to identify leverage points for transformation. The task was to replay recruiting moments within an re-enactment. The challenge was to set up a role play, where three persons took over the part of the company's perspective and preparing questions on economic, social and

ecological positions. At the end they had to discuss the behaviors and feelings in the re-enactment.

In the third and the last workshop *"Redesign - create the system intervention"* the leaders had to prototype with LEGO® Serious Play® the ideal leadership play. The first task was to answer reflective questions on the own purpose of leadership. The guiding model derived from the original IKIGAI model (Kamiya, 1966) that was presented to the participants before starting the challenge. The questions for the own reflection were adapted to the eco-social focus: What are you really good at? What do you love in nature? What does our society need? What do you need for your organization or team? Answering these questions and having had a deep inner personal reflection in the first two workshops, the participants had to redesign their mental model of leadership as a play.

After each of the three workshops the participants got a questionnaire via E-mail for evaluating the overall experience and describing transformational moments in their organizations.

Figure 2. SDOL Workshop, Celik P. (2022)

Results

The group discussions, observations, individual interviews and retrospective questionnaires produced the following results: 85% of the workshop participants had no former knowledge about Systemic Design and Systems Thinking processes and 41% would like to have even more information about the presented model "Synthesis, Critique and Redesign".

In addition to the transformations of the directly used tools, 82% of the leaders report that the playful exercises moved them to a changed self-perception and new behaviors. The exploration of the play inspired all leaders to use ludic interventions in daily business. Overall, 79% of the leaders report having better understood systemic leadership through the play workshops. Five leaders stated that playful moments made them think how to overcome the routines in their organizations and to be more sensitive for eco-social decisions in their teams. 92% of the participants were "very satisfied" with the task in the first workshop and the inner reflection. Three participant described the challenge in the first workshop "as a very emotional moment, becoming aware of mental role-models and their implications". One participant suggested to have a predefined selection of leadership motives, which they could have selected making a postcard story for leadership. 57% of the participants said that the role play in the second workshop was very challenging in terms of presenting in front of the group and 23% described "an overcoming moment of shame". Seven participants state that the role plays provide important projection areas for what they believe is inconsistent in application processes in large companies. Reflecting on the recruiting process in the company 87% have seen this as an enlightening moment to change something. For two workshop attendees play artefacts, f.e. rolling the dice on salaries, was an ethically critical moment that should be discussed further. Overall, 90% of the participants were inspired by the re-enactment challenge to further develop their own recruiting processes. In the third workshop 95% of the participants observed that the personal information shared between leaders in the "IKIGAI - challenge" was much closer to the "own heart" than it would be in a business context, where it is nearly always about "pretended roles" and rarely about self-reflective motivations. One participant commented that something like self-awareness does not usually happen in the business world, but that the playful workshops had managed to do this. Overall, 70% of the participants reported that the play workshops inspired them to change something about their leadership style. Across all workshops, 71% of the leaders reported that the activities gave them an inspiration for eco-social leadership development. 90% of the participating leaders would recommend a Systemic Design Oriented Leadership (SDOL) perspective through play and two leaders recommended more challenging play situations that could even take place in nature to reflect on eco-social decision making.

As a result of the three workshops, that is based on the feedback and the Systemic Design process of the author, a Systemic Design Oriented Leadership play kit was prototyped.

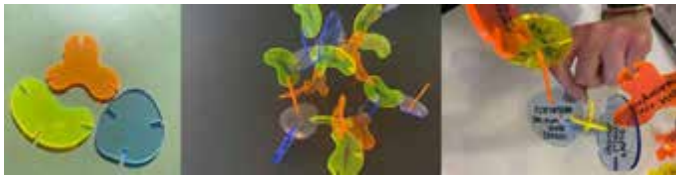

Figure 3. SDOL play kit, Celik, P. (2022)

The first idea of a SDOL play kit consists of three differently shaped elements of colored acrylic material. Each color or element refers to one of the systemic levels such as Synthesis, Critique and Redesign. These shapes can be connected and related to each other. The aim of the play is to answer questions on each level and to connect them. The questions on each shape are based on the questions from the third workshop, but also derived from the inner leadership reflections of the first and the second workshop:

- Orange (Synthesis level) = *What do you love in nature?*
- Yellow (Critique level) = *What does our society need?*
- Blue (Redesign level) = *What does your organization or team need for eco-social decision making?*

The play is prototyped for 12 participants and has three levels, where each participant has to create his/her artefact by answering the questions. The play takes 100 minutes in total. It starts with a short introductory presentation on Systemic Design and Systems Thinking (10 minutes). After the introduction the participants get the first question for the orange coded level of "Synthesis" *(What do you love in nature?)* presented and have to write down their answers (15 minutes). They are allowed to write one term on one acrylic shape and can use as much as needed. After this they have to answer the second question on the yellow level "Critique" *(What does our society need?)* by writing on the yellow parts (15 minutes) and after this they step over to the third blue level "Redesign" *(What does your organization or team need for eco-social decision making?)* (15minutes). After writing

down the answers for all three levels the participants have time to stick the single acrylic parts together. They have to decide on their own how to connect and relate the individual terms or answers on the color-coded levels to each other (15 minutes). With the elements of the play kit the participants create a structure or artefact that helps to understand complexity and reflects the personal leadership ecosystem. At the end, the participants are asked to present, discuss and reflect their artifact in groups of two (30 minutes).

Conclusion

A systemic orientation of the economy is needed, and this requires leaders who are trained to think in systems and create impact (Barge et al., 2008). Particularly young employees (Millennials and generation Z) might be questioning classic leadership roles and are orienting themselves towards companies that represent social and ecological values (Titko et al., 2020). There is a potential in serious play to evolve the role of leaders from "mitigators" and innovators to systems thinkers, interested in shaping ecological and social change.

The three workshops are related to the process of the authors Systemic Design Model (Synthesis, Critique and Redesign). The methods of Grounded Theory and Action Research took place in every step and allowed to reflect and develop the co-created SDOL play kit.

In the SDOL workshops there were plenty of playful moments and discussions about leadership values and the systemic perspective. A shared trust was quickly established in the play, which enabled honest feedback and made independent collaborations between the partners. Through the co-created plays in the workshops the leaders were empowered to experiment corporate cultures and to use ludic interventions to further develop the innovative power of their organizations. Set into the business context, systemic play suggestions, like the re-enactment and in particular the "salary dice", raised ethical questions. Leadership might have the inner conflict of acting fairly, both with new recruits and the annual salary negotiations. But fairness might be a question of perspective. This example shows clearly that the systemic perspective of the manager might be missing in order to be able to make a socially fair decision. Therefore the focus in SDOL is on a constant reflection with the participants on the effects and adequacy of the methods that were developed in a co-creative process. Especially in the third workshop, the participating leaders revealed a lot about themselves as they went to an inner journey to find their "IKIGAI". Inspired by the third workshop a first SDOL play kit was prototyped.

At present, this co-created play is still in work and evaluated. It is being tested with a bigger group of managers and there is a need to explore the play kit with a higher relation to nature as well as to specify socio-ecological questions regarding the particular fields of action in daily leadership.

Acknowledgments

I am grateful to my colleagues and my research assistant Olivia Hidalgo for their collaboration in the previous research project "LudiX", which was the starting point of my own research in SDOL. Further, I thank all the managers who participated in the workshops for their openness, creativity and feedback.

Abstract

After almost three years since the Covid outbreak, the structural damages the pandemic wreaked are finally becoming more evident than the death toll. A growing crisis that affects the public sector, families, and companies is anticipated by failed businesses and routines that have been disturbed by the fear of the invisible. The university enters this situation as a strategic place for research and a training ground for experts who will steer the transformation.

Grounded on a vision of design as a force of change, the Imagis Lab research group has investigated the different meanings of "design and transformation" since 2015, probing the transformative skills of distant professional worlds. The focus has been on understanding design's role in promoting change processes. So to know how to be a human and professional anchor capable of activating contemporary, sustainable and long-lasting organisational change.

The first part of the paper will provide a description of the main actions and insights from the Research Through Design approach. The research, started in 2018 and still ongoing, begins with an insight: digital transformation is human-driven. This a statement that prompted us to investigate the role that design, marketing and communication can play in organisational change processes. The second part of the paper is devoted to presenting the reflections on the transformative competencies inherent to the design practice, among which are: emotional agility (listening for self and others); leadership (motivation for self and others); creativity (breaking from automatism and identifying an actual solution); storytelling (insight and creation of new meanings).

As a result, we propose to look at the design(er) as a figure able to challenge contemporary complexity (strategy) through active listening and empathy (human-driven approach) for identifying contemporary solutions (marketing, product, and service) developed by sequencing seemingly distant dots (design) and conveyed through new meanings (storytelling).

Introduction

Almost three years have passed since the Covid outbreak, and the structural damage caused by the pandemic is now emerging clearly beyond the death toll. Failed businesses and routines disrupted by the fear of the invisible anticipate a progressive crisis that strains public administration, families and businesses. Into this scenario comes the university, which, on the one hand, stands as a privileged place for research; on the other hand, it prepares professional figures to lead the transformation (Stolze et al., 2018; World Economic Forum, 2020). In this technological, economic and social evolution context, digital transformation emerges as an increasingly relevant and unavoidable phenomenon in the business landscape (Kane et al., 2015). Suppose we understand Digital Transformation (henceforth DT) as a process enabling a major cultural transformation (Kraus et al., 2022). In that case, there emerges the need to understand how design, marketing and communication become crucial areas of a process that involves people first and foremost.

Our work aims to define how the practice of design emerges as an indispensable asset for developing cultural transformation within companies and what are the competencies of this new type of consultant: the designer for transformation.

Design (Manzini, 2015), marketing (Kotler & Keller, 2009) and communication (Jenkins et al., 2013) have historically been levers for reaching and engaging audiences. The difference from the past is that today, with the implementation of digital technology, they acquire a renewed ability to respond to audience needs. They become natural enablers in organisations' transformation processes because of their ability to collect and interpret data by understanding the target audience's needs and intervening directly in the relationship between supply and demand (Ronchi et al., 2020).

Main actions and insights coming from the Research Through Design

Grounded on a vision of design as a force of change (Design Council, 2021), the Imagis Lab research group has investigated the different meanings of "design and transformation" since 2015, probing the transformative competencies of distant professional worlds. The focus has been to understand the role of design in fields where the "know-how" connected

to a specific aim gives way to "knowing how to orient" in the unknown. So to know how to be a human and professional anchor capable of activating contemporary, sustainable and long-lasting organisational change.

Step 1 - Digital evolution pushes the transformation

In light of such premises, a scenario emerges in which the ubiquitous incorporation of the digital everywhere brings the entire market system facing an inevitable transformation. The consequence is that economic and social changes enormously alter the mediascape (Appadurai, 1990), pushing society toward a scenario in which relationship becomes a key element of communication and market innovation mechanisms, especially in its newer forms. In this sense, the shift from multichannel to omnichannel paradigm and digitization (Bloomberg, 2018; Mazzone, 2014; Rogers, 2016; Westerman et al., 2011) revolutionised outcomes and also work processes in many fields of application. Suppose we strive to read the contemporary in these terms. In that case, DT presents itself as a process of the evolution of business culture and a re-interpretation of the tools available to the enterprise.

These reflections prompted us in 2018 to investigate the role design, marketing, and communication can play in organisational change processes. The output of this first phase was a book that allowed us to focus on the insight that guided the research's development: DT is human-driven. Then, the main evidence was the understanding that to activate a DT, we must first activate a listening process. Therefore, figures who can listen, translate the needs gathered and mediate this information with the technology, and business aspects are needed.

From which a series of assumptions were then detailed:

- DT is a process of identity evolution;
- DT is a process of changing managerial culture;
- DT is a reinterpretation of the tools available to the enterprise;
- DT directly impacts people, and this determines the real revolution.
- DT is NOT a simple implementation of digital technology within business enterprises.

Step 2 - Focusing on design opportunity

From these insights, we wondered what the role of design and designer could be within the DT processes that become value-driven and human-driven.

Then, in 2019 we started to investigate the characteristics of the designer who leads the transformation, with the identification of the design opportunity: what characteristics enable design(er) to activate and lead the transformation?

Therefore, we decided to conduct experiments carried out in collaboration with different companies, applying a Research through Design (RtD) approach (Frankel & Racine, 2010; Frayling, 1993) that involved the collaboration of different stakeholders: researchers, practitioners, companies and students from the School of Design were involved in educational and design experiences that applied co-design methods (Björgvinsson et al., 2012; Sanders & Stappers, 2008) and open innovation (Chesbrough & Bogers, 2014).

All the experimentations allowed us to identify the design practice as an attitude to change. A design attitude, capable of fostering a cultural change and a new mindset that integrates design, techne, leadership and emotional intelligence: what we identified as competencies for transformation, investigated in the next step.

Step 3 - Design competencies for transformation

In 2020-2021, we focused on understanding the competencies potentially stimulated by design education curricula and professional pathways, following the adoption of the knowledge, skills, and attitudes model (henceforth KSA's Model) (Bloom, 1956; Krathwohl et al., 1956) for mapping human competencies and supervising three Master's theses on the topic.

The pathway stems from an in-depth study of the digital transformation process of the Italian business unit ABB Sace, a leading multinational company in the technological sector, carried by the design agency *Twig* (www.twig.design) between 2016 and 2019. In 2020, Giulia Sormani and Marco Ronchi were interviewed several times by Professor Paola Caiozzo, co-founder of the Commercial Excellence Lab (CEL) at SDA Bocconi. They illustrate with which mindset the organisation of processes, roles, skills, tools and actions was rethought: it emerges how much design has been recognized by the sponsors of the transformation as a discipline with a high contribution to agility and complexity resolution. Several questions emerge from the debrief, including those related to the distinctiveness of design dealing with organisations' transformation:

- What are the differences between a design-driven versus a technology-driven or economy-driven transformation?
- What competencies does design bring to make its contribution to transformation unique?

If we talk about design's authority:

- How fully is design recognized as a discipline capable of managing a transformative process?
- Why does the (Italian) market struggle to recognize the designer's governance of a transformative process, but more so its execution?

If we talk about design awareness:

- What prevents design from dialoguing at an equal strategic level with the (Italian) engineering, technology or business communities?
- Are there moments of organised awareness within design education pathways that allow young designers to question the transformative capabilities of the discipline and the strategic-executive ones?

The connection of Imagis Lab with Paola Caiozzo confirms the importance of involving a scientific community external to design and intrinsically linked to management and business organisation. Of all the areas explored, what forms the basis for further study is the common need to understand what competencies made design peculiar to change in an organisation with a strong engineering culture.

The master's thesis of Alice Cassanmagnago (2020), deepened the previous reflections of Bartram and SHL Group's model "The Great Eight" (Bartram, 2005; Bartram et al., 2002) within a methodological and cultural excursus that 1) analyses the competencies of the designer through the eight domains presented in the model, 2) selects among the 112 listed competencies those most consistent with its figure, and 3) classifies them into:

- Core competencies: the "know-how" classically acknowledged to design;

- Strategic competencies: the "knowing how to be," not yet fully recognized to design;
- Transformational competencies: "knowing how to change," not recognized to design.

The mapping activity highlights significant areas of overlap with the disciplines historically devoted to business management, identifying planning, listening, and collaborative approach as the distinctive characteristics that form the basis for the subsequent investigation of design's "transformative attitudes." Not forgetting all those "know-how" skills already recognized.

Then, Marco Ronchi and Serena Ballabio continue the investigation by supervising two more theses, focusing the insights of the first investigation into areas of high transformative need:

- The thesis of Filippo Collura (2020) investigates the role of the designer in sustainability-related processes using the framework previously developed by Alice Cassanmagnago (2020), and focusing on what skills can contribute to the adoption of effective circular economy processes. The dissertation 1) analyses models from The Circular Design Guide (*The Circular Design Guide*, n.d.), research from Delft University of Technology, and the Cyclon case study; 2) links insights from these sources with to the transformative skills identified in the previous dissertation; and 3) proposes a new tool aimed at design practitioners with an aptitude for sustainability. The result is a useful tool for navigating within circular economy processes and understanding how design skills can make an effective contribution to the development of circular economy processes: the *Design(er) for Sustainability Framework*.
- The thesis of Giorgia Calloni (Calloni, 2021) investigates the needs of the third sector in Italy through a side-by-side journey with the *Cooperativa Rapsoidea*, committed to solving the educational emergency triggered by the first wave of the Covid-19 pandemic in the province of Bergamo, Italy. The cooperative's mission is to build co-design experiences with different stakeholders in the area, pushing young people to take charge of the territory's needs by exploiting and investigating the possibility that the discipline of design supports them in the construction of their "life project". In this case, the output is the ETS Partnership activation toolkit: a tool aiming at guiding social workers in engaging third-sector entities, engaging youth, gathering needs, forming a group for the related development of design responses, and using a design-driven approach.

Step 4 - Humans through transformation

At the end of 2021, the collaboration with Cooperativa Rapsoidea took a specific shape during the Final Design Studio in Communication Design involving design students, local youth and stakeholders from the province's social, cultural and productive fabric of Bergamo.

Twenty-five young designers were provided with the basis for investigating the transformative competencies previously identified in themselves. Then, after framing the concept of competency, the students were asked to step into the shoes of coaches and facilitators of 20 youth from the area (aged 16 to 19), guiding them in listening to the needs of stakeholders and redesigning some symbolic places in the area:

- Stimulating in themselves the skills preparatory to activating, orienting and guiding a transformation process;
- Transmitting these competencies to youth who have never studied or heard of design, without directly contributing to the solution but exclusively transferring mindset and method (design thinking) to them.

At the end of the four-week course, students analysed their experience and skills through a questionnaire based on "The Great Eight" model to make them reflect:

- Whether in their undergraduate design journey, they had ever been aware of or had ever been placed in the conscious condition to question the above transformative skills;
- Whether in their undergraduate design journey, they had ever been trained explicitly on the transformative skills that emerged;
- Whether prior to the just-completed co-design experience, they felt that they were naturally predisposed to some of these skills;
- Whether, after the just-concluded co-design experience, they felt that they had activated some of these previously dormant skills;
- Whether they had questioned the importance of one or more of these competencies for their professional future.

Future framework for contemporary transformation

Through our experiences in the field and analysis of data from open innovation in education, we have identified three key moments in the design process in which transformation is enabled:

- Needs: design formalises the ultimate purpose of transformation (meaning), traces the processes to activate it (systemic vision) by placing human needs at the centre of inquiry (empathy);
- Competencies: design identifies externally (designers) and internally within the organisation to be transformed (internal stakeholders) the competencies (knowledge, skills and attitudes) needed to initiate and guide the process;
- Community: design creates moments of shared design (co-design) that enable designers to stimulate the transformative attitudes naturally present in internal stakeholders (engagement), transferring the design mindset (culture).

In particular, the area of "competencies" emerges as a moment to be further explored. Indeed, we understand that a better classification of competencies based on the continuous exchange and contribution from other fields can offer our discipline a different positioning towards managers who choose the path of transformation.

From this value proposition comes a new self-awareness framework dedicated to those who want to transform and those who want to support people that are getting things done. A tool based on four specific attitudes that design inherently promotes in the development of what we call "transformative courage," through:

- Listening to the self and the ecosystem as a whole (emotional agility) (David, 2017; Siegel, 2020), e.g. showing empathy and dealing with ambiguity;

- The search for purpose is what nowadays unites distant worlds (leadership) (Bruttini, 2007; Grant, 2013), e.g. making decision and motivating others;
- The breaking of automatisms and devising contemporary solutions (creativity) (Brown, 2019; Kelley & Kelley, 2015); such as analysing, evaluating information and thinking broadly;
- Identifying and constructing new shared meanings (storytelling) (Hansen, 2020; Roche & Sadowsky, 2003) in terms of negotiation and proactive communication.

These four fundamental competencies can be used transversely in design-driven transformative processes. However, they emerge in different proportions depending on the design process stage and the designer's characteristics leading the process. Whenever a designer addresses a path of organisational transformation in which the impact of change is primarily about people and their involvement, it happens systemically.

We understand through empirical observation in the field that the moment the designer comes alongside the ultimate target of the transformation–the user who will experience the outcome–he or she can decree the commitment and evolution of the process itself.

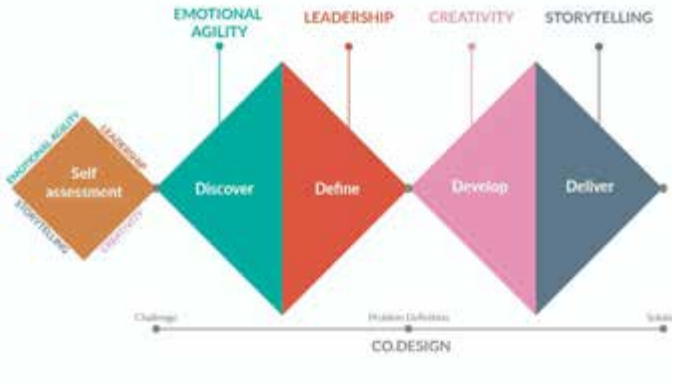

Figure 1. Visualisation of the 4 design attitudes across the double diamond in the design-driven transformative processes.

Final reflections

Historically, polytechnic culture has been credited with a multidisciplinary approach of intersections and tangencies between art, technology and humanistic culture, methods and technologies. Today, however, becoming a designer is not just about having acquired these skills and having gone through theoretical and design experiences: it is not (only) so much about "knowing how to do something better than others," but rather about "knowing how to stimulate in others what they have best to give," thus "knowing how to be without allowing for knowing how to do," interpreting contemporaneity and its scenarios, enabling the space and rhythm where others carry on the path according to their vision, while respecting their own identity and ability to contribute to the evolution of the ecosystem. The technical and tactical approach is fundamental. However, suppose we want to grow a new generation of designers "with transformative courage" to face the challenges of the contemporary world. In that case, we need to complement the technical skills with an expansion of the strategic ones that enables them to have a systemic vision by going beyond the strong pragmatism of Western culture (Morin, 2001).

In light of such premises, our purpose as a design research group is to propose the design(er) as a figure able to challenge contemporary complexity (strategy) through active listening and empathy (human-driven approach) for identifying contemporary solutions (marketing, product, and service) developed by sequencing seemingly distant dots (design) and conveyed through new meanings (storytelling). According to this, we must continue to promote and investigate these four aptitudes in the form of a framework.

To conclude, our goal for 2023 is to present and test the framework based on these four domains, which is useful 1) to design students as a pathway to self-awareness, 2) to business and public administration managers as a professional engagement tool, and 3) to designers themselves, to support the positioning of this new design attitude for transformation.

Change agents: designers interpreting 'the social' and 'social' interpretations of design

Laurens Kolks

St. Joost School of Art & Design, Netherlands
lag.kolks@avans.nl

Abstract

Designers are a positive breed, and many scholars studying the extensive field of design and its professional history – including some involved with Cumulus Antwerp 2023 – seem to agree that designers can contribute to positive 'societal impact.' In this paper I investigate how these optimistic views of designers' alleged 'social agency' are actually constituted, by describing how – over time – different notions of design have been mobilized in relation to various understandings of 'the social.' In current times of complex, layered, and interrelated crises especially, designers and design theorists need to get their vocabulary straight in order to specify what design *can* actually do – as well as what it *can't*. I therefore argue that to articulate relevant and meaningful roles design might play concerning various problematic entanglements, it is essential to differentiate *problems* that can be fixed, from *issues* that can merely be stabilized (Marres, 2007), and approach both phenomena precisely for what they are. Moreover, by acknowledging that both problems and issues are not a given but rather need to be *constructed*, 'designerly agency' in relation to 'societal change' can be understood as consisting of both the framing, setting and solving of problems, as well as the articulation of issues, through the creation of objects, environments, services and systems.

Author keywords

Design theory; sociology; social theory.

Introduction

Typically, designers are an enthusiastic, future-oriented, and positive breed. And by extension, many scholars studying the extensive field of design and its professional history seem to agree that designers – for better or for worse – can contribute to 'societal change' or, at the very least, emphasize the potential 'social agency' of the design profession as a whole. Numerous publications – not seldom featuring ambitious, if not plain out pretentious, titles – endorse high expectations regarding the agency of designers and their alleged potential for positive impact on 'the social,' 'societies,' or – even more overwhelmingly – on 'the world' as such (see, for example, Monteiro, 2019; Scalin & Taute, 2012; Van der Zwaag, 2014).

Whether designers are regarded a "class of aware, well-informed, trained and educated people who can navigate … complexity, negotiating the snaky processes of technosocial change and guiding them toward the sustainable" (Sterling, 2005, p. 75), or understood as 'activists that can disturb existing narratives' (Fuad-Luke, 2009), the design profession is often held in high esteem regarding its alleged capacities to engender 'societal change.' Accordingly, design scholar Alastair Fuad-Luke (2009, p. xxi, italics in original) describes designing as "an essential human expression that will help us *all* to move towards more sustainable futures" and design critic Alice Rawsthorn (2020, p. 8) states "design has always had one elemental role as an agent of change that interprets shifts of any type – social, political, economic, scientific, technological, cultural, ecological, or whatever – to ensure that they will affect us positively, rather than negatively." These bold claims and statements regarding designers' alleged 'social agency' make one curious how these optimistic views regarding design's positive 'societal impact' are actually constituted. Has contemporary design then really transformed itself from an "agent of capitalism" (Dunne & Raby, 2001, p. 59) – primarily concerned with desirable, but essentially unimportant, superficialities – into an "agent of social change" (Resnick, 2019, p. 15) – a field of practices that concerns itself with the transformation (or even emancipation) of the more substantive facets of life?

In this paper I describe how different notions of design have been mobilized in relation to various understandings of 'the social' during different periods of design's professional history. I will suggest that relations between 'the social' and the ever-expanding realm of design are shaped both by 'solution-oriented' and 'problematizing' approaches – two fundamentally different ways to entangle 'the social' and 'the material' through design. I will attempt to demystify and specify notions of 'social agency' contributed to various design approaches. I will conclude this paper by highlighting a number of key concepts I deem essential to sharpen our vocabulary when addressing (in practice) and debating (in theory) design's potential for 'social agency' or for contributing to 'societal change': the crucial differences between *problems* and *issues*.

Designers interpreting 'the social'

With the fairly recent emergence of terms like 'socially responsive design' (Thorpe & Gamman, 2011), 'design for social innovation' (Manzini, 2015) and 'social design' (see, e.g., Resnick, 2019), one might get the impression that the professional field of design has only just recently 'discovered' its entanglements with social life. However, from its 'modern' emergence in the eighteenth century onwards – characterized by the division of labour (Sparke, 1987, 2010) in which, for designers, the activities of *forethought* and *planning* are often paramount (Buchanan, 1989, 1992) – authors such as

William Morris (1882), Walter Gropius (1935), or Victor Papanek (1971) have written extensively on the 'social aspects' and presumed 'societal impact' of designed artefacts (objects, environments, services and systems), both positive *and* negative.

Whether through 'top-down,' designer-led 'social engineering' (Argamakova, 2017; Caroll, 2006) or 'participatory design' aimed at 'social innovation' (Manzini & Rizzo, 2011; Mulgan, Tucker, Rushanara, & Sanders, 2007; Thorpe & Gamman, 2011), numerous designers have explicitly sought to engender and/or support 'societal change,' motivated by divergent objectives and interests (Colomina & Wigley, 2016; Van Helvert, 2016; Whiteley, 1993). Bound up with the development of industrial-capitalist societies, design was simultaneously mobilized to create new consumer markets (Whiteley, 1993), to 'elevate the general public's taste' by disseminating 'universal aesthetic values' (Sparke, 1986), and to engender large-scale behavioural change – for example, towards 'a modern way of living' (Colomina & Wigley, 2016; Wilhide, 2016).

Although contemporary design approaches referred to as 'social design' or 'social innovation' often promote 'bottom-up' and 'egalitarian' methodologies that typically involve participatory, open-ended creative endeavours (Manzini, 2016; Manzini & Rizzo, 2011), these present-day approaches just as well seek to "enhance society's capacity to act" (Murray, Caulier-Grice & Mulgan, 2010, p. 3) by engaging with impactful developments taking place within industrial-capitalist societies, such as the restructuring of welfare states (Mulgan et al., 2007) or the local consequences of globally dispersed economic activities (Manzini, 2016). Therefore, from the eighteenth century up until the present day, both through 'top-down' and 'bottom-up' approaches, design has been mobilized as an instrument for *social engineering* – understood here as activities geared towards the "organization of social activity for the solution of existing problems and achievement of specific goals" (Argamakova, 2017, p. 70).

Interpretations of design as a 'change agent' with 'societal impact' align particularly well with the concept of social engineering as the latter notion presupposes a modernistic, mechanical worldview that objectifies social life, and therefore interprets 'the social' as *a mechanism to tinker with*. As many designers – especially those working in fields heavily informed by the sciences – are familiar with navigating complex contexts where research and marketing meet future-oriented creative practices of conceiving, planning and producing (see, e.g., Forty, 1986), their particular field of expertise seems especially promising when it comes to 'engineering the social.'

Against 'the social' as a distinct category

If one speaks of 'social housing,' 'social work,' or 'social design,' 'social' is understood as a distinct class of phenomena existing alongside other categories such as 'ecological,' 'political' or 'commercial.' Employing a less fragmentary and more 'entangled' perspective, however, scholars such as philosopher, anthropologist and sociologist Bruno Latour (1984, 1999, 2005) argue that 'the social' cannot, and *should not*, be considered a pre-given category or separate domain as such. By regarding 'the social' a particular *type* of relations that can be set apart from, for example, politics or economics, 'the social' is being mobilized as a specific means to specific ends. Accordingly, also within the realm of design, different approaches and perspectives render 'the social' in various and divergent ways.

Consider, for example, how design is regarded an important contributor to 'social innovation,' a phenomenon understood as "new ideas that work in meeting social goals" (Mulgan et al., 2007, p. 8) and regarded a decisive catalyst "for types of economic growth that enhance rather than damage human relationships and well being [*sic*]." In short: 'social innovation' is considered a means to "tackle social problems" (Mulgan et al., 2007, pp. 5-6) – an objective that is also typically associated with a 'branch' of design referred to as 'social design,' defined by Armstrong, Bailey, Julier, and Kimbell (2014, p. 6) as a field of activities that highlights "design-based practices [geared] towards collective and social ends, rather than predominantly commercial or consumer-oriented objectives." As such, various authors within the realm of design treat 'the social' as a distinct category that is specifically connected to so-called 'social goals,' 'social problems,' 'social innovation,' and 'social design.'

Bruno Latour (2005, p. 5), by contrast, states how one might describe 'the social' as "a trail of associations [or] a type of connection ... between heterogeneous elements" that aren't all necessarily 'social' themselves. He argues how 'the social' is shaped by – and constructed through – relations between human and nonhuman elements that make up 'collectives.' These elements – 'actants' in Latour's (1993) words – mutually constitute each other's conditions, whether intentional or unintentional (Verbeek, 2014). Hence, scholars such as Latour (1999) and philosopher Peter-Paul Verbeek (2014) argue that features like 'intentionality,' 'autonomy' and 'agency' – which since the Enlightenment are often considered typically *human* characteristics (see also, Taylor, 2004) – are actually the result of sophisticated interactions between both human beings *and* nonhuman 'actants,' such as (technological) artefacts. Latour (1993) and Verbeek (2014) therefore put forward that it is untenable to maintain a dichotomy between autonomous human subjects and solitary nonhuman objects, as it is the sophisticated *relations* between human and nonhuman elements that mediate phenomena such as intentionality and agency.

Entangling social and material elements through objects, environments, services, and systems might be considered the core business of designers. This begs the question what specific factors might then possibly constitute '*designerly*' forms of 'social agency'? Do designers indeed entangle 'the social' and 'the material' in specific ways that boost design's potential for 'societal impact'?

Demystifying 'designerly agency': what *can* design do?

Especially in those branches of design where engineering is a key component, designing is often primarily considered a range of problem-solving activities. This (ubiquitous) solution-oriented perspective on design is underpinned by the stubborn habit to consider even the most complex and layered phenomena *problems* – suggesting that they are *solvable*. Consider, for example, how designers Bruce Mau and Jennifer Leonard (2004, p.18) in their quest for 'massive change' render "the welfare of the human race ... a design project, a practical objective," or how design scholar Elizabeth Resnick (2019, p. 18) describes design as giving "shape and form to the material and immaterial products and services that can address problems and contribute to the well-being of humankind." These optimistic statements explicitly forge links between design and a worldview wherein humanity's welfare and well-being are considered *engineerable objectives*. A modernistic, me-

chanical worldview, moreover, which focus on life's presumed *manufacturability* is often reflected in contemporary design discourse (see, e.g., Escobar, 2017; Fry, 2009).

Accordingly, many (Western) definitions of design(ing) choose to specifically underline aspects such as intentionality, future orientation, and problem-solving. Design is described as "courses of action aimed at changing existing situations into preferred ones" (Simon, 1969, p. 55) or "the intentional solution to a problem within a set of constraints" (Monteiro, 2019, p. 21). Architecture scholar Samer Akkach (2003, p. 324, italics in original), however, interestingly points out that within the Arab language the relatively young word for 'design' depicts: "an act of determination, of sorting out possibilities, and of projecting a choice. It has little to do with problem-solving ... as the designer (*musammim*) seems to encounter *choices*, not *problems*, and to engage in *judging merits*, not *solving problems*."

This latter – 'Arabic' – understanding of both design and the designer *does* acknowledge intentionality and future orientation as key characteristics of design, but additionally stresses the importance of the many *contingencies* designers encounter within *any* design process. More specifically, it underlines that designers do not work on solving 'self-evident' problems, as it relates the agency of designers to the various contingencies they (un)deliberately may, or may not, *choose* to explore. Contingencies that, after a process of "judging merits," result in "projecting a choice" (Akkach, 2003, p. 324). According to Akkach (2003), therefore, this deliberate navigating and processing of contingencies render *any* act of designing inherently political.

Like Akkach (2003), authors such as Evgeny Morozov (2013, p. 3) problematize the tendency of many designers to first and foremost consider themselves *problem-solvers*, not seldomly unable to resist an "urge to fix problems that don't exist." Morozov (2013) argues that by primarily focussing on 'providing solutions' for situations, inconveniences, or even aspirations, *framed* as 'problems,' designers might consequently pay less attention to *issues*: problematic entanglements or disputes that – following sociologist Noortje Marres (2007) – are *not* necessarily solvable by political or scientific means, but instead need a perpetual exchange of perspectives, perceptions and ideas. In short: whereas *problems* might be fixed, *issues* are controversies that – at best – can only be temporarily stabilized. As such, they require different design approaches.

Problematic entanglements such as inequality of opportunity, poverty, or discrimination are so intricately complex and layered that they might – for better or for worse – be temporarily stabilized, but are very unlikely to be permanently fixed or solved by political or scientific means. This, however, does certainly *not* imply that these controversies fall outside of the scope of the subject matter which designers might work on. It just means that the approaches, aims and purposes within this particular field of political design work should be different. Addressing issues through design does not require a problem-*solving*, but a *problematizing* approach. As issues are *not* self-evident facts, designers can play meaningful roles in both supporting their construction and sustaining their articulation.

Problems versus issues

Art historian Claudia Banz (2018, p. 91) warns designers not to oversimplify problems or even *create new ones* by "incorrectly describing or delimiting the actual issue." As such, Banz (2018) underlines that problems and issues are distinct phenomena that are not self-evident consequences of particular circumstances, but instead come into existence through the purposeful activities of *problem setting* (Schön, 1983), and *issuefication* (Marres, 2012, 2014).

Social theorist Donald A. Schön (1983, p. 40, italics in original) describes 'problem setting' as "a process in which, interactively, we *name* the things to which we will attend and *frame* the context in which we will attend to them." In short: a situation first has to be understood, acknowledged, and framed *as a problem*, before it actually *becomes* one. Likewise, Noortje Marres (2007, p. 768) argues that "before a problematic entanglement counts as a matter of public concern, it must be actively articulated." Again, while both problems and issues are actively constructed, problems might be solvable by political or scientific means, whereas issues can merely be stabilized. Thus, besides providing solutions for situations that have been actively 'set' as problems (Schön, 1983), designers also have roles to play in the articulation of *issues* and the sustainment of a perpetual exchange of perspectives, perceptions and ideas regarding these controversies.

Problematizing design practices

Within the ever expanding realm of design practices and design discourse, one can identify several approaches that *do* explicitly oppose solution-oriented and problem-solving perspectives, and instead use designed objects, environments, services, and systems as a medium to address issues. Approaches that seek to *cause* friction, instead of to *prevent* it; approaches that purposefully employ design as a discursive catalyst, as a means to 'challenge mainstream perspectives,' 'raise awareness' about values and beliefs, or 'critically assess mass production and consumerism' (see, e.g., Malpass, 2017; Thorpe, 2012; Whiteley, 1993).

Designers and educators Anthony Dunne and Fiona Raby (2001, 2013) refer to a particular breed of these 'alternative' design practices as 'design fiction,' 'critical design,' or 'speculative design' – polemical forms of design that seeks to engage people with the political connotations and social contexts of designed artefacts. Design scholar Carl DiSalvo (2012, p. 35) describes a number of these overtly political practices as 'adversarial design' – design approaches that employ "a tactic of exposing and documenting the forces of influence in society and the means by which social manipulation occurs." Still other authors use labels such as 'interrogative design,' 'reflective design,' or 'design activism' to depict design practices that explicitly seek to bring about "dissensus through aesthetic activity" (Markussen, 2012, p. 45; Tharp & Tharp, 2018). Notwithstanding the wide variety of terms used to describe them, the various 'alternative' design practices in this field typically do not focus on problem-*solving*, but instead are geared towards problem *setting* (Schön, 1983) and *issuefication* (Marres, 2012, 2014). Moreover, beyond partaking in the mere *construction* of problems and issues, many of these design approaches actively support the perpetual exchange of perspectives, perceptions and ideas regarding these concerns, controversies and disputes.

Keeping it real

In current times of complex, layered, and interrelated crises especially, designers and design theorists need to get their vocabulary straight in order to articulate what design *can* actually do – as well as what it *can't*. In their enthusiasm to solve

problems, designers should be weary not to become instrumental in disguising the complexity, dynamics, and interrelatedness connected to issues. Primarily framing the renewable energy transition as a design project and engineerable problem, for example, might steer attention away from crucial related factors such as capitalist modes of production, consumerism, and geopolitics related to critical mineral resources needed for renewable energy technologies (see, e.g., Boehnert, 2018; Thorpe, 2012).

As such – instead of using the two terms interchangeably – I deem the conceptual differences between 'problems' and 'issues' fundamental for design discourse in order to articulate specific, relevant, and meaningful forms of 'designerly agency' in relation to 'societal change.' When problematic entanglements such as inequality of opportunity, poverty, or discrimination are approached by the design community *precisely for what they are* – inherently complex and layered controversies underpinned by a perpetual exchange of perspectives, that are therefore unlikely to be settled permanently – they can be addressed by specific forms of design work accordingly. Instead of proposing 'solutions,' designers rather have roles to play in engendering and/or sustaining public engagement with these issues.

Consider, for example, how designed artefacts by companies such as *Fairphone* or *Tony's Chocolonely* contribute to the issuefication of, and public engagement with, conflict-ridden supply chains. While the latter company uses design to forge relations between the hitherto 'innocent' chocolate bar and contemporary forms of slavery, the former business' brand name and its alternatively designed products render all other smartphones potentially 'unfair.' Beyond setting an issue and 'raising awareness,' however, the artefacts these companies design and mass-produce facilitate publics engaged with conflict-ridden supply chains with new ways to address their concerns. By employing design to entangle the social and the material in specific ways, these businesses have rendered using a specific smartphone or eating a particular bar of chocolate, a material form of political participation (see also, Marres, 2012).

Whereas *Fairphone* and *Tony's Chocolonely* are hopeful that their (future) products and services might be part of some sort of solution by engendering 'systemic change' (see, e.g., Georgi, 2022; Ibrahim, 2019), other designers use their professional skills to imaginatively entangle the social and the material into artefacts that do not seek to provide any solutions whatsoever.

Design supporting spaces of contest

When it comes to addressing *issues*, designers have a role to play in supporting the perpetual exchange of perspectives, perceptions and ideas concerning these disputes and controversies. Design projects such as *Smogware* – in which crockery is finished with a glaze that contains particulate matter 'harvested' from urban environments (Carlson, 2022) – or *the Rain Project* – in which unfiltered rain water collected from multiple locations is converted into consumable popsicles (Tharp & Tharpe, 2018) – provide publics with new ways to articulate their concerns with the issue of environmental pollution. Ways, moreover, that are not solution-oriented, but rather seek to "establish linkages among objects, people, and actions to create open, interpretive, and participatory spaces of contest" (DiSalvo, 2012, p. 93).

In short: one might understand 'designerly agency' in relation to 'societal change' as consisting of both the framing, setting and solving of *problems*, as well as the articulation of *issues*, through the creation of objects, environments, services and systems. More importantly, however: in order to address them in *relevant* and *meaningful* ways – and thus neither frame trivialities or critical parts of social life as 'problems' (Morozov, 2013), nor create new problems by ignoring underlying issues (Banz, 2018) – it is important for both designers and design theorists to acknowledge that problems might be *fixed*, but issues – that need a perpetual exchange of perspectives and therefore can never be permanently settled – can merely be *stabilized* (Marres, 2007). Therefore issues especially, need to be approached by the design community *precisely for what they are*. Instead of proposing 'solutions,' designers have roles to play in underpinning public engagement with these disputes, and supporting the perpetual exchange of perceptions and ideas regarding these controversies. Designers can use their expertise in entangling the social and the material through the creation of objects, environments, services, and systems, to imaginatively shape new and alternative ways for publics to address their collective concerns.

Conclusion

In this paper I have described how design has been mobilized in relation to different interpretations of 'the social' in a number of divergent ways. Ways that describe various assumptions regarding the notion of designers as 'change agents' with 'societal impact.' Ways, moreover, that suggest both problem-*solving* and *problematizing* design approaches. In current times of complex, layered, and interrelated crises especially, designers and design theorists need to get their vocabulary straight in order to articulate what design *can* actually do – as well as what it *can't*. Let us therefore refrain from describing even the most complex and layered phenomena as *problems*, suggesting that they are *solvable*. Instead – in order to articulate relevant and meaningful roles design might play concerning various problematic entanglements – it is essential to differentiate *problems* that can be fixed, *from issues* that can merely be stabilized (Marres, 2007), and approach both phenomena precisely for what they are. By acknowledging that both problems and issues are not a given but rather need to be *constructed*, 'designerly agency' in relation to 'societal change' can be understood as consisting of both the framing, setting and solving of *problems*, as well as the articulation of *issues*, through the creation of artefacts.

Acknowledgments

I would like to thank Prof. Dr. Willem Schinkel (Erasmus University Rotterdam) and Prof. Dr. Bregje van Eekelen (Delft University of Technology) for their unrelenting enthusiasm and invaluable feedback on my work. I also like to thank the anonymous reviewers who provided helpful comments on the previous version of this paper.

Abstract

In the last twenty years, design research and design practice have mutually influenced each other in rethinking the role of design in an increasingly complex world. New areas, for example, service design, systemic design, and transition design have emerged out of this research-practice interaction. With the rise of these new fields, designers have developed new skills, new responsibilities, a different sense of agency, and, sometimes, a new mindset. This is especially the case for transition design, a field that deals with design processes over longer periods of time and that requires close collaboration with multiple other disciplines, exposing the need to reflect on the role and agency of the designer. In this research, ten design practitioners in the Flemish design agency landscape were interviewed to gain a deeper insight into the skills and mindset designers need today and in the future. During these interviews, the time was taken to thoroughly discuss agency in the design process, the changing relationship between client and service provider, and the concept and consequences of transdisciplinarity. This resulted in an overview of the changing characteristics of design and designers regarding their soft and design skills, their role & ethics when dealing with complexity, the business model of design agencies and changes in the design process and team. With the insights from this research, we invite design education researchers to reflect on design education addressing our complex world. Besides training designers how to design, they could teach them about the world in which design exists and is implemented. Additionally, the results could motivate service providers to rethink the composition of their teams, their relationship with the clients, and their business strategy, so they will be fully prepared to navigate through the rapid transitions of our current and future world.

transition design; design skills; design for complexity; transdisciplinarity; design education

Introduction

The world we live in today, driven by technological changes and globalization, is changing rapidly, increasingly resulting in the emergence of **wicked or complex problems** (Weber, 2021). These problems are described as multiple, circular problems with no obvious relationship between causes and effects (Kurtz & Snowden, 2003). A need for a transition to more regenerative and resilient systems with a focus on planetary health and life-conducive mindsets as an answer to these challenges, is expressed. Research on **socio-technical transitions** has known a quick rise since 1990 and finds its roots in innovation research and sustainability sciences (Loorbach et al., 2017). Gaziulusoy defines transitions and system innovations as "multi-phase, multi-level dynamic processes which take place over extended periods of time and result in mainstream practices becoming outdated and being replaced by a set of new practices. Transitions and system innovations cover not only product and process innovations but also changes in user practices, markets, policy, regulations, culture, infrastructure, lifestyle, and management of firms." (Gaziulusoy & Brezet, 2015).

In dealing with this complexity, combining the knowledge and skills of a multiplicity of people and perspectives is necessary. Since designers are predominantly trained and involved in problem-solving and innovation, it seems obvious that they too can have an interesting added value in these contexts. **Transition design** (together with service and social innovation design) emerged from this changing context and was originally introduced by Gideon Kossoff (Kossoff, 2011). It promotes social transitions towards a more sustainable future which is to be led by design as well in lifestyle, as existing systems and infrastructures. Typical characteristics of transition design are: working towards a long-term vision to tackle complex problems, integration of deep research, and working transdisciplinary on diverse levels of scale (Irwin, 2015)

The role of the designer has been through significant changes throughout the years. In the past, designers were primarily concerned with the aesthetics of products. However, as technology advanced and the scope of design expanded, the role of the designer evolved to include user experience, interaction design, business & strategy design as well as data visualization and information design. This shift led to the recognition of the significant role that designers play in shaping the functionality and usability of products, services, and systems. As a result, designers are now integral members of cross-functional teams, collaborating with professionals in fields such as engineering, marketing, and research to create innovative and effective solutions. The modern designer must have a broad skill set that includes both creative and analytical abilities as well as a series of soft skills (Yin, 2013). The skill set and role of the designer

can vary for these different fields and has been thoroughly researched for most of them (Fiore, 2020; Hansson et al., 2018; Tjahja & Yee, 2022; Yin, 2013). For transition design, this remains theoretical and speculative as it is not yet established as a widespread design practice.

Besides the role of the designer, **the environment** in which they work is also affected when dealing with complex problems. Subsequently, the current consultancy business model and design education system are questioned (Meyer & Norman, 2020; Rozentale & van Baalen, 2021): how will the design discipline deal with these changes and how will the new generation of designers be prepared for them? Gradual changes in the **education system of design** can be observed: research has been criticizing the current design education system and multiple universities offer courses in rising design disciplines such as service design, systemic design, and transition design (*Academic Programs*, 2023). Additionally, a shift in focus is found in students at Design Universities: they show an increased interest in tackling global and complex challenges such as climate change or inequality. This is visible in the program of design fairs like the Dutch Design Week, where a strong sense of urgency and a collective mission facing these challenges is a recurring theme in the submissions from students and young designers (*DDW22*, 2022). According to Mintzberg, an organization focused on innovation should not be led by (economical) efficiency and have an organic structure with project teams consisting of experts from different specialties (Hendrick, 2017; Notebaert & Delagrange, 2019). Since the essence of transition demands transdisciplinary work on a long-term scale with many different stakeholders, it is assumed that this **business model** should be reconsidered: how would a design agency that deals with transitions and complexity differ from regular design agencies?

This paper explores the changing characteristics of design and designers regarding their soft and design skills, their role & ethics when dealing with complexity, the business model of design agencies and changes in the design process.

Method

Given this is an emerging topic involving many perspectives, qualitative research methods were used. Semi-structured in-depth interviews with ten design practitioners in the Flemish design agency landscape were conducted. The interviews featured open-ended questions as well as exercises that were used to gather different sorts of data and spur conversation. They were structured as follows:

1. The interviewer asked which skills the interviewees (and their colleagues) use to deal with complexity, and which skills they lack at this moment.
2. The interviewee rates a chosen set of skills on importance (1 = not important, 10= very important), firstly for now and secondly for the future. The rated skills are a mix of design skills, soft skills, and skills needed for transition, based on literature (Jordan et al., 2021).
3. The interviewee is asked about their practices when dealing with complex topics: do they see a difference in project phases, how do they feel when handling these topics, what skills do they need.
4. The interviewee places cards with different actors involved in the design process on a chart according to their involvement. The design process is the core of the chart, with concentric circles around it that indicate decreasing involvement further away from the core. Follow-up questions are asked about the difference in relationships between actors. The same exercise is done for transition design processes in the future.
5. Finishing questions on the role that respondents would assign to themselves as designers, how that could change in the future and what is needed for that change.

Interviewees

This study focused on designers working in design agencies. Interviewees who have extensive experience working on various kinds of complex issues were recruited, based on their previous projects: did they experience a certain degree of complexity in the issues they addressed as a designer? Designers from different agencies and with different grades of experience were interviewed, with interviews taking between ~1h and ~2h. Out of ten interviewees, nine have an education in product development and one is educated in philosophy.

Table 1. Overview of interviewees and context

Interviewee (Self-described role)	Years of experience	Sector focus
1. Systemic designer	35	Service- & systemic design for public sector
2. Participation designer	3	Participation design
3. Business designer	12	Regenerative design & consulting
4. Service designer	3	Commercial product & service design
5. Business&strategy designer	2	Business innovation
6. Business&strategy designer	11	Commercial design & innovation agency
7. Business&strategy designer	7	Service design for public sector
8. Design researcher	15	Commercial product & service design agency
9. Product designer	20	Social innovation
10. Process designer	20	Strategy design consulting

Data analysis and interpretation

To analyze and interpret the data in a meaningful and holistic way, steps were taken to go beyond the typical phases of thematic analysis. With a Describe – Compare – Relate approach (Bazeley, 2009), themes were linked and a clear coordinated picture was formed to draw conclusions from. To start, all interviews were transcribed and coded using the NVivo software. The context and background were specified for each interviewee (sector focus, self-described role, and years of experience). Then the authors discussed the clustering and naming of discovered themes in a collaborative workshop. To interpret the data, recurring themes were linked to the context of the interviewee, as to see under what conditions themes arise or what could cause them. The different themes were also viewed in relation to each other. The conclusions drawn from this data analysis are discussed in the next section.

Results

Skills

When investigating the necessary skills for design teams in the future, the respondent's answers fell into two key areas: soft skills and design skills. Taking a closer look at the soft skills, multiple interviewees brought up **deep listening** and **creating networks**. "Critical listening is key, they might say A but that can have B, C and D hiding behind it" (4, personal communication, 23/11/2022) The transition designer needs to be **assertive** yet even more **empathic**, to see which societal needs there are. Their ability to listen and understand is key to working out a sound strategy. (6, personal communication, 25/11/2022) The ability to **communicate** allows professionals to effectively engage with stakeholders and build consensus around change initiatives. "There is a need for a certain diplomacy in your interactions with clients and stakeholders, there is no room for political baggage or general tension in the room. You want to keep people close since they remain involved" (6, personal communication, 25/11/2022). **Another important skill is adaptability, which allows professionals** to respond to challenges and pivot as needed.

In addition to soft skills, design-specific skills are frequently mentioned, such as being **facilitators**. This brings diverse perspectives together and helps create a shared understanding of the challenges and opportunities at hand (Lor, 2017). Facilitating collective learning processes, meetings and co-creating processes is an important strength in design as it is today. "You have to be fast at making links between things stakeholders bring to the table, ask the right questions in response, without pushing them in a certain direction." (1, personal communication, 11/11/2022). The interviewees mention that their less experienced fellow designers struggle with this: they tend to be more specialized in visualizing designs rather than facilitating workshops and discussions (6, 1, personal communication, 2022). Furthermore, **holistic synthesis** was mentioned, a way of synthesizing information without losing sight of the system as a whole. "It is important to synthesize all the information so you can communicate it in bite-size to the stakeholders to encourage them to take action" (7, personal communication, 30/11/2022) Lastly, we noticed **visualizing** played a significant role. "90 percent of my job is meetings and massaging people about ideas. You need to visualize your ideas to the stakeholders to get them on board" (3, personal communication, 22/11/2022). This skill is already an essential design skill but will be even more important when dealing with complex problems and abstract futures.

Role of the designer, the design team, ethical considerations

Nowadays, designers take on different roles during the design process. "When interviewing you are doing research, then you are a journalist. At a certain point you also really have to choose, you must decide. You are more of a judge. Sometimes you must be able to go completely wild and dream visionary." (9, personal communication, 19/12/2022). Designers guide and connect people, they make strategies, concepts, and visions tangible. Additionally, it was mentioned that "Designers talk to different stakeholders to synthesize all findings." (8, personal information, 2022). In the future, the role will become more strategic (1, 3, 4, 5, 6, 10, personal information, 2022). According to some interviewees, designers should even be involved on a policy level (4, 6, 9, personal information, 2022). They will become the link between different areas of expertise and ensure that the right knowledge will be deployed at the right times (4, 9, personal information, 2022). This shift also has an impact on the composition of **design teams**. A close collaboration with experts in other fields and a different role for stakeholders as part of the design team, together with a strong connection both with policy and the academic world will be necessary when tackling the complexity of transitions. One of the interviewees added to this with the value of experience: "(...) you will understand that you have your limits as a designer, which will entail a certain modesty, I guess. By becoming more mature as a professional, you grow towards what I call a systems being." (1, personal communication, 2022). With this changing role, the interviewed practitioners reported a shift in the importance of **ethical considerations and values**. Although these topics were not explicitly questioned, they came up in multiple interviews. Designers put a greater emphasis on inclusivity and empathy for stakeholders (2, 3, 6, 9, personal information, 2022). Having a strong moral compass can aid professionals in making ethical decisions and ensuring that their actions align with their principles and benefit the well-being of all stakeholders. Particularly regarding balancing short-term gain with long-term sustainability.

Complexity and design process

Transition processes concern wicked problems. When asked to define a wicked problem all interviewees could give a clear definition. They were also aware of the difference between straightforward problems, and wicked problems. However, the respondents reported no structural changes in the design process when asked about the ways these complex problems were approached differently from other design challenges. The types of phases stay the same, remarkably close to the traditional double-diamond model (Kochanowska et al., 2022). Most interviewees mentioned that more work goes into the analysis phase, as it is of higher importance for complex problems, and deep insights into the system are required to define a solution space (2, 4, 6, 8, 9, personal communication, 2022). But the business model of design agencies working for clients calls for efficiency, which limits the possibilities in the analysis phase. Another difficulty in this first phase is that there is no clear cutoff point. Many interviewees mentioned it is difficult to conclude the analysis and start to design. This could be because they approach analysis in the same way as traditional problems. An alternative could be a system mapping approach (Jacoby & Van Ael, 2021), where three phases are defined: framing the system, listening to the system, and understanding the system. This is a better fit for complexity analysis, but clearly not an established model in the design agency world.

Some designers also discussed that they miss an implementation phase after they deliver a product or service or that they feel like they could also have been valuable in the phases before they are usually consulted by clients. Interviewees reported they sometimes feel frustrated with the current model and would like to approach things differently. Therefore, designers and/or design agencies might have to rebrand themselves and promote what they could offer beyond the design of a product or service. That also implies changing the design

process and methodology, since it is currently most fit for straightforward problems.

Business model

The business model of design agencies is mostly focused on consultancy, where a design team is hired by a company at an hourly rate, cooperates with the company for a short amount of time, and needs to work as efficiently as possible (1, 2, 7, 8, personal communication, 2022). This manifests itself in an internal-external paradox: the designer becomes a part of the client's company until the assignment is finished and splits off again: never being integrated completely, but having to cooperate intensely, often in change processes. The limitations of this work process result in limited room for long-term thinking or reevaluation with the client afterward (1, 2, 4, 8, personal communication, 2022). This in turn impacts the implementation phase of the solution, which is lacking in many projects (2, 4, 7, 8, personal communication, 2022). Both elements are of big importance to transition design in order to have impact and organize change. When asked about alternatives for the current business model that would suit design for complexity, some suggestions for essential elements are given. A shift from a short-term to long-term mindset is necessary. Only consulting external designers for a short amount of time to create something is not enough to foster transition. According to interviewees, a continuous collaboration between designers and the client is essential (2, 4, 8, personal communication, 2022). Some even question the agency model and advocate for a more design-led organization (2, 8, personal communication, 2022).

Discussion

To understand the changing role of the designer in complex design processes, ten interviews with a homogenous group of Belgian design practitioners were conducted. The study is constrained by a limited sample size and the fact that the concepts of transition design and systemic design are still relatively unfamiliar within the Belgian design sector. This homogeneity allows for the isolation of similarities in perspective but also means that a more diverse range of views on the importance of transition design and the designer's role may be missing.

It would be interesting to expand upon these findings by comparing them with the experiences of other countries and cultures. Ideally, we would opt to implement a more diverse group of designers (*Twomey & Gaziulusoy*, 2014). To implement significant changes across all aspects of society, we need to reinforce the co-evolving areas of knowledge, action, and self-reflection to develop new methodologies for design (*Irwin*, 2015). A transdisciplinary team is necessary to cross-contaminate each other's fields to shape desired societal development. To approach complex problems holistically, we should zoom in to relate to the context and the stakeholders, as well as zoom out to grasp the interconnectedness within the broader system(s).

Furthermore, the changing landscape challenges designers and design agencies. The findings from the interviews suggest that traditional problem-solving approaches are still being utilized for complex issues. An additional inquiry is needed to understand why design agencies continue to rely on the traditional methodology and agency model when addressing such problems, despite the availability of alternative techniques such as system mapping and the three horizons model. And finally, further research is required to alter the business model and the client-designer relationship, to engage designers during appropriate stages that align with their specialized and useful abilities, rather than simply being temporarily consulted for specific tasks.

Conclusion

A radically changing and increasingly complex environment has a substantial influence on all professions, one of them being the field of design. Socio-technical transitions have increased pressure on society, producing some new design disciplines such as service design, design for innovation and transition design. The paper focuses specifically on transition design and examines - through qualitative analysis of ten semi-structured interviews - the extent to which design practitioners are familiar with this field and the skills and mindsets required to work in this context. Should the design education system and the consultancy business model be reconsidered?

Fashion design matter: the role of design in guiding a sustainable transformation in Europe

Erminia D'Itria

Design Department, Politecnico di Milano, Italy
erminia.ditria@polimi.it

Abstract

Today, sustainability is one of the main, most dynamic, and influential topics, for all sectors. The growing emphasis on sustainability is relevant to everyone, as today, there is a need to focus on sustainable objectives, approach them, and consider all the modern processes to implement sustainable development and value-creation strategies. As underlined by several scholars, over the next few years humanity needs to adopt a paradigmatic change from a consumeristic society where well-being is measured in terms of economic growth to a new society that can reach the same levels of prosperity but consuming less and relying on renewable resources (Vezzoli et al., 2021; Keitsch, 2015; Thackara, 2005; McDonough and Braungart, 2002). It is, therefore, necessary to change the way demands are met and to develop sustainable consumption patterns and lifestyles that are based on better consumption of far fewer resources. There is an urgent need to move towards new socio-technical systems capable of operating within the planet's limits. This means operating inside the nine planetary boundaries that are the spaces within which humanity can continue to develop and thrive for generations to come (Rockström et al., 2009). These systems will address not only the technological sphere but also the environmental, social, cultural, institutional, and organizational ones. The proposed understanding suggests that sustainability is the defining concept of the whole system and not a characteristic of its individual elements. Therefore, achieving sustainability requires a process-based approach, sustainable development, which must be intrinsically applied systematically and in different dimensions to plan new virtuous paths. In the presented scenario, the Fashion industry is one of the main actors as it influences ecosystems making a sizeable contribution to climate change, resource exploitation, and systemic pollution. But it also shapes cultural developments, their driving forces, and patterns of change (Bertola et al., 2016). According to the above, the presented paper discusses the fashion necessity of facing the challenges of sustainability - and the related complexities – with a radical transformation of the current development model. Through the analysis of different case studies, possible directions for the sustainable transformation of fashion systems are defined and presented. Specifically, such direction addresses how it becomes essential to review development paths with the aim for the fashion sector to dissociate sustainable innovation from the notion of exploitation of resources through a strong focus on proposing material and meaning that are alternatives to the very notion of "new".

Fashion Design for Sustainability; Sustainable Development; Industry Transformation.

Introduction

Today - fashion is one of the most significant, dynamic, and influential industries, as well as one of the most impactful due to its highly invasive processes, especially the ones involving environmental aspects and consumption of the finite resources of our Planet (EU, 2022; EMF, 2017). Moreover, this industry profoundly influences with its approaches and practices the environmental and economic dimensions due to its vocation to codifying current patterns of change (Bertola et al., 2016). In this context, it also strongly impacts changes related to the social and cultural spheres. As argued by Kate Fletcher (2018), the fashion industry is a powerful cultural driver which influences the consumerist economic model based on mass production that currently characterizes the economies, even if our experiences of fashion are now dominated and limited by this same model that involves fashion in essential issues.

Niinimäki et al. (2020) argue that the industry consumes vast quantities of water, land, and raw materials. For example, the fashion sector produces 8% of all carbon emissions and 20% of all global wastewater, with an anticipated 50% increase in greenhouse gas emissions by 2030 (Bailey et al., 2022). The sixth annual State of Fashion report by The Business of Fashion and McKinsey & Company (2022) reveals that globally, the fashion industry is responsible for around 40 million tonnes of textile waste a year, most of which are either sent to landfill or incinerated. This can be attributed to the current development models promoted by the industry that encourage an increase in clothing consumption and, therefore, fashion production. Pro-capita fiber consumption almost tripled from 1950 to 2008, increasing from 3.7 kg to 10.4 kg per person (Sanchis-Sebastiá et al., 2021). From 2007 to 2014, textile fiber production increased by an additional 20.2 million tons to 90.8 million tons, and this number is expected to grow by 3.7%, compounded annually (Pensupa et al., 2017). These phenomena are the direct results of the economic model based on the linear development of the fashion sector (Dissanayake and Weerasinghe, 2021). This model is dominant, a legacy of the first industrial revolution, which is based on so-called cradle-to-grave dynamics that exploit natural resources and then directly dispose of them without taking into account their regeneration potential and

the possibility of reusing them in the next production and/or consumption cycle (Braungart and McDonough, 2009). This fuels the phenomena of production overabundance, compulsive consumerism, physical and semiotic obsolescence of the fashion product, and disaffection culminating in irresponsible behaviors of serial accumulation and early disposal of garments. This context is so alarming that it prompts the Global Fashion Agenda, a leading forum for sustainability in the fashion industry, to conduct a study to quantify global fashion consumption in the Pulse Report (2017-2019). The purpose was to return a numerical figure that would allow manufacturers, and their consumers, to compare their impacts. The study estimated that if current trends remain unchanged, apparel consumption will increase 63% to 102 million tons by 2030 (Global Fashion Agenda, 2019). Since consumption is no longer focused on satisfying a need but on fulfilling a desire, it is bound to remain unavoidably insatiable by its very nature. This realization is also the direct consequence of a garment's semiotic and physical impoverishment. This deficiency allows production costs to be drastically lowered. And the consequent lowering of prices will enable buyers to purchase garments more easily. In this landscape, the logic of waste is established as a direct consequence of a supply chain that turns out to be excessive, misleading, and distorted. Waste becomes an entity in this context and acquires all its characteristics: value, importance, and impact (Binotto and Payne, 2017).

Considering what has been discussed, reviewing linear development paths is essential. This can be done by adopting more sustainable models of development, such as the circular economy model, which is to date recognized as the leading entrepreneurial model for meeting the goal, for the fashion industry, of decoupling sustainable fashion innovation from resource exploitation through a strong focus on proposing alternative materials and meanings to the notion of "new" (Dan and Østergaard, 2021; Rathinamoorthy, 2019; EMF, 2017). In this context, this paper investigates how, from a design perspective, new trajectories are being defined in the contemporary fashion industry to contribute to the development of a closed-loop system in which the goal is to recover or recycle secondary raw materials in multiple stages of the supply chain (Muthu, 2018).

Methodology

The article aims to present the result of an investigation conducted on how fashion companies are pursuing circular initiatives, making it possible to create strategic actions that can stimulate a new understanding of what virgin material is and encourage a reinterpretation of the concept of new. The data analyzed were extracted from the knowledge repository produced by the – *Fashion in Process* - Research Lab. at the Design Department of Politecnico di Milano of which the author is a member. The data were generated from: (1) the research conducted by the research Lab (DGGROW, Mapping Sustainable Fashion Opportunities for SMEs, 2019; Erasmus+, FashionSEEDS, 2019) and (2) the doctoral research of the author (D'Itria, 2022). According to the authors' investigation, a mapping of "secondary" raw materials-driven circular practices of European fashion companies is carried out through an iterative process: an initial desk research phase followed by applying a case study methodology. This process allowed the selected research field to be narrowed into topics that emerged from the analysis and codified the main approaches to circularity that inform the definition of directions for addressing sustainable development issues. Defining the directions allowed the boundaries of the study to be identified. A selection of best practices is presented among the case studies identified. The author focuses on specific cases and uses them as a sample of the context of interest. However, as Johansson (2007) discussed, such a methodological approach includes many variables and qualities for reworking explanatory knowledge.

Methodologically, three phases were conducted: (1) the first phase was desk research to identify current practices in the fashion industry. This mapped current sustainability practices and identified best practices; (2) the second phase was an in-depth qualitative analysis of the best practices identified during the desk research; (3) and the last phase systematized the previously produced knowledge to define business directions for implementing sustainability through practices of recover or recycle of secondary raw materials at multiple stages of the supply chain, from design to retail and waste collection. The mapping led to the identification of 68 companies located in 21 nations in the

Figure 1. Companies' locations.

European continent, which have addressed aspects related to new sustainable development models by using secondary-raw materials in their practices (Fig.1).

The choice to focus on the European region was driven by the interest in investigating a context undergoing a solid transformation due to policy initiatives put in place for the sustainable transformation of the examined sectors (Green Deal, https://commission.europa.eu/strategy-and-policy/priorities-2019-2024/european-green-deal_it; EU Strategy for sustainable and circular textiles, https://www.interregeurope.eu/news-and-events/news/new-eu-strategy-for-sustainable-and-circular-textiles), by reasons of geographic proximity, and by past experiences of collaboration with local companies. The composition of the company was heterogeneous. They were textiles companies (24%) and brands of shoes (9%), apparel (60%), and accessories (7%). Of the 68 companies mapped, 6 were selected as case studies (Table 1).

Table 1. Case studies list.

Country	Name of Initiative	Description of Initiative	Sector	BIG	MEDIUM	SMALL	MICRO
France	Vestiaire Collective	Online marketplace for second hand high-quality designer fashion.	Apparel			X	
Italy	Fulgar	Sustainable textiles brand.	Textiles	X			
Italy	Manteco	Sustainable textiles brand.	Textiles	X			
Sweden	Filippa K	Longer technical life, lease, sharing own product take back.	Apparel	X			
United Kingdom	Christopher Raeburn	The RÆMADE ethos in particular has pioneered the reworking of surplus fabrics and garments to create distinctive and functional pieces.	Apparel			X	
United Kingdom	Helen Kirkum	The studio ethos in particular has pioneered the reworking of surplus fabrics and shoes to create distinctive pieces.	Footwear				X

All these companies stand out for the way they are pursuing implementations of sustainable practices within their system, often adopting a design-driven approach as support. The following phase consists of further desk analysis to prepare for long-distance interviews with representatives from selected companies. These companies have distinguished themselves for their approaches to designing waste out of the system, using it as new raw materials or products. This phase allowed for exploring possible theoretical relationships and allowed for a deeper understanding of the subject through the use of these case studies (Tellis, 1997). The third phase focused on data interpretation. This phase supports the author in understanding the criteria a company must meet when working on design-led sustainable practices to move to new circular development models for better use of available resources. These aspects are now linked to the concept of waste recovery and lead toward circularity, decoupling economic growth from increasing environmental problems by imagining and implementing processes and practices with sustainability characteristics with three particular approaches at different stages of the supply chain: (1) *reducing/sourcing*, redesigning materials, products, and services so that they are less resource-intensive; (2) repurposing/manufacturing, recycling waste, and scrap, without destroying them, to create products that have more value; (3) and reusing/retailing, making products and values last by transferring them to another user.

The Directions

This paper codifies the data collected to identify the directions that drive current design-led practices related to a new concept of waste in the fashion industry. This section discusses the results of the presented methodology by introducing several case studies that illustrate the main approaches identified by the study. Such approaches could inform and foster relevant new directions in sustainable fashion design. This paper aims to define potential pathways for developing a closed-loop system that aims to either reduce resources exploitation, repurpose secondary raw materials, or reuse the fashion product - at different stages in the supply chain (Fig.2).

From an operational point of view, the work identified three macro directions in the approach to sustainability through design-driven practices that emerged from the case analysis. Companies such as Manteco or Fulgar are acting upstream in the supply chain. They are working to improve their strategies to capitalize on the circular distinctiveness of their products. They are now pursuing actions to develop

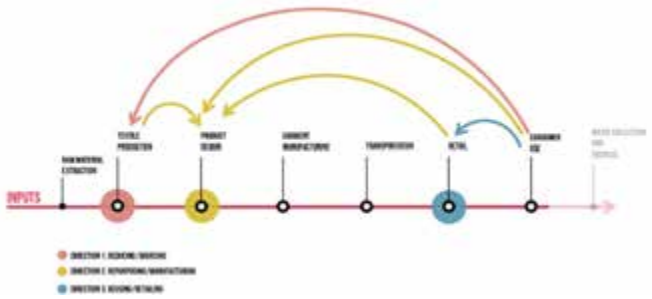

Figure 2. The directions model.

a new approach that can significantly reduce textile waste by rethinking sourcing practices through traceability. On the other hand, Christopher Raeburn and Helen Kirkum are experimenting with the designer's role in reworking surplus textiles and garments to create distinctive and functional pieces, underscoring their attributes of conscious manufacturing. Companies like Vestiaire Collective or Filippa K work down the supply chain. They keep items out of landfills, changing traditional retail's linear "take-make-away" model (EMF, 2017). So the author discusses strategies with a common pattern of avoiding waste and working on the meaning of "new." The study examines how these identified directions work for a common goal but differ from each other. The analysis offers insight that aims to describe the behaviors identified comprehensively. However, the author acknowledges that there are limits within which these behaviors are adopted. Although a common guideline is highlighted, the different cases need to be understood in the specificity of their context, territory, and actors involved. In the following sections, the selected cases are explored.

Reducing/Sourcing

The first direction refers to companies working upstream in the fashion supply chain. They work on their sourcing to achieve sustainable supply chains by leveraging their position at the beginning of the flow of goods and services. Companies rethink the system by redesigning the processes of buyers' access to materials, production, logistics, and transportation, and distribution. To achieve this, transparency in supply chains is critical to validate the origin of sustainable materials (Fung et al., 2021). For example, the Italian textile company Manteco launched Project43. This is a unique strategy based on circular economy principles. They aim to optimize existing materials and design pre-consumer waste out of the system by recovering offcuts from the garment manufacturers that

use their fabrics. The collected materials are then regenerated into 'new' fabrics. Manteco acts as a single point of contact between all the actors along the supply chain to monitor the material lifecycle. Project43 is now reducing and regenerating textile waste using the company's facilitates through a transparent system. (Fung et al., 2021). By addressing the critical issue of traceability, Project43 is also a tool capable of overcoming the linear waste model and providing the fashion sector with a different understanding of "new" materials. Another company that is making a significant contribution on this front is Fulgar. It is a leading manufacturer of synthetic yarns. It is now experimenting with the traceability of its eco-friendly Q-nova yarn. This is an environmentally friendly fiber made exclusively from raw materials regenerated through a mechanical process rather than a chemical one. A special ingredient in polyamide, the innovative traceability system called ID (Identity), makes it possible to verify the authenticity of the recycled origins of the yarn. The ID system allows third-party organizations, such as consumer groups and governments, to verify the reliability of the data provided. All the presented companies working on this first approach recognize that traceability is a crucial aspect of supply chain sustainability (Naden, 2017; Sodhi and Tang, 2019). While for some companies, traceability helps to identify environmental issues and is a starting point for the improvement of the entire supply chain, which is actively involved in the process of mapping the existing material, in other cases, the monitoring process takes place directly within the company, acting on the material, in the intimate mixture, to generate a cascading effect on actors inside and outside the fashion supply chain.

Repurposing/Manufacturing

The second direction characterizes the rising strategies fashion companies adopt through a project approach that enhances the use of discarded goods' materials and components to transform them into new, high-value products. Christopher Raeburn is a pioneer of upcycling in fashion. He started his eponymous brand in 2008 using British Army parachutes as his primary fabric source to create new garments. Since then, he has developed expertise in reconstructing military surpluses, such as parachutes, parkas, and military jackets. This process is called reappropriation by the designer. The designer's approach is guided by research on the garment and the process of deconstruction itself; even the shape and silhouette of his designs are developed based on the source of the fabric rather than being cut and shaped on the design. Designer Helen Kirkum carries out similar experiences. Through her work, Helen Kirkum is hacking the footwear industry using waste as a raw material. The designer uses recycled and dead stock materials as sourcing. These materials are transformed into sneakers crafted to provide an individual experience to consumers. The design philosophy applied to these products is to mix the components of the "repurposed" products, allowing the seams between the different parts that compose the final shoe to be visible. Accentuating these points of connection aims to stimulate emotional value to allow the user to own something inherently personal and unique. The approach developed positions her as a pioneer of the "deconstructed" aesthetic in the sneaker industry and at the forefront of the sustainable footwear movement. In all the cases presented in this section, the circular link with the development of products made through innovative and disruptive craftsmanship becomes a challenging tool for maturing the meaning of consumption and the way we interact with the products we own. Moreover, creating a story around the product gives additional intangible value to the object.

Reusing/Retailing

The third direction addresses sustainability issues related to bringing second-hand clothing back into the market, creating a circular system. Fashion companies in this category must devise and implement innovative business models that reflect the changing landscape and evolving consumer behaviors. One example of a company engaging consumers in using products as long as possible and keeping them in the market loop is Vestiaire Collective. This online platform, launched in 2009, allows customers to buy and sell secondhand fashion items. Sellers place items on the marketplace and, after validation by Vestiaire's team of curators, the items become available for sale. Vestiaire is exploiting the enabling power of digital technology to recontextualize the concept of new applied to unused clothing items. Providing these products to new customers increases the number of uses, giving a second, third, or even fourth life to existing products. In addition, through the creation of a community the company has created a sense of belonging among those who share values and actively choose to enter a circular system. Filippa K proposes a different approach to this direction, which involves - in its practices - actors within its supply chain such as logistics departments and retail. In 2008, the brand opened its first second-hand store in collaboration with a local entrepreneur, Judit's Second Hand. The initial model operated as a consignment store where customers returned their Filippa K clothes, shoes, and accessories for resell. What characterized this initiative was the fact that the customer maintained ownership of the product and after the product was sold, the customer received 50% of the profit. If not sold, the product was returned to the owner again or donated to a charity. The success of this resale initiative allowed the brand to recognize the program's potential to enable a circular business model. The company's pilot program was scaled up to become the "Preowned" program. This program is now running only in Sweden. Customers return a used garment from the brand to the store, or if the physical location cannot be reached, the customer uses the brand platform. In return, the customer receives a monetary incentive. Garments brought to a physical that are ready for resale are machine or dry-cleaned using environmentally friendly cleaning processes. Users that post garments on the platform earn either cash and receive 60 percent of the resale price, or they can choose to receive 100% as a credit toward the purchase of Filippa K garments from the current season. The cases presented here discuss how the same product creates revenue multiple times by offering new ways to involve stakeholders, both when consumers resell their clothes and when different actors along the stages of the supply chain (logistics, retail, collection/waste management) engage in reintroducing "new" second-hand clothes back into the market.

Conclusion

From what has been illustrated, the rethinking of waste and its connotation of "new" emerges as a strategic factor that is now leading the transformation of fashion companies towards a sustainable development model. Here are presented

the opportunities that have occurred, for fashion companies, to trigger innovative processes that favor iterative activities to disrupt the linear economy logic of waste and nurture a change in operating models. Such models could inform directions toward a circular paradigm enabled by adopting design-led practices in the European fashion industry. One of the most critical levers the fashion industry can pull to preserve non-renewable resources and eliminate waste is to design it out of the system. The different approaches suggest that to reach this goal, the link between circularity and design-driven innovation in the fashion field is related to a systemic perspective. The one illustrated here represents a system that is now starting to be rolled out at scale, promising to limit the extractive production of virgin raw materials and decrease textile waste. As these approaches mature, companies will need to embed them into the design phase of product development while adopting reducing, repurposing, and reusing processes. The key element linked to this systemic transformation is the reorganization of the supply chain to achieve the goal of eliminating the concept of waste by involving all stakeholders, from designers to consumers. Each company connected to the supply chain must develop company-specific strategies. Directions for further development of the work based on this study are being outlined within the specific framework of the Italian Recovery and Resilience Plan (https://www.mef.gov.it/en/focus/The-National-Recovery-and-Resilience-Plan-NRRP/). The author is involved as a researcher at her institution in SPOKE 2 - Circular and Sustainable Made in Italy. The material presented here provides the initial impetus for the work that is being developed on the investigation of possible directions for the evolution of waste reduction practices towards the complete reintegration of materials into production flows and design-led strategies that impact upstream through the decisions of designers (e.g. choice of materials, garment construction, and finishing) that could implement design practices to plan waste out of the system by intention. Directions for further development of the work based on this study are being outlined within the specific framework of the Recovery and Resilience Plan presented by Italy, in which the author is involved as a researcher at her institution in SPOKE 2 - Circular and Sustainable Made in Italy (https://www.mics.tech/). The material presented here provides one of the initial knowledge inputs for the work that is being developed on the investigation of possible directions for the evolution of waste reduction practices towards the complete reintegration of materials into production flows and design-led strategies that impact upstream through the decisions of designers (e.g. choice of materials, garment construction, and finishing) that could implement design practices to plan waste out of the system by intention.

Abstract

If it is true that in recent years the concern with climate change has been growing (Bell, Poushter, Fagan & Huang, 2021), there is still a long way to go to make our lifestyles more sustainable. Several companies and brands have been thinking of strategies that allow them to become more sustainable (Hodgson, 2021), albeit with very different levels of success.

The fashion industry is, in this context, a very paradigmatic case since it is responsible for the emission of more than "1.2 billion tons of greenhouse gases each year, accounting for more than 10% of the world's carbon footprint" (Motif, 2021). With such a large footprint, several brands and designers have sought to transition to more sustainable fashion. However, despite the efforts made, the truth is that the message does not always reach consumers. Thus, if, in fact, consumers' awareness of the environment and sustainability has grown in recent years, if it is true that consumers have become more demanding in relation to the processes used by brands, we still continue to see a gap between the willingness to buy more sustainable brands and the effective purchase of these brands (Wong, 2021).

In this context, consumers are looking for more transparent and sustainable processes and where brands are already working in this direction. For a long time, it was believed that the price prevented the effective purchase of more sustainable products. Still, this idea has been removed in recent years, which leads us to question whether the problem is not in the communication strategies developed by brands to communicate their processes and products. Are consumers aware of what sustainable fashion really means? How have brands been able to convey and explain the difference between concepts such as Ethical Fashion, Circular Fashion, Slow Fashion or Conscious Fashion?

Unsure about the effectiveness of this communication, in this work, we seek precisely to analyse how some of the leading brands that are assumed to be sustainable (Abbas & Shipin, 2021; The Good Trade, 2021) have communicated, particularly in social media, spaces that aggregate a large number of consumers, but above all capable of defining trends and habits. On the other hand, these are also the platforms where the new generations are present, gaining even more importance in conveying the message to those who are the consumers of tomorrow and the guarantors of the planet's future.

Introduction

According to "The Pulse of the Fashion Industry 2019 Update" report, the efforts made by the fashion industry in terms of sustainability are slowing down. The document, created by the Global Fashion Agenda and Sustainable Apparel Coalition in partnership with Boston Consulting Group, reveals that "the fashion industry has improved its social and environmental performance in the past year (2018) but at a slower rate than the previous year (2017)" (Pulse of the Fashion Industry, 2019, p. 1). Following an indicator created to evaluate the goals and sustainable practices by entities of the fashion industry, the report alerts to the fact that "fashion companies are not implementing sustainable solutions fast enough to counterbalance negative environmental and social impacts of the rapidly growing fashion industry" (ibidem). However, the problem no longer resides only in fashion companies, it is also a cultural matter. Thus, only can we comprehend the fact that consumers continue to adopt fast-consumption habits. As the report also states, "the question is no longer whether it is necessary to improve sustainable business practices, but rather how long it will take before consumers stop buying from brands that do not act responsibly" (op cit. 2019, p. 11).

This situation is clearly aggravated by our society's way of normalizing extreme consumerism, promoting wasteful lifestyles, and following online trends such as "clothing hauls" or "beauty empties" videos, where YouTubers display their newest acquisitions until their next binge-purchases to their followers. In this sense, we found ourselves in a paradox since social media are used to promote fast fashion, yet these platforms are also used to build consciousness among consumers. Customers are using digital means to interact with their brands. Therefore social media is highly important to a new fashion brand (Scheide & Marques, 2018).

The report finds that "mentions of sustainability in social media increased a third faster than overall social media growth between 2015 and 2018" (op cit. 2019, p. 2). However, sustainability is still not a priority during buying decisions. If quality and aesthetics truly dominate consumers' decisions, as "Pulse of the Fashion Industry" indicates. In that case, it is up to the industry to transition to a more sustainable world. Following this logic, this study seeks to col-

lect several examples of Portuguese brands with sustainable motivations, both in production and culture. Our proposal is to identify these brands, their products, and their communication strategy, namely taking into account their interaction with social media users. In terms of methodology, this research uses content analysis of the brands' websites and their social media pages.

With this work, we attempt to reflect not only on fashion industry problems but also on how these issues are intrinsically linked to lifestyles, culture and communication habits. Per Byrum (2017, p. 219), "the connection between mass communications messages disseminated via social media and the diffusion of information among environmentally conscious consumers requires further study". Considering the Portuguese sustainable fashion market, the current paper is structured as follows: the next section provides the literature review, and then we present the methodology and results in sections. Finally, conclusions, implications, and further research are presented.

Communicating sustainability through social media

Per The State of Fashion, consumer behaviours and social media transform fashion industry communication.

> (...) the attitudes of executives also reflect evolving consumer behaviours that are forcing industry players to "self-disrupt" (the #1 trend identified by executives for 2019.) (...) Social media has an increasingly important voice in dictating consumer demand, helping small brands grow explosively. Across the industry, speed-to-market and responsiveness to consumer needs are becoming critical success facts (2019, p. 12).

The report is clearly highlighting the recent decisions and moves made by fashion industry players, who recognized the need to disrupt the system with new ways of thinking and communicating, using social media as a platform to touch consumers directly and obtain data, a trend also approached by The State of Fashion the year prior, as executives considered "mobile obsessed" consumers as the most important prediction made by the 2018 report (The State of Fashion, 2019, pp. 12-13).

Fashion brands also need to recover from bad press and communicate better with their consumer; the fashion industry has ignored sustainability and ethical practice for a long time, this is mainly due to the lack of information and transparency from fashion brands, and therefore, the need for brands to communicate about sustainability and ethical measures is more-than-ever crucial. Yet, in this case, transparency is much more important for consumers than sporadic "good public actions" from brands. Generations that are now the main target as consumers, both Gen Z and Millennials, have been defined by their quest for more sustainable economies and industries based on their preferences for digital solutions and their concerns about our planet's fate. In the quest for sustainability, however, emerging brands seem to have more success with these generations (especially Millennials), than established brands, as they are capable of relating with these generations through social media and have a more approachable and conscious image than their counterparts. These smaller companies are, for the most part, being very careful with production by choosing national manufacturers, and keeping a close look on their supply chain by producing less, preferring quality over quantity, thus allowing them to transparently communicate their brand's values to their consumer through social media live streams from their factories. Per The State of Fashion (2019, p. 74), "digital technology gives small brands an easy way to engage with consumers, who are increasingly glued to their smartphones and the internet".

Social media is more than a communication system; modern consumers have used it to praise brands and destroy them (Byrum, 2017). Consequently, brands have to be very cautious when advertising on social media, as their every move is captured, and a simple comment by an angry customer can make headlights. Consumers are now more informed about the actual cost of their fashion statements. They can no longer ignore what this industry has done to the planet and its inhabitants over the last roughly 100 years of industrialized production of garments, and since the apparition and escalation of fast fashion over the last 50 and 30 years (Dopico and Crofton, 2007).

Social media phenomena and trends such as Fashion Hauls, GRWM (Get Ready With Me), OOTDs (Outfit Of The Day) or Unboxing Videos have also contributed to this "buy now, think later" mechanism. The popular demand for "influencer's merch" (merchandising pieces, such as t-shirts or hoodies with an influencer's brand or catchphrase), sometimes sold at high-end prices, still made from cheap materials and produced in non-audited Chinese manufacturers, is also part of the problem.

On the other hand, new lifestyle trends have appeared on social media, such as minimalism (a modern re-take on the late XXth century movement), the Zero-Waste movement and methods to buy less, and influencers of these movements have been praised for their way of living. Emerging brands have clearly used social media to their advantage, challenging established players by getting closer to customers and taking the time to explain and be as transparent as possible to their followers. According to Minton, Lee, Orth, Kim and Kahle (2012), "sustainability is inherently social", which could explain why brands have chosen social media platforms to communicate their sustainable practices, as well as the 50% annual growth of advertisement spent on Instagram by brands (The State of Fashion 2019, 71).

Exploring businesses and their online influence on consumers, Loureiro, Serra and Guerreiro (2019, 375), found that the brands' interaction with consumers, their consistency in posting and updating content, as well as their product's endorsement by celebrities and influencers were the main factors of their online success. As per Byrum (2017, p. 210):

> the consumer who chooses to engage in environmental purchasing may be influenced by multiple motivations, including social pressures and the desire to escalate in status. These desires, fulfilled through eco-purchasing involvement, may further contribute to the consumer's willingness to share information with a corresponding peer set via social media.

Hence, social media platforms are a weapon of choice for emerging sustainable brands (Huang, Clarke, Heldsinger & Tian, 2019), as they allow tight communication and a relatable environment for consumers, who are also the best at communicating and spreading their love for a brand via their social media accounts.

In their 2020 Fashion Transparency Index, Fashion Revolution ranked 250 of the world's most prominent and established fashion brands on their environmental and ethical practices (Fashion Revolution, 2020). The organization concluded that "most brands and retailers lack transparency on social and environmental issues. More than half (54%) of brands score 20% or less". However, compared to the year prior, the report was also pointing at silver linings, "there are fewer low-scoring brands this year compared to 2019, 28% of brands score 10% or less, compared to 36% of brands last year", the report also shows that "of the new brands added to the Index in 2020, 15 brands score 5% or less, including Canada Goose, Fashion Nova, Pepe Jeans and DKNY" (Fashion Revolution, 2020, p. 4). Nevertheless, it is essential to note that transparency does not guarantee sustainability, as fast-fashion brands such as H&M ranked in the best brands in 2021 and 2022 (Fashion Revolution, 2021; 2022).

In general, the report also related that brand needs to communicate their efforts better and improve on transparency, as well as international policies such as the Paris Climate Agreement, as "only 16% of brands publish Science Based Targets, which means their environmental goals are aligned with the Paris Agreement's aim to limit global heating to below 2°C above pre-industrial levels" (Fashion Revolution, 2020, p. 6). So, who is to blame for the continuous success of fast fashion and the non-sensical "buy now, think later" logic still happening?

Social media is a powerful tool for fashion brands. As consumers are now more than ever informed about the fashion industry's toll on the planet (Mosca, Civera & Casalegno, 2018), brands have understood that they can use social media to their advantage to communicate their changes and environmental policies more efficiently. Yet, they are not the only ones who need to inform their consumers, as social media influencers have a great responsibility when endorsing products and advertising their lifestyles. Influencers have a real duty to educate themselves on the products they recommend, even if a brand does not pay them. By sharing products and services, they influence others to try something they might not need to feel closer to an influencer's lifestyle. Finally, consumers have a right to know and an obligation to search for better alternatives, answers, and solutions to buy smarter.

Methods

The present work fits in the line of the case studies since it is an empirical investigation that explores "(...) a contemporary phenomenon (the "case") in depth and within its real-world context, especially when the boundaries between phenomenon and context may not be clearly evident and (...) relies on multiple sources of evidence, with data needing to converge in a triangulation fashion" (Yin, 2018, pp. 45-46). Since our work is centred on the online environment and in particular on the online social networks of a set of specific brands, but also in the analysis of their way of communicating sustainability, we believe that this strategy was the one that best suited our purpose, since we:

> might favour choosing case study research, compared with others, when (1) your main research questions are "how" or "why" questions, (2) you have little or no control over behavioural events, and (3) your focus of the study is a contemporary (as opposed to entirely historical) phenomenon - "a case" (Yin, 2018, p. 32). The strong descriptive dimension of the case studies and the fact that the researcher is involved in the investigation means they are normally associated with qualitative plans. But the case study in this article ends up appearing in the context of a mixed investigation plan (Coutinho, 2015), as in addition to the descriptive and qualitative dimension, it will be considered a quantitative dimension, namely in the identification of terms used by the brands to communicate sustainability on social networking sites.

Considering that the main objective of the work is to analyse how fashion brands communicate sustainability on their websites, especially on social networking sites, we decided to use multiple sources of data; that is, we decided to collect data using different techniques, following the principles of Yin which state that "one principle is to use multiple sources of evidence (evidence from two or more sources, converging on the same findings)" (2018, p. 153).

In this work, we decided to make a direct observation of recording patterns in terms of the brands' websites and social media networks, trying to understand what aspects are used in these online spaces to communicate the sustainable purposes of the brand.

The selection of the brands that we analyzed in this work was made in a completely random manner. Still, following the indications of some magazines in the fashion area, articles specialized in generalist magazines and also the indication of associations and organizations that promote sustainable consumption. Thus, different sources were considered, and an analysis was made of articles that in different media refer to various brands as models in terms of sustainability. Although the selection process was random, as we mentioned, without concern for representativeness, we tried to select at least one brand per product type, thus trying to avoid over-representing specific sectors. The selection resulted in choosing 24 Portuguese brands, which we will present briefly later in the presentation of the main results (see Figure 1).

On the other hand, since "the data obtained with this type of instrument are quantitative (numerical) and their analysis

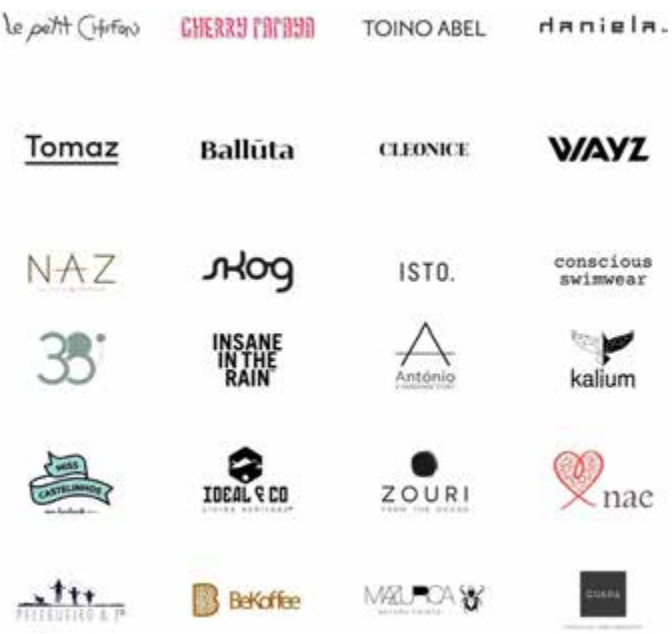

Figure 1. Brands analysed in this study
(Source: Made by the authors from the brands' websites or social media pages)

is carried out using descriptive and even inferential statistical analysis techniques" (Coutinho, 2015, p. 137), in part dedicated to results, we will present the main trends registered for each brand in the form of percentages, to display and discuss precise numbers (see table 1).

Discussion of the results

In table 1, we inserted the main data collected. At this point, we will try to summarize the principal aspects that caught our attention in the observation made and through the notes we were taking during that observation. Based on the gathered data, we can verify that only 16% of the brands studied are older than five years. It can indicate that the creation of brands in the fashion area with concerns in relation to sustainability is a recent trend, or at least it has been a gamble of recent years. On the other hand, we must highlight that one person founded 64% of the brands, an aspect that also helps to understand the context of brand development, that is, with small teams and structures often supported by the families themselves (table 1).

Table 1. Comparison of the brand's social media pages/webpages at the time of the study.

Brand Name	DoC	Market	Founder	Online presence		Social media followers

The brands analysed, which, as mentioned above, were chosen at random and from a set of articles that highlight them as being sustainable, working in specific sectors and having well-defined targets. The data collected allowed us to verify that 20% sell kidswear, 16% produce footwear. These aspects should be highlighted since they help to prove how sustainability has expanded to various sectors and is not exclusive to clothing production. On the other hand, we cannot fail to mention that 44% of the brands target specifically women, relevant data not only because women remain at the top of the biggest consumers, but above all, it also tells us that brands most often direct their messages to women. This aspect is also interesting because men are less challenged by brands, which can also be explained by the fact that women created 71% of the brands analysed.

Looking in particular at the online presence, we can see that the totality of brands owns a website, in addition to being present on different social media, but above all in two: Facebook and Instagram. Most brands bet mainly on these two social media platforms, although some are on other platforms, such as Pinterest, Youtube, Twitter, Vimeo and Linkedin. We also found that 60% of the brands concentrate their social media following on Instagram, which is assumed as the platform of choice for brands to communicate. This fact is evident not only at the level of followers but also in updating publications. Most brands have posts from the last two days or the last week on Instagram, which is no longer valid on Facebook pages. So, we can consider that Instagram, due to its characteristics, is the social medium privileged by brands to disseminate news about their products. However, it seems that in terms of transmitting messages related to sustainability, both the website and the Facebook accounts play an important role. In this regard, we must emphasize that many brands even dedicate specific separators in their websites to explain the sustainable dimensions of the brand, both in terms of production and distribution.

At this point, it is also important to remember that a small number of brands that are part of the sample, and that was considered when we started this work, meanwhile interrupted their activity or have at least paused the projects they were developing, mainly due to the COVID-19 pandemic. However, they were considered because of the analysis that had already been carried out, but also because despite having temporarily interrupted their projects, the ideas presented helped us to understand the importance of the communication and positioning of a brand, which claims to be sustainable.

Observing in particular how brands present themselves, we tried to register which are the main terms used, that is, which words and expressions are privileged by brands to make themselves known as sustainable brands. It is, therefore, at the level of sustainability communication that we are located at the level of the brands' own identity. Thus, considering the previously established categories, we can observe that 63% of the brands refer they are local and producing in Portugal, 50% declare they produce "premium" or "high quality" and 50% claim to be sustainable. It is interesting to see that there is a bet in local production by these brands and that this is a fact highlighted in terms of the presentation of brands and also in the communication of products, at the same time that it is associated with high-quality, on the one hand, and with a reduction in the number of products that are made. These dimensions are necessarily related to sustainability, but above all, to how sustainability is communicated. By highlighting the national production and the quality of the products, the brands try to make themselves known as sustainable brands. It is not just about asserting themselves as sustainable, but about showing, namely through local producers and the durability of products.

Directly linked to the issue of sustainability, we also find that 46% of the brands consider themselves "ethical", with 38% re-using materials/excess supply and 29% even producing "vegan" products, even if "vegan" derived leathers and products cannot be necessary considered sustainable (Minh & Ngan, 2021), and many examples of greenwashing derive from the use of "vegan" in fashion. It is also worth mentioning that the brands are concerned with presenting themselves as ethical brands which respect not only the workers but also the raw materials and the entire production process. Also standing out in communication, the bet on reusing materials and even using new materials to create innovative and differentiated products in ecological terms. It is, therefore, not just a matter of using a label but of embracing and communicating the adoption of a whole set of responsible practices in sustainability during all phases of production.

Finally, it is also worth mentioning that 38% of the brands use terms such as "heritage", "tradition" or "tribute" in their presentation and in the communications they establish with consumers and society as a whole, which is relevant from the point of view of the brand's identity, since it is not just communicating the way you decide to face the market. Still, it is something deeper rooted in the history of brands.

Conclusions

The fashion industry is far from sustainable, despite recent improvements and consumers' higher level of information. Findings show that fashion companies are not implementing sustainable solutions fast enough to counterbalance the rapidly growing fashion industry's negative environmental and social impacts. In Portugal, recently created SMEs try to improve their consumers' and collaborators' quality of life. However, 23% of consumers prioritize quality, and only 7% purchase with sustainable goals, although good quality can also mean fewer purchases in the long run (The Pulse of Fashion, 2019). Among the brands observed in this study, 84% were created in the last five years. Not only do they try to create sustainable fashion pieces, but they also aim to influence consumers on social media by showing the importance of sustainable practices and adopting a lifestyle respectful of the environment.

These creators try to send this message through other vehicles in the creation of associations, workshops, courses, podcasts, and other activities. We can say that although mass culture and fast fashion continue to dominate, the idea of a sustainable society is slowly beginning to grow, with designers who have already realized the need to convey this lifestyle on social media, not just as a marketing tool.

This study aimed to comprehend how sustainability is communicated online by fashion brands. Through our observations of the brands' online websites and social media accounts, we observed that sustainable brands mostly use social media to communicate their mission and values and raise consumer awareness. We also found that 60% of the brands concentrate their social media following on Instagram, which is also in line with the target audience and following of these brands.

Further research is encouraged on this topic by gathering more information on sustainable brands and their communication, observing different countries, and still focusing on emerging brands through ethnographic methodologies. On the other hand, it could also be highly interesting to perceive how consumers receive the information and how influencers can be real game-changers in disseminating conscious messages and sustainable awareness.

Prototype dialogues: re-balancing design thinking through negotiations with fabrics, form and future

Malene Pilgaard Harsaae, Anne Louise Bang

VIA University College, Center for Creative Industries & Professions, Denmark
mhr@via.dk
anlb@via.dk

Abstract

In this paper, we discuss and challenge design thinking as a process model. Though initially intended as a process for solving wicked problems, including inequality, environmental issues and poverty, focus in the later years appears to have been mainly on development for growth. Faced with the emergent need for green transition and connectivity in times of disruption and conflict, new ways of thinking and conducting creative processes are needed. Thus, a re-balancing of design thinking seems to be beneficial.

The implementation of design thinking as a process model has contributed to an increased focus on the early research phase, particularly on the interaction between user and products/services with an emphatic approach to understanding users. While we in no way wish to undervalue knowledge of user needs, we contend that this intense user focus partly cannibalizes the emphasis on research through experimentation and prototyping in the fuzzy front-end of a design process. We explore if it is possible to re-balance the design thinking process by re-connecting experiments and prototypes to the very early phases?

At VIA Design & Business we have observed that Fashion BA-students in their graduation project tend to carry out predominantly desktop research and some fieldwork for a considerable amount of the project time. Consequently, they postpone hands-on experiments and prototyping, apparently feeling that prototyping is the physical outcome of the research and process instead of prototyping actually being research and process; sometimes to a degree where the knowledge generated from tangible experiences emerges too late to bring value to the project. The students thereby miss the opportunity to include and benefit from substantial knowledge coming from early hands-on experiments.

We discuss how didactic approaches can initiate prototype dialogues in the early stages of the design process to evaluate the consequences and to re-balance design thinking models. To support the discussion, we introduce examples of early prototyping from two BA courses with different perspectives on prototyping. With these two examples, we demonstrate ways in which early prototyping in the fuzzy front-end of design thinking supports and enhances students' dialogues with the material of a situation and how it is beneficial for the further process.

Introduction

The fashion industry will undoubtedly experience many changes in the coming years. New policy such as EU strategy and national strategies (N.N., 2022; N.N., N.D.) are expected to place new demands on the way clothing is produced, used and disposed of. It will increase the need for new knowledge about product responsibility and resource consumption as well as disrupt our design methods and the way we act in design practice. There is a need for innovation and alternative approaches to problem solution and to prepare students to act as change agents in societal as well as industrial contexts. Future designers must be able to choose and ask for materials appropriate for the intended use, handle material flows and have skills in design for recycling, disassembly and longevity. They must also have knowledge about circular economy and business models and last but not least be prepared to learn as they go. At the same time, researchers are pointing at the challenges within the fashion industry with a significant focus on circular economy as a relevant way to go. A focus that might lead to a misplaced perception that it is possible to create a 'good Anthropocene' (Brooks et al, 2017).

In this paper, we discuss what we have coined 'prototype dialogues' as an asset in design thinking, advocating that prototyping plays a pivotal role in all steps of the design thinking process.

Background and design thinking theory

The recent years of COVID-19 lockdowns and online teaching have undoubtedly contributed to less focus on hands-on methodologies, e.g., prototype development and material experimentation. However, it is simultaneously relevant to reflect on teaching methods and approaches when the students choose work processes that the teachers consider less appropriate in relation to creating the innovative and/or alternative solutions needed by the industry and society. Based on the observation of our BA Fashion students' approaches and design process, we scrutinized the course program and curricula and realized that the processes we teach predominant-

ly are founded on a design thinking approach that includes high user focus, trend studies and market research in the front-end of the design process.

Design Thinking

The introduction of the concept of 'wicked problems' (Rittel & Weber, 1973) and the later interlinkage to design thinking (Buchanan, 1992) has been central to the initial approach in the concept of design thinking. Around the 70's, an interest emerged in the role and responsibility of the designer (Simon, 1969; Papernek, 1971). During the 80's, there was an intensified focus on the working methods within the design professions, (Lawson, 2005; Cross, 2006; Schön, 1991) and the concept of design thinking emerged. The concept began to be applied to business problems (Brown, 2009) and spread, specifically through IDEO and their working processes.

Several design thinking models emerged, including Ideo, Stanford dschool and British Design Council. Though they use different terminology, generally all models include similar phases consisting of; 1) Discover, focus on users and research, 2) Define, identify the problem based on user need 3) Ideate, generating ideas, often through brainstorming and post-its. 4) Prototyping, construct a 3D version of the idea. 5) Test, testing ideas on the market and the stakeholders. In the years 2013 – 2015, VIA Design & Business developed and launched their own design thinking process model; The Strategic Design Practice 5F model (McElheron & Harsaae, 2016a, 2016b). The model drew on inspiration from the extensive literature about design thinking, including the above mentioned and was intended to close the gap between our design and business students. 'Practice' deriving from the design disciplines, including prototyping and experimenting, 'strategic' related to the business disciplines, and 'design' as the linkage between the two.

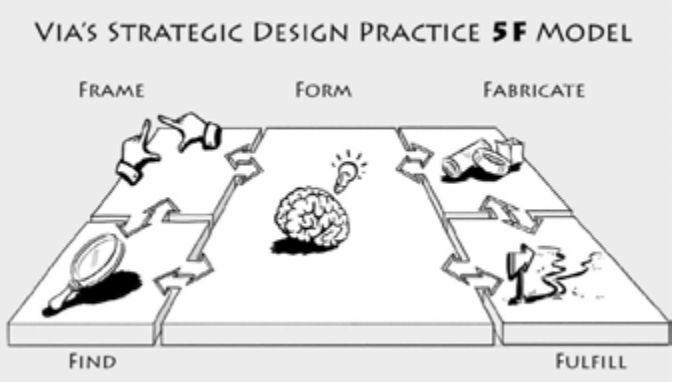

Figure 1. VIA Design 5F Model; McElheron, P. & Harsaae, M. 2013

In light of the current environmental situation and the urgent need for green transition, we are embarrassed to admit that at the time when we developed The Strategic Design Practice 5F model, the green transition was neither at the forefront of process development nor the goal of the model. The point of departure for the development was the focus on creating a process model tool which contributed to a better cooperation between design and business specifically with a focus on our students. The original idea of the model was also not to present it as a linear process, but instead to focus on a more open and unstructured process. However, during the use of the model and its diffusion within the education programs at our university, we experience that it is articulated and used predominantly linearly.

The predominantly linear approach might be the reason why we at VIA University College, Design & Business, have observed the earlier-mentioned tendency among our BA Fashion students. In combination with the need for green transition, this observation points to a need for re-balancing our approach to design thinking, supporting an urgent need for alternative didactic approaches.

VIA Design & Business students are introduced to The Strategic Design Practice 5F Model at two different common module courses, one course placed on the 1st semester and the other course placed at the 5th semester. All students regardless of disciplinary specialization build a shared knowledge about design thinking as a process tool. In addition to the two introductions common for all study programs, the various programs choose individually the extent to which design thinking should be part of the curriculum. In the following sections, we discuss how didactic approaches can initiate prototype dialogues in the early stages of the design process to evaluate the consequences and to re-balance design thinking models. We do this supported by examples from two very different course modules.

Prototype dialogues – introduction to and discussion of examples

We set out to discuss how didactic approaches can initiate prototype dialogues in the early stages of the design process to evaluate the consequences and to re-balance design thinking models. To support the discussion, we introduce examples of early prototyping from two BA courses with different perspectives on prototyping at the forefront of the design process. The two courses have very different approaches, structures and expectations to outcome in terms of learning goals.

Elective; Changemaking Design

The elective 'Changemaking Design' is offered to students in their final semester. We invite the students to experiment with a variety of biomaterials during a three-week elective. The students come from fashion, furniture, and graphic design specialties. We specifically ask the students to individually experiment with biomaterials, including bio leather and alginate composites related to individually chosen concepts within their core design disciplines. The prototypes created by the students were speculative as these materials have not yet been commercialized. This allowed the students to examine the concept, taking an early hands-on experimental approach to explore the materials. The elective focused on the process and the students' ability to learn from their

Figure 2. Prototype Dialogues: Biomaterials.

experiments and move back and forth between experimentation, knowledge generation, and insights. The output of the course was an individual portfolio documenting the process and displaying the different samples. Samples that the students evaluated as having potential for further development and commercialization were supported by recipes and reflections on further development. All of the students (9) performed really well and generated numerous material samples that pushed them in new and alternative directions that they stated have not been part of their considerations until then.

The course revealed advantages and disadvantages of the didactic approach. It was remarkable that some of the generally 'weaker' students matched or even surpassed the other students when working in this way. Some of the students were so taken up by the experimental approach that they put several extra hours into the project beyond what was expected. Others clearly had more difficulty navigating the very open approach that did not require the students to produce a specific, final result. Some students became so enthusiastic about the experimental approach that they resumed it in their final BA exam project and started with the development of materials and/or experimenting with form and shapes in existing materials. Some of them also transferred this approach to their work with deadstock or second-hand materials.

This example demonstrates how early prototyping in the fuzzy front-end of the design process supports and enhances the students' dialogues with the physical material of a situation beneficial for the further process. It does, however, also reveal that not all students adapt to and benefit that easily from this alternative approach right away. A catalogue of predefined subtasks may have supported these students in their experimental process. However, the explorative approach caused the students to develop materials that it is hard to imagine they would have developed if the point of departure had been user research, and in general the students' final portfolios revealed several material proposals worth investigating further in an industrial context.

Interdisciplinary Module

The second example is an interdisciplinary module for students across nine disciplinary study programs in the 5th semester of the BA. The aim of this module was to develop a concept for a case company that contributed to the company's sustainable development. The module is divided into two parts, a two-week introductory part and an eight-week processing a part. In the introductory part, the first task was to prototype future visions as 3D scenarios. The students worked in groups of four, and based on the identification of two megatrends and their countertrends, they created a scenario cross with four different scenarios and selected one for prototyping. Contrary to the elective described above, the aim of this exercise was clearly defined. The students should visualize a future scenario as a 3D prototype which they should present to the other students and use as point of departure for their concept development.

Figure 3. Prototype Dialogues: 3D future scenarios.

Working with scenarios gives students tools to discuss possible, plausible, probable and preferred futures (Dunne & Raby, 2013; Voros, 2022). Using megatrends as guidelines for scenario development allows students to anchor their own intuition and move between feelings and qualifications. In this way, they work with data-based descriptive scenarios and/or intuition-based prescriptive scenarios (Margolin, 2007). This early prototyping gave the students the opportunity to have a very concrete dialogue about future utopias and dystopias. The prototype functioned partly as an icebreaker through conversation with the material of a situation (Schön, 1991), a way in which the students could get to know each other across disciplines and partly as a point of departure for the subsequent concretization of their idea and concept development.

This example demonstrates a different approach to early prototyping in the fuzzy front-end of the design process. Contrary to the first mentioned approach, this approach supports and enhances students' dialogues with abstract material of a situation beneficial for imagining and discussing potential futures as a framework for the further process. Moreover, the use of scenarios is an acknowledged approach in business (World Economic Forum, 2018) and political (Fritsche et al., 2021) contexts to identify future challenges and opportunities.

Conclusion – Re-balancing design thinking as a process model

With these two examples, we demonstrate ways in which early prototyping in the fuzzy front-end of design thinking supports and enhances students' dialogues with the material of a situation, in the form of the very concrete example from the elective or the more abstract example from the interdisciplinary module. From different perspectives, both types of dialogues are anticipated to be beneficial for the further process.

Material does and makes us do

In their article "Material driven design (MDD): A method to design for material experiences, Karana et al. (2015) argue for qualifying material "[...] not *what it is*, but also for *what it does*, *what it expresses to us*, *what it elicits from us*, and *what it makes us do*", emphasizing that materials need not only to be characterized by their functionality but also how a material contribute to create user experiences.

Focusing on Karana et al.'s notions about what *material does and what it makes us do* resonates with a focus on using material experiments as the point of departure for a design process intended to create not only long-lasting products but also products that last (Fletcher, 2012). Long-lasting products as well as products that last bear the potential to foster a green transition.

What material *does* is transferable to the properties required to make long-lasting products whereas what material *makes us do* might contribute to creating products that last. We suggest that if our didactic approach focuses on employing material experimentation at the front-end of their design process, we might facilitate a design process with focus on *"material experiences when a particular material is the point of departure in the design process"* (Karana et al., 2015:37).

The two courses we have presented in this article both relate to Karana et al.'s approach. The elective 'Changemaking Design' very concretely employs a similar approach with its focus on material experimentation and how this is applied by the designer to *"create and materialize concepts which make the transition from design intention to material/product design"* (Karana et al., 2015: 39). The interdisciplinary module, however, relates more abstractly to material and material experimentation as the approach is to focus on the dialogue with the material of a situation (Schön, 1991) through the building of scenarios.

Design Thinking and the Green Transition

Evaluating these approaches against the Strategic Design Practice 5F model's FIND phase implies a need to broaden the understanding of the user studies, encouraging designers to empathize and research on reveal relevant societal challenges, by adding concrete and hands-on material experiments and scenario prototyping as part of the initial research and exploration phase and as such add more perspectives to drive the further process.

Design thinking has a great potential. However, with this paper we argue that if supplemented with an explorative and experimental approach through prototype dialogues, there is an even greater potential for fostering new ideas that will contribute to the green transition.

Future fashion: new and ancient systems at the intersection of anthropology, ecology and innovation

Kirsten Scott

Istituto Marangoni, London, UK
k.scott@istitutomarangoni.com

Abstract

This research offers an analysis of an emergent subculture of resistance to the fashion status quo that embraces natural, indigenous textiles in contemporary clothing. It shows how three small luxury designers employ radical indigenism (Watson 2019), soil to skin (Burgess 2019), natural fibres, slow and conscious processes, and aesthetic sustainability (Harper 2022), to offer a persuasive counter narrative to the incumbency thinking that perpetuates the prevailing fashion system. Case studies of Noir Mud Silk, Monad London, and Oma Space have been formed from semi-structured interviews and the analysis of their products and processes. Key to this research has been defining the values that inform these designers' praxis, such as the importance of craft, the rejection of growth-logic (Fletcher and Tham 2019) and the desire to promote human, environmental and even spiritual wellbeing through work that reflects a sophisticated intersection of anthropology, ecology and innovation. Research outcomes suggest the importance of reframing indigenous technologies as innovative rather than primitive and of learning - with humility - that traditional knowledge systems have much to offer our future by teaching us how to live within planetary boundaries (Watson 2019, Nakashima 2010, Magni 2017, WCED 1987). Although designer-artisan collaborations are common within the existing fashion system, a focus on the ability of material systems to reconnect us with the whole earth community, holding us within Nature's limits, has received less attention (Watson 2019, Berry 1990). When radically indigenous materials are suggested for fashion, questions of scale-ability quickly arise, as the impulse to commercialise and grow is privileged over relational modes of knowing, being and doing (Escobar 2018: xi). This research therefore, shows ways to collaborate with traditional textile knowledge systems to re-imagine, produce, value, use, and ultimately discard clothing while affirming natural and restorative systems, demonstrating a simultaneously new and very ancient paradigm of fashion.

Radical indigenism, slow luxury, textiles knowledge systems, fashion and nature, ecological design.

Introduction

The fashion industry is closely tied to a system of extractive globalization that contributes to the degradation of our planet and its peoples through its use of fossil fuels, over-production and mass-consumption, waste, exploitation, and human rights abuses in the supply chain (Fletcher and Tham, 2019; Ellen MacArthur Foundation 2017). Since the early 1990s, fashion industry growth has escalated around the world, but business models focused on growth are irresponsible when the imminently finite nature of the earth's resources and the impacts of climate change are no longer deniable. A reduction of 75-95% of material resource use is needed, but this is self-evidently impossible in an industry that was forecast to grow by a further 81% by 2030, at least prior to Covid-19 (Fletcher and Tham, 2020; Global Fashion Agenda, 2022).

We have now less than a decade left to prevent irreversible climate damage (Global Fashion Agenda, 2022): the fashion system must change radically and so too must our relationship with clothes. Many fashion designers now acknowledge that a change of pace and scale is needed: indeed, Giorgio Armani spoke passionately about this in an open letter published in WWD in April, 2020 (Armani, 2020), where he described the acceleration of production cycles, increased volumes and frenetic fashion seasons as 'criminal'. How we transition to postgrowth fashion is unclear, however, although it is obvious that we need to produce less, produce more slowly and consciously, and produce clothing that will last both physically and emotionally: clothing that is untied from seasonal trends and more reflective of personal values (Edelkoort, 2020; Armani, 2020; Harper, 2022). Therefore, a complete reset is needed in the systems, materials, designs and relationships embodied in and articulated by our clothing, so that we may transition to live in a "mutually enhancing relationship" with the whole earth community (Berry, 1990:53; Escobar, 2018). But where do we begin?

> *We have plenty to be sorrowful about, and are not emerging into a golden age. We need a gentle approach, a non-violent spirit, and small is beautiful. (Schumacher, 1973:129).*

Fashion, as we now conceive it, has exceeded the carrying capacity of the Earth. Instead, we need an ecology of small, diverse and conscious expressions of clothing to meet the challenges of the Anthropocene. The future must be small: smaller labels have an autonomy to make decisions about their operations that larger brands don't, are without ac-

countability to shareholders, and are able seamlessly to reflect their values and beliefs about fashion, the world, and even the cosmos in their operational models (Schumacher, 1973; Kibbe, 2015; McRobbie et al, 2016; Moulton et al, 2019). Luxury is an area of fashion that - although arguably undemocratic - is highly influential. Characteristics of true luxury products are quality, craftsmanship, exclusivity, heritage, aesthetic sustainability and creative innovation, all of which support sustainability (Danziger, 2016). This research examines the practices and values of three small, independent, luxury fashion labels that offer fresh approaches to fashion conception and realisation that embody ancient knowledge, natural systems and skilled craft traditions, and which operate within planetary boundaries, in case studies of Noir Mud Silk, Monad London, and Oma Space.

Much is claimed about the potential of new technologies to solve fashion's sustainability problems, perhaps in the hope that current, mainstream business practices focused on efficiency, profit and growth may somehow be maintained (Deeley, 2022; Manal et al, 2022; Shoaib, 2022). However, this research explains how an alternative vision for luxury fashion is grounded in the belief that the knowledge we need about how to live well on the Earth already exists, that it does not need to be invented but rather rediscovered (Orr, 2004; Berry, 1990).

Looking back to move forward: anthropology, ecology and innovation

A growing body of independent fashion and design thinkers are advocating looking back in order to navigate a better way forward, applying anthropological research and ecological systems thinking to how they locate, understand and source materials, techniques and processes, in the design of products, and the end of life of those products. In an interview for the Royal College of Art, John Thackara emphasised the importance of learning from other cultures that have historically specific, less damaging ways of making things; he suggested that we have reached "peak-digital" and that the materiality of craft is now "at the centre of where design is coming from" (Thackara, 2020). Li Edelkoort, in an interview for Bloom Brasil in May 2020, described a move towards "less and better, minimal and exceptional, sustainable and intuitive" and "the future is handmade". She foresees much stronger links between farms, fibre houses, textiles houses, fashion houses and retail – that they would belong to each other, invest in and help each other in a more relational, transparent system (Edelkoort, 2020). This model relates closely to the Fibershed movement – local and regional networks of fibre producers, 'from soil to skin' (Burgess, 2019) - which allows us not only to know who made our clothes, but exactly where and how the fibre was grown, how it was dyed, spun, knitted or woven, cut and sewn and by whom, as part of a new - but also very ancient - holistic, transparent and relational system (Burgess, 2019). In many ways, this echoes the fibre and textile production systems still found in some indigenous communities but which are at risk of being lost forever. These systems demonstrate a sophisticated and harmonious relationship between people and their local environment.

Radical indigenism

Radical indigenism is a term defined by Princeton professor and citizen of the Cherokee Nation Eva Marie Garroutte and discussed specifically in relation to design by architect Julia Watson (Watson, 2020). Reflecting the Latin origins of 'radical' – *radix*, meaning *root* – radical indigenism asserts the need to re-examine the traditional wisdom rooted in the cultures of many global communities that may rebuild our understanding of how to work in collaboration with natural systems (Garoutte, 2003; Watson, 2020). Indigenous knowledge is passed down through generations within a community, and encompasses the "understanding, skills and philosophies that span the interface between ecological and social systems" (Nakashima, 2010: 1-2) – as such it forms part of their intangible cultural heritage. Making requires local, organic materials so that connection to the surrounding environment is reinforced and production may naturally be constrained by season or by other essential activities. Material resources are considered precious, so little waste occurs: everything produced may be repaired, repurposed and will naturally biodegrade to nourish the soil. This approach is now crucial to revive if we are serious about the transformation required in how we produce and use the things we wear.

Craft as sustainable process and resistance

Craft and design have historically "reveal[ed] themselves as the forces of anti-Mammon" (Greenhalgh, 2002: 9) in times of excessive consumption. Craft is central to the textile practices of indigenous makers who use slow techniques that have sustainably been refined over time. Long supply chains and anonymous producers have disconnected consumers from those who make their clothes, obscuring the human and environmental cost of how they are made. The radical transparency of relational sourcing strategies that know and name specific indigenous makers may not only support cultural sustainability but also promote aesthetic and environmental sustainability.

Subcultures form in resistance to the symbolic order of a culture and "contradict the myth of consensus" (Hebdige, 1979:18). The three critical fashion practitioners selected for this study are part of a growing movement that is creating clothing and accessories in alternative ways to the mainstream, trend-led fashion system. Their approaches involve personal, aesthetically sustainable design strategies and slow, meditative , craft-led techniques and processes that embody a harmonious relationship between peoples and planet. This may seem romantic, but these idealists offer hope. "The world does not need to be remade but rather revealed" (Orr, 2004:32) and this small group of independents is "rediscovering old and forgotten things" (Orr, 2004:32) drawing on ancient knowledge systems that are important to maintain.

Methods

In order to understand not just what, where and how, but also why, qualitative research methods were used to construct case studies of Marcella Echavarria (Noir Mud Silk), Daniel Olatunji (Monad London), and Oma (OMA Space). Semi-structured interviews were conducted through zoom between July and October 2020 to delve deeper into their individual approaches and the values and beliefs that inspire these. The interviews asked the same questions of all participants, but offered scope for follow up questions on information that arose organically through conversation. Their collections were analysed - through their websites, through social media, through journal articles, and through physical examination in the case of Monad London - to define the distinctive material and aes-

thetic characteristics of their work and how these might promote sustained relationships with between consumers and their clothing.

Case Study 1 - Marcella Echavarria

> *When you have certain pillars that define your life, then your work is not a separate thing (Echavarria, 2020).*

Sourcing and cloth

Marcella Echavarria, currently based in Spain, describes a profound sense of gratitude for everything she has personally: for nature, for family and for the beauty in the world that informs her practice. Although reluctant to describe herself as a designer, Marcella's entire career has involved her working closely with artisans to develop luxury, artisanal products - respecting people who "work with their hands and their hearts". She is co-founder of the XTANT textiles festival that takes place in Mallorca each year. She describes the fabrics she uses as "embodiments of nature" and is committed to sustaining indigenous knowledge systems.

Marcella started Noir Mud Silk as a way of honouring and promoting Chinese mud silk, which has been designated part of the Intangible Cultural Heritage of Humanity by UNESCO. She first came across the silk in Beijing, attracted by the distinctive, almost musical sound it makes when worn and by its unique texture. She began to research the cloth, to learn more about its 2,500-year history, as part of the material culture of the Hakka people of Guangdong Province, and its tangible and intangible properties. Naturally 'white' silk fabric is dipped in a solution containing the juice of a species of yam to mordant the cloth, transferring its medicinal properties and improving its durability while also dyeing it a rich red-brown. The cloth is laid out to dry on the ground in the sunshine and may be dipped and dried many more times, before coating on one side only with iron-rich mud from the Pearl River to create a unique surface: shiny, black – sometimes looking like leather, like paper, like parchment "so many textures in one". The finished cloth is stronger and more water resistant than other silks, washable and comfortable to wear in humid summer conditions.

Figure 1 & 2. Ancestral shapes in mud silk by Noir Mud Silk.

The production of the cloth is closely tied to natural, seasonal rhythms, constrained by the drying season from March to November and in conjunction with the artisans' other activities, such as farming. It represents an ecologically sound model of textile production.

The design strategy

Marcella's designs draw consciously on "ancestral shapes" that are based on indigenous Asian cutting techniques, working sympathetically within the physical properties of the cloth such as width, available length and drape, rejecting season, size and gender to create timeless limited "editions" rather than seasonal collections, and responding to the naturally constrained availability of the fabric (Figures 1 and 2). Because Marcella appreciates the fabric so much no scraps are wasted, so many items contain elements of patchwork: "I don't call it upcycling or recycling: I call it appreciating". This is reflective of the ways that many indigenous communities in the world (and indeed most communities, historically) work resourcefully with the materials available to them. The designs consciously embrace any imperfections and inconsistencies in the cloth and how this wears over time. Noir Mud Silk has a following of customer-collectors, who understand that the garments and materials not only look beautiful but also feel beautiful on the body. Many Chinese customers have come to appreciate Marcella's interpretation of their cultural cloth, suggesting that "someone has to put value into something of your own for you to value it". She describes herself as honouring something that already exists: first of all – and foremost – respecting the fabric, of looking back in order to move forward. She has no plans to grow her business, but rather organically to be limited by what is possible to produce within Nature's systems and timeframes.

Case Study 2 - Daniel Olatunji

> *...the Fulani tribesmen that are growing the cotton I work with are very much limited to what they can grow...they can only produce a certain amount, handwoven, and it kind of works hand in hand with nature, so you're not over-producing anything. (Olatunji, 2020)*

Sourcing and cloth

Daniel Olatunji, based in the United Kingdom, emphasises the importance of slow craft traditions in every aspect of his menswear business Monad London. Central to Daniel's business model is sourcing materials directly from small, indigenous producers, emphasising the benefits of the relational and of "meeting people with really interesting stories". He identifies James Rebanks' The Shepherd's Life (2015) as a major inspiration for him, in revealing the value of the local and specific place of origin, leading him to seek out rare wool weavers and ultimately to work with one of the few remaining handweavers of Donegal Tweed, Eddie Doherty. Traditionally, Donegal tweed represented a perfect, ecologically-sound symbiosis between animal, land and people: using wool from local sheep, dyed with local lichen, berries and moss, as part of a small cottage industry that supplemented income from subsistence farming (Hoad, 1987).

In addition to Donegal tweed, Daniel sources the cotton he uses from Fulani tribesmen in northern Nigeria, who grow it in certain quantities and at certain times of the year, around other crops and activities (Figures 3 and 4). This, and the amount of

Figure 3 & 4. Handloom, indigo dyed cotton, wabi-sabi aesthetics by Monad London.

Figure 5 & 6. Handwoven, textural garments by Oma Space

time it takes to pick, spin and strip-weave the cotton by hand, places natural limits on fabric production to operate within planetary boundaries and results in irregularly textured fabrics that powerfully communicate the maker's hand. The community also comprises indigo dyers that continue a 600-year-old tradition passed down from father to son for centuries. Daniel buys this fabric for specific orders, never asking for more than can be produced slowly and consciously.

The design strategy

Craft is where Daniel draws his inspiration from and how he develops and produces garments for his customers, primarily in the UK and Japan. His philosophy of making embraces the Japanese concept of *wabi-sabi*, of finding beauty in the imperfect, which can accommodate and even celebrate irregularities in surface and weave. The deceptively raw edges on his garments are impeccably finished inside to ensure their durability (Figure 4). He is also inspired by the way that garments take on characteristics of their wearer over time, for example, how sleeves may start to fold in distinctive ways, or become distressed in a manner that is both beautiful and personal. The precious fabric scraps from cutting are incorporated in new garments. Monad's editions are small – never more than four of a specific piece - working within the availability of slow, traditionally-made natural materials. It is this specialness - Daniel's craft, the craft of the makers behind the exquisite, timeless garments, and the knowledge that these embody - that his customers appreciate most (Figures 3 and 4). He plans to grow slowly and organically, only in response to demand, but maintaining his values as a slow, artisanal brand and working within the boundaries of what may be produced without compromise. He hopes to educate and inspire others to work with unique, artisanal fibres and indigenous materials, to keep these skills alive, and that this will lead people to ask about who made their clothes, where and how.

Case Study 3 - Oma Space

> *Something made with an awake mind and with good spirit in it is real luxury. (Oma, 2020).*

Sourcing and cloth

Oma Space is a small, independent fashion and textile studio in South Korea whose design practice is materials-led, working solely with natural, biodegradable fibres and the innovative application of traditional processes to which Oma attaches a spiritual dimension: "to dress the body and soul". The fibres used are hand spun and include wild silk, cotton, linen, ramie, hemp, wool, and Korean Hanji paper, naturally dyed with plant matter including fermented ebony fruit that changes shade over time, or with indigo to "detoxify the bad energy accumulated in the body" with its natural, antibacterial properties. Hemp, in particular, is beneficial to soil health, growing well without use of fertiliser or pesticide. Oma works closely with weavers in northern-eastern Thailand, who grow indigenous species of cotton that they spin and weave themselves, and who are very receptive to the collaboration because their skills and knowledge are otherwise at risk. Central to Oma's work is a desire to prevent handcrafted, traditional textiles from disappearing: keeping them alive by keeping them worn, rather than preserved in a museum.

The design strategy

Oma believes that a radical change in production systems is needed, that we must make things consciously, avoiding trends. She suggests that another word for fashion is now required: one that reflects an alternative paradigm - not clothing, not garments, but something different. She is mindful of the consequences – and indeed the responsibility - of making anything at all now: that it must be able to disappear [biodegrade] very naturally, as everything comes back on us, so carefully considers the ecological impact of her decisions and processes. She begins by playing with a fabric for a few days, to touch, smell and feel it, trying to "hear how the fabric wants to be expressed"; only then does she begin to draw. Oma's limited editions of slow, handcrafted clothing can be worn for any occasion, using shapes that are simultaneously timeless and modern, local and transnational (Figures 5 and 6) supporting their aesthetic sustainability.

Customers predominantly are based in London, Amsterdam, Tokyo and Seoul and share Oma's appreciation for the craftsmanship and unique properties of artisanal materials. The irregular surfaces and natural colours convey the spirit of the makers' hand and the natural world, reflecting Oma's Buddhist beliefs and embracing natural imperfections (Figure 6). Process is promoted: Oma's atelier in Seoul includes videos and images of the artisan's techniques and a loom to reinforce the fact that the fabric is the results of slow skill. In addition to

Table 1. Summary of research findings

Measure	Noir Handmade	Monad London	OMA Space
Values	Gratitude, appreciation; artisanal craft; respect for makers; preserving nature and indigenous textile knowledge. Fabric first.	Slow craft, perfectly imperfect, relationship with makers, preserving local, rare, indigenous textile knowledge. Fabric first.	Preserving nature and indigenous textile knowledge by keeping it worn and used; responsibility; promoting conscious practices. Fabric first.
Sourcing	Directly from artisans in Guangdong Pearl River Delta region, China.	Directly from artisans in Northern Nigeria and Ireland; collaborations with artists.	Directly from artisans; collaborations with artisans in Northern-Western Thailand, Laos, Japan and in South Korea.
Names makers/groups	Groups	Yes	Groups
Indigenous textile knowledge system	7500-year-old tradition, using local, natural resources: scale limited by seasonal nature of production due to weather and other activities; at risk due to laborious production processes, climate change affecting the drying season and water pollution affecting iron content in local river.	Kano, Nigeria – traditional hand spun, strip-loom woven indigenous cotton species; supplementary income for indigenous communities; naturally dyed in 600-year-old indigo dye pits; knowledge at risk as younger generation seek other employment; handwoven Donegal tweed from one of the last remaining handweavers – at risk due to labour intensive nature of work deterring apprentice weavers.	Traditional hand-spinning and weaving, natural dyeing systems; supplementary income for indigenous communities; at risk as new markets are needed for their work and older artisans are dying out; Korean hemp traditions were almost eradicated after the war but now are being revitalised.
Fibres	Silk	Indigenous species of cotton, wool, silk	Hemp, wild silk, indigenous species of cotton, wool, ramie, Hanji paper.
Fabrics	Traditional mud dyed silk. Plain or crepe weave.	Handwoven strip loom cotton; wool tweed.	Handwoven; felted, textural, tonal.
Dye	Diospyros cathosa with iron-rich mud; indigo. Dyes that carry beneficial properties	Indigo carries beneficial properties; tweed dyed with local plant matter from Donegal, such as lichen.	Indigo; ebony fruit; always natural. Dyes with beneficial properties to body and soul.
Waste strategy	All scraps are kept and reused, patched together to make more garments	Scraps are kept and reused in other clothing products.	All materials are fully compostable, can safely be returned to the earth.
Aesthetic qualities	"Ancestral shapes" traditional, simple and timeless styles. Exceptional quality. Aesthetic sustainability.	Timeless garments that adopt a wabi sabi approach – the aesthetics of wear. Exceptional quality. Aesthetic sustainability.	Simple, timeless, traditional shapes; highly textural; aesthetics of the hand made Exceptional quality. Aesthetic sustainability.
Collections	Editions – new pieces added depending on the availability of the fabric. Natural constraints due to seasonal availability.	Editions – never more than 4 made of any garment. Naturally constrained by the availability of the cloth.	Editions – new pieces added depending on current collaborations with artisan groups. Also creates an textile art installations and combines tradition with new technologies.
Showcase	Exhibitions; showrooms; events; online.	Showroom; Horizon in London, other stockists in Japan.	Own studio on Seoul; galleries; specialist stockists, such as Livingstone Studio in London; online.
Position on growth	No desire to grow.	Would like slow, organic growth – without compromise.	No desire to grow.

clothing, Oma Space creates experiential textile installations that promote artisanal processes and improved consciousness, sometimes introducing digital technologies. Oma Space has no intention to grow their business, but rather is happy to stay the same size year on year.

Conclusion

This research is significant in showing how a subculture of independent, luxury fashion labels has developed small, distinctive, and successful practices while refusing to be complicit in a problematic system (Table 1). Marcella Echavarria, Daniel Olatunji and Oma share a strong appreciation for unique, locally specific, natural, indigenous materials, sourced directly from artisans who use slow, traditional, craft processes conducted in symbiosis with natural systems in ways that have sustainably been performed for many centuries. They show us how these materials may be used to create limited editions of clothing that is physically, aesthetically, and environmentally responsible. Their clothing primarily is installed in gallery spaces, exhibitions, showrooms and online platforms, rather than in conventional fashion stores. This has the potential to change perceptions of the garments, by framing them as artefacts to be examined, understood and valued in ways that promote responsible consumption, rather than as disposable commodities, and which provides opportunity for information to be shared about the indigenous people and systems that formed them (Geczy and Karaminas, 2019).

While the price points of their clothing reflect the investment of time and skilled craft knowledge which positions their work as exclusive, and therefore inaccessible to many fashion consumers, these labels do provide role models to some young designers who wish to produce luxurious clothing in meaningful and sustainable ways. Their approach contrasts dramatically with that of major global luxury brands that have similar price points, but which produce unsustainably. As such, they form part of an ecology of diverse fashion practices that contribute ideas for a responsible future. If, like many indigenous communities, we are to live in synchronicity with natural systems rather than in opposition, this diversity is key: too much of one species is detrimental to local ecology. There is no single solution or business model that by itself will solve the problems created by a global fashion industry that has exceeded the carrying capacity of the Earth. The transformation of the fashion industry to become truly sustainable requires a radical, whole-systems approach involving multiple stakeholders – including governments with the vision, integrity, and courage to commit to, support and incentivise meaningful change through policy and legislation. The three case studies demonstrate one possible approach; further research is needed to explore the transferability of this to other markets and contexts.

Important to this research has been defining the values that inspire these designers' approaches, which include their rejection of the orthodoxy of growth, having a strong sense of sufficiency and their desire to promote human, environmental and even spiritual wellbeing through clothing. Their business models are naturally constrained by their use of indigenous textiles that are closely identified with specific peoples, places, materials, and techniques – and which are part of ancient knowledge systems that reflect natural limits to growth. These systems demonstrate a harmonious relationship between human creativity and nature, using local, natural resources wisely, preserving culture and knowledge, and supporting artisans' livelihoods and dignity. Marcella, Daniel, and Oma demonstrate that it is possible to have small, successful fashion businesses that are not growth-focused, sharing a mission to draw attention to, preserve and learn from indigenous textiles knowledge systems that are at risk of dying out.

However, when radically indigenous materials are suggested for clothing, questions of scale-ability quickly arise as the impulse to commercialise and grow is privileged over the relational modes of knowing, being and doing that these embody (Escobar, 2018: xi). If we are ever to transition fashion to be produced and consumed within planetary boundaries, then scalability is the wrong focus: small is beautiful. The research underlines the importance of reframing indigenous technologies as innovative rather than primitive, in operating within planetary boundaries. These traditional knowledge systems now have a crucial role to play in re-orientating fashion towards a future where we all may thrive (Watson, 2019; Nakashima, 2010; Magni, 2017; WCED, 1987; Berry, 1990). We must look back - before it is too late - to navigate a way forward.

Design fiction localised

Liene Jakobsone

Art Academy of Latvia
liene.jakobsone@lma.lv

Abstract

This paper presents results of an ongoing research aimed at analysing design fictions created in the Baltics. This research is put forward with purpose of rendering the geography of design fiction more complete and fostering appreciation for diverse worldviews and a pluriversal imagination. The paper introduces the method of design fiction, offers a concise overview of its history, and explains its functionality and use. It discusses the necessity to increase visibility of design fictions from diverse geographical and cultural contexts and places a particular emphasis on Eastern Europe and the Baltic states. Four examples of design fictions generated in this region are presented, all of which are related to a recurring topic of interest in this region: a confident and even intimate relationship with nature. The paper demonstrates that these design fictions reflect (on) one or more of the following factors: 1) arguably nation-wide societal beliefs, assumptions or concerns; 2) a specific natural or artificial environment typical to the area in consideration; 3) a personal lived experience of the author in the given context.

Author keywords

Design fiction, critical design, diversity, localised, futures.

Introduction

Design fiction as a medium for creative expression as well as a research tool is becoming increasingly popular. It is a trend that ought to be cultivated as this kind of reasoning is of political significance. Design fictions are propositions of alternatives; however, they are not projects or designs to be implemented, nor hypothesis to be verified. Rather, they are "advanced with the consciousness that it is an inadequate, subjective and pictorial manner of conception, whose coincidence with reality is, from the start, excluded" (Vaihinger, 1925, p. 268). The purpose of design fiction is "to suspend disbelief about change" (Sterling, 2017, p. 18), to offer new insights and perspectives.

This paper discusses the significance of geographical locality and cultural context of design fiction and aims to counteract the occasionally criticised Western "neo-liberal worldview" (Thackara, 2013) that dominates this branch of design practice. The author claims that fictions generated in various locations can increase the diversity of our collective imaginary and illustrates it by analysing four examples of design fictions created in the Baltics (term used to denote three countries in North-Eastern Europe, Estonia, Latvia and Lithuania). The insights communicated through these fictions have the potential of being relevant and applicable also elsewhere; however, the purpose of this study is not to claim any kind of universal knowledge, as it would be contrary to the author's aspiration of promoting the pluriversal imagination, as formulated by Arturo Escobar (2018, p. 21). Rather, the value of this ongoing research lies in discovering and fostering appreciation for this rich ecosystem of design fictions that are both a result of and a food for our collective imagination.

The examples discussed in this paper are not an exhaustive overview of design fictions that are produced in Baltics and present embeddedness in the local context. It is merely a selection that supports and illustrates the argument, while also complying with the restrictions of the paper length.

History of design fiction

Employment of design fiction as a tool for research, reflection, and inquiry is not only a present-day phenomenon. One of its most significant episodes in design history has been the radical design movement that took place in Italy and Austria in the 1960s and 1970s. Collectives and designers such as *Superstudio*, *Archizoom*, *Memphis*, *Alchimia*, *Haus-Rucker-Co*, Walter Pichler, Hans Hollein, among others, conceived utopian and dystopian visions that were presented by means of various media, such as photocollage, video, drawings and writings, but also tangible objects, performances and exhibitions. They challenged modernist values and worldview and refused the idea of design and architecture as tools in service of the industry, used to promote consumerism and conformity. Their method was aimed at "introducing strange bodies into the system [...] in order to draw attention, arouse interest [...] and inspire actions and behaviours" (Superstudio, 1969). These projects were not intended as proposals for alternatives to the existing reality, but rather—as radical and critical reflections on this reality (Dautrey & Quinz, 2015, p. 24).

The next crucial episode in the history of design fiction is the emergence of the critical design movement in the United Kingdom in the 1990s. Critical design follows in the footsteps of radical design and its "primary intention is to make us think: to raise awareness, expose assumptions, provoke action, spark debate, and even entertain in an intellectual way like literature or film" (Raby, 2008, p. 94). It also employs fictional objects and stories in order to reflect on a vast range of topics, such as implications of technological development, the impact of the material environment on the society, aspects of professional and civic ethics, industry and consumerism (Jakobsone, 2022). The term 'critical design' was first coined by Anthony Dunne and Fiona Raby (Dunne & Raby, 2013, p. 34), who were among the very first to practice and theorise this approach. They were soon followed by others, such as James Auger & Jimmy

Loizeau, Noam Toran, Alexandra Daisy Ginsberg, Tobie Kerrigde, *Sputniko*, Thomas Thwaites, Revital Cohen & Tuur Van Balen, *Superflux, Near Future Laboratory*, and many more.

However, not all designers who produce critical work in form of design fiction, outside the realm of industry and marketplace, identify themselves with the term 'critical design', hence many other denominations are in use to describe this practice, such as speculative design, design fiction, design futures, interrogative design, adversarial design, and discursive design (Dunne & Raby, 2013, p. 11). Many practitioners refuse to be associated with critical design as defined by Dunne & Raby, because Dunne & Raby conceive it as the opposite of the so-called affirmative or conventional design. Although "the direction of this thinking is appealing, its present formulation is [..] vague [and attaches] strong value judgments to it: affirmative design is [..] amoral [..], while critical designers are described as moral agents who seek to change society for the better" (Bardzell & Bardzell, 2013, p. 3299). Design fiction as a tool and approach, however, is not discussed similarly. It is more about envisioning alternatives but without attaching value judgements to them.

Functional fiction

The approach of fiction and speculation is still gaining relevance and is increasingly considered a useful instrument in generating and communicating new knowledge. Speculative design can be employed as a method of inquiry since it "has transcended design and become a contribution to the world of research" (Boserman, 2019, p. 125). Critical design that involves creating fictional products and scenarios can also provide valuable insights for diverse commercial design practices "if adopted by the designer as part of a critical mindset" (Jakobsone, 2019, p. 561). And this method of visioning can prove useful in activating stakeholder reactions, considering that "compelling future-oriented visions are needed to inform and inspire projects in the present" (Irwin, Kossoff, & Tonkinwise, 2015, p. 8).

Design fictions and design futuring have a political significance as well, for "without serious propositional clashes between different materialized futures, we have no politics, and we have no democracy" (White, n.d.). It is within these alternative, critical design environments that the conformity of mainstream design is acknowledged and problematized (Dunne & Raby, 2001, p. 58), and prevailing ideologies [1] and dominant social paradigms[2] are challenged. It can be argued that design fiction is necessary because Western societies have ceased dreaming (Dunne & Raby, 2013, p. 1). Faced with unsolvable problems, designers too seem to start realising that there will be no more 'technological fix' and that we need to change our values, attitudes, beliefs, and behaviours (Dunne & Raby, 2013, p. 2). This is where design fiction plays an important role. Fiona Raby claims that "this kind of design has a value within future decision-making processes", and therefore calls them 'functional fictions' (Raby, 2017, p. 41-42). This term is conceived as the opposite of 'fictional functions', which, according to Raby, characterises many existing, commercial products that may be desirable, but have functions with "no relationship to reality" (Raby, 2017, p. 41). This point of view situates design fiction within the problem-solving design paradigm, even though it acknowledges a different kind of 'usefulness' and 'functionality'. Design fiction can offer other perspectives and worldviews, other points of view that allow us to notice both the unusual and the ordinary that otherwise remain unseen.

Giving voice to the periphery

Lately, awareness in academia of the limitations of the current knowledge production has been growing, followed by an ambition to decolonise knowledge through encouragement of other-than-Western perspectives. It has been widely acknowledged that not only the realities, but also peoples' experiences of reality in various parts of the world can be diverse, and hence such are the imaginaries of our collective futures as well.

Design fictions are predominantly (but not exclusively) future related: they attempt to envision a reality that is credible, but different from the actual one. They are often provocative as well, allowing us to question our collective future without suggesting the preferable path to follow. Design fictions offer insights on potential alternatives that expand our understanding of the world and challenge our assumptions about it.

This paper presents an ongoing work of filling in the blanks in the geography of design fiction, which itself is the result of the imagination. This endeavour builds upon the author's preceding research of critical and speculative approaches in design, and Tony Fry's assertion that there is a false "assumption that, like thinking, imagination is intrinsic to the mind." Instead, according to Fry, "[t]he 'stuff' of imagination comes from what one's being-in-the-world has been exposed to as the basis of what the imagination assembles, transforms and reacts against in its process of prefigurative construction" (Fry, 2022, p. 15). The same applies to the critical potential of design fictions, as one and the same thing can seem unusual and provocative for certain cultures and absolutely mundane for others (Bardzell & Bardzell, 2013, p.3299).

However, in the attempt to decolonise knowledge there is an increased interest for the communities of Global South, while the Eastern regions (the post-Soviet and post-socialist space) of Europe have been almost entirely overlooked (Müller, 2018); or, instead of being viewed as a place where considerable knowledge can be (and is) generated, they have been used merely as research subject (Jehlička, Grīviņš, Visser, & Balázs, 2020). In addressing this issue, the paper proposes an analysis of selected design fictions developed in the Baltic countries that can in certain respects be linked to the local context. The research methodology includes unstructured interviews with designers in question and a review of their writings in relation to the selected projects. These sources, aside from the researcher's interpretation of the fictions' form and content, also allow tracing the designers' intentions and motivations, revealing their interest in research questions and design solutions that are determined by their natural and artificial environment and personal experiences. This research shows how lived experiences in combination with physical surroundings and social habits characteristic to the region translate into design work and allow to arrive at place-specific discoveries.

1 This refers to the writings of Dunne & Raby who discuss the role of designed object as the medium of ideas, values or, in other words, ideologies: "[...] all design is ideological, the design process is informed by values based on a specific worldview, or way of seeing and understanding reality. Design can be described as falling into two very broad categories: affirmative design and critical design." (Dunne & Raby, 2001, p. 58)

2 Dominant social paradigm is a term for a constellation of common values, beliefs, and shared wisdom about the physical and social environments which constitute a society's basic worldview (Dunlap & Van Liere, 1984).

Local stories

A design fiction can be tied to a specific context and based or determined locally in various ways. The examples discussed further represent fictions that reflect (on) one or more of the following factors: 1) supposedly nation-wide societal beliefs, assumptions or concerns; 2) a specific natural or artificial environment typical to the area in consideration; 3) personal lived experience of the author in the given context.

Although many more examples can be given, this paper, due to the limit of length, focuses on only one of the recurring themes for designers in the Baltic region: nature and people's relationship with it. Baltics, along with Scandinavia, is characterised by a relatively low population density compared to the rest of Europe, and by "beliefs of the close ties between the natural and social environments" (Agarin & Grīviņš, 2016, p. 245). Some authors, drawing from the political, social and ideological occurrences of the past couple of centuries, even claim that "the natural environment of the Baltic peoples was actually a national environment" (Sikk & Andersen, 2009, and Agarin, 2009, as cited in Agarin & Grīviņš, 2016, p. 246). The nature seems to be abundant and very meaningful in the Baltic region, and people's peculiar relationship with it also manifests in the topics chosen and approaches taken by designers further described.

Figure 1. Aistė Ambrazevičiūtė, computer renderings of fictional lichens.

For several years, Lithuanian architect **Aistė Ambrazevičiūtė** has been carrying out an interdisciplinary research and design practice that focuses on lichens as a source of new knowledge. As she later realised, her creative practice had been defined by her fascination with nature, in particular, with the wild forests of her homeland: "After my walks [in the forest] I always had plenty of dried lichens at home and it inspired me to document and imitate, play, deconstruct that emotion in 3d space" (Ambrazeviciute, 2021, p. 98). She has studied the biology of lichens, their behaviour as a species as well as separate plants, their materiality, form, logic of construction and growth patterns. Her objective is to explore the "grammar of lichen" and to build her own "alphabet of design" inspired by that of nature (Ambrazeviciute, 2021, p. 98). By means of 3D design software, she then creates an enticing but entirely fictional virtual universe of incredibly intricate volumes and shapes that all comply with the grammar of lichens (figure 1). However, unlike other organic forms and constructions that are quite common throughout the history of architecture and design, these creations are not aimed at being adopted for real-life objects and buildings; instead, they remain virtual and fictional, without ever assuming any specific scale, materiality or function. For Ambrazevičiūtė, this project is more about "searching for unexpected and scattered manifestations of beauty" (Ambrazeviciute, 2021, p. 98). Nonetheless, it is not a mere imitation of visual characteristics, but also an attempt to reveal the "hidden wisdom" of nature (Ambrazevičiūtė, n.d.).

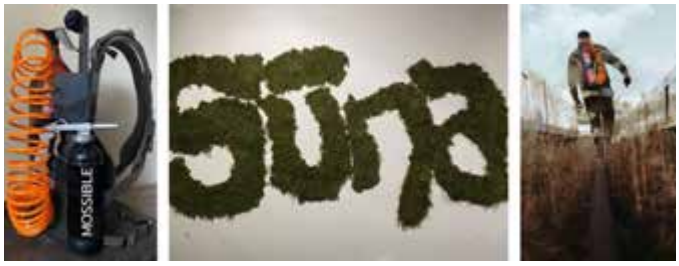

Figure 2. Viesturs Reinis, Mossible.

Similarly, the project *Mossible* by Latvian designer **Viesturs Reinis** manifests the author's personal and familiar relationship with local nature [3] that is expressed by his ongoing interest in moss, considered both for its material and ecological characteristics, and its perceived symbolic meaning (Reinis, 2022, p. 14). In this work, he conceives a fictional product: a device that would allow to create graffiti by using a mash made by mixing water and desiccated, crushed moss, instead of paint. The object is supported by a use-case scenario that, in videos and photocollages, depicts a graffiti artist in action, and it is exhibited along with a realistic reproduction of a graffiti tag in moss (figure 2). Reinis's work seeks to change people's rather negative attitudes towards graffiti by turning it into a tool for capturing CO_2, filtering fine dust and lowering temperatures in cities. When explaining his conceptual approach, he draws parallels (Reinis, 2022, p. 7) with the speculative design project *Pigeon d'Or* by Revital Cohen and Tuur Van Balen (Cohen & Van Balen, 2010). In this project, Cohen and Van Balen consider pigeons as part of the solution for the problems they cause in the city: by use of synthetic biology, they develop bacteria that can modify the metabolism of pigeons in order to make them defecate soap, thus cleaning the surfaces instead of making them dirty. For the sake of the argument, it is worth noting that this fiction too is influenced by a specific context—Belgium[4], where pigeon breeding and races have historically been particularly popular. Hence, we can observe how these very similar topics, both involving purification of the built environment, are approached from two different perspectives that both draw inspiration from local culture and personal experiences.

In their project *Arion Vulgaris*, Latvian designers **Tīna Alise Drupa** and **Jana Ločmele** tackle the complex ecological, ethical and emotional issues related to the Spanish slug: an invasive species that causes serious threat to horticulture in Latvia and elsewhere. There are various methods of containment and elimination of Spanish slug in gardens, but most of them can be considered emotionally disturbing, especially for present-day gardeners (Jakubāne, Pilāte, Stalažs, & Ruņģis, 2022, p. 31-46). Hence, almost like inviting us to some sort of therapeutic session, Drupa and Ločmele challenge our imagination even further by offering a scenario that posits people as natural

3 Reinis is based in Latvia, and furthermore, his hobby reportedly requires him being in the woods. (Reinis, 2022, p. 14).

4 Although currently based in London, Tuur Van Balen is originally from Belgium (Cohen & Van Balen, About, n.d.).

predators for Spanish slugs in a speculative attempt to re-establish equilibrium in the ecosystem. This fiction builds upon the local tradition of gardening and that of pickling as a method of preserving home-grown food for the long winters. Designers propose fermenting Spanish slugs to make them edible for humans, but they materialise this fiction in a very traditional and locally recognisable kitchen scene, thus hinting at how our habits, perception and worldviews oftentimes change faster than our material environment (figure 3).

The choice of the topic for this fiction is clearly prompted by the popularity of gardening in Latvia. Throughout the times of scarcity—both during the Soviet occupation, the transitional period in the 1990s after the fall of the USSR, as well as the crisis of 2008 and the one caused by Covid 19—gardening has been an important source of sustenance and has provided a sense of sovereignty to people in this region. Aside from food provisioning, gardening as an activity and the garden as a place are intimately bound to people's identities providing connection with knowledge and legacy transmitted across generations.

Figure 3. Tīna Alise Drupa & Jana Ločmele, Arion Vulgaris.

The project *Sartorial space* by the Estonian architecture practice ***b210*** also proposes engaging in a close and intimate relationship with nature. From local sheep wool that is otherwise discarded by the industry, they create an object that can be described as something between a piece of clothing and a nomadic shelter housing one person (figure 4). These architects imagine a future world where "owning land and real estate is less attractive and people's freedom and mobility have increased", where "our own space also accompanies us" and "adapts to the body and environment" (b210, n.d.).

Figure 4. b210, Sartorial Space.

Aside from the material used, this fiction seems locally bound also in terms of geographical specificity—a sparsely populated region where one readily gets a feeling of privacy whenever out in nature. This allows designers to suggest that this shelter, which might seem rather individualistic, would actually encourage cooperation and refusal of real estate ownership, since "only someone [..] who doesn't feel the need to defend their personal boundaries" (b210, n.d.) would be willing to share more with fellow humans.

Conclusions

This research into the relationship between the designers' environment, societal or personal beliefs, experiences and the products of their imagination as content for design fiction, is advanced with the ambition of promoting awareness of diversity in knowledge, worldviews and perception in various geographical regions. The author does not claim that all the fictions of a particular region are related only to certain topics, nor that the same subjects could not be considered for design fictions elsewhere. Rather, it aims to show how design fictions can be locally inspired and determined, and it uses concrete examples as illustrations for this claim. These examples are all related to the local context and personally relevant issues; they stem from designers' own experiences, as well as local culture, traditions, upbringing, etc.

Designers' own descriptions and comments on their reasoning and intentions play an important role in this research as they clearly reveal the significance of lived experiences. These experiences are certainly not universal, and nor are the visions and fictions generated as a result. Interviews carried out during this research demonstrate that designers themselves often do not even realise or pay attention to this diversity: for them the issues tackled in their work seem rather obvious. In a broader context, however, certain designs can seem quite radical and offer a new worldview or paradigm, and in any case—increase diversity.

Transit oriented development used to formulate design guidelines for an improved bus network in Malaysia

Blair Kuys, Jo Kuys

Swinburne University of Technology, Melbourne, Australia
bkuys@swin.edu.au, jkuys@swin.edu.au

Abstract

Transit Oriented Development (TOD) underpins the innovative use of urban spaces to create more compact and walkable (more accessible) urban infrastructure. The TOD approach is an innovative form of development that helps diversify transportation systems and provides a new range of development patterns for households, businesses, and cities. In this paper, we outline the TOD method and show how it was used to influence design guidelines for an improved public bus network in Malaysia. We use the TOD Standard Metrics Scorecard to evaluate the current bus system in Kuala Lumpur and highlight the main issues requiring design intervention.

The TOD Standard scoring system distributes 100 points across 12 categories and these points reflect the level of impact of each area when using TOD. The accumulated points within the TOD scoring system refers to how well the studied area is supporting sustainable urban infrastructure. Applying the TOD principles for Kuala Lumpur is intended to form a long-term solution, with short-term impact. As the changes required according to the TOD principles can involve significant urban restructure, there are suggestions given that are not possible in the short-term but should be considered for long-term benefit. A longer-term change proposal will reflect the TOD principles as an optimal outcome to improve the current state of Kuala Lumpur's public transportation networks (beyond 10-years), however, for this paper a shorter-term change is put forward with realistic implementation possibilities within the next 5-years.

Understanding how to use the TOD Standard metrics helps assess existing infrastructure against proposed improvements and gives a clear view of how TOD can radically change the urban landscape with public transportation at the core of all activity. There are obvious limitations to this as certain infrastructure simply cannot change, such as surrounding buildings and major road networks. However, it is important to include TOD principles where possible to establish a framework for design with consideration of what is possible, what is impossible, and what could be possible. From a design point of view, TOD provides a strong justification for design decisions used to better educate stakeholder's around future change. By supporting design proposals with evaluative research underpinning the design intent, we provide greater certainty for design when used to inform decision makers that may not understand or appreciate the impact design intervention can have on urban environments.

Transit Oriented Development; Human Centred Design; Public Transportation; Design Intervention

Introduction

Aligned with the Malaysian governments response to the National Automotive Plan (NAP), this study provides a structured plan to improve the current state of the bus network in Kuala Lumpur, Malaysia. The NAP includes bus development to increase the patronage of sustainable public transport, which is identified as the weak link in the current Mass Rapid Transit (MTR) in Kuala Lumpur. This study presents the outcomes of using Transit Oriented Development (TOD) as a tool to evaluate eight core criteria against the current Malaysian network which is then used to guide design interventions. We provide opportunities for improvements for the Malaysian government to prioritise a sustainable bus system with an aim of increasing patronage for the ailing public transportation network.

Transit Oriented Development was first identified by an American architect and planner named Peter Calthorpe in 1993. As a leader of the New Urbanism Movement, Calthorpe describes TOD as a mixed-use community within walking distance with transit stops and core commercially developed areas (Calthorpe, 1993). Calthorpe argues that transit is more than merely the transportation system; it also comes with fundamental land use logic. He established the general accepted walking distance of 0.8 km in between train stations and 0.4 km walking distance in between bus stops. This is further noted by Jarrett (2012) who describes the unglamorous but essential struggle over the spacing of consecutive stops or stations on a transit line being an area where there's a huge difference in practice around the world.

Figure 1. The geometry of stop spacing as identified by Jarrett (2012).

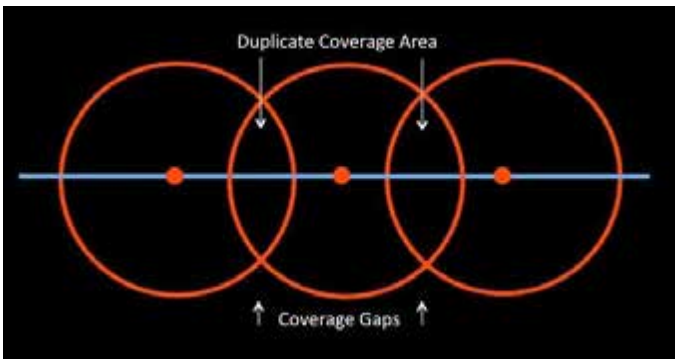

Figure 1. The geometry of stop spacing as identified by Jarrett (2012).

Literature

Support for walking and cycling has a clear need in urban planning (Newton & Bai, 2008). Most current public transportation models operate at the metropolitan scale and fail to include aspects of local scale walking and cycling (Stradling et al., 2007). However, there should be an emphasis on walking and cycling support when developing a public bus system with a human centred design approach (Kuys et al., 2022). This is particularly important to Kuala Lumpur where temperatures rarely drop below 27 degrees Celsius. The hot, humid, sub-tropical climate is uncomfortable and this leads many people to the comfort of their air-conditioned vehicles. While it will be very hard to replicate the comfort of an air-conditioned private vehicle, there will be many other benefits to using an improved bus system that will be much better than a private vehicle such as costs, commuter time, parking, sustainability, safety and the ability to complete other tasks along the journey rather than having to concentrate on driving.

These positive reflections can be evaluated using TOD principles to provide the necessary guidelines to improve the current state of transportation systems in developing countries. By using a TOD approach it aims to reduce vehicle usage and encourage the use of public transit and human-powered transport modes through high density, environmentally friendly development within areas of walking distance (Sung & Oh, 2011). Such TOD approaches have been recognised as one of the key planning methods to solve traffic congestions and to promote uptake in public transportation usage in Asian countries such as Korea, China, and Taiwan (Sung & Oh, 2011). TOD has been increasingly promoted and implemented as a solution to the problems of urban growth (Galelo, Ribeiro & Martinez, 2014). Using the TOD approach provides greater potential in the reduction of vehicle use, increased public transportation usage, and giving a sense of community to the neighbourhood (Newman & Kenworthy, 1999). TOD can be done in different scales depending on the local context it is implemented in. Some cities can implement minimal change while still improving the neighbourhood while others can implement maximum change that drastically improves the community.

Kuala Lumpur has the density which gives locational advantage for using the TOD approach to be successfully implemented. Human centred design studies conducted prior to this study (Kuys et al. 2015; Kuys et al. 2022) shows there are more pedestrians negotiating their way around public infrastructure than those using the public transportation options available. Understanding human behavioural factors is critical to achieving the successful implementation of sustainable public transport systems through more effective and more considered urban design. An improvement in public transportation service quality can attract new users and promote modal shift from private vehicle to public transportation (Eboli & Mazzulla, 2007). Public transport users in the city are mainly concerned with safety, reliability, ease of transit, comfort level while using the public transport system, safety and supervision of the bus stop (Andaleeb, Haq & Ahmed, 2007). These elements can be addressed when introducing the TOD approach in such public transportation development. The TOD approach will not only provide possible future solutions, but also give highly feasible outcomes.

Method

To better understand the present problems with the public transportation in Kuala Lumpur, Malaysia, a field research study based on user observations was carried out. The "fly on the wall" technique was employed as a tool to gather accurate user data in a covert and cost-effective manner (St. Matthew-Daniel & Kamper, 2001). Following this, an online questionnaire was conducted to better understand the present issues that require attention and to demonstrate the value of a HCD strategy. The structured questionnaire was completed by 102 Malaysians and asked ten questions about the participants' experiences with public transportation were posed (refer to Kuys et al. 2022). Major findings from the user observation revealed common pain points and issues when using the current bus system in Kuala Lumpur. Six key themes were identified as follows:

1. Getting on and off the public transport (ingress and egress)
2. Access to remote bus stops and train stations (safety)
3. Smart ticketing system (better integration)
4. The road condition (physical constraints)
5. Real-time display (wayfinding and timetables)
6. Stricter rules around other road users (dedicated bus lane)

These findings were then used to formulate key questions for the questionnaire. Major findings from this phase showed significant favouritism for private car transportation revealing that 75 % of all respondents use their private car daily. Disturbingly, bus usage was one of the least popular choices of daily (7-days per week) and/or often (4–6 days per week) transportation at 8 %, and further to this, over 60 % of respondents had never used the bus system before. 80% of respondents were dissatisfied of the physical design of the bus (interior and exterior), and when evaluating the HCD principles associated with the current bus system, convenience formed the overwhelming majority, followed by the choice of daily transportation and improving the bus shelter location and access (Kuys et al. 2022).

The outcomes of both the user observation research and the questionnaire were used to evaluate the TOD scorecard which is the focus of this paper. We highlight the TOD Standard method used to identify objectives for each principle with measurable indicators evaluated according to the closest approximation of performance against the objectives. The scorecard evaluated the eight key principles of TOD against a score for each section. The maximum score for the evaluation is 100 points divided amongst the following, and the evaluation was determined through careful review of the literature and the aforementioned research from the authors (Kuys et al. 2015; Kuys et al. 2022).

Table 1. Scorecard of the TOD Standard metrics developed by ITDP.

TOD principle	Maximum score
Walk: Walkways, crosswalks, visually active frontage, physically permeable frontage, shade and shelter	15
Cycle: Cycle network, cycle parking at transit stations, cycle park-ing at buildings	5
Connect: Small blocks, prioritised connectivity	15
Transit: Walking distance to transit	Requirement
Mix: Complementary uses, accessi-bility to food, affordable hous-ing	15

Evaluation

To triangulate data and verify our evaluation, a workshop was organised with Dr Luc Nadal, Technical Director of the Institute for Transportation and Development Policy (ITDP) Urban Development to support the proposition of using TOD as a method for improving the current state of Kuala Lumpur's transportation network. This workshop was held in New York and formed a critical part of this study by setting boundaries around TOD principles to help focus the design intent. ITDP is an organisation that was prominent within the literature for TOD principles. ITDP manages a wide range of sustainable urban transportation solutions to improve urban living worldwide and were responsible for developing the eight key principles for the future of mobility in cities with multimodal integration.

For this research, the focus was on the bus network for Kuala Lumpur, however the conversation around TOD principles is relevant to all areas of urban design linking people to transport. The workshop which ran for 3-hours and consisted of four members from ITDP and both authors of this paper, broadened the scope of this research by focusing on the external influences associated with design development, rather than just the design outcome itself. Discussions were focused on implementation using real-world examples where TOD has successfully been implemented. The authors used this workshop as a key milestone to ensure the research had direction from ITDP for validation and oversight of this project.

This demonstrates the translation of literature and research methods into research outcomes based off referenced theory. Along with this previous research, the below evaluation received expert advice from Dr Luc Nadal at ITDP during our workshop. The following summary relates to the TOD Standard Metrics Scorecard used to evaluate the current bus system in Kuala Lumpur. This was useful to provide an informed understanding of the current context to identify areas in need of design intervention.

Table 2. TOD Standard Metrics Scorecard used to evaluate the current bus system in Kuala Lumpur.

TOD principle	TOD Evaluation	Max. score	Score given
Walk	• Walkways: 0 points. Less than 100 per cent of block frontage had safe wheelchair accessible walkways. • Crosswalks: 1 point. 90 per cent of intersections or more have basic requirement meeting local accessibility standards. • Visually active frontage: 2 points. 50 per cent or more have visually active frontage segment measured by windows and accessible open space located along the street wall. • Physically permeable frontage: 2 points. Average number of entrances such as shop entrance per 100 metre of block frontage is 5 or more. • Shade and shelter: 0 points. Less than 75 per cent of all walkways have adequate shade or shelter amenities.	15	5
Cycle	• Cycle network: 0 points. Less than 90 per cent of street is safe for cycling resulting in maximum walking distance to cycling streets is more than 200 metres. • Cycle parking at transit stations: 0 points. Multi-space racks are provided only in some transit stations. • Cycle parking at buildings: 0 points. Less than 95 per cent of buildings provide ample secure cycle parking. • Cycle access in buildings: 0 points. Cycle access is not required by building codes or bylaws.	5	0
Connect	• Small blocks: 4 points. Some blocks within the development is less than 150 metres in length. • Prioritised connectivity: 1 point. Number of intersections representing prioritised connectivity ratio is low.	15	5
Transit	• Walking distance to transit: Does not meet TOD standard requirement. Maximum walking distance is more than 1 kilometre to a high-capacity transit station or more than 500 metres to a direct service station.	—	—
Mix	• Complementary uses: 0 points. Less than half of the floor area of a development in predominantly residential uses have non-residential uses. • Accessibility to food: 1 point. 80 per cent or more of the buildings are within walking distance to a source of fresh food. • Affordable housing: 4 points. 20 per cent or more of all residential units are affordable.	15	5
Densify	• Land use density: 0 points. Total residential population, jobs and visitors is lower than the baseline density. Baseline density is determined by estimation of total residential population, number of jobs in the area.	15	0
Compact	• Urban site: 1 point. One side adjoins built-up sites creating low interaction points. • Transit options: 1 point. Minimal number of different transit options that are accessible within walking distance.	15	2
Shift	• Off-street parking: 1 point. Non-residential parking area is equivalent to 35 per cent or less of site area. • Driveway Density: 2 points. Average driveway density is 2 or less driveways per 100 metre of block frontage. • Roadway area: 5 points. Motor vehicle area is 20 per cent or less of site area.	20	8
	TOTAL	**100**	**25**

This evaluation shows significant improvement required for the Malaysian bus network having received a score of 25/100 when scored against the TOD Standard Metrics Scorecard. Results were then used to convert the TOD metrics into specific issues with suggested plausible solutions. Key criteria for this evaluation showing how the initial TOD analysis led to design intervention is as follows:

- To identify gaps and opportunities for improvements.
- Implement walkability and cycle friendliness where possible.
- Evaluate existing structure to identify investment opportunities.
- To provide guided policy and regulations relevant to urban planning, transport planning and urban design.

This criterion was then used to effectively highlight defined issues mapped against proposed design intervention as follow:

Table 3. Main issues identified as needing design intervention to improve the current bus system in Kuala Lumpur.

Issue identified	Design intervention
Getting on and off the public transport (ingress and egress).	Ensure buses have a low-floor platform and the bus stop aligns with the bus floor, while accommodating all users (eg. Wheel-chair bound patrons).
Access to remote bus stops and train stations.	Overlaying TOD principles to the entire bus network ensures walking distances to bus stops are reduced and network recon-figurations connects different modes of transport to the new bus network.
The condition and size of the pave-ments (and roads) – public infra-struc-ture.	Recommendations to prioritise public transport usage over private car ownership. Development of new bus stops to im-prove the public infrastructure along the bus routes. Emphasis on a human centred design approach to ensure the user is at the forefront of development.
Efficiency of service – frequency of bus-es.	It is anticipated that an improved bus network will increase patronage allowing for more frequent services. Infographics and improved bus stops will be more informative and users will better understand waiting times. Dedicated bus lanes and priority given to the bus network will significantly improve the efficiency of the service.
Comfort and recog-nition of bus stops.	Complete redesign of bus stop allowing for modular construc-tion for installation in different contexts – such as terrain, space allocation, popularity of area (heavy tourist usage), and existing infrastructure.
Wayfinding and public communica-ti-ons including timetables.	Digital displays (solar powered) integrated into each bus stop and buses are colour coded to align with each route. Bus routes are developed to be more recognisable and link to each bus within the network. Bus service times are displayed on each bus to allow the user to know exactly how long the waiting time is. Clear and accurate information improves the overall customer experience.
Stricter rules around other road users – dedicated bus lanes that are not infringed upon.	Proposing clearly defined dedicated bus lanes which could include concrete step barriers on the central reservation of motorways. This would physically prevent vehicles from using these dedicated lanes and will ensure they are reserved specifi-cally for the Kuala Lumpur bus network.

These suggestions are realistic and based off significant research by those that would use the newly developed bus system for Kuala Lumpur. The solutions identified above through the TOD evaluation were all advanced into design proposals. Due to size limitations of this paper, we provide two examples. The first shows the inclusion of dedicated bus lanes, improved footpaths and dedicated cycling lanes to existing infrastructure, and the second shows an improved bus stop which includes multiple solutions listed above.

Application

TOD principles have helped define parameters for change – some significant, and others incremental. The below section shows how TOD principles can be used to change existing city infrastructure with minimal negative effect to the streetscape. This has been done by many cities around the world ensuring that buses, pedestrians and cyclists have priority over vehicles. By making positive change to the infrastructure, the bus and the developed bus stops will further be enhanced. The holistic view of this system needs to address all negative elements seen within the research to maximise acceptance of this new system. The two examples provided below have been developed within one identified area of Kuala Lumpur. These examples show how TOD principles informed design development and are used for others to better understand how a design method (TOD) is applied to design recommendations.

Dedicated bus lanes, improved footpaths and dedicated cycling lanes

The Kuala Lumpur CBD centres around the high tourist area of the Patronas Twin Towers. Surrounding this highly populated area is a network of two and three-lane highways circling the city. A network of interconnected roads in a city that is dominated by private car ownership makes this area highly congested. Figures 2 and 3 show one identified area on the fringe of the CBD – A three-lane highway with adequate room for improvements without having to change much of the infrastructure. The main changes would be dedicated bus lanes either side of the highway, a dedicated cycling lane on one side of the highway, and improvements to the footpaths on both sides of the highway. It is understood that this would still cost a considerable amount of money, however this is significantly lower than major public transport interventions such as improved rail. Private car owners and bus drivers will also need education of the changes suggested and the laws will need to be enforced to ensure bus lanes are not interfered with.

The inclusion of dedicated bus lanes (burgundy), improved footpaths (yellow) and dedicated cycling lanes (blue) are all possible in the current infrastructure without radical development. By doing this, we would immediately address a number of issues identified in Table 3.

Bus stop design

A major intervention based off the TOD evaluation is the design of an improved bus stop. Research showed that promoting bus usage requires wider consideration of the whole system. When people have a poor experience at bus stops while waiting for the bus to arrive it directly relates to the whole bus riding experience. As mentioned by Beirão (2007) improving the quality of the bus stops will result in better service quality. Often time waiting at a bus stop can exceed the actual time on the bus, so the experience commuters have while waiting is just as important as the experience commuters have while travelling.

Figure 2. A major highway on the fringe of Kuala Lumpur CBD.

Figure 3. Intervention to the current road network of KL using TOD principles to suggest immediate change.

Designing a bus stop must consider user needs and should include user wants. Creating an informative and pleasant space for the users to wait for their bus is particularly important given the hot sub-tropical weather conditions in Malaysia. It is understood, however that creating an improved bus stop environment may actually cause a transverse effect and bus stops may become a social space people enjoy being at. Creating a multipurpose waiting area for people to use will have a positive reflection on using the bus, however intervention may be required if people misuse this space to simply relax and stay out of the sun if they occupy all the available space away from genuine commuters.

Effective and safe spaces need to be developed to understand the relationship between systems, environments and the entire systems structure which sets the design guidelines for design development in this area. The following is a selection of initial concept sketches exploring new developments for the bus stop for Kuala Lumpur, based largely off TOD principles.

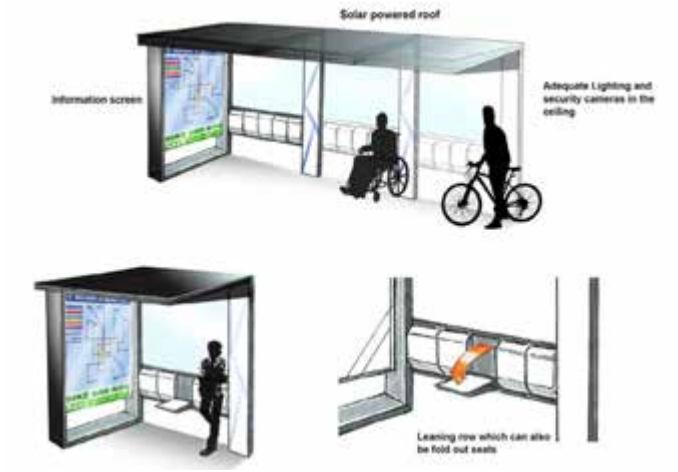

Figure 4. Concept sketching of bus stops incorporating proposed design solutions.

Refinement of selected concepts was completed with emphasis on passenger comfort during waiting, information graphics and wayfinding, as well as passive cooling techniques. Ingress and egress design elements were also a major focus to ensure the bus stops accommodate a wide range of users and integrate seamlessly with the bus network.

Conclusion

Field research and analysis of the questionnaire, along with the application of TOD principles, helped define the research objectives by narrowing down the focus in areas of specific importance to Kuala Lumpur. Observations found inadequate pedestrian and road conditions in Kuala Lumpur, as well as a lack of priority given to the bus network. Overall, the user experience of travelling by bus in Kuala Lumpur is poor. Alarmingly, the questionnaire revealed that over 60% of respondents never use the bus system available in Kuala Lumpur, showing the overwhelming majority of potential patrons are private car users creating a large segment to target with an anticipated modal shift. In order to entice people from their private car to a public transportation system, improvements must be made. This led to the urban planning metrics using the TOD Standard. This framework focused on an improved bus system to create a more sustainable city and attract patrons back to public transport. With an improved public bus system, there will be increased uptake resulting in more vibrant, sustainable communities. This is where the true value of TOD implementation lies and with small steps implementing these principles in critical areas comes large change. To put simply, a better system working off a very poor current base in Kuala Lumpur, will create greater uptake and influence modal shifts toward a more sustainable alternative. This is a slow process to implement, however governments must not be complacent and lead change in a positive direction. By supporting and changing the physical infrastructure and improving the existing networks, people will see the benefits. This is critical as the human behaviours toward such systems have to change and positive government intervention will help influence this change. TOD can be used as an alternative form of urbanism that reduces heavy reliance of the private vehicles (Cervero & Day, 2008). As highlighted in the eight principles of the TOD approach, integrating TOD principles will bring positive change to current lifestyles by better connecting people with the city they live in. Many successful businesses and organisations embrace user involvement methods in their innovation process (Steen, 2011). TOD is used to support community vitalisation and to gain great benefit for the community, not only environmentally but also socially.

Exploring sustainable ecosystems in the "15-minute" urban living circle — take Shanghai Urban Space Season 2021 as an example

Ran Tan[1], Yu Wu[2]

Abstract

As a new urban model, the 15-minute city has gradually become a touchstone to measure the future sustainability of cities. With the time-limited planning of urban living circle, urban residents can be allowed to access basic daily needs such as food, health and education while walking or cycling, thus reducing motor traffic and carbon dioxide emissions and contributing to the improvement of people's well-being and the environmental climate. The proposition of building the 15-minute Community-life Circle has been put forward in Shanghai Master Plan 2035. Since 2016, such working standards as Shanghai Planning Guidance of 15-Minute Community-Life Circle, Spatial Planning Guidance Community Life Unit have been continuously released and updated for gradually conducting progressive and incremental circle practices and exploring a path of low-cost, low-emission and low-pollution urban sustainable development. In September 2021, with the theme of 15-minute Community-Life Circle – People's City, SUSAS2021 carried out a two-month urban space art season in 16 communities and 1 theme exhibition area, demonstrating the construction practice of low-carbon life suitable for living, working, traveling, learning and raising in Shanghai.

With SUSAS2021 as a specific case, this paper is aimed at exploring a system design method of sustainability concept in the construction of urban life circle with a time limit of 15 minutes. By applying the method of interdisciplinary research, this paper makes a systematic analysis and impact evaluation on its climate adaptability from four aspects: urban renewal, shared community, low carbon living and smart network platform. With the practice results as the research evidence, this paper summarizes the experience of sustainable ecological construction in urban life circle, introspects and discusses the practical problems and comprehensive feedback during the practice, and then puts forward a sustainable system design framework for 15-minute urban construction and a feasible adaptation scheme for studying this method. Under the ever-changing climate environment, the new zero-carbon city model will be an extensively, profoundly systematic change in economic and social development.

Introduction

The concept of the "15-minute City" was proposed by Professor Carlos Moreno and widely used by the mass media in 2016. It was then adopted by policy makers in Paris and sparked discussion in other cities around the world. The concept supports the demand for indicators based on proximity to better serve urban areas (Moreno et al., 2021). It also points out that the quality of life in cities is inversely proportional to commuting time, especially in the use of cars. Excessive car use on city streets can significantly increase greenhouse gas emissions and energy consumption, resulting in poor urban air quality and lasting negative impacts on biodiversity and quality of life. In addition to psychological and social losses, the negative consequences of traffic congestion are also translated into time, economic and ecological losses (Gössling, 2020). So, the re-thinking of cities to facilitate walkability and cycling would, in turn, inspires the creation of parks, squares and public places within neighborhoods (Gehl & Rogers, 2013) and helps realize the vision of urban sustainability and resilience and build a sustainable climate adaptation framework for urban ecosystems.

At present, Paris, Melbourne, Ottawa and other cities have started the practice of chrono-urbanism planning to actively deal with urban problems. In 2017, Shanghai put forward the idea of creating a "15-minute community life circle (CLC)" in its 2017-2035 development blueprint, and formulated unified action guidance. Since then, Shanghai has progressively put the concept into practice. Shanghai Urban Space Season 2021 (SUSAS2021), which will be studied in this paper, is a concentrated demonstration of the practical achievements of the "15-minute CLC" in Shanghai. This paper adopts the research method of case analysis. Firstly, the paper combs the key theories and relevant research literature, then summarizes a feasible sustainable system design method based on the case of Shanghai Urban Art Season, and finally discusses and reflects on the adaptability of sustainable system design in the

15-minute city based on the actual case feedback. The study of the ecological characteristics and convenience of urban renewal based on the theory of chrono-urbanism. The purpose is to explore a sustainable system design scheme based on the 15-minute urban concept to address many challenges brought by future urban problems and climate change.

Literature Review

15-minute CLC

At present, urban development is facing multiple challenges caused by climate change and social ecology. In this context, reconsidering the sustainable urban development model and transformation has been regarded as the future direction and inevitable choice of global urban development (Jabareen, 2013). As early as the 1950s and 1960s, Japan put forward the concept of "life circle" in a broad sense for the first time in response to urban problems such as resource concentration, regional differences and environmental pollution (Zuopeng et al., 2014). The concept defines the space scope of work, shopping, leisure, education and medical care required for daily life based on the residence of residents, and defines this scope as the basic space unit of the life circle. Subsequently, South Korea and Taiwan(China) in Asia have also carried out research and practice on the concept of life circle. At the Paris Climate Summit in 2016, Carlos Moreno first put forward the concept of a 15-minute city based on " chrono-urbanism" (Mulíček et al., 2014). This concept emphasizes the proximity of all basic services to solve the dependence on cars, thus promoting ecological sustainability, social interaction and public participation. In the same year, Shanghai formulated the planning guidelines for the construction of the "15-minute CLC", and proposed the community as the platform for urban basic life. The goal is to build Shanghai into a sustainable, safe, friendly and comfortable smart city. Residents can meet the needs of education, culture, medical care, elderly care, sports, commerce and other public service facilities within the 15-minute walking range. From the perspective of radiation scope, they all radiate outward from the center, emphasizing the accessibility of space within the time limit, whether it is the concept of life circle proposed by Japan in the early years, the 15-minute city proposed by Carlos Moreno, or the 15-minute CLC plan implemented in Shanghai. However, there are still obvious weaknesses in the current urban environment. The city vision of a 15-minute city (or 15-minute CLC) has not been achieved, and more research and practice need to be invested in the future.

Sustainable System Design

Design for Sustainability, derived from the concept of sustainable development, is a design practice that seeks innovative solutions to cope with environmental, social and economic factors. Systematic thinking is a holistic view of people's view of the world. In the 17th century, French philosopher, mathematician René Descartes (Capra, 1997) created the method of analytical thinking, which promoted the emergence of modern science (Capra & Luisi, 2014), but is not a clear theory. Since the 1920s, system science has experienced a hundred years of development from its infancy to its maturity. At present, as an emerging interdisciplinary discipline, it is at the forefront of international scientific research (Liu & Vrenna, 2021). However, system design is the process of designing a new system that can meet the target requirements to the maximum extent by using the theories and methods of system science. Sustainable system design and sustainable design are interrelated and inclusive, but in the face of various complex and changeable problems in the real world, the overall systematic thinking will help to develop sustainable solutions, and promote the realization of sustainable development goals with the purpose of harmonious coexistence between people, people and nature, people and society.

Case study: Shanghai Urban Space Season 2021

Shanghai's biennial Urban Space Season has been held since 2015 under the theme of "Urban Renewal", "Connection", "Waterfront Space" and "15-Minute CLC" respectively. It aims to combine the display of space art with the practice of urban organic renewal, change the traditional static display into the dynamic interaction in public spaces, so as to explore more connotation and value of urban space. The most recent edition, the 2021 Urban Space Art Season, focused on the building of 15-minute CLC. Compared with the previous seasons, this one lay more stress on people's life, community building and urban ecology.

As an international city, Shanghai occupies a major position in China in terms of economy, culture and society. However, in recent years, due to the impact of urban development and expansion, traffic congestion, housing shortage, environmental pollution and the unacceptably far distance between homes and workplaces have become common urban problems. Cities with complex functions, livable environment, open and sharing surroundings, and local cultural characteristics will become people's vision of future cities. The highest measure of building a people's city is the sense of gain brought by the community life circle. It's imperative to build diversity and richness based on the unique culture and resources of the community and create a differentiated low-carbon and healthy proximate community lifestyle according to local conditions, so as to achieve convenient and shared space quality and open and intensive urban space pattern(Neuhaus, 2015). It is not difficult to see that this is consistent with the temporal urban guidelines of "Proximity, Mixity, Density, Ubiquity" proposed by Professor Carlos Moreno.

Systematic 15-minute CLC planning

Figure 1. 15-minute community life circle planning.

SUSAS2021 showcased the results of organizing living space with the time limit of 15 minutes in Shanghai in the past four

years, emphasizing the connection between the law of life and low-carbon behavior. Focusing on the concept of "livable, workable, travelable, education-friendly and health-friendly", it aimed to improve the quality of space and optimize sustainable ecosystems. The specific measures are as follows:
Livable: Built affordable and sustainable community housing supply systems, ensure that people from all walks of life could settle down in Shanghai, and supported shelters, livable ecology, whole-age care, smart living and resilient security; Increased public space, maintained and updated public facilities, so that citizens could enjoy high quality of life within a 15-minute radius.

Workable: Created more employment opportunities for community life circles within the time limit, reduced the threshold and cost of innovation and entrepreneurship, and provided employment opportunities and services; Effectively alleviated traffic congestion and work-family imbalance caused by long-distance commuting, reduced greenhouse gas emissions caused by traffic, and strove for energy saving and carbon reduction.

Travelable: Created colorful and ubiquitous community leisure space so that people could get close to nature; cultivated green and healthy travel and lifestyle; built distinctive community transportation networks that were slow-paced, friendly, and convenient to travel.

Education-friendly: Provided diverse learning systems, aesthetic classes and community education activities; Encouraged a green, low-carbon and sustainable lifestyle, and created a good learning atmosphere and promoted a lifelong learning philosophy.

Health-friendly: Provided a full life cycle of care within a 15-minute space, including hospitals, rescue stations, nursing homes, public living facilities and care gardens, reduced travel risks and helped reduce carbon emissions.

Figure 2. Key elements of the 15-minute community life circle planning in Shanghai.

The planning of community life circle is to meet people's basic daily needs within the range of walking distance, so as to reduce the number of people's long-distance trips and achieve the goal of reducing carbon emissions. From the perspective of service objects, the planning measures for the whole age group increase the inclusiveness of the project and contribute to social equity. In addition, systematic thinking plays an important role in the 15-minute CLC planning. The emphasis in the project is no longer a single transportation facility or community service planning, but a systematic consideration of the specific needs of people of all ages, both physical and spiritual, starting from public life. Systematic community life circle planning is not a simple addition of all elements. There is overlap and interaction between livable, workable, travelable, education-friendly and health-friendly. For example, the promotion of low carbon life to health, the attraction of public space for the healthy landscape, and so on. Unlike linear relations, systematic planning can promote the interaction between various elements to enhance the ability of self-organization and self-repair, and make it more adaptive.

Sustainable System Design

Figure 3. Community Meta-Box in the theme deduction area of SUSAS2021.

Figure 4. An ecological rain garden in Xinhua Community.

The sustainable system design centered on the 15-minute CLC consists of the key elements of energy, materials, water, ecology, society/economy and culture. The complete plan is to achieve the energy cycle, material cycle, water cycle, ecological cycle, social/economic cycle and cultural cycle, and the six key elements are related, thus forming a complete system. Among them, low-carbon travel, waste material regeneration, rainwater garden, solar power generation, and other measures are all committed to the principle of zero emissions in the community, transforming output (waste) into input (resources) to form a self-generating system. The

Figure 5. Cloud: The public art facilities in the theme deduction area of SUSAS2021.

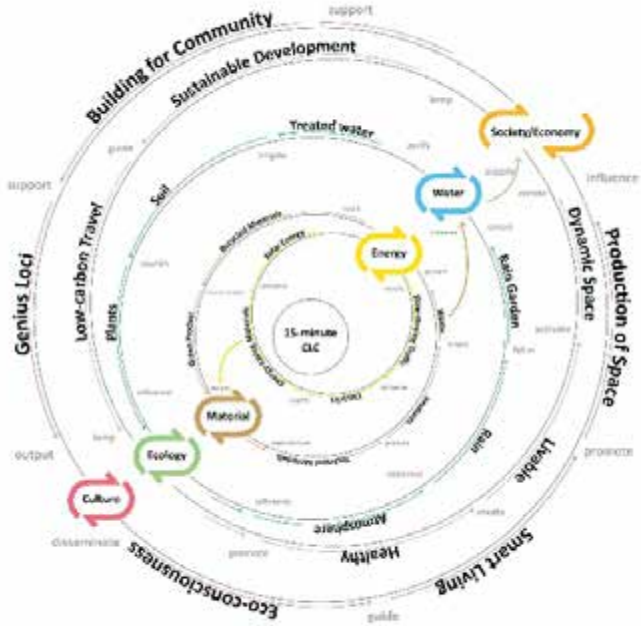

Figure 6. Eco-cycle system model about 15-minute community life circle.

main area of the system design is the local production and consumption system. In addition to the material resources involved, the social, economic and cultural aspects are realized by the participants in the local socio-economic activities. Therefore, the collaborative cooperation of community residents or other stakeholders can help promote the positive interaction between key elements and create new opportunities. Public participation is a key step in the sustainable system design of the 15-minute community life circle, and also an important factor in improving the cohesion and well-being of the community.

It has gradually become the international consensus in the post-epidemic era to regard community as the basic unit of a city and respond to urban problems as communities. To respond to global climate change and fulfill the commitment of the United Nations Climate Conference on net zero emissions, various countries and cities are actively exploring the road of climate adaptation for future urban development. This paper attempts to evaluate the climate adaptability and sustainable ecological effects of Shanghai based on specific urban practices from four dimensions of its urban renewal, shared community, low-carbon life and smart network platform, evaluating the key factors influencing climate change in practice and specific measures for net-zero emissions.

Urban renewal: In the process of building community life circle, the "acupuncture-like" renewal method of minimal design adjustment, actions and implementation cost is proposed; With a focus on the improvement of environmental quality, the existing community gray space was transformed

Figure 3. Spatial typologies: Formal learning space; Individual area; Group area; Webinar / 3600; Arcade / e-learning; Encounter area (Developed by B. Elizondo & D. Gamboa))

into ecological garden featuring carbon sequestration, abandoned factories were preserved and renovated into cultural industrial parks, preserving the cultural characteristics of the city and meanwhile allowing residents to enjoy a high-quality space environment in the adjacent space. Compared with traditional means of demolition and reconstruction, urban renewal with minimal intervention can ensure the goal of improving spatial quality, but at a lower cost. Also, it helps save resources and reduce wastage and carbon emissions. From environmental, economic and cultural perspectives, urban renewal with minimal intervention is more sustainable.

Shared community: Shared community is mainly reflected in sharing governance achievements, tapping into community needs, creating governance mechanisms and building community homes. In the practice of building diverse and shared communities, Shanghai encouraged community planners, social organizations, social workers, volunteers and local enterprises to participate in the joint construction of communities, with emphasis on the planning, construction and management of life circles to ensure localized and sustainable shared communities. At present, more than 180 community projects have been completed in Shanghai. The governance model of shared communities helps multiple stakeholders work together to build low-carbon communities, and share climate responsibility and governance outcomes.

Low-carbon life: low energy, low consumption, low cost lifestyle can start with saving electricity and gas, as well as recycling. On the one hand, as mentioned above, the theme interpretation area of SUSAS2021 is represented by Community Meta-Box, and the materials used are recycled plastic and recycled wood. Clean solar energy was used to power the pavilion, providing a green and low-carbon living place and a new perspective on the sustainable development of the space for the surrounding residents. During the art seasons, sustainable circle experience activities were organized to guide the public to participate in community ecological experience and ecological education in the form of game invitations. Public participation played the most persuasive role in low-carbon environmental protection. On the other hand, proximity to basic services helps to save time wasted on transport, reduce energy

and carbon emissions, and thus promote sustainable transport. The construction of "livable, workable, travelable, education-friendly and health-friendly" 15-minute CLC is conducive to the formation of sustainable ecological effect.

Intelligent network platform: The world is experiencing the fourth industrial revolution featuring ubiquitous information and communication technology (ICT). The proposal of the 15-minute city is considered timely(Allam, 2019). Shanghai explored smart application scenarios on the basis of a 15-minute CLC and took into consideration the community-built interactive scenarios from design, management and governance, ensuring the accessibility of basic amenities and sustainable development of urban space by means of technical support.

Discussion

Community is the basic unit of urban development and the "last kilometer" of multi-stakeholder participation. Life circle planning with a 15-minute radius emphasizes the connection between production, living space and behavior habits, effectively allocate public resources, improve service efficiency, inspire a new low-carbon lifestyle in the post-epidemic era, and enhance the climate adaptability of urban development and public life(Pozoukidou & Chatziyiannaki, 2021).

So far, the practice of "15-minute" CLC in Shanghai has made good progress. The development framework established by SUSAS2021 and the development model of multiple collaboration have begun to bear fruit, and the results of SUSAS2021 have been widely supported and recognized by the public. This practice verified the feasibility of building a sustainable ecosystem of 15-minute CLC, laying a good foundation for the future sustainable urban renewal and climate change adaptation. However, in terms of building sustainable urban system in the future, the current practice of Shanghai is still in the early stage. It is not difficult to find that there is no obvious evaluation standard for the quantification of practical achievements at present, and the development of public space and community construction lacks clear policy incentives. In the future, in the design and transformation of the overall functional zoning of the city, more emphasis should be placed on multiple and composite structural design on the basis of preserving the spatial characteristics, so that the construction of proximate and accessible life circle network can be truly realized, and a sustainable low-carbon urban development environment can be created.

In this study, the exploration of urban sustainable living circle is still in its early stage, but the development framework and practical results proposed are worthy of being applauded. As a relatively successful case of urban transformation, Shanghai's micro-renewal has received widespread attention and recognition from other cities. After SUSAS2021, a total of 52 cities jointly signed the document "15-minute community life circle" Shanghai initiative. It can be expected that in the future, more cities will join in low-carbon and sustainable urban construction and provide climate adaptation solutions for urban development in response to global climate change.

Conclusions

This paper mainly studies the promotion effect of "15-minute CLC" on the construction of sustainable urban ecosystem based on the proximity urban design scheme. Taking SUSAS2021 as an example, this paper studies its climate adaptability and sustainable ecological effects through specific renewal schemes, and points out the positive role of community planning to make it livable and resilient, so as to promote sustainability and reduce carbon emissions.

As the "15-minute CLC" has gained attention and been put into practice in many cities around the world, further research is necessary to demonstrate the differentiated solutions of different cities. In the face of the growing challenges posed by climate change, both rural and urban communities should contribute to future climate adaptation programs. How to establish a sustainable urban ecosystem to support the sustainable development of cities in the critical period of global urban development and transformation is a priority for researchers and urban decision-makers, and also the direction of human efforts to respond to climate change. Obviously, the planning practice of "15-minute CLC" is a solution that helps alleviate urban contradictions and enhance urban climate adaptability.

Research into proximate urban design or the 15-minute CLC will continue, and the concept will be enriched and improved as more cities and stakeholders join in. Let us work together to build sustainable urban ecosystems that are low-carbon, resilient, diverse, inclusive and equitable.

Abstract

The paper describes the first implementation of the Unified Citizen Engagement Approach (UCEA), a newly developed design-oriented framework for citizen engagement in the energy transition. The preliminary testing and evaluation of several of its pathways in Groningen, the Netherlands, show that the role of design in the energy transition is not limited to the adoption of (co)design tools and methods. Instead, design should be integrated in the process in a more holistic way and on multiple levels, taking into account broader issues than energy, the maturity of local initiatives, and effective communication with stakeholders.

Author keywords

co-design, citizen engagement, energy transition, positive energy districts

Introduction

The transition from fossil-fuels to renewable energy sources has become increasingly urgent, not only in the context of reaching the climate goals, but also due to the recent rising costs in energy. Although the energy transition is often perceived to be the responsibility of (national) governments, regions or local governments such as municipalities, it is the citizens who play a pivotal role in the process, as in most cases they are the ones who will ultimately have to implement the appropriate sustainability measures in their homes, change their energy production and consumption patterns and bear any financial consequences (Kalkbrenner & Roosen, 2016; Lennon et al., 2020).

In several countries, such as in the Netherlands, the importance of local energy initiatives, consisting of similarly-minded citizens who have organised themselves in order to collectively address energy-related issues in their own neighbourhoods is acknowledged (Arentsen & Bellekom, 2014; Hasanov & Zuidema, 2018; Soares da Silva & Horlings, 2020). Oftentimes functioning as intermediaries, these initiatives act as repositories for knowledge and manage relations between stakeholders, while in some cases they can play an active role in the strategy formulation for the local energy transition of their district (Hargreaves et al., 2013).

Specifically, the citizen-centred perspective on the energy transition, has led to an interest in exploring the role of co-creation and co-design in the process (Ambole et al., 2019; Ryszawska et al., 2021; Sillak et al., 2021), as the stakeholders involved need to agree on a joint vision in order to successfully implement sustainable interventions, often consisting of (technically and logistically) complex, long-term projects that can have significant impact on a neighbourhood and its residents.

Citizen engagement approaches relating to energy transition are oftentimes designed to only address one actor or stakeholder, leaning towards either technological or social aspects. In the context of this study, the *Unified Citizen Engagement Approach* (UCEA) has been developed, , adopting a more integrated and designerly stance, by combining the perspectives of three main actors (the individual, the initiative and the municipality), and by mainly consisting of (co) design methods and tools.

This paper will discuss the preliminary findings of the testing of several 'pathways' that have been taken through the UCEA by local initiatives in the city of Groningen during the MAKING-CITY project during 2020-2022. The research provides a unique opportunity to evaluate this design-based citizen engagement approach from the local initiatives' perspective, by gaining insights into the implemented co-design tools, as well as into the strength of the model itself in practice.

Background

MAKING-CITY, a Horizon 2020 project funded by the European Commission, aims to demonstrate the possibilities of Positive Energy Districts (PEDs), which are districts that annually generate more (sustainable) energy than they consume (MAKING-CITY, 2023). Eight European cities participate in the project, with Groningen in the Netherlands designated as a pilot city, along with Oulu in Finland. As co-designing the PED together with local residents was one of the main tasks in MAKING-CITY, the project partners in Groningen developed the UCEA, which was based on some of the partners' existing approaches. These include the *Customer Journey to a Natural Gas-free Home* (De Koning et

al., 2020), the *Cooperative Approach* (Grunneger Power, 2023) and the *District Energy Approach* (Municipality of Groningen, 2019). In addition, the Hanze University of Applied Sciences (HUAS) conducted social research, which supported the UCEA's construction.

Co-design in citizen engagement approaches

In the Netherlands, the importance of citizen engagement in the energy transition, particularly through local energy initiatives, has been acknowledged since the past decade (Hisschemoller, 2012; Dóci & Vasileiadou, 2015). Therefore, several citizen engagement approaches have already been developed, such as the *Smart Energy Cities* (SEC) model (Smart Energy Cities, 2023), which integrates the technological and social routes. Other approaches focus on specific audiences, such as *Becoming Sustainable Together with Residents* (Kort et al., 2022), *Moving Together Locally* (Eerland et al., 2020), the *Toolkit Engaging Entrepreneurs in the Energy Transition* (Van Nijkerk et al., 2023) and the aforementioned *Customer Journey*, which focus on home owners associations, local initiatives, entrepreneurs and individual citizens, respectively. Examples of approaches which include multiple stakeholders

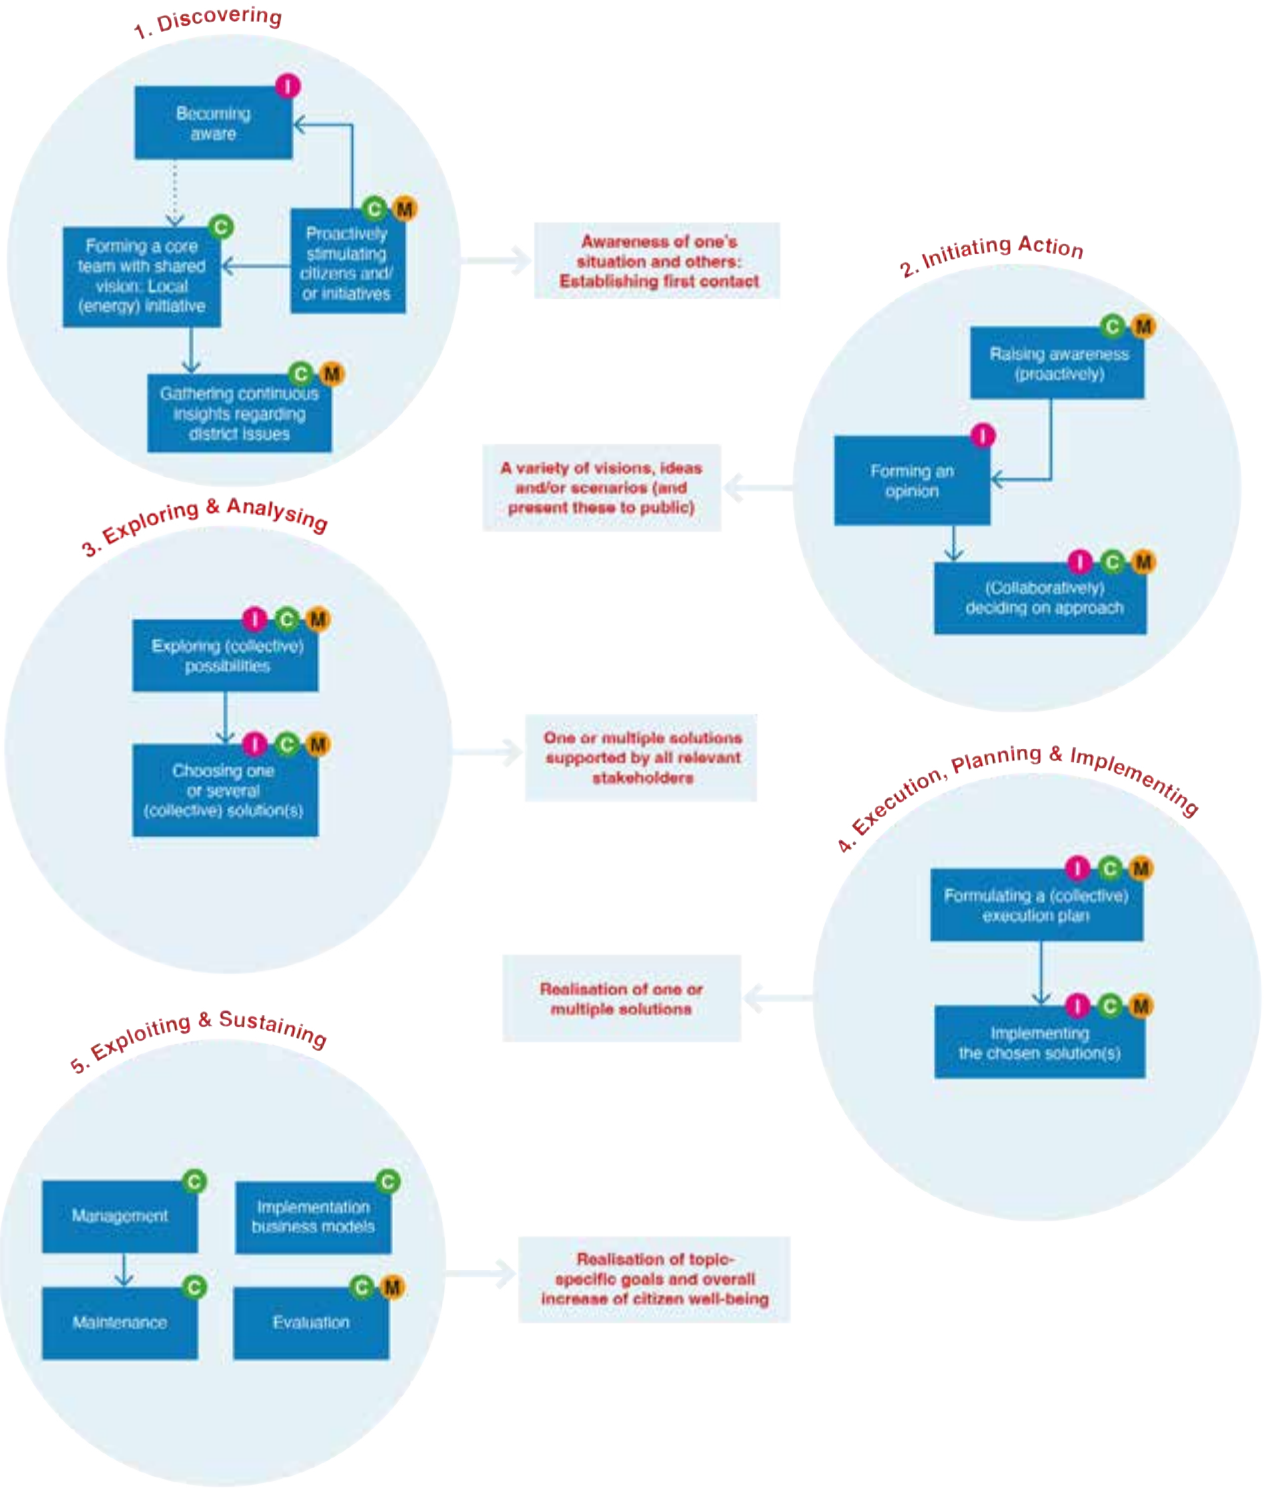

Figure 1. The five phases of the Unified Citizen Engagement Approach (UCEA), outlining actions for the three main actors: the (I)ndividual, the (C)ooperative or initiative, and the (M)unicipality.

include serious games such as the *WE-Energy Game* (Ouariachi, 2021) and *Energy Safari* (Ampatzidou & Gugerell, 2019).

Despite the increasing interest of involving a variety of stakeholders in the energy transition, implementing co-design in the process is currently far from being standard practice. In the citizen engagement approaches discussed above, for example, co-design is not an integral part of the process, or in some cases, is not included at all. Shortall et al. (2022) reviewed 28 recent EU-funded energy transition projects, discussing the extent of citizen participation alongside the associated methods and tools. Although the authors consider co-design as one of most inclusive forms of participation, their review shows in only six projects a form of co-design was used, with only three projects taking a (co)design philosophy as their departure point.

The UCEA aims to go one step further, by including multiple actors and integrating (co)design tools and methods in all of its phases as well as fostering the dynamic nature of the design process, which is reflected in its iterative approach.

The Unified Citizen Engagement Approach (UCEA)

The UCEA consists of five iterative phases, or spaces: 1) *Discovering*, (2) *Initiating Action*, (3) *Exploring & Analysing*, (4) *Executing, Planning & Implementing* and (5) *Exploiting & Sustaining*. Within each space, key activities are outlined for the (I)ndividual, the (C)ooperative or initiative and the (M) unicipality, supported by (co-design) tools that can be used by these actors to reach the objectives within the respective phase (see figure 1). In addition, each activity comes with associated (design) tools and methods (see table 1), which are aimed to help the actor move forward in the process.

The spaces can be initiated or accessed at any time, depending on the questions or needs of the respective actor(s). Activities by different actors can occur simultaneously, both within a phase and in multiple phases. Similarly, going back-and-forth between spaces is also possible, particularly in the first three spaces. This flexibility is inherent to the approach and was designed on purpose, since experience from the field has shown that citizen engagement often does not necessarily follow a linear path. For example, if an activity in a certain phase did not yield the expected result, an actor could choose to initiate an activity from another phase or even take a step back to a previous phase.

Table 1. Excerpt of list of tools & methods for UCEA Phase 1 (Discovering), listing the relevant actors

	Activity		
Tools	Raising awareness (proactively)	Forming an opinion	(Collaboratively) deciding on approach
Collective SWOT analy-sis		I C M	I C M
Design charrettes		I C M	I C M
Ecosystem mapping	C M	C M	C M
Fast idea generator		I C M	

Methodology

The development of the UCEA was preceded by an extensive social research phase conducted by a multidisciplinary research team in close collaboration with local citizen initiatives, which providing insight into various social aspects, such as social cohesion, sustainable behaviour and appropriate communication (Tjahja, 2022). These qualitative research studies, which were conducted during the development of the UCEA, informed the design process of the approach, and influenced the testing and evaluation process.

As it was not feasible within the scope of the project and the time span of the five UCEA phases to test the entire approach, since this would require several years and long-term commitment of stakeholders, a number of pathways through the model have been tested in three districts in Groningen: Hoogkerk, Oosterpark and Oosterpoort (see figure 2). The districts differ in terms of built environment, spatial development and sociodemographics, and the key criterion for selection was the willingness of the respective local neighbourhood initiatives to participate in the project.

All three districts started with the first phase of the UCEA, taking the perspective of the cooperative/initiative, as the pathways were designed in close collaboration with the collaborating local initiatives, considering their current progress, needs and respective local socio-economic context. In addition, each pathway consisted of activities spanning multiple phases, with some of the tools and methods being tested during co-creation events organised by the project partners in collaboration with the local initiatives. The tools were evaluated by means of surveys and interviews with some of the participating actors, such as key members of the initiatives and municipality representatives.

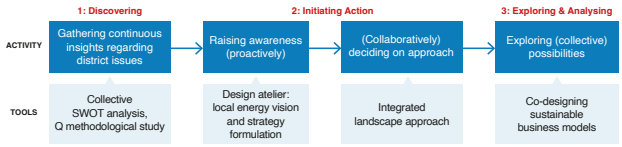

Figure 2. An example of one of the three pathways. In this case, the pathway tested in the district of Hoogkerk in Groningen (October 2021 – June 2022).

Findings

The main findings of the preliminary evaluation of the UCEA have been grouped in broader themes, which will be discussed separately in the following sections.

Broadening the focus

Both the social research studies, as well as the evaluation of the implemented UCEA path in Hoogkerk, show that co-creation events with residents should have a broader focus than only energy transition. Oftentimes, issues related to sustainable energy are intertwined with other (social) issues in the neighbourhood, such as (energy) poverty, social exclusion and safety. Addressing these issues separately is therefore not conducive, necessitating the adoption of a more comprehensive approach. In Hoogkerk, the implementation of the *integrated energy landscape approach* (De Boer & Zuidema, 2015; Picchi et al., 2019), in a number of participatory events, was particularly useful when co-designing a PED-district, as it takes into account the values assigned to the place by the local community.

Maturity and flexibility

The choice of tools and methods used in each stage of the UCEA process should be chosen carefully, as this decision depends on the level of development and readiness ('maturity') of the local initiative and community in relation to local energy transition. Moreover, taking into account the other two actors and trying to connect and potentially include them within suitable moments of the emergent pathway, can be of great importance. Flexibility is recommended when implementing these tools, as they may need to be modified to fit the needs of the initiative or other stakeholders, with some tools being more suitable for certain groups in particular phases or activities.

The evaluation of UCEA finds that while it is adaptable to different contexts, there are inherent restrictions when working with local citizen initiatives or cooperatives. The aforementioned maturity level of the initiative, lack or resources (time, manpower) and their own planning may restrict the types of tools that can be applied. Additionally, initiatives may not follow the same timeline as municipalities or researchers, and their pace should be respected when organizing activities or events.

Moreover, due to the long-term nature of the energy transition process and the variations in maturity of initiatives, it may not be possible to fully follow all five phases of the UCEA, and it is recommended to set up specific pathways instead. The UCEA should be used as a framework to support and guide the actors through the process, without enforcing a certain pace or deadlines, as there is a risk of initiatives abandoning the approach due to this. Additional tools and methods can be added as needed, but their value and impact on other actors and stakeholders should be considered as well as the added value they have over existing tools and how their input/output connects to the other tools in the UCEA.

The importance of a solid communication strategy

The purpose and goals of participatory events should be clearly communicated to both the organizers and attendees, and an explicit framework outlining the process should be used and followed during events. Additionally, the events should be held consistently and on a regular basis, as the outcomes of one event can be used as input for future events. It is also important to consider the number and types of participants, as they can have a significant impact on what in/output is generated. When communicating with the local community, it is important to tailor the strategy to take into account local perspectives on the energy transition. The social research studies conducted in the preliminary phase have shown that events are oftentimes geared towards specific groups, such as homeowners, while unintentionally excluding others, such as tenants, students and landlords. In addition, when using a certain tool or method, it is important to clearly explain the intentions and reasoning behind these decisions to the local community and municipality and to involve them in the process.

Discussion

The findings show in the energy transition is not limited to the usage of (co)design tools and methods with stakeholders, but can play different roles on different levels. First, the expansion of the scope to include broader societal issues than solely the energy transition, should also be reflected in the overall approach, necessitating the inclusion of holistic (co)design methods, such as the aforementioned integrated landscape approach. Consequently, suggested interventions based on these analyses will most likely have a broader (physical) impact on the neighbourhood as well. The inclusion of the municipality as an actor in the UCEA is therefore essential, as these interventions can have an impact on public space.

Second, in addition to co-designing with residents one specific events, such as neighbourhood gatherings or events, the energy transition process as a whole should be a joint effort from its inception, which is evidenced by the fact that the maturity of the initiatives will determine the scope, feasibility and impact of the proposed (design) interventions. Moreover, since input and output of certain tools, in some cases, can be dependent on one another, a careful consideration is needed to determine *which* tool to use *when* and which actions to undertake next. By coordinating the sequence of tools within a pathway in an effective way, a local initiative could, for example, also inspire the two others actors to contribute and encourage them to initiate action themselves.

Third, there is also a role for design in the communication activities surrounding the energy transition process in a neighbourhood, as how the interventions are communicated can potentially influence the awareness, perception, expectations, and ultimately, the degree of support and participation of local residents. The social research studies conducted have shown that communication is often aimed at particular audiences, such as homeowners with a relatively high income, while inadvertently excluding other groups, such as social tenants, students and migrants. A comprehensive communication strategy, for example, through *transmedia storytelling*, which entails systematically conveying a narrative through multiple channels, with each medium providing its own unique contribution (Jenkins, 2008), could be a suitable means to address this issue.

Conclusion

This preliminary evaluation of the UCEA has demonstrated that design can play a much broader role in the energy transition than traditionally envisioned. Furthermore, the inclusion of the three main actors enables fine-tuning of the process, which can have a positive effect on the effectiveness of the tools used as well as the eventual outcome. Although these initial results are promising, more research needs to be conducted to explore other pathways and test the strength of the of the approach itself by investigating the pathways' sequences as well as the tools associated with them. The complete framework as well as its development is described in the project deliverable *D3.11 New citizens' engagement strategies in Groningen* and can be found on the MAKING-CITY website (makingcity.eu).

Abstract

Media trust has been one of the greatest societal challenges given viral outbreaks within a new media landscape, amplifying fear-inducing measures, and information avoidance. Although some research has been carried out on the media (mis)use to inform about viral infections, there has been general lack of information on media design to create this awareness. The purpose of this paper is to contribute to establishing practices to develop virus epidemiologic-themed digital games to raise awareness for viral infections in young adults. Using a qualitative development research involving twenty-six informed individuals in microbiology and game design and thirty-four young adults aged between 18 and 35, a set of guidelines within the project PLAYMUTATION were proposed: (i) Validating the information on the transmission of the virus, measures to prevent and treat viral infections as a topic; (ii) Virtual modelling of the viruses physical interactions; and (iii) Showing implicitly the bio-psycho-social consequences, among others. This paper advances the knowledge of connectivity and creativity in times of conflict by simulating game-based scenarios that may prepare players for acting upon future health crises and outbreaks.

Introduction

The past few years have seen increasing animal and human infections worldwide, which heightened the need for information about pathogens, host-pathogens interactions, and their spread in the general population. Over the course of history, humans have been challenged to lead the eradicating these infections (e.g., smallpox), controlling them by massive vaccination (e.g., measles, mumps), or behavior change – e.g., HIV/AIDS awareness. However, human mobility, and misleading media discourses that may impact people's attitudes, fears and behaviors emphasize the urgent need to leverage science-society debates and digitally mediated health communication strategies to educate about microbial and virus infections and viral outbreaks. Fighting against misinformation and overabundance of information about viral outbreaks also sets a priority in youth education, being media design an important dimension to deal with uncertainty, and medium credibility (Knudsen, Dahlberg, Iversen, Johannesson, &Nygaard, 2022). This latter dimension also tends to be highly dependent on media use.

In fact, the use of media and, in specific, digital games may constitute great opportunities to raise awareness of viral infections and impact behavior change (Putri et al, 2021; Furstrand et al., 2020). In particular, digital games may be a suitable medium for simulating models of infection and dissemination of some pathogens – i.e., easily spread and disseminated airborne viral diseases, comprising a set of pathologies that can be caught by breathing when infected people cough, sneeze, or talk, spewing nasal and throat secretions into the air, beyond touching a contaminated surface that harbors these agents, followed by touching eyes, nose, or mouth that may also result in infection. Some examples of these airborne diseases include COVID-19, the common cold, the common flu, varicella, mumps, and measles. Moreover, games may foster collaborative problem-solving (Li, & Tsai, 2013), stimulate scientific curiosity, and learning about the virus's nature, transmission, and infection (Wang, & Huang, 2021; Lima et al., 2017; Jenson, Taylor, & de Castell, 2011).

In this sense, the aim of the ongoing PLAYMUTATION research project (https://playmutation.web.ua.pt/) is to: (i) Map the use of games in microbiology and media interventions in youngster's attitudes and behaviors relative to viral infections; (ii) Develop and validate the virus epidemiologic-themed digital game interventions (through gameplay and game-it-yourself initiatives); and (iii) Assess the youngsters' attitudes and behaviors relative to viral infections. This paper provides an overview of the game Mutation developed under this project and discuss the role of games to create awareness for health in times of crisis.

The paper is divided into three sections, including the introduction and conclusions: Section 'The Project PLAYMUTATION' presents the aim, approach, and context of the project. Then, the section 'The Digital game Mutation Madness' briefly describes some of the design and development decisions of the game. Finally, section 'Game Design for Situation Awareness

for Health in Times of Crisis' discusses the way this media enables the awareness about viral infections and preparedness in times of crisis.

The Project PLAYMUTATION

The PLAYMUTATION research project – Virus Epidemiologic-themed Digital Games and Youngsters' Attitudes to Viral Infections aims to analyze the use of digital games to inform about the evolution of viral genomes, transmission, and mutations, as well as to promote self-care and infection prevention in youngsters.

The research question that guides this project is "How can virus epidemiologic-themed digital games raise youngsters' awareness of viral infections?" and, as such, it is divided into three phases. For instance, the research begins with the map of the use of games in microbiology and media interventions in youngsters' attitudes and behaviors relative to viral infections (PHASE 1). Then, a virus epidemiologic-themed digital game is developed (PHASE 2), which will serve as the intervention to assess the youngsters' attitudes and behaviors (PHASE 3).

In a broader sense, qualitative research is followed to understand the main design components of virus disease-themed digital games to raise young adults' awareness of virus diseases. PLAYMUTATION began in March 2022 with the consultation of twenty-six informed individuals in microbiology and game design using a 3-round Delphi method to achieve a consensus relative to the requirements of the game, i.e., the informed individuals were asked about the top-leading actions for raising people's awareness of viral infections and rate the whole suggestions in the following rounds.

The game Mutation Madness was then developed within this project, taking the individuals' perspectives into account. The characteristics of the game are described below with the challenge of balancing players' engagement and learning goals beyond intertwining information accuracy and fiction.

After its development, thirty-four young adults aged between 18 and 35 tested and evaluated the game in terms of the player experience (i.e., surveyed about game learnability, clarity of the goal, reward motivation, perceived self-progress, intention of activity repetition, balancing gameplay, item use and sense of control, involvement) and learning and behavior (i.e., surveyed about ways to fight and prevent viral infections, virus characteristics, mutations, preparedness for viral outbreaks, change in perspective), positive and negative aspects, and areas of improvements.

This ongoing project also involves a second stage in which the participants build their own versions of the game Mutation Madness with accurate and validated data about viral infections. This later stage of the project is grounded in the fact that digital games can be used as a mean for fostering youngsters' self-expression in health crisis and communicate own bias and (mis) representations.

In brief, this research sets out to determine the main design components that Game-based Learning should have to learn microbiology, while generating awareness to viral outbreaks and epidemics. The use of games in citizen science and self-expression in the healthcare domain are presented as the major contributions of this project to Game UX design for health education and science learning.

Moreover, the contributions are aligned with the sustainable development goals of ensuring quality education and good health and well-being with the use of media for increasing knowledge in virus epidemics, and changing behaviors associated with pandemics.

The digital game Mutation Madness

The digital game Mutation Madness was developed under the project PLAYMUTATION, aiming to raise young adult's awareness for viral infections. This is a 3d third-person epidemiologic-themed shooter portraying a virologist's attempt to fight against different waves of virus and variants, using different in-game items.

Figure 1 illustrates the gameplay of the game Mutation Madness and acquisition of in-game items using genetic points.

Figure 1. Mutation Madness gameplay and acquisition of in-game items

Each game level corresponds to different city scenarios named after essential concepts relative to viral infections, e.g., Cell city in which virus multiply acting as intracellular parasites, and virus-inspired structure RNA Road and Spike Station as viral genomes, and spike proteins (Flint et al., 2015).

Beyond fighting viruses, the player must find the mystery boxes hidden in each level that unlock different pieces of information relative to the Mad Virus. Figure 2 shows the panel 'Virus Research' to complete with the characteristics of the virus such as its structure, family, distribution, modes of transmission, pathogenicity, symptoms, risk factors, and control measures.

Figure 2. The Virus Research Panel

» Disinfectant that refills the virologist weapon and this is particularly important given that it may inactivate viruses and reduce viral transmissions (Lin et al., 2020);

- Vaccine that acts as the player's shield within time-limit constraints. Vaccines induce immune responses and protect the individuals from viral infections. However, these may lose effectiveness given virus mutations (Louten, 2016);
- Paracetamol is used for the player to restore health-related wellbeing. Paracetamols are analgesic and antipyretic that may make the individual feel better during a viral infection and reduce the effects of its symptoms (France, 2022); and
- Antivirals that enable to deactivate nearby viruses, given its role in blocking the life cycle of the virus (e.g., attachment) and prevent its replication (Louten, 2016).

In a nutshell, the game Mutation Madness addresses the following educational content: Virus characteristics and behaviors; Prevention of viral infections; and Emergence of virus mutation and new variants.

Game Design for Situation Awareness for Health in Times of Crisis

A major contribution of the project PLAYMUTATION was the proposal of guidelines and practices to inform the process of designing and developing digital games to deal with health crisis scenarios.

When designing a digital platform that intends to generate awareness for a specific situation, one should consider the "perception of the elements in the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future" (Endsley & Jones, 2004, p.13). As such, this is a three-stage process in terms of the user experience, i.e., perception of elements in the environment; analysis of the situation; and projection of future actions (Endsley & Jones, 2004).

Additional challenges are posed when analyzing, producing, and evaluating these artifacts with this purpose like ensuring information accuracy, updating, and putting it into context to prevent possible manipulations or misinformation especially when using a media that both fiction and facts are blended. Hence, the following recommendations are proposed:

- Ensure proximity between information sources and game developers during the initial phase corresponding to requirement analysis and initial validation.
- Carefully use the narrative to inform about the situation to not amplify fear-induced messages, panic, or conspiracy theories. Be aware of public policymaking and communication guidelines relative to crisis scenarios.
- Attend the individual's goal relative to health crisis situations – i.e., awareness of health data, goals interpretation, and prediction to achieve the goals.
- Enable role-playing of health crisis communicators and decision-makers to understand the implications of possible health policy-making and societal measures concerning healthcare crises.

In the specific case of the project PLAYMUTATION, the following recommendations arose either from the involvement of informed individuals and young adults who tested the game *Mutation Madness*: (i) Validating the information on the transmission of the virus, measures to prevent and treat viral infections as a topic; (ii) Virtual modelling of the viruses physical interactions; (iii) Showing implicitly the bio-psycho-social consequences; and (iv) Enabling players to spread the message of these activities in their social networks to increase the outreach. In terms of the game-based learning outcomes, most of the participants emphasized that the game allowed them to learn about the occurrence of virus mutations and possible ways to fight against viral infections.

Conclusion

This research set out to establishing practices to develop virus epidemiologic-themed digital games to raise awareness for viral infections in young adults. A three-phase qualitative development was, therefore, followed under the ongoing project PLAYMUTATION: 1. Surveying twenty-six informed individuals in microbiology and game design to identify the game requirements; 2. Development of the game 'Mutation Madness'; and 3. Evaluation of the game with thirty-four young adults aged between 18 and 35. Based on the results from the first- and third- phases, a set of guidelines were outlined, including the validation of the information on the transmission of the virus, measures to prevent and treat viral infections as a topic, virtual modelling of the viruses' physical interactions, among others.

In terms of the second-phase relative to the development of the digital game *Mutation Madness*, a game design awareness process was adopted in its development, incorporating associated stimuli to the representation of viruses, comprehension of the situation, future projection, and decision-making towards a set of actions and feedback, in which the learning content was transmitted implicitly. Beyond applying this process of designing for situation awareness to product design, there is also potential to be extended as the use of media within the city landscape. Participants have revealed that the game enabled to learn possible ways to fight and viral infections, followed with the characteristics of the viruses. Indeed, it demonstrated potential to raise knowledge about viral infections and their virus mutations and variants. Further work is being carried out in the projects PLAYMUTATION2 and YO-MEDIA: Youngsters' Media Literacy in Times of Crisis, in which game development ('Game-It-Yourself' initiatives) is being explored to foster youngsters' self-expression in health crisis and communicate (mis) representations. Games are expected to foster media trust by validating information with specialized individuals in relevant areas to the healthcare crisis, present clearly what results from fiction and reality, present different scenarios, and perspective-taking with possible actions to deal with the crisis.

Finally, it is worth emphasizing that this work advances the use of game design and development activities to self-express in times of crisis, being these contributions essential to understand the role of media development for increasing knowledge and preparedness in times of crisis.

Abstract

The business requirements for environmental responsibility also cover the low environmental impacts for customer use process in addition to low production harm. The environmental impacts caused when the customer needs to search for, use and dispose of the business solution should also be decreased by sustainable business development. This paper describes the content and gamified learning solution for a Massive Open Online Course (MOOC) for small-scale businesses about low impact customer solution design. Since these businesses are unskilled in both user-driven design and service design, and the environmentally responsible customer behaviour tools are multifaceted, the creation of the learning material has applied gamified, step by step solutions. Gamified learning supports planning and problem solving for real-life contexts. Low impact customer solution tools such as canvases, design guidelines and ideation cards also point to game-based possibilities. The MOOC solution used canvas game-boards with stories and challenges to gradually build and interact with the customer solution. The navigation sections included the basics of dual responsibility business needs, a customer-driven approach, service design and communication. The basic canvases and tools included a dual loop for consumption-production systems analysis, customer personas for customer information role play and customer journeys for detailed solution design. The game setting tried to set boundaries to explore the complex systems content in a safe enough environment to promote engagement, self-confidence and control for the small-scale business managers. The MOOC-solution will be tested with small-scale business owners in the late spring and early autumn of 2023. The critical aspects in the material are comprehensibility, support for a customer-driven approach and a low impact customer solution design. The time use efficiency and usability for the busy business learners will be crucial features to follow and improve.

Introduction

Due to the threats of climate change and the drastic decline in biodiversity that relate to the abundance and overconsumption in developed countries and subsequent resource scarcity, the business requirements for environmental responsibility have shifted from merely reducing the environmental harm of production to including low environmental impact from the customer-user processes. Solutions to the ecological sustainability crisis require a reform of economic operation models including the low impact consumption patterns of everyday needs: accommodation, energy and water use, mobility, food and products and services. (Lettenmeier et al., 2019, p. 4-5). Around 70% of CO2 emissions in developed countries are caused by the daily consumption of residential households (Salo & Nissinen, 2017, p. 3-12). Calculations for staying within the 1.5-degree global temperature rise indicate that the environmental impacts of consumption in developed countries should be reduced by 70% by 2030 and 90% by 2050 (Lettenmeier et al., 2019, p. 45). Businesses should support consumers in this necessity of consumption behaviour change.

Many businesses have made efforts to lower their production carbon footprint or other production impacts. Attention is now also being focused on the environmental handprint which points to the climate benefits, or the emissions avoided when the customer is using a product, process, or service. This perspective also traces the positive future effects on emissions instead of focusing on the current negative ones (Sitra, Carbon Handprint). The Finnish Upright project has started to calculate the net impact of companies (Upright project) reducing the handprint from the footprint. The net calculations urge companies to pay attention to their handprint effects, the environmental impact during the consumption process of the solution.

A Massive Open Online Course (MOOC) is being developed for small-scale businesses about issues and tools suitable for the low impact customer behaviour design. It is being created in two overlapping projects focusing on responsible and effective service and product development in the LAB University of Applied Sciences in Finland. The MOOC content includes systems thinking, customer-driven design principles with customer personas and customer journey, and the design

for behaviour change tools. In addition to the business interviews, benchmarks and expert consulting, the material applies earlier gathered and tested collections of customer-driven design tools for environmentally responsible solutions. The array of materials includes qualitative user research-based design guidelines, service design tools and cross-disciplinary, multifaceted environmentally responsible customer behaviour tools (Kälviäinen, 2022; Kälviäinen, 2021; Kälviäinen, 2019). The complex support material for customer-driven development of the low environmental impact customer solutions makes the course content demanding for the business managers suffering from time scarcity. For these reasons the MOOC content has been developed considering the possibilities provided by gamified learning and step by step approaches in coaching the manager-learners.

The learning requirements leading to gamified MOOC idea

The MOOC development so far has consisted of 17 small-scale regional business manager interviews carried out in spring 2022. The businesses demonstrated a lack of customer-orientation but interest in customer understanding. Customer-orientation was interpreted in a narrow way and included aspects such as feedback surveys, or customer encounter feedback. There was a lack of customer studies and customers were not involved in the co-development of products or services. Service design theory suggests providing extended understanding about the pre-, during- and post-stages of the customer journey for the developing customer experience (Stickdorn et al., 2018, 112). Many businesses saw questions of environmental responsibility as big and challenging and experienced difficulties in environmental responsibility communications. There was intimidation around these issues, and in communication a fear of becoming accused of greenwashing.

The needs of these small-scale businesses in terms of the content, structure, and scope of the learning materials indicated that usable material should be easy to obtain from a digital platform and should contain targeted information from experts in the field. The businesses hoped for plain language usage, explanations of important concepts and examples from their own business fields. Practical, easy-to-use tasks to apply on a company-by-company basis were hoped for.

The drafting of the material and learning guidance further happened though business benchmarks in spring 2022 and a series of lectures and co-design training sessions during the spring and autumn 2022. The participant companies in the training sessions requested for memory lists and having practical examples of the solution parts. Additionally, needs for the course to be engaging, innovative, pleasurable, and encouraging were stated. This also meant variation in the material format including videoclips. It was also observed how some of the participating companies were advanced in their environmentally sustainable activities while some were beginners.

The requirements for the guidance for design, ease of use despite the complexity of the materials, needs for engagement and requests for special, business field applicable materials led the MOOC creation group to seek inspiration from gamified learning solutions. These seemed to offer support in coping with the systemic and applied learning demands. Results from gamified learning solutions compared to other non-traditional ones point to learning support for planning, problem solving, imagining real-life situations and creativity (Safapour et al., 2019, 284). Psychological tools for behavioural change have also been found to overlap with gamified learning in environmentally low impact solutions design and in other behaviour change demanding solutions (Kälviäinen, 2021; Bucher, 2020).

Gamified learning involves ways of applying game-oriented thinking to achieve learning engagement through stories, autonomy, meaningful content, challenges, interaction, feedback, and the feeling of achievement. A game setting can provide boundaries to explore content on complex systems in a safe enough environment to enhance self-confidence and control (Kapp, 2012, 15-16). The participating managers of the small-scale businesses hoped for engagement support among other pressing duties and when facing complex content. One support means was a meaningful storyline that interacted with their own business case and development goals. Autonomy, as well as variable levels of knowhow concerning environmentally sustainable business aspects, in addition to specific business needs were met through level-based solutions where the basic learning route was complemented by opportunities to go deeper into specific business or knowledge needs.

The grounds for using gamification rose also from the nature of the game type of tools at hand: canvases describing systems, visual process descriptions, design guidelines and ideation cards. The aim of the gamification was to apply the basic features of games such as game boards, a story, and a challenge so that they unfold gradually and support remembering, a sense of control, decision making, mastering and a sense of achievement. The idea of selecting a customer role persona for a gamer was applied to support the customer-driven perspective. It seemed important not to add other means of gamification to avoid any extra cognitive load.

To avoid cognitive load the whole material in the MOOC was divided into smaller sections, where the interaction for the learner's own business case could be built in small steps through tasks and supporting examples. This tutorial approach of giving first some simple tasks and repeating them by increasing the variation and effort level gradually also points to gamified solutions. Specific business examples were added to the tasks and further support was provided by videos in which selected experts from consultancies and businesses shared their own development perspectives, or the learner was shown how to use the canvas tools. Since in a service design process there are no right answers, memory list types of materials were used at the end of each section for the learners to check if they had considered the provided design instructions. The gamification development led also to ensure the content section titles were visible all the time so that the learners could navigate back when they needed to check information from the earlier sections. This feature is also important as it supports iteration in design thinking.

The section themes created were:

1. The environmental sustainability pressures for businesses and a presentation of the different types of customer groups for sustainable consumption. Tasks include an analysis of the current business situation and a selection of a baseline customer persona role.
2. A customer-driven approach for service solutions with the presentation of the customer journey tool, sustainable consumer trend information and research information about different motivational and behav-

ioural consumer segments. Condensed instructions to carry out qualitative customer research. The tasks include application of the customer journey into the learner's own business offering, its environmental consumption impact areas and developing the stereotyped customer persona into a more realistic business customer for the solution.

3 Service and product redesign instructions about how to avoid environmental consumption impacts, barriers and hindrances to this, and drivers for sustainable consumption. The basic customer journey canvas is elaborated in a form that integrates behaviour change psychology with the drivers for sustainable consumption. Tasks include rethinking the activities where customers produce environmental harm and redesigning the customer journey considering the behavioural psychology features of customer motivation, capabilities, and opportunities in the service moments of pre-, during and post service phases.

4 Communication about the solution with justified, transparent, understandable, and motivating way. The tasks include planning the suitable communication for the selected customer persona and creating a campaign to differentiate the solution in the markets.

The systemic development idea described as a double loop canvas

In addition to regional business interviews a benchmark analysis was conducted in the spring of 2022 scanning national Finnish and international product and service development solutions that support customers' environmentally responsible activities. A systemic double loop canvas was created by analysing these examples to support a modelling the low-impact consumption and production system (Figure 1). It describes the actions of the company and the customer in parallel demonstrating the possibilities and the consequences of dual responsibility for businesses.

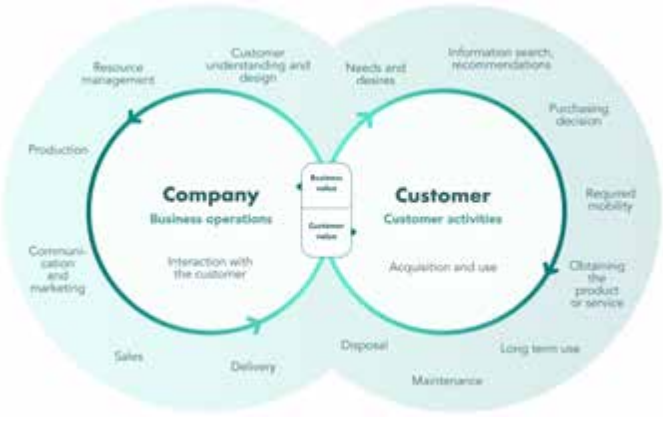

Figure 1. Double loop description of the consumption and production system (figure by Enna Eloranta and the project group 2022).

The idea in the new solution development is to consider first the customer-users, and to point the service moments when the solution can reduce the environmental impact of the customer. This indicates how to change the offering towards low consumption. The idea is to only then analyse the demands of low impact customer-orientated solutions on production. A comparable double loop is used in the United Nations' Sustainable Development goals number 12 Sustainable Consumption and Production pointing to the unsustainable patterns of consumption and production as root causes of the triple planetary crises of climate change, biodiversity loss and pollution (United Nations). The circular economy business solutions point to the need for systemic change in consumption-production systems where many of the solutions are based on services-based processes to reach the outcome of reducing the use of materials and keeping them in closed use circles. With product solutions these include sharing platforms, products as services and product lifecycle extensions. (Sitra & Deloitte 2022). With the consumption-production systems and circular economy solutions it is important to notice that a systemic change towards low, adequacy-based consumption models is necessary in addition to ensuring efficiency of these systems. (Bengtsson et al., 2018).

The advanced layers are provided with two triple loop canvases that make it possible to model the multi-level operations of co-working companies, distribution companies and platform companies offering recycling or customer peer-to-peer services. The loop canvases form the basic canvases or game boards that orientate the business learner to the learning content so that their own customer offerings and production form the starting point with an analysis of the current situation. The loop canvases also provide the vision for the learning so that the initial learning story provides a promise of returning to the production-distribution part of the loop when the customer-orientated design is completed. The loop models help businesses to build a system-based flow understanding of how their services and products offer different service moments and interactions with the possibilities to reduce the environmental impacts of customer use and how then these solution shifts change the related production-distribution activities.

According to the executed training sessions, the loop-based canvases seem to work well to concretize the current situation and in demonstrating the meaningful transformation possibilities within the limits of the current resource situation and collaboration possibilities of the small-scale businesses. The loops also help to change the business perspective from business-centred environmental sustainability to include the customer journey and customer value point of view and even to ask the big questions of adequacy-based consumption. This question is if the customer needs can be satisfied in totally new, low consumption ways.

Game roles from the customer-user perspective

An important notion in transformative design towards low-impact environmental consumption has been to consider how to help businesses meet these challenges of everyday consumption behaviour. A basic understanding of the user-driven development process should begin from an understanding of customer motivation and activities. The customer persona tools help to consider the consumption activities and journeys with the business offerings (Stickdorn et al., 2018, 41-42). The idea in the MOOC is to ask the business owners to put themselves in the roles of their customers and start the learning and solution creation process in the customer's shoes.

The customer section provides information of changing consumption trends. A change towards environmentally responsible desires and increasing consumers' expectations in terms of sustainable choices was clearly visible in 2022 (Ac-

centure Interactive, 2022; Euromonitor International, 2022; Greene & Korkman, 2022). Greene and Korkman (2022) illustrate the changes in the product relationships globally highlighting the consumption shift from the satisfaction of needs and desires to adequacy-based consumption, although still emphasizing the pleasure of consuming. It is relevant to notice the consistent findings in consumer research about the nature-positive attitudes of consumers towards environmental responsibility, but in practice evidence of the lack of responsible actions and behaviours (White & Habib, 2018, p. 9).

In Finland and internationally customer research has demonstrated that there are different types of consumer motivations and actions on the questions of environmental sustainability. Customers expect companies to support their own changing needs for low-impact consumption and to provide products and services based on their sustainability values. By combining information from several earlier studies, a chart of different consumer profiles was created to support the MOOC learner to see the solution from the customers' perspective (Kälviäinen 2022, p.80-103; Kaitosalmi et al., 2021; Salonen et al., 2014). In the first section of the material a four-fold field chart provides the learner with four rather stereotyped personas to represent some different types of sustainable consumers (Figure 2).

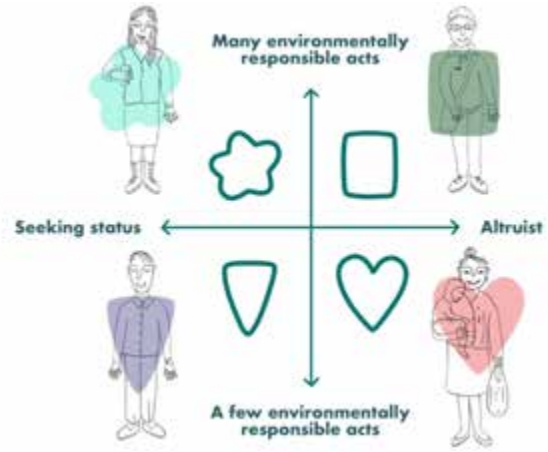

Figure 2. A four-fold field for different consumer profiles and consumer persona examples for environmentally sustainable consumption (figure by Enna Eloranta and the project group 2022).

In Figure 2 the upper parts' consumers perform many environmentally responsible acts and the lower parts' consumers do little. The left parts represent consumers who are concerned with themselves and their own status or image and the right parts those who care about the benefits for the close people or even for the whole planet. The provided stereotyped persona in the left upper corner is a young person who leads an eco-chic life using small, trend-based sustainable solutions. In the right upper corner is an adult student who is deeply committed to environmentally sustainable solutions. In the left lower corner is a technology orientated elderly man interested in status-related environmentally sustainable technology solutions, and in the lower right corner is a mother who seeks family benefits and does some environmentally sustainable acts connected to them.

For the learner, in the first learning section it is possible to select one persona closest to their own customer group to start up the customer-driven learning. The personas are also marked with symbols providing links in the following steps to practical examples concerning each persona. In the second customer-driven section the learner is guided to create a persona or personas that more accurately resemble their own realistic business customers. As a check list the stereotyped personas provide examples of how to create a customer persona and what could be important to find out as customer understanding for the different phases of the consumer journey.

The customer journey as the canvas and process for the design steps

The specific tool to design an offering that supports customers to reduce their environmental impact is a customer journey. This provides a system of service moments where the different possibilities to reduce the individual environmental burden can be designed. Already via the loop canvases in the first section the business managers can mirror their current customer journey against the phases of pre- (finding, choosing, accessing), during (learning to use and using) and post- (disposing, recommending) service. In the second section they are asked to move their offering mapping to a customer journey canvas (Stickdorn et al., 2018, 44-53). This analysis points out the environmental impact areas the customer journey entails in their business. In the third section they start to use relevant consumer advice on low environmental impact to design the new customer journey. The advice is presented from studies of consumer-based carbon emissions and as advice collections attached to a carbon footprint calculator (Salo & Nissinen, 2017; Impiö et al., 2020). The means to reduce emissions due to consumption include reductions of accommodation, mobility, food, and product related environmental impacts (Salo & Nissinen, 2017, p. 14–22). Many of these occur not only in the core service use but in the pre- and post-service use phases.

The gap between consumers' environmentally positive attitudes and less responsible choices and behaviour is influenced by the motivational consumer interests, the pressures of busy everyday life, emotional biases in decision-making, and the lack of necessary individual capabilities (Kälviäinen 2022, p. 155–162). The overflow of choice and marketing in the saturated markets make information about responsible solutions difficult to find and understand, and the messages may be contradictory and confusing (Kälviäinen 2022, p. 180-195). Consumers need service solutions that are interesting, easy to find and understand, are smoothly integrated into their daily lives, and offer suitable support, help and rewards in the required habit changes (Kälviäinen, 2022, p. 209–211). Behavioural psychology explains this using the COM-B model, where the factors of capabilities, opportunities, and motivation all come together supporting a person to behave in a certain way (Mitchie et al. 2011; Bucher, 2020, 116-122).

Figure 3 explains the consumer journey with COM-B factors where the required support for crossing the barriers and providing support can be embedded for a new, low impact customer journey covering the pre-, during-, and post-service stages. On customer journeys and the related service moments and touchpoints, it is possible to integrate interventions to the solutions to both overcome obstacles and utilize customer interests related to them (Kälviäinen, 2022, p. 6). The new customer journey should be made suitable for the customer persona created. Figure 3 is layered with the consumer profile symbols marked examples of service moments and touchpoints suitable for each customer type.

Figure 3. The customer journey with the COM-B model containing service moments and symbols for customer persona related examples (figure by Kälviäinen and the development team 2022).

Advanced level customer-driven tools for service moments and touchpoints are additionally offered based on psychological advice on decision making heuristics and biases that can be used to support behavioural change (Kälviäinen 2022, pp. 22-30; Lockton, 2018). The vast amount of these materials is edited to a minor range and offered in a form where advice is attached to suitable pre-, during- and post-service phases. The pre phase is important for raising interest and the last ones for the formation of new habits. The selection considers the need to build support for behavioural change as a process (Kälviäinen, 2021).

The feedback for the new solution design is offered in the form of guidelines for low impact, customer-driven solutions (Kälviäinen, 2022, pp. 217-219). These guidelines serve as memory cards to check if the solution fulfils the advice given. At the end of the design section the results are further transported to the initial loop canvas, where the consequences of the change in the customer journey can be applied to the production or distribution of the offering.

The fourth learning section for communication uses the achieved design solution as the basis. The step-by-step analysis reminds managers that the information about environmental impacts should be based on true actions and described as factual information. Some of the consumer segments will be interested in this. The customer-driven part for communication reviews the drivers and ways of informing the different types of customers with consumer profile symbols indicated examples. Finally, it proposes ways of carrying out campaigns for differentiation and provides examples of these.

Conclusion: The critical points of the learning material

The main content for the MOOC is challenging as it needs a combination of customer understanding, environmentally responsible possibilities for consumption, and the creation of customer journeys with the needs to encourage psychology-based behavioural change. It is especially challenging for small-scale businesses that struggle even with developing their production-centred environmentally sustainable responsibilities. To ensure the ease-of-use, and a smooth and functional whole the MOOC course will be tested together with a set of regional small-scale businesse managers before the launch in the autumn of 2023. Based on the results, the further development of the support material will be carried out during autumn 2023.

Considering the MOOC-material aims and learning with it, as the conclusion of the work so far, several critical perspectives can be stated. The requirements from the small-scale businesses suggested finding ways of supporting them in sufficiently easy ways despite the complexity of the challenge of the dual responsibility. The comprehensibility of the content has been tackled by trying to build up a step-by-step development story that would make sense from the business managers' point of view. The value for the business in it has been emphasised. Each of the steps is supported by visual canvases that are gradually built to be more complex and are in this way filled in during the development. Examples are offered to support understanding the content.

The, for many small-scale companies, challenging customer-driven attitude is supported by dedicated material, examples and tasks. In addition to basics of it, the low impact customer solutions provide a further challenge because they might require customers to do something they are partly reluctant or too lazy to do. The materials have tried to support the attitude change towards customer-orientation and provide for the customer information and examples attached to the customer personas in the learning and design process.

Support for low impact customer solution design has been the central focus of the learning material. The material has been tested with different types of companies participating during the compiling process. The viability of the material used comes partly from the fact that it contains materials from a long period of development and use with design students and company cases (Kälviäinen 2022). The independent setting in which business managers should be able to use the tools for redesign of their varying business offerings is a new one. These learners do not necessarily possess design skills, and it sets further demands for the usability of the material. The step-by-step redesign process and the usefulness of the different canvases, visualisations and supporting examples can only be verified when the materials are further mirrored against different companies and their customer profile needs.

Time issues for small-scale companies are also central. The editing of the material has considered how to keep the content short enough and further editing should be done on the points where the material and tasks prove to be too time consuming. The time perspective also includes basic usability and ease of navigation.

The aim of creating the learning material has been to support small-scale businesses to identify their own starting points and resources, and to take advantage of consumers' growing interest in environmentally responsible everyday life. The input of regional small-scale businesses in environmentally sustainable transitions is of importance. They are especially influential in local transformative processes, as their offerings typically support consumers in their everyday consumption habits. The support for the small-scale businesses' dual environmental responsibility is important, and it should be made easy and meaningful for them to use. Increasing their customer-driven environmental design expertise strengthens their force to activate the local green transitions for sustainable consumption.

Acknowledgments

This research and development work is conducted by LAB UAS Institute of Design and Fine Arts during the years 2022-2023 in the Coaching for Responsible and Effective Product and Service Development project and in the Anticipating Responsible Service and Product Development project. Both projects are funded by the European Commission Social Fund distributed by the Regional Councils the first one by that of Päijät-Häme and the second one by that of South Karelia.

Abstract

Design is a medium that allows for storytelling, at the same time design can be inspired, informed, or improved by stories. In Design Education, past year's efforts have been made to let the content speak more vividly to the students. We introduce the Future Scenario Development Play and Design methodology as a process for Research through Design. Based on the Future Scenario Development Design methodology (Eggink & Albert de la Bruheze, 2015), this scenario development approach aims at exploring futures that are more than just a few years ahead of us. We expanded the method with a serious game and a general conceptual design phase. The scenario of a plausible future, broken into three-time horizons (5, 15, and 30 years), provides the requirements, opportunities, and constraints for the design. The serious game SES (Scenario Exploration System) (Bontoux & Bengtsson, 2016) provides a safe sandbox for the students to explore two contrasting future scenarios of their own making. Through this half-day experiential exploration students empathise with relevant stakeholders by taking up their role. This approach allows the students to stumble upon the intricacies of their scenarios and set their own creative constraints for the conceptual design phase to follow.

With a case study, based on the results of an Industrial Design Engineering Master course concerning the design of the "Future of Food", we will show how this Design of the Future methodology is able to explain the present and future interplay between society, culture and technology. We will dive deeper into how the experiences from the game sessions influenced the design phase and eventually the design concepts presented by the students.

From the results of the case study, we can conclude that our proposed method provides the students with an effective arsenal of tools to use in their design process while offering them a well-rounded experience through which to envision, empathise with, design and create for the future.

Introduction

In an interconnected and ever-changing world organisations are called to overcome challenges in a fast-paced way. To be prepared for future challenges organisations need to have a level of informed foresight. As Anna Valtonen notes: "The arrival of COVID-19 implies that there will be an even greater need for us to be able to address uncertainty and align ourselves with even more radical transformations. What new practices emerge, and how design can contribute to these changes, is a discussion we have only just begun." (Valtonen, 2020, p.523). To form this new alignment, it is important not only to formulate potential future scenarios but also to succeed at understanding them vividly. This process is complex, data heavy and often-times tedious therefore a structured method can help (Daalhuizen, 2014). Especially for the novice designers that students are (Dorst & Reymen, 2004).

Design by its nature is future-oriented since we use design to envision and create things that do not exist yet. While at the same time, when a design becomes reality, it helps shape the future.

As Göransdotter has stated so eminently: "design is not only – or even primarily – about making things that take on material presence in our lives. Even more, design is about proposing that things could be otherwise. It is about proposing that we could do things differently" (Göransdotter, 2020, p.301). Design education therefore needs to prepare the new generation of designers for challenges in the future. Challenges such as the uncertainty that comes with discussing about the future and the difficulty to try and predict potential effects a design might have on a rapidly changing environment.

In this paper we propose the Future Scenario Development Design & Play methodology aimed at helping designers vividly explain the interplay between Society, Culture, Economy and Technology in the potential futures they create. To expand future scenarios to their full social, economic, and environmental implications we use a combination of scenario building, tangible exploration, and practical design. This method allows designers to interact with the envisioned futures and struggle with their challenges. In this paper we will argue that this helps in creating better/fairer/more responsible/more inclusive results and designs.

In addition to highlighting our methodology, we present a

case study, based on the results of an Industrial Design Engineering Master course concerning the theme "Future of Food".

SES & future studies

Since humanity's early times humans have learned through games and stories (Andreu-Cabrera, 2010). Even though both stories and games today are considered primarily forms of entertainment they can be powerful teaching tools. Serious games have been used in a variety of educational purposes such as mechanical engineering (Sousa, 2020), collaborative ideation (Sousa, 2021) and socio-ecological dynamics (Orduña, 2020). Methods for applying (serious) storytelling in education and design have also been introduced in recent years (Lugmayr, 2017).

The serious game used in this paper has its origins in policy making and collaboration. Created by the Joint Research centre of the European Commision, the Scenario Exploration system (SES) has been used "...to engage stakeholders with foresight scenarios created to support the EU policy-making process." (Boutoux & Bengtsson, 2016). We have made several changes to the game mechanics and philosophy to apply it in the design field while keeping in line with the role-playing and turn-based strategic character of the game.

The SES version we used in this course can be described as a way to explore focal issues in future scenarios. It is designed to help players engage in systemic thinking, discover and create alternative futures, and create novel engagements between stakeholders. In the context of this course, the SES was used as a role-playing serious game where the students/ designers had the opportunity to embody real stakeholders, discover blind spots in their future scenarios and consider the social, cultural and environmental consequences of their potential design.

At the same time the process of creating and playing a game added fun and enthusiasm in the course and allowed the students opportunities for serendipitous discoveries. We found out that students tended to empathise better with the futures they created and the people who would inhabit them, generating better insight into potential dynamics between stakeholders. Aspects such as counter-movements, friction between powers, unexpected events and social pressure were explored, painting a more realistic picture and helping them to avoid utopian/dystopian tropes.

Scenario Development Method

A scenario is a way to envision a possible and plausible future. By making different scenarios, designers can prepare for future events in an ever-changing environment (Göransdotter, 2020). The future is very uncertain, but for our design methodology it is not necessary that the future plays out in the way it is envisioned in a scenario. As Valtonen (2020) indicated, it is all about anticipating a possible future that might be radically different than our present day. A design for a certain scenario may have relevance for any kind of future. By tactically choosing scenarios, it is possible to capture, and design for, a wide spectrum of different futures.

To find these relevant, possible and plausible scenarios', a seven-step method was followed, building on the 6-step method in the Future Scenario Development Design methodology (Eggink & Albert de la Bruheze, 2015), which in its turn is an elaboration of the five-step explorative context scenario methodology (Eggink, Reinders & van der Meulen, 2009). In our continuous effort to improve the methodology. Some alterations were made in order to incorporate the Scenario Exploration System (Bontoux & Bengtsson, 2016) serious game. Together this forms the Future Scenario Development Play and Design methodology presented here see Table 1.

At the end of this process the final scenarios are presented in a visual way and one scenario is chosen to continue within the design phase. It is important to note here that the students were asked to come up with daring and thought-provoking scenarios within the confinements of their chosen focal issue and initial research.

Table 1. Future Scenario Development Play and Design methodology.

Step 1	Focal Issue	A confined theme that is relevant within the context of the given area of interest (in our case food).
Step 2	Actors & factors	An actor network of stakeholders involved in the focal issue categorised in: Policy, Business, Civil Society Organisations, Academia and Citizen groups. Relevant aspects are also outlined.
Step 3	Uncertain-ty/ Rele-vance ma-trix	A matrix mapping the actors and factors based on their uncertainty and relevance on a two-dimensional space. Items that are identified as both important and uncertain, are the building blocks for the different sce-narios.
Step 4	Strategic space	The two key long-term uncertainties are used to create a second two-dimensional space. For an example of a strategic space see Figure 1
Step 5	Scenario plots	Creation of three coherent and plausible scenarios are inspired by balanced developments and extremes in the strategic space.
Step 6	Scenario elaboration	Scenario Plots are fleshed out into full scenario narratives using the structure of three time horizons in the future, forming the basis for exploration.
Step 7	SES game session	Using materials from the 6 earlier steps an SES version is developed. Two contrasting scenarios are chosen to be explored in a 4-hour session.

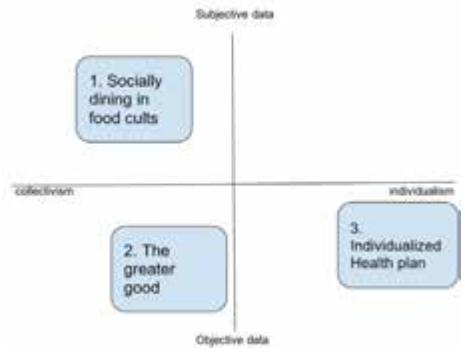

Figure 1. Strategic space example.

Game design//SES

We applied SES as a board game in order to encourage discussion and offer tangible representations of each action, resource and consequence. Yet playing a unique game for each team comes with an amount of necessary preparation. For the game/SES to be played, the outline scenarios of the game need to be created, player's roles as well as event dynamics need to be defined, and finally material needs to be printed.

Starting from the scenarios, these were adapted into three short 200-word stories representing the three time horizons and a short six-bullet summary for conciseness that could fit into cards. Next, four "explorers" (individuals leading existing organisations) were chosen to be played during the game by each of the players. Mostly, actors were chosen to represent a voice from the quadruple helix: Policymaker, Business, Civil Society Organization (CSO) and Academia. Each role has a different dynamic to play in the game, complementing each other from a broad perspective on dynamics at play in future societies. In addition, a large and existing group of individual citizens is chosen, to serve as the "public voice". One participant is assigned to express social judgement of the explorers' actions based on the biases of this group.

Finally, personas were developed for each of the 4 explorers forming a well-rounded character complete with personal information, values and professional goals. The personas were aimed at fostering empathy between the player(student) and explorer(character) as well as offering a framework based on which the player can interpret information and make decisions from the lens of the character. Using the U/I matrix, from the "important & certain region", six so-called mega trends were selected, factors that will be important in any future scenario. In addition, six what-if cards were defined, denoting large-scale events that could disrupt scenarios, to be used in case the game became stale. In addition, one student assistant was appointed for each session as a facilitator. Consecutively, 4-hour sessions were run see Figure 2. The goal of the games was to find the needs or wants of the future society and/or find an opportunity for design.

Directly after the game itself see Figure 3, a short facilitated reflective session was held per group. Making sure to summarise thoughts and get some discussion going about the long session. Events and actions taken in the game were reflected on, answering questions like: How diverse groups of people would feel during the scenario's playing out? Was this a desirable future? What could design do to influence this future, or the road towards it? In the final phase, it was up to the groups

Figure 3. SES game board at the end of a game.

themselves, using their design knowledge, to make a design set into this future.

Design Case: Future of Food

Food as a broad topic is interconnected with both nature and humanity. Therefore, on a macro level food supply also faces challenges from population increase and climate change, while on a micro level food relates to personal health, culture, lifestyle, and preferences. The future of food is therefore an excellent carrier for the investigation of the future interplay between Society, Culture, Economy, and Technology. A lot of the current and future challenges that food faces (climate change, migration, cultural shifts) are complicated issues calling for transdisciplinary collaboration aimed at transformational change.

The future of Food was investigated within the master course Create the Future. The course itself was set out as project-oriented education (Ponsen & Ruijter, 2002), arranged around the theme of Food. It lasted ten weeks and needed the workload of five European credits. The course was split into two sections: building, exploring and visual presentation of future scenarios, followed by development of design concepts within these future scenarios. Forty students took part in the course organised in eight groups, resulting in eight unique design examples from which we have selected the two examples presented here.

Design Example 1: Lokaal is Lekker (Local is Delicious)

The students chose to focus on the future of Nutrition and Health for adults in the Netherlands. The focal issue was then

Figure 2. SES game in process.

Figure 4. "Lokaal is Lekker" design.

formulated as: "How will our society evolve if global trade, mobility and large-scale food distribution becomes non-viable?".

Putting a lot of weight into availability of nutritional information, legislation, marketing, food availability and environmental factors, the students chose one of the four scenarios they developed in the course as their future context. This scenario is characterised by increased general population health and improved wealth equality in the context of a highly regulated market and full transition to local produce. In this future context a stock market crash has limited global trade and caused imported food prices to rise drastically. As a result, population growth and migration slow down while food supply becomes local. The envisioned scenario was also altered during the SES game. While an environmental crisis destabilised national food production, a community-spirit emerged from the collaboration among the explorers.

The students designed the structure of a Community-"Supermarket"-Greenhouse complex (see Figure 4 aimed at helping local communities with food independence in seven steps: Preservation of food and agricultural knowledge via a *Museum*, a *Greenhouse* for local and seasonal food, a *Community* area for collaboration and learning, *Educational* programs with experts, a *Restaurant* for tasting and gathering, a *Supermarket* offering the locally grown crops and *Delivery* for citizens with restricted mobility.

The complex aspires to be self-sustaining by integrating with the infrastructure of the community and reusing resources (such as compost, sewage and rainwater). While at the same time applying old and traditional agricultural methods such as crop rotation to preserve soil fertility.

Design Example 2: Food Delivery / Kitchen of the Future

The students chose to focus on the future of food distribution and delivery in the Netherlands. Based on the growing trend and normalisation of food delivery, attached to health and environmental challenges, the students formulated their focal issue as: "How will our society evolve if food delivery will be the norm instead of an exception?".

They chose one of the four scenarios they developed in the course as their future context. In this scenario, today's platform economy, where restaurants offer meals through a delivery platform, becomes the norm. Positioning themselves as a commodity for every family, these restaurants minimise end-consumer cooking effort while trying to preserve family-style dinners by offering family meal options. Citizens, in this scenario, put emphasis on convenience and are universally accepting of this new system. Everyday food has been industrialised, minimising food waste and optimising efficiency. At the same time cooking ability is decreased within the younger generations and is treated as a niche hobby.

Figure 5. design of "Kitchen of the Future"

The future scenario was altered during the SES session when the need for strict food quality and nutritional standards regulation became clear. At the same time, the social aspect of cooking itself and not just eating was highlighted, prompting the students to envision alternatives for the cooking experience in VR as well as in cooking seminars, similar to today's sewing or woodworking seminars.

The students designed a food delivery system along with a living space arrangement considering emission minimization, preservation of food quality in the supply chain and social structures Figure 5.

Discussion

While envisioning the future it is easy to fall into our own biases and overlook social and environmental side-effects of a design. For us to think about the future and have future-oriented discussions in a structured and informed way futuring methods are needed, despite the level of complexity and uncertainty they force us to accept. An explorative process can therefore be beneficial to fully utilise future predictions, and in that regard, we succeeded in introducing this new method to students. We managed to get them some preliminary experience with futuring methods and by extension, role-playing and explorative methods at large, so that they can apply it when they are called to design for our future.

One remaining challenge is for the students to fully immerse themselves in the scenarios, which would be advantageous to help them empathise more with the situations at hand and the people involved. Not all groups achieved a satisfactory level of immersion. Compared to other methods, like day in the life scenarios, it helped them to look at all aspects of the theme. Students depended on their teammates to embody their characters fully, therefore some teams lacked the right degree of dynamics in their play. Of course, this kind of method requires practice, and it was apparent that students who already had some role-playing experience were easier to adapt and embody their characters. Interestingly even a small amount of experience appeared to be sufficient. When the second scenario was played (about 1,5h of play) students appeared more motivated and immersed. A break in between the two time horizons, with some discussions about the flow of the game, may have facilitated this improvement.

From a practical perspective, the course had been quite intensive on academic staff resources, as for every SES session a facilitator needs to be hired for a 4-hour session plus preparation. To lessen the burden on the resources, we would like to try expanding the teams to 6 students and allow the students to self-moderate their own sessions.

In the Design Phase, students focused on a need they discovered in their scenarios after the exploration phase. In our opinion a lot more can be done with addressing the responsibility of Designers regarding their creation (Eggink et al., 2020). A design is at risk of becoming one-sided, especially when real (future) stakeholders do not exist yet (Dorrestijn, Van der Voort & Verbeek, 2014), and tools to understand the influence on people can be quite suitable. An example of such a tool that fits this method well is the Product Impact Tool (PIT), that looks at different modi of influence of designs on people (Dorrestijn & Eggink, 2014; Raub, Dorrestijn & Eggink, 2018). In addition,

there is value in looking at the social implications of introducing such a technology, to establish some kind of dialogue with future societies. A tool that would be well suited for this is Constructive Technology Assessment (CTA) (Rip, Misa & Schot, 1995; Kuhlmann, 2012). In future research, we would like to explore how together these tools can add to the Future Design & Play method to allow for a more comprehensive way for responsible future design.

Conclusion

Futuring projects are complicated and uncertain yet they are needed for us to think about the future and have future-oriented discussions. An explorative matter is necessary, and in that regard, we succeeded in introducing this new method to students.

Linking the previous six-step scenario method to the SES tool, creates a powerful way to envision the future and at the same time empathise with the stakeholders in the envisioned future situations. It allows for designing propositions that can be relevant for the future, even if the future does not play out as in the scenario. This allows designers to prepare for many futures.

The method worked to make scenarios more tangible, stretched the students' thinking and helped understanding the possibilities and uncertainties they will inevitably face.

About utopias, apocalypses, respawning and zombies and how understanding images of space and time may inform design for sustainable behaviour

Abstract

This paper presents justification for, and experimentation with an artistic method designed to help designers better understand how people imagine time, and connect this consciously or subconsciously to their norms, values and intentions which ultimately shape their behaviour. Four monologues were created, put on video, and a pilot experiment suggest high potential for further development of this artistic method, extending the designer's toolbox to identify points of interventions when designing for sustainable behaviour.

Author keywords

Sustainable behaviour; narratives; temporality; artistic research; performative research.

Introduction

Fuelled by a desire to expand the toolkit of design researchers beyond conventional approaches in design for sustainable behaviour, an interdisciplinary 3-year project 'Narrating Sustainability' was initiated early 2022. This project brought together researchers from design, psychology and literature studies. Internally funded with three full time researchers and three supervising professors, the project allows for, and sets out to explore interdisciplinary avenues of inquiry which may challenge more conventional disciplinary approaches. The aim of this paper is to introduce our motivations and rationale for using unconventional methods of inquiry, and provides one example of doing so.

Background

Design research is occupied with equipping designers with tools to understand complex contexts, in order to identify opportunities for interventions which can change undesirable situations into desirable ones. It draws on a range of disciplines from engineering, social, business and natural sciences as well as the humanities (e.g., Lockton et al. 2010, Zachrisson & Boks, 2012). In the past 15 years, design research has increasingly focused on sustainable behaviour and practices, applying psychological and sociological understanding of what enables or prevents users from behaving in sustainable ways, in exploration of solution spaces and design of interventions. Behaviour is shaped by normative, habitual, intentional and situational processes (Klöckner & Blöbaum, 2012), and design interventions have mostly been focused on the situational and habitual context, as these are most likely to provide concrete, hands-on and well-defined design challenges. For example, to support reducing food waste, design interventions are typically aimed at providing recipes for leftovers, designing appropriate storage units, designing apps for more conscious food purchases, and so on. However, research demonstrates quite clearly that norms and values heavily influence our intentions to behave responsibly and to make use of opportunities which facilitate interventions such as these (Pahl et al., 2014; Slovic, 2020). As Paul Slovic, preeminent researcher of risk perception in the public, has said, the strongest predictor of what someone perceives as a meaningful risk is the extent to which it stirs up emotions in them—not any quantitative markers of the extremity of said risk. In his words, "the public is influenced by worldviews, political ideologies, and values." This makes it likely (and environmental research bears out) that people often intend to act in environmentally friendly ways, but then do not always act in accordance with these beliefs. That is, they may theoretically agree that climate risk is great enough to motivate action, but in their daily life, the perception of this risk remains theoretical, and therefore does not motivate environmentally sustainable behaviours. Indeed, this constellation of norms, values, and emotions surrounding them are well-known to have impacts on human behaviour, especially when it relates to controversial, politicized topics (Kahan et al., 2012). Yet, uncovering norms and values, in particular when elements of awkwardness, embarrassment and even shame may play a role, is understudied in design research (Trondsen & Boks, 2022). Sustainability design studies in particular could benefit from such research, as it is subject to narratives about who and what is responsible, which informs and is informed by norms and values (Fausey et al., 2010). For instance, while the belief-action gap has been widely researched in environmental studies, the role of the aforementioned values, norms, and worldviews (including specific social desirability biases

which may limit the extent to which participants are able or willing to be frank about such values) has not been addressed to a large extent, in particular not in design research. In this study we intend to adhere to norms and values that we think we can or at least should be able to manage, in particular the ways we all justify non-politically correct, or unpopular opinions or actions with narrative explanations that ease the cognitive dissonance mentioned by Festinger. Festinger's famous dissonance theory (1962), has led later scholars to urge for "application of belief-system theory," via a "self-confrontation strategy to make inconsistences between values a person holds and their behaviour visible" (Grube et al., 1994, qtd. In Klöckner 2022, p. 6). Festinger famously theorized that most people will find some sort of way to bridge the gap between their actions and their beliefs, if they are misaligned. Pairing his findings with those of narratology, we theorize that people most likely use brief, aphoristic narratives to justify or explain away moments when they are doing something that does not align with their beliefs, or which may be seen as shameful or unpopular by others. We also theorize that people draw from the logic in infrastructures around them to develop these aphoristic narratives (of which, more directly). Aphorisms are short statements which attempt to package a general truth in a brief statement. Work in management theory has confirmed that a two-fold process of reflection and cognitive reframing can affect how people consider their own motivations for tasks or behaviours (Hewett, 2023). For instance, we may know it is best to sort plastics for recycling or to avoid buying unnecessary clothing items or air travel tickets. But nearly everyone at some point does not properly sort recyclable goods and does indulge in unnecessary purchases. Per Festinger, people will seek to resolve these dissonances. People may say, for instance, 'one contaminated recycling load does not affect so much', or 'no one can live without any indulgences', and consciously or subconsciously justify taking that sun-and-beach filled holiday after all.

As stated, researching norms, values, and behavioural intentions which may modulate the efficacy of sustainability design solutions, has received little attention in design research; the question whether design research can contribute to redesigning norms, values and resulting intentions seems more distant from common design research and practice – perhaps for obvious reasons. Yet, per Hewett 2023, it is the same tool of narrative which individuals appear to use to adjust their behaviours and beliefs, and find greater determination to change such behaviours. Admittedly, both the complexity and the morality connected to such topics adds a layer of complexity to any research design initiative, because not only is it hard to make change or receptiveness to information happen, but also because researchers may be limited by participants' Social Desirability Bias, or other elements of shame or embarrassment, "should-ought" thinking that may limit self-report-based investigations. Thus, while there are many limiting factors to sustainable behaviour, one that has been largely ignored so far, are the norms and values that make it difficult for people to admit—even to themselves—how they actually think, feel, or believe information regarding climate change, sustainability, and the future. This prevents change-makers such as design researchers to become informed about essential parts of behaviour-influencing factors, which compromises ideation and testing of design interventions. In short: if users will not admit that they 'cheat', are lazy, or cannot be bothered, and neither can articulate why, or why they think it is OK, designers will be ill- or even misinformed and misled when designing for sustainable behaviour.

Less conventional approaches towards user insights

Partly inspired by acknowledgement that conventional user-centred design methods may not provide a full picture, designers have in the past decade stepped away from solely using conventional product and service design, and more recently explored approaches including design futuring, design fiction (Hebrok & Mainsah, 2022), design activism (Julier, 2013), speculative design (Dunne & Raby, 2013), (norm-) critical design, and norm-creative design. (But how to see narratives explicitly as both an element of the toolbox and/or as part of solution spaces is still ill-explored. Literature (both within and outside design research) reports on many physical and digital experiments where narratives are used to create awareness, reflection and action. Such experiments contribute to expanding design for sustainable behaviour research and thereby extend the designer's toolbox by using narratives about sustainability to enable, facilitate, nudge, tempt and seduce towards desirable behaviour. But they mostly conceptualize narratives as an instrumental tool for changing behaviour, instead of an existing, given phenomenon which may have influenced more static worldviews or zeitgeists, which are in fact (as research verifies) quite difficult to shift. They may, for instance, change over time and not through a single design intervention. Thus, we argue that such impacts need to be studied as a determining, independent variable. Another common research design modality is asking participants to imagine a future they want, or to imagine the future differently. Our rationale would see such interventions as short-sighted because they do not consider that the imagination is necessarily an extrapolative force, expanding upon that what we have already been given or exposed to, and thus unlikely to bear fruitful new ideas or truly cosmologically innovative imaginings. Indeed, Cultivation Theory, long used as a standard in media studies, holds that "exposure to media messages over time fosters homogenous attitudes and beliefs about the world among frequent viewers," lending credence to the notion that asking participants to imagine futures is somewhat circular reasoning (Giacacardi, et al., 2016).

Zooming in on the temporal element in sustainability narratives

If behaviours and values are impacted by our world views, these same are impacted—indeed, limited in many ways—by the worldviews we are surrounded with in media and society. Indeed, media studies scholars, a derivative field of narrative and literary studies agree that media is a form of collective memory, and a means of renegotiating or re-shaping cultural memories (Gambarato, et al., 2022). Narrative theory would suggest, in addition, that the possible futures we can imagine are shaped greatly by the possible futures we have been shown in media. We then decided to focus on the concept of time and temporality, since imagining is, first and foremost, always a temporal exercise—whether imagining the future, or re-imagining one's past, or even imagining a completely random series of events, one is necessarily envisioning a timeline different than the one actually inhabited. Risk-analysis, too,

involves imaging consequences and outcomes in a future space based on present conditions. Since sustainability, even at an etymological level, indicates a concern with the feasibility of a set of conditions to continue safely over time—a question of risk which involves extrapolative (e.g., future imagining) considerations, we opted to explore the interaction of narratives about time upon sustainability beliefs.

Studies of climate change focusing on addressing the belief-actions gap widely acknowledge the problematics of time as a complicating factor in communicating the urgency of a problem, which is, by definition, slowly evolving—at least as far as the scalability of the human extrapolative imagination is concerned. Thus, how people perceive time plays an important role in influencing individuals' attitudes and behaviours towards climate change and other sustainability issues (Milfont et al., 2012). Perhaps the most often-mentioned temporal dimension of climate change is its extension into the future. That is, while impacts are already happening, the most significant and far-reaching impacts of climate change lie in the future, creating a distance between our lives now and these future climate change impacts (Pahl et al., 2014). This is considered to be the primary hinderance to pro-environmental behaviours in the here and now (Gifford et al., 2009). The way this distance is perceived and framed in individuals' minds is likely to vary across people (Pitt and Casasanto, 2021; Nicholson-Cole, 2005), and it can be presumed that few consciously understand how images of past, present and future affect their behaviour. Moreover, even fewer will consciously understand how they end up with such images in their heads. Researchers themselves lack specific understandings of how timescapes are constructed as spatiotemporal cognitive models (Pitt and Casasanto, 2021).

From a Design for Sustainable Behaviour perspective, it would be valuable to obtain insights on how these images come about and how they, consciously or subconsciously, affect everyday choices people make. Preliminary work has explored how individual differences in media exposure impacts pro-environmental beliefs and behaviour through interaction with the variable of future-oriented thinking (Nicholson-Cole, 2005). Because semi-structured interview design alone is subject to demand characteristic bias and social desirability bias, we believe it would be useful to study how media influence could be used to allow participants a face-saving means of pivoting or shifting their environmental beliefs. Per the scholars cited above, this would theoretically allow participants the chance to reflect upon and change spaces of cognitive dissonance causing a belief-action gap in their sustainable behaviours, and which may be embarrassing to admit or perhaps even unrecognized. This, we propose, would be foregrounded on an initial study design which further explores the correlation between such media consumption and belief formation in the first place. With such insights, designers could create interventions that potentially unlock thought and value patterns in users' minds, and thus open up for design strategies which stimulate sustainable behaviour or avoid unsustainable ones.

Introducing our experimental approach

This article proposes an approach which explores if and how explicit visualisations and interpretations of how 'time works' can make people realise how their own conscious and, so far, subconscious perceptions of time and space affect their beliefs and the choices they make. What if people subconsciously believe that utopian or dystopian futures, or futures based on disconnected, alternative realities are unavoidable and behave accordingly? If a utopian future is to happen anyway, but to be preceded by an apocalyptic event, why would one behave sustainably now? What if the popular video game notion of respawning subconsciously enables people to believe in the infinite restorability of the coral reefs, rainforests, and the ozone layer, and belief that any climate crisis can be "fixed" by starting over from a safe back-up? These questions are explored by linking a typology of space and time interpretations to personas which will help people to identify their mental models of space and time and how they affect their behaviour in relation to everyday choices and their effect on sustainability. Using a conventional design research approach would imply using for example interviews, focus groups, cultural probes and diary studies to probe and identify temporality aspects of sustainability narratives 'that people think are out there and may have an impact on them'. Then, it may be followed by developing personas to help respondents recognize which one they identify with and what temporal understanding of the world they have in relation to sustainability challenges. But because of the above explained expected lack of imaginative capabilities, we wanted to approach the problem from a more performative, artistic, and retro-engineered perspective. We decided to ask, not what participants can imagine on their own, but to enable them to reflect on how their imaginative processes may have already been shaped by the imaginative possibilities afforded by the media diet around them. So, rather than asking participants to draw on their own, by-definition limited imaginative capacity, or extracting new imaginative possibilities from already marginalized groups, we sought an approach which allowed experimentation with exploring, as others have sought to do, how scalar (in temporal, spatial, and personal realms) imaginaries are limited by narrative affordances in the environment, which we hypothesize make up a large proportion of the cultural zeitgeist which people are influenced by and add influence to. We hypothesize that streaming media today, which has become a nearly ubiquitous pipeline of TikTok filters, binge-worthy fantasy-scapes, and competing narratives of "fake news", must have an effect on what, how, and how far people can take their imaginings. So, in seeking an ethical means of testing these narrative bounds at their limits, and find out what humans are capable of imagining (or are limited in their imagination), we turned to a readily available reality-pushing-but-hegemonic discourse: science fiction and fantasy tales on streaming media.

Developing monologues of temporality

So, instead of using conventional user research to collect potential ingredients for 'sci-fi and fantasy-based narratives of temporality in relation to sustainability crises', we used a more artistic approach to create these. Using our expertise in media studies, social narratives and sustainability research, we co-wrote four different monologues, and recorded videos with the same actor speaking out these monologues in an informal kitchen setting: The Matrix video, The Star Trek video, The Groundhog Day video, and The Zombie video, each incorporating two different ingredients: aspects of temporality, and emotions (Figure 1).

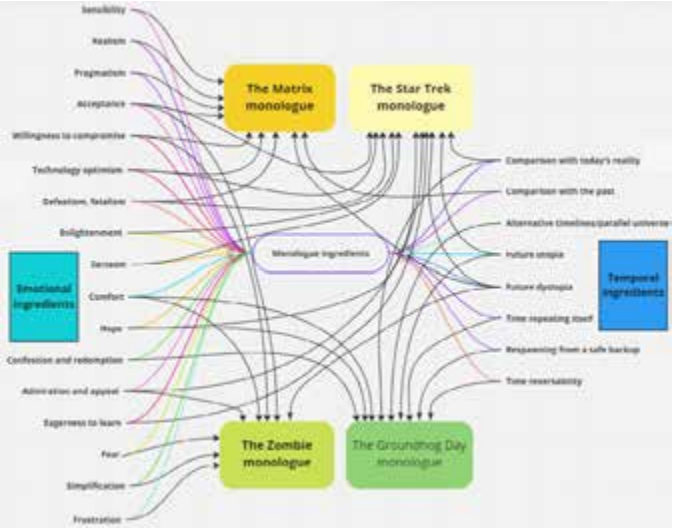

Figure 1. Emotional and temporal ingredients for our four monologues

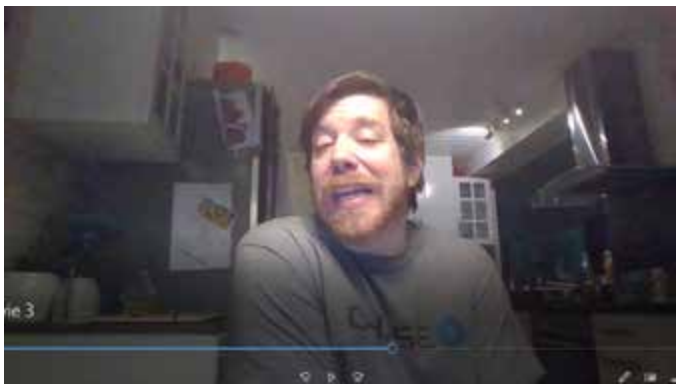

Figure 2. Still from a video

Each monologue also contained an element of self-criticism, like *'I know I probably sound weird'*, a fallacy or element of cognitive dissonance *'I know it doesn't make sense, but still, if you think about it...'*, as well as a comment in the vein of *'I think many people think like me'*. Dramaturgical clues in the scripts helped the actor to act in the exact intended informal style, resulting in 4 videos in which an 'average Joe' casually yet somewhat embarrassed 'admits' his personal views, and reflects a bit on what other might think of that (Figure 2). A questionnaire was developed to measure the impact of the videos on the audience, and to assess the validity of this sort of research design. Thus, the questions asked about how participants felt during and after viewing the videos, and framed quantitatively and qualitatively in tandem, for each question. Next, In a pilot experiment, a small sample (n=12) of master students in the Department's Sustainability Transitions course were shown the 4 videos and then asked to fill out the questionnaire. The results revealed several interesting avenues for further study and further iteration of our research design. Very few differences were seen between discourse analysis of qualitative versus quantitative responses in the survey. Similar levels of irritation or frustration were shown in response to each video, as was true for feelings of solidarity (i.e., feeling agreement with the perspective shown), vicarious embarrassment for the speaker, and reassurance. The main difference in reactions was shown in terms of what opinions viewers felt recognition in relation to (i.e., having seen others with these opinions), which was quite high for two of the videos. The Matrix-inspired video, which emphasized a future-scape in which alternate reality technologies provide simulated satisfaction with life but also emphasized trust in such technology to help us accepting effects of climate change. The second video which was highly rated as a "recognizable" perspective involved influence from video games such as Minecraft, and partly inspired by the movie Groundhog Day. This video emphasized the notion that we can redeem the errors of the past with "do-overs," much like respawning or reloading from save points in video games, where an element of forgiveness or a clean slate is built into platform modalities.

While viewers did not rank The Matrix video as indicative of their own beliefs the majority of the time, instead labelling this a view they had seen in others, they also frequently labelled it as "what would be best for the planet," and "what would be best for mankind," as well as "what would be most moral (according to your own values)". This may suggest that while viewers do not necessarily consciously recognize their own beliefs in a narrative (and are instead more likely to say "others" have that belief, or that it is familiar but not personally held) they nevertheless reveal subconscious alignment with these beliefs, but a lack of awareness that they themselves ascribe to it. This is shown by the divergence in "solidarity" (I have felt this way) responses with the "this would be best for..." series of responses. Intriguingly, this majority selection of The Matrix video as the top choice in the "this would be best for..." series itself diverged only when participants were asked what they felt would be personally best for them and their families, in which case they chose The Star Trek narrative about working together to build utopias. At the very least, this suggests further cognitive dissonance and directions for further research, as there seems to be a distancing of what participants feel is their personally held belief and what they deem to be the most positive narrative for them.

Conclusions

Our pilot experiment suggests that exposing respondents to these videos allows for new ways of inquiry which may uncover new insights relevant for Design for Sustainable Behaviour. Colleagues and friends from a wide variety of disciplinary backgrounds also enthusiastically responded to the videos. They saw immediately the potential of having an anonymous person articulate narratives and using this to evoke responses and reflections from respondents, once they are shown these videos. They intuitively seem to "get" that these videos addressed a wide variety of research design "blind spots" necessitated by the norms of each of our disciplines. Seeing another person 'somewhat inarticulately' articulate thoughts and opinions, which may or may not reflect an informant's own responses, may contribute to probing and understanding how people create images of how 'things work', and where those images come from. Supported by these positive responses, we see several future research opportunities, including:

- Using larger sample sizes to allow for statistically significant results based on analysis of both qualitative and quantitative responses to the survey.
- Creating new sets of monologues addressing other elements of sustainability narratives beyond the time aspect, and/or focused on specific themes such as climate crises, resource efficiency or consumerism. Pending further investigation, monologues such as

these could be an increasingly large "toolbox" for designers to implement in exploration of a range of topics.

- Experimentation with different formats of exposing respondents to monologues, such as using social media, public interventions and/or theatre settings), and with different forms of collecting feedback (surveys, interviews, group discussions).
- Using larger sample sizes would allow us to better assess this homogeneity of variance and parse out the relationships between self-recognition or lack thereof in viewers.

It is our hope (and expectation) that our unconventional, partly artistic and performative research design may, once refined, extend the (design) researcher's toolbox and reveal new possibilities to identify intervention points towards designing for sustainable behaviour.

Acknowledgments

We thank our colleagues in the Narrating Sustainability project and at our department for fruitful discussions and enthusiastic response to the videos, and students in the Sustainability Transitions course for participating in our experiment.

Introduction

> 'The danger isn't that AI destroys us. It's that it drives us insane'
>
> — Jaron Lanier [1]

While our preparations were running, generative AI systems such as ChatGPT and Dall-E suddenly headlined and underlined a new era of fear and hope. As the quote above of a prevalent virtual reality pioneer underlines, this requires a critical mindset with a passion for innovation. The Metaverse, 3D printing, artificial intelligence, and similar phenomena are re-shaping the role of the designer: a novel skillset and attitude is required to convert these digital capabilities into valuable tools and methods. This might require defining types of cyber-physical or augmented craftmanship, not forgetting about sustainability, social inclusion, and aesthetics. Furthermore, how can we ensure that the human (both collective and individual) stays in the driver seat, while political and economic agendas complicate a true human-centered design in times of industry 4.0, algorithms, distributed data, fuzzy intellectual property, and so forth.

For this track we received over 167 proposals that, after a double-blind review, resulted in 37 high-quality papers and 11 posters. These contributions go beyond the technical, to envision the capabilities of software/hardware as a meta-medium, with specific applications for the creative industry, and to frame the educational/ethical challenges in case studies and reflections.

The section ***new crafts and craftspeople***, revolves around the intersection of craft and digital immersive technologies, exploring hybrid workflows and production processes for creating augmented textile artefacts and fashion-tech products. The papers discuss learning experiences and experiments in digital fabrication, as well as the design of hybrid workflows and business models to engage with Industry 4.0 technologies in craft production.

Research through design in the cyber-physical era deals addresses the integration of technology with music-making and human-computer interaction in designerly ways, exploring physical interactions and sensory experiences in the design of digital products, and rethinking traditional paradigms of disability and the body in relation to technology.

The section entitled ***redefining the role of designers***, explores the intersection of computational thinking, design, and fabrication in creating augmented and accessible museums. The papers cover a range of topics such as co-creating 3D materials with synesthetic AI, speculating futures in an age of nostalgia, and the use of cabinets of curiosities to explore collections and tokens in the postcolonial context. The papers highlight the potential for technology to enhance the museum experience and promote inclusivity, while also addressing the challenges and complexities of curating collections and representing diverse histories.

The section ***usability and performance of innovations*** addresses the importance of evaluating and asessing new designs, with an increasing role of technology in enhancing learning, work, and shopping experiences.

Design for and with extended reality focuses on the intersection of immersive technologies, creativity, and materiality. This includes applications such as virtual reality and the metaverse, for creative expression and communication. The papers explore how these technologies can be used to assist in ceramic creation, stimulate storytelling and communication competencies, and introduce the concept of material experience in virtual environments. Additionally, the theme also touches upon the purpose of furniture in the metaverse.

The section ***design for and with digital fabrication*** provides new insights towards design methods and techniques in the field of additive manufacturing (AM). The papers also highlight the importance of knowledge transfer and collaboration in advancing the commercialisation of AM. Additionally, there is a focus on the use of new materials and technologies in the design process, such as electronic textiles and circular design materials. Finally, the papers address the impact of automation and technology on traditional craft practices.

1 https://www.theguardian.com/technology/2023/mar/23/tech-guru-jaron-lanier-the-danger-isnt-that-ai-destroys-us-its-that-it-drives-us-insane

The digital on an urban scale covers exploration and design of urban spaces in the context of technological advancements, particularly in the realm of smart cities and extended reality. They examine the relationship between technology and urban environments, exploring concepts such as data activation, engagement, and the use of 5G technology to create smart product-service systems. The papers also address the need to rethink traditional notions of urban planning and design, to create more flexible and adaptable urban spaces that can respond to the changing needs of communities.

The section ***technology-driven design education*** covers new insights in the integration of technology into design education, specifically AI and virtual reality, as well as the need for collaboration and interaction in the design process. The papers also touch on the evolving role of designers in a technology-driven world.

Finally, the common themes of the section ***digital fashion*** are sustainable fashion, the use of digital technology in fashion, and the evolution of fashion into the virtual space of the metaverse. The papers explore the potential of digital twins, media technologies, NFTs, and direct-to-avatar retail experiences to improve sustainability, design knowledge, and customer engagement in fashion. They also discuss the challenges and opportunities of deconstructing materiality in fashion and creating new forms of value and expression in the metaverse.

Apart from these academic papers, we hosted workshops, posters, and this time also a curated collection of lecture/performances featuring cyber-physical artworks. We Thank the authors and reviewers for their hard work and hope that this set offers a new chapter to Cumulus, to provide a guide to move from traditional design and heritage to critical integration and convergence.

Fashion craftsmanship 4.0: learning experience about industry 4.0 technologies for hybrid digital fashion-tech products, processes, and business model design

Daria Casciani[1], Olga Chkanikova[2]

[2]Department of Business Administration and Textile Management, University of Borås, Sweden
olga.chkanikova@hb.se

Abstract

The European fashion craftsmanship sector is renowned worldwide for its excellence and competitive value in producing tangible and intangible cultural heritage (ICH) in creative practices and material artifacts. However, the competition of mass production at lower costs and the increasing jobs digitalization threatens the survival of fashion craftsmanship knowledge. In this context, Industry 4.0 (I4.0) technologies could become a trigger to transform fashion craftsmanship by hybridizing workflows via new tools, gestures, and creative acts. Due to a technological and socio-cultural divide between the old and future generations of fashion craftspeople, new educational models are necessary to update the skills and imagination of future fashion professionals towards the revival of crafts ICH while accounting for holistic multidimensional sustainability. Therefore, the paper presents an interdisciplinary challenge-based learning experience conducted at Politecnico di Milano and University of Borås, combining a design and business management methodological approach to deliver Fashion-Tech proofs of concepts (covering product, service, process, and business model innovations). Delivered proofs of concepts demonstrate the potential of I4.0 technologies to preserve cultural diversity and local heritage, improve multiple dimensions of sustainability, and empower creativity and connectivity between different stakeholders. New products, services, processes, and business ecosystems of hybrid fashion craftsmanship can contribute to interdisciplinary learning spaces where different users/stakeholders connect and engage in co-creation and co-learning activities. Besides, the developed educational model can be applied to training fashion craftspeople 4.0.

Author keywords

digital design; digital fabrication; fashion craftsmanship 4.0; education for Fashion-Tech; sustainability.

Introduction

The technological and socio-cultural divide between old and future fashion craftspeople is nowadays impacting the lack of generational turnover and the preservation of intangible cultural heritage (ICH) in the Italian and European fashion craft sectors. The meaningful application of Industry 4.0 (I4.0) technologies via new educational models could bridge this gap by enabling digital literacy, the connection of stakeholders, and the pursuit of environmental, political, cultural, and socio-economic sustainability. The paper presents the results of an interdisciplinary learning experience and discusses the implications of training future professionals in the hybrid (i.e., analogue/digital) fashion craftsmanship sector, focusing on creativity and collaboration.

Literature review

Traditional and future fashion craftsmanship at risk of extinction

The European fashion craftsmanship sector is recognized for its quality, creativity, and competitive economic value in producing cultural content embedded into creative practices and material products. European (e.g., Italy, France, Germany, Spain, Portugal) fashion micro-enterprises of craft-based high-end personal goods (e.g., textile and clothing, jewellery, eyewear, and leather goods accessories) represent 74% of the global value of these products (EC, 2023a). In particular, the EU textile and clothing craft sector employs 1.5 million people and produces a turnover of €147 billion (Euratex, 2022); meanwhile, about 36K enterprises generating a turnover of €48 billion and employing around 435K people produce leather crafts (EC, 2023c). Fashion craftspeople inherit and preserve the knowledge, expertise, and skills of crafting unique and excellent artefacts as Intangible Cultural Heritage (ICH), being custodians of traditional expertise situated in specific territories and communities (UNESCO, 2003). However, the competition of global mass production at lower costs, the delocalization of manufacturing to places with cheaper hand labour, and the spreading digitalization are forecasted to cause a shortage of traditional fashion and textile artisanal experts across the operational, technical, managerial, creative and scientific sectors (ETP, 2016). Passing the tacit artisanal knowledge through the familiar entourage and on-the-job learning practices inside workshops further

reduces the number of available expert craftspeople in the fashion sector. For example, in 2013, Confartigianato Imprese predicted an unexpected death of Italian craft entrepreneurs, specifically in the sector of design, fashion, and personal luxury items (e.g., leather, footwear, clothing, and jewellery), thus impacting the decrease of 'Made in Italy' economy by 9.1% (Bonfanti et al., 2015). Since the fashion craftsmanship sector is a significant asset for economic, cultural, social, and environmental sustainability, the European Commission primarily focuses on revitalizing European urban and rural areas by nearshoring the craftsmanship processes toward a feasible and resilient governance of a post-emergency society (EC, 2023b).

Exploiting digital technologies toward fashion craftsmanship 4.0

To stay competitive against mass globalization and production, small and local artisanal enterprises could exploit I4.0 technologies to develop highly customized products through on-demand production at fair and competitive prices on the market, while increasing product uniqueness and quality. In addition, they can become a trigger for encouraging new generations of artisans' to produce new crafts through new workflows aided by I4.0 technologies, thus hybridizing traditional practices towards a systemic paradigm change in the fashion ecosystem (McCullough, 2015; Bertola and Teunisen, 2018). I4.0 technologies could also help digitize traditional fashion crafts gestures and processes, translating the intangible fashion knowledge into teaching materials to incentivize mutual learning between humans and technologies, thus nurturing the future generation of fashion professionals in old craft sectors (Casciani and Vandi, 2022). Besides, studies demonstrate that I4.0 technologies define new relationships between artisans and technologies, particularly in assisting or augmenting daily manufacturing tasks toward operators' health, well-being, and safety (Burden, Donovan, Caldwell, Teixeira, 2022). However, the digital transformation in Italian fashion crafts enterprises is still far from a mature reach, with 9.5% in the eyewear sector, 5.8% in jewellery, 14.2% in the clothing and apparel sector, 8.4% in textile, 1.6% in footwear (Digital Manufacturing Lab, 2018). The main constraints for this limited adoption from Italian and European fashion crafts enterprises are the inadequate knowledge about I4.0 technologies' opportunities which is related to a different business strategy and culture of the enterprise, the lack of internal/external competences, constrained financial resources, and the difficulty in identifying the right partner to drive the digital transition (Digital Manufacturing Lab, 2018; Kusters et al., 2017). Adopting I4.0 technologies represents a complex challenge for the present craftspeople with limited digital skills across engineering, design, and business management domains (Jimeno-Morenilla et al., 2021). The advantages of embracing digital technologies in fashion craft-based workflows rely on boosting products' quality and exclusivity, improving working conditions, increasing productivity and efficiency, and reaching sustainability. From a cultural perspective, digital technologies could help revive the crafts communities and maintain cultural diversity and local identity (Brown and Vacca, 2022). Despite this, craftspeople face sociocultural barriers toward I4.0 technologies in terms of expectations, reluctance to use, perceived lower quality of implemented crafting processes, and fear of the complete automation of work towards the disappearance of artisanal practices and job loss (Mosca and La Rosa, 2019).

Training future fashion hybrid craftspeople

The shortage of craftspeople and associated skills and knowledge in the fashion sector is expected by 2030 (ETP 2022) due to a huge turnover of employees after the retirement of highly specialized artisans. Besides, fashion craftspeople face the challenge of adapting their workflows to respond to the green and digital economy transition, with the conflicting demand of focusing on retaining existing competencies, and attracting new talents (ETP, 2022). Hand-based craftsmanship has lost its attractiveness and safety with a consequent decrease in interest by a younger generation of professionals. However, research has forecasted a future scenario of fashion industries in 2030 focused on the Renaissance of the Crafts regarding production, employment, required skills, and competences (Skills 4 Smart TCLF Industries 2030, 2022).

The intergenerational technological and socio-cultural gap between old and new fashion craftspeople should be mitigated to preserve and transmit the fashion craftsmanship ICH through digital literacy provision to the older generation of artisans, meanwhile incentivizing the interest of the younger generation to hand-based craftsmanship hybridized with the use of I4.0 technologies. New educational models aim to achieve the aforementioned objective and to drive the digital transformation and sustainability of the European fashion eco-system, preserving both specialised traditional skills while advancing the new ones relevant to the digital evolution of the sector (Bertola and Vandi, 2021; Digital Education Action Plan (2021-2027), 2021; Unesco, 2017). Besides, new educational models should also foster the encounter of traditional and future craftspeople, supporting collaboration and peer-to-peer learning and education. In this direction, a series of piloted learning experiences (LE) have already suggested that innovative proof of concepts of sustainable Fashion-Tech solutions could be enhanced by the use of a challenge-based learning (CBL) approach, by combining design and business model perspectives (Casciani et. al, 2020; Casciani and Colombi, 2022; Ma, 2022;). In the CBL approach, students face real-life and multidimensional problems involving social, cultural, economic, technological, and environmental dimensions and are encouraged to formulate their solution by collaborating with different stakeholders involved/affected by the process or solution, thus allowing the connection between students, teaching staff, professionals, technologists, researchers, and artisans (Nichols and Cator, 2009; Nichols et al. 2016). Due to the complexity of the real-world challenges, the CBL approach supports the connection of knowledge among different disciplines, resulting in sharing common glossaries, and perspectives toward the synergistic integration and modification of disciplinary contributions. Hence, education is crucial to maintain, and valorise fashion craftsmanship ICH by cultivating and nurturing future fashion professionals that combine digital skills while preserving the traditional material and manufacturing competences.

Methodology

The paper presents an international and interdisciplinary LE conducted by Politecnico di Milano and University of Borås collaborating to train the hybrid fashion professionals of the future with soft skills, technical/digital, and subject-specific skills while boosting integration between the human, so-

cio-cultural, and economic perspectives. The LE focused on the implementation of the more operative I4.0 technologies such as 3D printing (3DP), 3D scanning (3DS), laser cutting (LC), collaborative robotics (CR), virtual and augmented reality (VR/AR) in the design of new craft products/systems of products, new hybrid digital crafting processes, and new business models that also account for a multidimensional perspective of sustainability. By coupling design-driven and business management innovation perspectives inside an interdisciplinary action-oriented pedagogical approach, we aimed to encourage a positive and culturally meaningful paradigmatic shift, bringing students closer to crafts and craftspeople and preserving and enhancing traditional practices through digital transformation. The combination of design and business model innovation education is crucial to support the possibility of achieving a real and fruitful digital transition in the fashion craftsmanship sector (Jin & Shin, 2021). Focusing on the comparison between pre- and post-course skills self-assessments, derived from the answers from the questionnaire and by the analysis of the LE results such as proof of concepts and group project reports, the paper aims to discuss the impact of the piloted educational models for the fashion crafts' digital transformation towards sustainability. In particular, this study intends sustainability as a holistic multidimensional concept entailing environmental, economic, social, and cultural dimensions (Fletcher, 2014; UCLG, 2010; British Council, 2020).

LE design: developing collaboration, toolkit, and educational methodology

Growing interdisciplinary Fashion-Tech partnerships

The LE has been offered to 21 international and interdisciplinary students (76% female, 19% male, 5% non-binary gender) from graphic design (5%), product design (21%), fashion design (52%), architecture and landscape (10.5%), and business management (10.5%). They worked in 5 interdisciplinary groups mentored by 2 academic researchers/teaching staff from the involved Universities and 2 professional tutors from a Fashion-Tech start-up focusing on digital transformation, and non-standard fabrication technologies (Materea). The company participated actively in the LE design, delivered technology-focused lectures as expert trainers, and mentored students during the CBL phase. Students were asked to select one between five different applications of the fashion craftsmanship sectors (jewellery, textile and clothing, small and medium accessories in leather, footwear, and eyewear) since these sectors are at the forefront of Italian fashion craftsmanship (Bonfanti et al. 2015). Students were expected to focus on specific historical craftsmanship expertise and techniques with no geographical boundaries. However, being asked to include the craftspeople of the selected applications in the research and design processes, many focused on the Italian geographical context because most students were based in Italy. However, the LE allowed for a broader geographical scope/context to account for international students' interests and competences. In particular, some students focused on fashion craftsmanship in the Far East and Asia. Students have developed solutions such as low-fidelity prototypes, visualizations of workflows, and mock-ups of designed solutions, tools, and software. These outputs were shown to the stakeholders to test and provide a reality-check of the proposed proofs of concepts (PoC). Craftspeople were surveyed (7) and interviewed/observed (11) during their activities and were confronted with the hybridized crafted processes. Targeted final consumers were interviewed (12) and surveyed (78) to define needs and feedback in relation to the proposed hybridized crafted solutions.

Setting connected learning workspaces

The LE was delivered through 13 digital lectures divided into an initial theoretical part (DISCOVER), providing basic knowledge on design, methodology, engineering, and business management topics, and followed by a CBL part (DESIGN). It was aided by a system of educational tools providing an individual personalised learning path, such as Fashion-Tech Open Educational Resources (OER, 2022), and digital collaborative visual boards structured on MIRO to aid the communication, interdisciplinary exchange, collaboration on design activities and project management, toward a sharing of disciplinary glossary and methodologies, and asynchronous and synchronous interactions. OERs were focused on levelling the knowledge for students of different backgrounds to easily drive the CBL. Collaborative visual spaces were useful to both set up the activities, control the progress through the course timeline, and set a fruitful partnership between the instructors and learners as co-researchers/designers of the solutions during mentoring activities.

Joining design and business-driven innovation methods toward sustainability

To conduct a digital LE, a user-centred design approach combined with principles of design for sustainability/circularity and sustainable/circular business model (BM) innovation perspective was decided (Fig.1). User research aimed to understand craftspeople workflow, activities, tools, materials, needs, and challenges in integrating I4.0 technologies. This was complemented with final customer research to delimit main market segments for hybrid fashion craft. In addition, students focused on sustainability strategy, starting from the project groups' vision, mission, and core sustainability values formulation and then connecting it to specific Sustainable Development Goals (SDGs). Subsequently, the hybrid systems of product, process, and business model concept ideas were conceived, integrating research of available digital technologies adaptable in the fashion craft sector. Simultaneously running the product, process, and business model conceptualization stages aimed to facilitate the systemic interdisciplinary approach toward sustainability within the project teams. According to students' reports and evaluations, this allowed for a number of iterations and simultaneous adjustments of ideas that were detailed and visualized with low-fidelity mock-ups to be tested and validated with users (artisans + customers), thus providing a further design iteration (Fig.1).

LE results: hybridizing fashion craftsmanship practice through education

Hybridizing crafts system of products, processes, services, and business models

Implementing I4.0 technologies in students' solutions of hybrid systems of products, services, processes, and business models influenced the redefinition of fashion design, production,

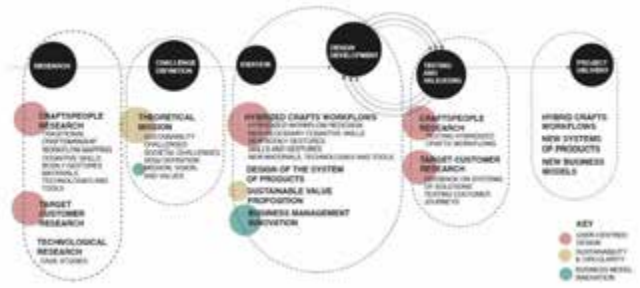

Figure 1. LE workflow from research to project delivery, blending design, and BM education

and consumption logic by challenging existing unsustainable models while attempting to preserve fashion craft ICH (Fig.2).

Students have developed 5 proof of concepts (PoCs) focusing on purely hand-based craft sectors (e.g., jacquard crocheting, stringing beads, hat weaving) and hybrid sectors already using technologies in some parts of the manufacturing processes (e.g., eyeglasses and dress shoemaking). In the latter, they focused on niche artisanal products, still very traditional and based on manual workflows.

PoC1 aims to preserve the jacquard crochet legacy by customizing the design of bags and small accessories, empowering international artisans with digital technologies to parametrize the design phases and augmented tools with sensors that amplify and extend their gestures. An online configurator allows product customization, and direct connection between artisans and customers, aiming to promote awareness of the crafts' tradition amongst the general public. PoC2 develops personalized advanced modular and long-lasting Italian dress shoes, augmenting traditional workflows of perfect fit and personalization with 3D scanning and Virtual Reality (VR) try-on technologies on a digital online configurator. The repetitive and cyclical activities of material cutting are aided through 3D printing and laser cutting, while the assembly is through collaborative robots. PoC3 develops 3D-printed interlocking beads made from recycled filaments, improving the efficiency and operability of international craftspeople during the beads stringing process, while allowing beads customization via simplified parametric digital configurator and VR try-on. PoC4 focuses on customized headwear weaving, combining the precision and speed of laser cutting with the uniqueness of traditional Vietnamese crafts techniques, thus promoting local economic development and customer personalization via head scanning and an online configurator. PoC5 creates a digital platform to connect a network of artisans able to offer sustainable and fully traceable glasses made of recyclable materials, thus offering a service of disassembly, repair and renovation throughout Italy, to extend the life cycle of glasses while allowing a customized artisanal work through face scanning, digital design, and fabrication.

Similar solutions are already present in the activities of researchers and design practitioners working on creative experimentation and co-creative practices, investigating the interaction between humans and robots (Ugur, 2020; Performative robotic micro-factories, 2021), humans and digital fabrication (Pistofidou & Olmos, 2019; Morpurgo, 2017) to design hybrid crafts workflows and new solutions. Several examples exist in using online configurators for on-demand design and purchase of fashion products (Nervous Systems, 2023; Nike by you, 2023) and craftspeople networking platforms (Italian Artisan, 2023) strenghtening alliances to better reach the market. Interesting processes and solutions for highly manual-based craft sectors such as knitting (Rosner & Ryokai, 2010), crocheting (Smith et al. 2015), embroidering (Flanagan & Fraietta, 2019), and beading (Nicholas et al. 2022) have already explored the possibilities of using I4.0 technologies for detecting, archiving, and teaching traditional crafts expertise, meanwhile creating more accessible data to be passed to future professionals.

Embedding multidimensional values of BM innovation and sustainability

Interweaving traditional artisanal processes with technologies toward multidimensional sustainability dimensions, the

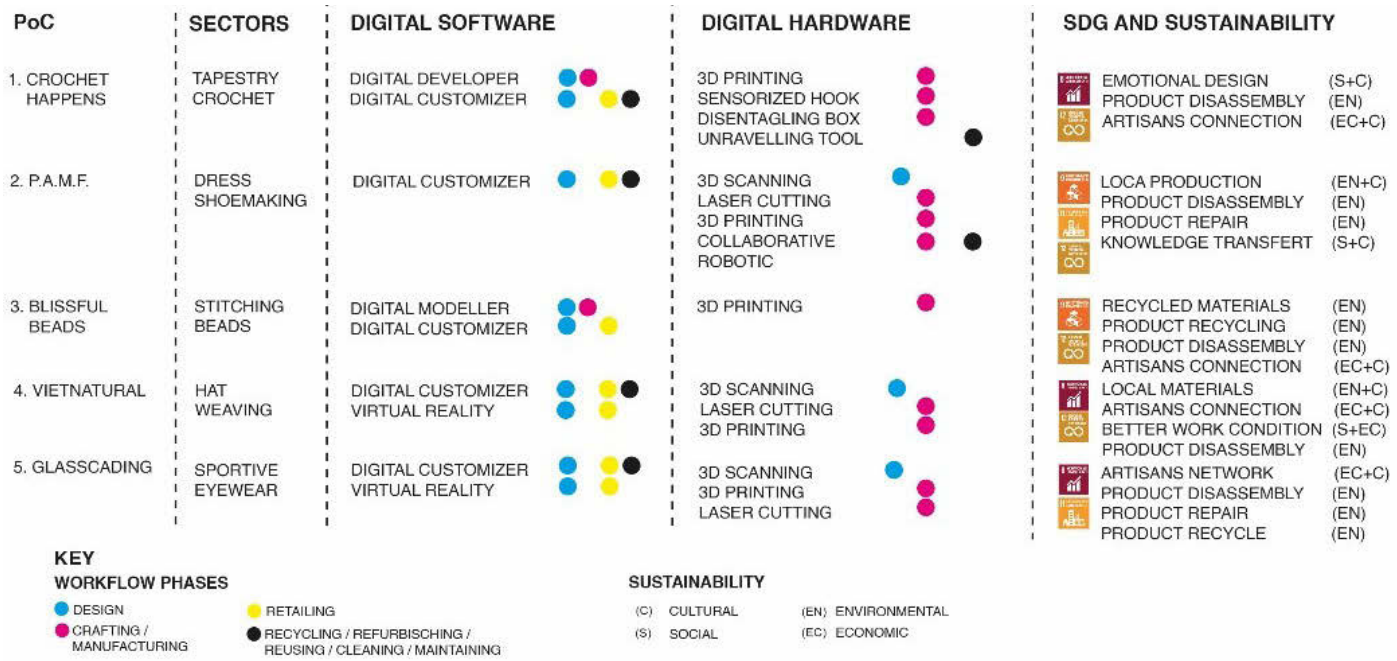

Figure 2. Hybrid sustainable fashion-tech solutions PoCs

PoC	CUSTOMER VALUE PROPOSITION	MARKET APPROACH	VALUE CREATION APPROACH	VALUE CAPTURE / REVENUES	BUSINESS MODEL TYPE
1. CROCHET HAPPENS	customizable crochet bags for self-expression, emotional durability, responsible consumption based on products uniqueness and process transparency	**narrow differentiation** (focus on limited range of customer segments and product differentiation)	. direct interaction of artisans with customers via customization and transparency services on digital platform allowing to follow production process in real-time; . increased efficiency of complex artisanal tapestry crochet process by enabling simpler, and less wasteful on-demand production	. Product sales via digital and physical channels where price is calculated based on degree of customization; . repairing service and online advertisement fees	**Limited product and market portfolio model** (providing some range of customization options of the products for specific customer segments) **to slow resource use by extending product lifespan.**
2. P.A.M.F.	Hyper-personalized (on individual measurements) dress shoes with focus on high quality long-lasting performance and emotional durability enabled by caring and upgrading services to meet different seasonal, functional and aesthetic customer needs	**Broad differentiation/ mass customization** (focus on broad customer base and product differentiation)	. On-demand local personalized production where customer is involved in value co-creation during production and use phase (via post-sales upgrading services); . digital technologies augment traditional artisanal process allowing for better working conditions, improved productivity and customer service	. Product sales via digital and physical channels where price is calculated based on degree of customization; . repairing service and online advertisement fees	**Extended product and market portfolio model** (providing broad range of customization options of products and services for broad customer base) **to slow resource use by extending product lifespan.**
3. BLISSFUL BEADS	Customizable beads and jewelry designs with focus on creativity, self-expression and sustainability (e.g., by using post-consumer and recyclable materials as input resources)	**Narrow differentiation** (focus on one specific customer segment and product differentiation)	Users engagement in co-design and artisanal workshops activities, quicker, easier, more creative and cost-efficient beads production and jewelry assembly process	Physical and digital product sales enabled by virtualization of design process, workshop fees	**Extended product portfolio model** (wide range of customized beads/jewelry designs for one specific customer segment) **to close resource loop by using post-consumer and recyclable materials as input resources.**
4. VIETNATURAL	Custom-tailored headwear enabling self-expression, uniqueness and sustainability (e.g., by supporting crafts sector, enabling less wasteful production and promoting use of bio-based input materials)	**Narrow differentiation** (focus on limited range of customer segments and product differentiation)	On-demand local personalized/customized production, 3D design file sent directly to manufacturer, digital platform connecting artisans, designers and customers enables more simple, faster and less wasteful artisanal production	Physical product sales (hats and repair kits), customization fee, repairing service fee	**Limited product and market portfolio model** (providing some range of customization options of the products for specific customer segments) **to slow resource use by extending product lifespan.**
5. GLASSCADING	Custom-tailored high quality sustainable glasses from fully traceable materials including the product renovation services during the use phase	**Narrow differentiation** (focus on limited range of customer segments and product differentiation)	Product and accompanying renovation services (e.g. maintenance, repair) are provided by the network of artisans connected virtually together and with customers via digital platform, artisanal process is enabled by knowledge-sharing, digital upskilling (education on use of digital technologies, e.g. laser cutting), improved flexibility and lower cost in production and services provision due to use of complementary resources/capacities	Subscriptions	**Limited product and market portfolio model** (providing some range of customization options of the product and services for specific customer segments) **to slow resource use by expanding product lifespan.**

Figure 3. Business models typology of PoCs

solutions encompass different types of value creation: (i) emotional values via increased transparency and storytelling about craft processes, products, and artisans themselves; (ii) cultural value of preserving and spreading the craft ICH; (iii) sustainability/circularity improvements extending product use, and offering repair and recycling services; (iv) increased efficiency, visibility and thus competitiveness of small artisans and their products/services in the mainstream fashion market; (v) customization/self-expression opportunities for to final customers' engaged in co-creation with artisans/designers; (vi) connectivity enabled by technological tools. To monetize the developed hybrid craft solutions, the suggested business models focus on combining products and market portfolio models (e.g., different customized product offerings target different market segments) while aiming to slow resource use and close material loops. These models are acknowledged as part of the digital transformation of creative industries (Feng 2020). Traditional revenue streams based on product sales are complemented by customization, repair, and after-sales support services, whereas one of the suggested business models is subscription-based. More details on the BM typology of PoCs are presented in Figure 3.

Encoding hybrid crafts workflows in new workshops through augmented tools

All projects configured new sustainable and hybrid manufacturing workflows reflected in the design of customised digital software, augmented tools and hardware, workbenches, and spaces to conduct and streamline hybrid crafts activities, representing the affinity between craftspeople and their work environment/material organisation (Oxman, 2007). They supported the design, manufacturing, selling, and repairing phases, establishing a good encounter and negotiation between hand and digital dematerialized activities. The proposed tangible tools augmented with technologies were designed to offer the artisans functional performances, strengthening manufacturing activities in terms of dexterity, process simplification, and gestural digitalization to record crafts activities and encode them to assist craft planning and training. Tools ranged from the

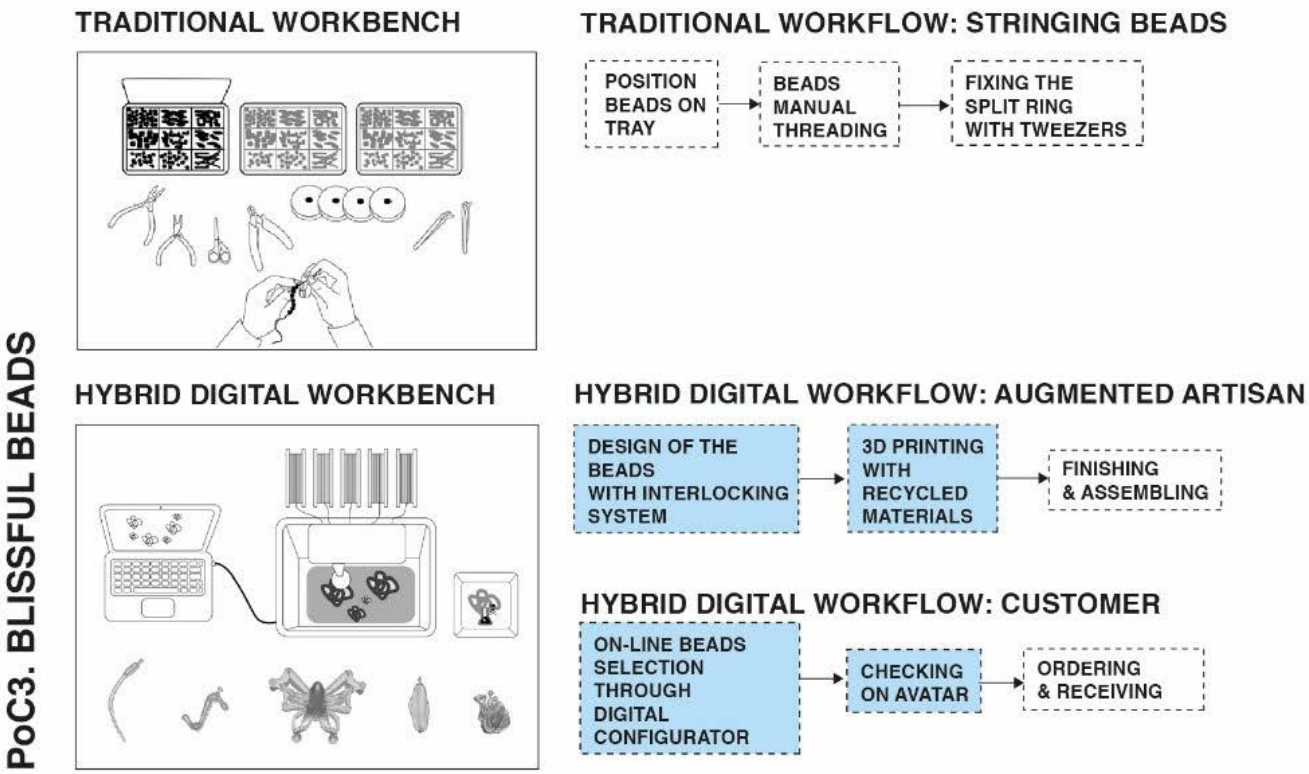

Figure 4. Example of comparison of traditional / hybrid digital workflows and workbench / tools.
PoC3 Blissful beads courtesy of Bachmann B., Xuan G., Lombardi B., Melodia E., Wang B.

smallest integration of sensors and actuators in augmented hooks for enhanced jacquard crocheting (PoC1) to the customization of CR hand-effectors for aiding cyclic assembly and cleaning stages (PoC2). Almost all PoCs equipped the artisans with customised digital parametric software with more intuitive interfaces to simplify artisan-computer interactions. The software is aimed to streamline digital 3D modelling toward digital fabrication (PoC3), develop and engineer made-to-measure craft productions, create networking platforms among artisans in the same sector (PoC4), and aid the configuration of customised craft artefacts by the final consumer. An example of traditional and hybrid workflows, workbenches, and designed solutions is reported in Figure 4. Both digital tools and software were designed to be connected in real-time, aiding both hybrid craft practices and on-demand retail channels, allowing streamlined automation from the design to the crafting of products, thus contributing to the empowerment of craftspeople overproduction.

Connecting stakeholders in the hybrid fashion crafts

Almost all the developed PoC aimed to shorten the distance between stakeholders. Thanks to co-design practices allowed by digital configurators, final customers can access fashion ICH, by watching the workflow progresses of hybrid crafting of their customised products, thus unveiling the complexity, meaning, uniqueness, and beauty of fashion crafts. Therefore, digital technologies enhance the emotional values of craft products, promoting long-lasting connections between users and products, thus contributing to more responsible consumption practices, including extended product use, repair, and recycling. From the artisans' perspective, all PoCs aim to link them with the global fashion markets by preserving their local communities and ICH.

Evolving from multidisciplinary to interdisciplinary skillsets

Students ranked soft skills acquired during the course as 3.75 (based on the Likert scale of 1-5) with particular appreciation of creativity and innovation, collaboration/teamwork, problem-solving, and critical thinking based on sustainability and interdisciplinarity considerations. They rated 4 and above subject-specific skills: fashion-tech design process and methodology, user-centred research, craftsmanship digitalization, and sustainability-oriented business model development. According to students' evaluation, mentoring activities provided: directive guidelines on how to improve the solutions (75%), inspiration and motivation to identify creative solutions (16.7%), contribution to joint co-production of knowledge/ideas in the group projects (33.3%), space for critically and independently reflecting on what improvements are needed (41.6%). Based on students' reflections in group reports, the focus on the design-driven approach complemented by business model thinking toward hybrid crafts innovation was perceived as challenging but beneficial. The business model innovation approach allowed the development of a critical stance on the economic viability of hybrid design of fashion crafts, enabling students reflection on how to attractively frame the value proposition, develop possible revenue streams and consider important partners/collaborations for intended value creation.

Conclusions

By demonstrating new educational models based on interdisciplinary, CBL, and systemic approaches (Bertola and Teunissen, 2018; Pal, 2017), this paper argues that education is a crucial lever to help fashion craftsmanship to stay competitive on the market and preserve its tangible and intangible cultural heritage while promoting sustainability and circularity. Higher education Institutions (HEIs) can drive new learn-

ing experiences based on complementary employment of design, and BM approaches, facilitating industry/multi-stakeholder collaboration and educating future fashion professionals to drive the digital transition towards sustainable hybrid fashion craft solutions.

CBL approach empowers the creation of networks of stakeholders involved/affected by the designed solutions, bridging and bonding the actual craftspeople with the new generation of hybrid fashion professionals across design, technology, and business domains. However, it is crucial to enable stakeholders' involvement at the early stage of research and design for early validations and iterations. According to recent literature, students should develop communication and negotiation skills through visualisations and low-fidelity prototypes to enhance the engagement of the involved stakeholders and craftspeople throughout the process (Mayer et al., 2022).

As demonstrated by delivered PoCs, I4.0 technologies integration in craft workflows offers opportunities for co-designing, co-crafting, and co-learning activities between artisans-students, artisan-technologies, and artisans-customers. If I4.0 technologies were used to make the craft knowledge transfer more engaging, traditional craftspeople still retain fear and doubts about the security of collected gestural data meanwhile crafting (Muller, 2019). Additional reflections on the role of artisans, designers, and computers/machines/robots gaining agency in crafting products are thus necessary to understand the evolution of creative leadership (Stevens, 2020).

The possibilities of exploring interwoven human-machine systems offered by the presented LE have nurtured students' inspirations and skills to design craft artefacts with more complex geometries and augmented precision, while improving its uniqueness through the design of pre-determined configurable parameters, thus impacting aesthetic languages and the hyper-customization of the output (Fig. 4). Provided with design and business joint training, students have gathered an understanding of traditional craft workflows, skills, and ICH, and proposed purposeful integration of technologies to increase the entanglement of traditional and digital crafts processes towards the future competitive and sustainable hybrid fashion craftsmanship sector.

However, the limitations of this kind of LE are related to the limited time to improve and develop high-fidelity prototypes to be tested iteratively with both fashion-tech professionals and traditional craftspeople inside their workshops. Therefore, a follow-up of this LE could be developing a residency model where students could develop functional prototypes and test them directly through on-field study research, and learning-by-doing activities. This Residency approach could amplify, extend and strengthen the implications of digital technologies in transforming fashion craft professional skills while retaining ICH, and in the change of creative processes, workflows, and tools toward more sustainable and meaningful fashion solutions.

Crafting hybrid workflows for the design of augmented textile artefacts

Delia Dumitrescu, Riikka Talman

The Swedish School of Textiles, University of Borås, Sweden
delia.dumitrescu@hb.se, riikka.talman@hb.se

Abstract

In the textile field, digital crafting is a relatively unexplored domain that requires further investigation in relation to the tools of the field and the aesthetic consequences of their use on the design. Computer software such as SDS-ONE APEX4 and computerised flat-bed knitting machines made by Shima Seiki are examples of the digitisation of analogue textile processes, and make use of digitally controlled material-fabrication methods. In adopting an exploratory approach to textile digitisation, this research aims to: i) explore methods of digital craftsmanship with a focus on textile materials and tools for the design of smart textiles, and ii) test the aesthetic possibilities of sketching smart textile artefacts using a hybrid workflow.

This paper presents a hybrid workflow composed of methods emerging from the synergy between experiential knowledge of materials and experiments with digital media. One category of experiments addressed the material level. By utilising digital tools for the virtual sampling of colour-changing smart materials, two changes in textiles were explored: from white to coloured in response to UV light, and from bright to dark in light-emitting yarns being recharged by UV light. The different timings of the colour changes and dimming of the smart yarns were documented and digitised, resulting in a library of colour swatches of gradients based on dynamic material behaviour. The swatches were combined with multi-layered textile structures, digital textures, and simulations of smart and conventional yarns to design the surface of textiles using the knit and weave design software SDS-ONE APEX4. In the sketches, every pixel represented a knit stitch or meeting of a warp and weft thread, providing information about material, structure, and colour at a specific point in time. Another category of experiments addressed the relationship between material and form; the colours swatches were further mapped on three-dimensional objects in Blender software to generate new forms and explore how dynamic surface effects influence the perception of form.

The experiments presented in this case study suggest that digitising a process that is based on the physical behaviour of yarns and textile structures offers an alternative medium for exploring smart materials more sustainably, expanding physical experimentation into the digital. This hybrid process enables designers to move between software packages and collaborate across professional knowledge domains, with the potential to develop cross-disciplinary and more sustainable material practices.

Author keywords

Digital crafting; hybrid workflows; smart textile design; sustainable material practices.

Introduction

Digital craftsmanship in the field of textile design has generally been linked to industrial manufacturing processes; it requires work with digital machines that necessitate field-specific technical knowledge of yarn behaviour, textile structures, and programming textile-specific closed-source software. Digital textile environments and manufacturing tools have typically been developed to increase production efficiency, and are optimised for work with conventional materials, rather than being seen as parts of exploratory processes. From this perspective, the design process is technologically assisted and seen as a linear workflow moving smoothly from idea to material production as part of a bottom-up process.

Thus, in the textile field, experimental approaches to digital crafting are forming an emerging design space that requires further investigation in relation to the tools used by practitioners and the aesthetic consequences of their use on the design (Clarke & Harris, 2012).

State of the art

Today, the knowledge of the textile designer has expanded beyond the traditional domain of experimental analogue processes to include digitisation and advanced manufacturing using industrial machines. Thus, digital craftsmanship has begun to make use of exploratory processes that use digital modelling software and digitally controlled fabrication technologies to imagine new material concepts (Harris, 2012). Similar to the 3D-printing technologies used in product and architectural design, computer software such as SDS-ONE APEX4 and computerised flat-bed knitting machines made by Shima Seiki are examples of the digitisation of analogue textile processes, and make use of digitally controlled material-fabrication methods (Taylor & Townsend, 2014). In contrast to conventional digital form-modelling environments used in product design and architecture, the forming process used in SDS-ONE APEX4 relates strictly to textile materiality; the design process requires knowledge of knitting and weav-

ing in terms of yarn structures and qualities, and allows the geometrical principles of forming using textile methodology to be expanded upon.

Recent research in the textile field has exemplified how analogue and digital knowledge in the textile domain can interact in the design process to open up a greater degree of creativity for textile practitioners. The 'Responsive Knit' research project (Scott, 2018) introduces a new perspective on using analogue knowledge of structural textile behaviour to design a new workflow by exploring shape-changing materials that react to moisture. Informed by knowledge of analogue processes, the result exemplifies how the textile hierarchy of fibre, yarn, and knitted structures can be implemented in a digital material workflow to fabricate new materials inspired by biomimicry. Another research project explores the link between analogue and digital textile knowledge by developing methods for power knitting that are suitable for the design and manufacturing of soft robotics. The workflows include exploration of tendon placement, methods of shaping, and studies of anisotropic textures. The artefacts produced represent an experimental way of exploring the possibilities of digital knitting technology to combine textile qualities with actuation systems, resulting in complex shapes that are able to exhibit smart behaviour such as shape-changing (Albaugh et al., 2019). Similarly, the responsive textile installation *Lumen* (Sabin, 2019) uses a digital form-finding workflow based on the use of architectural tools such as Rhino, Grasshopper, and Kangaroo to fabricate a tensioned, knitted canopy. The knitting strategy used to create the installation was based on the whole-garment method developed for Shima Seiki machines, and uses digitally designed knitted tubular shapes. The diverse range of colours of the UV-reactive yarns is directly embedded in the knitting process, as the striped pattern follows the weft direction of the knitted cones.

Revisiting the role of experimental knowledge and analogue processes in digital workflows, Woolley and Huddleston emphasise the importance of craft in their own process: "For the craftsperson, the retention of some element of direct physical proximity is vital because physical contact underpins the interplay between perception, skill, knowledge and creativity on which practice depends" (2016, p.93). Although digitisation is strongly present in the textile field, the creativity that is the result of the experiential freedom of analogue processes – relating to e.g. knowledge of tactile qualities and material behaviour – is still present, and can be used in a meaningful way to inform digital designs with regard to new material concepts.

Aim and method

Adopting an exploratory approach towards textile digitisation, this research aims to: i) explore new methods of digital craftsmanship with a focus on textile materials and tools for the design of smart textiles, and ii) test the aesthetic possibilities of sketching smart textile artefacts using a hybrid workflow. Two types of light-responsive changes were explored in physical and a digital space: colour change from white to coloured in response to UV light, and colour change from bright to dark in light-emitting yarns being recharged by UV light. This was undertaken in order to establish a hybrid workflow of methods emerging from the synergy between experiential knowledge of materials and experiments with digital media.

Previously, Kooroshnia(2014) developed a method for creating two-phase patterns for print design by mixing glow-in-the-dark and conventional pigments for a coloured pattern in daylight and a pattern of gradation of light in darkness. Her research further stresses the need for new tools that allow for simulation of the effects of the pattern to aid the design process. In this case study, the gradation of colour and lightness is approached from the perspective of the textile structure, by embedding UV-reactive yarns into knit structures. Knit software SDS-ONE APEX4 and 3D-modelling software Blender were used to simulate and visualise the changes in colour and lightness, in parallel with physical experimenting feeding into the digital process by documenting and making knit experiments. In the workflow presented in this case study, three variables for designing UV-responsive colour changing textiles were identified: i. the placement of the UV-reactive yarn, ii. the choice and proportions of materials and iii. shape of the knit (Table 1).

Table 1. The design variables for UV-responsive colour changing knits

Design variable	Function in the design process	Type of sketching
Placement of UV-reactive yarn	Defines the surface texture or pattern of the knit in its coloured or light-emitting states	Hand- and machine-knitting, SDS-One APEX4: Design 64
Choice and Proportions of materials	Defines the texture, tactile properties and behaviour of the knit, and how visible the changes in colour and brightness are	Hand- and machine-knitting, SDS-One APEX4: Design 64
Shape of the knit	Defines what parts of the 3D shape are subjected to UV-light for colour change, or visible when emitting light.	Hand- and machine-knitting, Rhino 3d, Blender and Adobe Photoshop

Experiments

The first experiments addressed the material level. Changes were explored and mapped in UV-reactive yarns to translate their properties into a digital form for further experiments. When the yarns were placed in either sunlight or a dark room, it was noted that both the colour-changing and light-emitting yarns had different reaction times and intensities of colour or light. In order to understand how the expression of the textile might change over time when using these yarns and how, and for how long, the different yarns either change colour or emit light, the changes were documented and translated into digital colour charts. The glow-in-the-dark yarn samples were recharged outside, then placed in a dark space and documented at regular intervals for 3.5 hours, after which time all of them had stopped glowing. Colour charts showing the brightness of the yarns at specific points in time were made. Similar documenting was undertaken of the colour changes in the UV-reactive colour-changing yarns by taking the samples outside and documenting the changes at regular intervals until no further changes occurred (2 minutes after they had been placed outside). The yarns were taken inside, and the changes were documented until they had returned to their original colours. A series of colour charts showing the colours at specific points in time was made, showing when there were notable changes in the colour palette (i.e. a colour appearing or disappearing; Fig. 1).

Figure 1. Colour charts mapping the changes over time in the brightness of the glow-in-the-dark yarns (left) and colours of the colour-changing yarns (right).

The colour charts were then used to produce several series of gradients (Fig. 1). In the gradients, every pixel represented a knit stitch or the meeting of a warp and weft thread, providing information about material, structure, and colour at specific points in time. Two series gradients of the glow-in-the-dark yarns were made, visualising how the expression of textiles changed over 3.5 hours, i.e. the time taken for the yarns to go from fully recharged to no longer emitting light (Fig. 1). The colour charts for the UV-reactive colour-changing yarns were also used to create gradients to explore how the colours changed over the 34-minute period during which the yarns changed from white to coloured and back to white (Fig. 1). However, the UV-reactive colour changing yarns have a range of different colours, and they appear and disappear at different rates, unlike the glow-in-the-dark yarns, which primarily change in the intensity and duration of light. This gave the resulting gradient a striped expression.

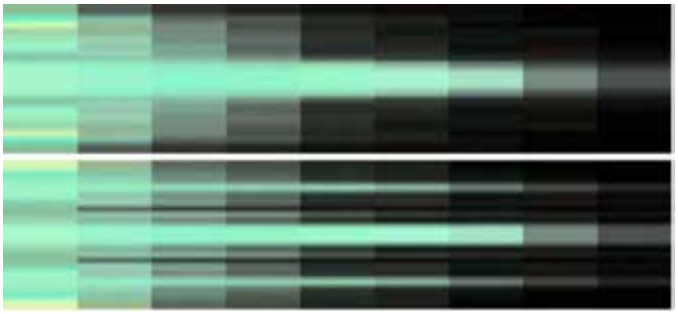

Figure 2. Two gradients showing changes in the colour of the light being emitted by glow-in-the-dark yarns over a 3.5-hour period: from bright to dark (above) and contrasting stripes (below).

Samples were knitted out using Dubied hand-knitting machine. Experiments combined a white single-jersey structure with floats in the colour-changing and glow-in-the-dark yarns, organised in a gradient from the most intense and longest-lasting to the lightest, fastest-dimming colour or glow. Different proportions in the placing and materials in the floats were tested, and one in which the distance between the floats was gradually increased as the gradient progressed from more to less reactive yarns produced a clear gradient in a dark room. The colour effect, however, was not particularly visible. To make the colour changes more visible, two threads of colour-changing yarn were plated together with a thicker white wool in a single-jersey structure (Fig. 3). The glow-in-the-dark yarn floats were organised as a striped pattern that mixed brighter and dimmer glowing yarns, creating a fabric with two different faces with contrasting changes.

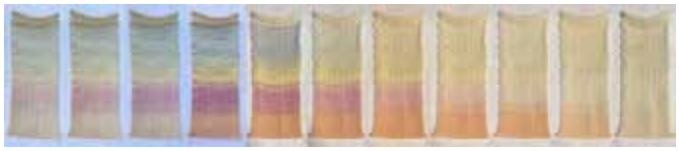

Figure 3. A gradient in UV-responsive colour changing yarns over a 55-minutes period first outside (images 1-4 from left), then inside (images 5-11 from the left). Single jersey with plating and floats on the reverse side.

In order to be able to digitally sketch changes in colour and amount of light emitted in a medium connected to textile materiality, the colour charts were transferred into the knit and weave software SDS-ONE APEX4. Exact shades of each colour chart, depicting the colours of the yarns at a specific point in time, were input as their own custom colourway. This made it possible to see how the expression of the textile would change over time by viewing it in relation to different colourways (Fig. 4). The software allows yarns that have similar sizes, weights, and textures to the physical UV-reactive yarns to be chosen, making it possible to translate the properties of these yarns into digital form and combine the changes in colour and amount of light emitted with textile structures, materials, and textures. Thus, it was possible to simulate what the textiles would look like at different stages of change.

Figure 4. SDS-ONE APEX4 simulation using the colourways of colours of the UV-reactive colour-changing yarns over a period of 34 minutes. Single-jersey structure with plating.

Two simulations were undertaken used knitted gradients with ten colourways to cover all of the increments in the colour changes of the yarns over a period of 34 minutes. The first simulation was undertaken using a single-jersey structure with a single thread of the colour-changing yarns. The second simulation was also a single-jersey structure but for this the colour-changing yarns were plated on a thicker wool yarn (Fig. 4). This created a heavier, denser fabric similar to one of the experiments undertaken using the hand-knitting machines (Fig. 3). The gradients of both experimental results were striped.

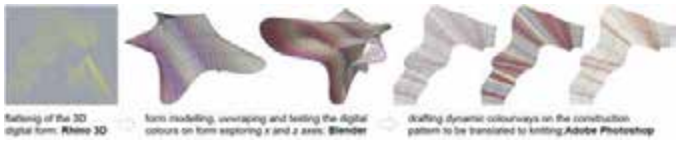

Figure 5. An example of flattened surface patterns prepared for knit construction; a simulation of a dynamic colour gradient created by applying colour gradients on the form in Rhino 3D.

In order to test the impact of different colours on form, an organic form was generated using Rhino 3D and Grasshopper (Fig. 5). These software packages allow three-dimensional objects to be flattened, which is necessary to translate the digital form to the physical knitting process. The form of the construction pattern was used to plan the sequence of colours and select yarns in terms of their quality when designing the knit forms. The same construction pattern could then be translated in the knitting software and fabricated using a partial knitting technique which allows direct shaping in the machine. Digital colour samples in the Blender software were mapped on the object to explore the effect of dynamic colour and texture on perception of form. The sizes of the stripes and direction of colour gradation and contrast were important to consider when planning colour placement on the form to emphasize its curvature and helped to plan the succession of colours on the construction pattern to be translated to the knitting program.

Conclusion

Smart materials react to various stimuli, which means that the designer needs to understand the textile's expression in multiple stages and consider how placement, heat, and light, for example, can influence the changes in expression that can occur. Three-dimensional modelling software packages such as Rhino 3D and Blender facilitate exploration of smart materials and changeable expressions in different contexts, as they allow parameters such as colour, form, space, and intensity and direction of light to be tweaked. Thus, the workflow presented in this paper explored the relationship between analogue and digital craftsmanship with a focus on colour, textile construction methods, and proposing tools for designing smart-textile artefacts. Similar to the research of Scott and Albaugh et al., it was found that navigating between various digital software packages allows the designer to fabricate and flexibly include dynamic variables, design variations, and smart-material agency in customised workflows for knitting design. In a comparable way, the hybrid workflow used in the creation of *Lumen* (Sabin, 2019) demonstrates that digital form-finding can be influenced by the limitations of the chosen knitting technique, and that such processes can be accurately translated into knitting technology. In addition, this research expands on these previous works by exploring the digitalization of smart colourways and their application on 3D forming process for knitting. Software packages such as SDS-ONE APEX4, which simulate conventional materials, allow the development of alternative workflows that are customised by the designer to function with colour-changing yarns, allowing changes in colour over time to be planned, predicted, and visualised directly on textile structures and digital artefacts. To further develop the method, the accuracy of colour expressions could be improved by documenting changes in yarn samples in a more controlled manner by using a colour scanner.

Generally, the introduction of digital sampling and form-finding supports the development of sustainable textile practices by reducing the need for material testing and consumption. However, software packages such as SDS-ONE APEX4, as well as Scotweave, TexGen, and Blender, should not be seen purely as means of recreating smart yarns in digital form in order for them to then be produced as physical textiles. Instead, they can be approached as alternative ways of working with smart materials and customised workflows, allowing the designer to develop sustainable and innovative practices relating to the Industry 5.0 model (Xu et al. 2021): they can facilitate exploration of values, expressions, materials, structures, and scenarios that might not yet be possible, or relevant, to realise in physical form.

Abstract

The DISTANCE project (digital immersive technologies and craft engagement) is a novel practice-led experiment in the use of immersive technology to enable dispersed craft practitioners to apply their haptic skills and material knowledge in a digital immersive space, learning from peers through remote collaboration. Craft practice is rooted in tactile interpretation of materials expressed through tacit, haptic processes (Ray, 2009). In this paper we ask; what role can haptic crafts skills play in a virtual studio environment? The paper reflects on the interaction between different craft disciplines and thus how different kinds of tacit knowledge impact on the act of creation in an immersive space (McCullough, 2004). How does a VR studio relate to a material studio practice (Corazzo, 2019)? Conversely, what are the drawbacks of such places in terms of collaboration when craft practices are rooted in material knowledge and haptic skill? Through a series of semi-structured workshops, practitioners shared their experiences of working alone and collaboratively within immersive space and discussed the unique challenges and opportunities of integrating and sharing haptic-driven creative processes and experiences with digital space. Thematic analysis of workshop discussions, interpreted by both craft and HCI experts, are presented alongside analysis of the work produced. This paper describes the role that haptic skills can play within immersive environments for craft practitioners and discusses current challenges to be addressed and opportunities for future work in hybrid digital-physical spaces. The paper also reflects on the role a virtual studio space can play as a shared learning environment. What are the barriers to adopting a virtual studio practice using VR? How does a VR studio connect to a physical making place? It is becoming increasingly important for creative practitioners to gain digital skills and competencies, both for creative production and for collaboration (Palani, 2022, Helgason *et al*, 2023). While the Covid pandemic meant that many more activities were conducted online or through digital means, this technological transformation has been underway for many years already (Cavalheiro *et al*, 2020). In the United Kingdom, the term "CreaTech" has been coined to describe the emergence and importance of this intersection where digital and data skills meet creativity (Bahkshi *et al*, 2019). Finally, the paper reflects on what role a virtual studio can play in supporting a sustainable craft practice: how does a virtual creative place that offers limitless options in terms of scale, material exploration, unhindered by physical limitations impact physical making practices?

Introduction

The DISTANCE project (digital immersive technologies and craft engagement) took place during the UK COVID-19 lockdown of 2021 and is a novel practice-led experiment in the use of Virtual Reality (VR) to enable physically dispersed craft practitioners to apply their haptic skills and material knowledge in a digital immersive space, learning from peers through remote collaboration. Here we consider craft practice as both a skill and process (Adamson, 2007, p. 3), as a way of doing things, rooted in a tactile interpretation of *materials* expressed through tacit, haptic processes (Ray, 2009) and embodied in both manual and mental skills (Pye, 1968). The craft practitioners involved in this project are referred to as makers throughout this paper.

The pilot DISTANCE I took place online between February and April 2021 involving six makers in three partnerships, whilst the DISTANCE II roll-out phase took place from June 2021-January 2022 and engaged with eight craft makers and three collaborations. The project was developed and managed by the makers collective, Applied Arts Scotland (AAS), who sourced the funding and resourced a technical expert to support the project. Each maker was loaned a VR set (Oculus) over a period of three months (phase I) or eight months (phase II): each headset was set up and preloaded with the software required and supplied with a set of tailored instructions with regular technical and peer support sessions across the period, thus making the 'threshold' lower than if makers would have undertaken on their own. The collective journey of the maker participants was important in this project. Each craft maker had a different material expertise which ranged from product design, weaving and knitting, ceramics and glass, silversmithing and jewellery making. It is notable that the group had diverse and uneven prior digital production

skills which ranged from novices to proficient digital fabricators using 3D modelling and 3D printing. This paper describes the impact VR had on this diverse group of craft makers and how this technology was adapted to individual as well as collaborative making practices. The paper thus reflects on the interaction between different craft disciplines and what different tacit knowledge bears on creating in an immersive space. Conversely, what are the drawbacks of such places when craft practices are rooted in material knowledge and haptic skill? This paper also explores the role that haptic skills can play within immersive environments for craft practitioners (referred to as makers throughout) and discusses current challenges to be addressed and opportunities for future work in hybrid digital-physical spaces. Finally, this paper sums up the role VR can play in future craft practices and outlines further scope for study.

This paper has been based on data gathered 1) by active participation as makers by three of the authors, 2) from a series of semi-structured workshops facilitated by AAS in which the fourteen practitioners shared their experiences of working alone and collaboratively within the immersive space, and discussed the unique challenges and opportunities of integrating and sharing haptic-driven creative processes and experiences with digital space and 3) additional thematic analysis of workshop discussions, informed by both theory and practice. We use the terms immersive space and digital space throughout this paper as overlapping terms, since the project relied on shared non-physical spaces that were occupied as immersive spaces within VR headsets and/or as supporting digital spaces where work created could be supplemented, edited and curated, with the makers moving back-and-forth between these dimensions as needed.

Distance project: digital pivot

The DISTANCE project was developed for and by craft makers through AAS. DISTANCE I was financed by Creative Informatics, a four-year R&D project funded by the UK Arts and Humanities Research Council (AHRC), to support Data Driven Innovation (DDI) in the creative industries in Edinburgh and the South of Scotland region whilst DISTANCE II was funded by Creative Scotland with further plans for an international rollout. It is this cascading effect of small R&D interventions which deserves attention as well as the innovative collaboration developed in this project.

During the period of global lockdown of 2020/21, the cultural and creative sector became a proving ground for data driven innovation. The shift towards digital technologies was significantly accelerated by the global pandemic, condensing five years digital adaptation into two months (UNESCO, 2020; Baig *et al*, 2020). The swift digital pivot of the creative industries in the wake of the pandemic highlighted possibilities in the use of online spaces for not only disseminating creative work, but to connect, share, collaborate and create. Access to physical spaces for creative production was made difficult or impossible during lockdown, halting not only production of works but also limiting scope for research and development for creative practitioners who routinely rely on access to physical spaces and specialist equipment to create work. Whilst the use of online platforms enabled creatives to connect digitally in a virtual space, the DISTANCE project brought an added dimension by exploring how craft practitioners might be able to collaborate and create together in a virtual three-dimensional space, remotely.

The recent democratisation of VR through a marked decrease in the purchase price of VR headsets has enabled more creatives to explore this technology. However, this has coincided with the adoption of the software (e.g. Tiltbrush, owned by Google) and hardware (e.g. Oculus Quest, owned by the Facebook company Meta) by tech giants. VR technology is evolving rapidly which makes this risky for sole practitioners to experiment with as the technology may no longer be supported in the near future, making their investment of time and capital obsolete. The large tech companies are proving critical in both lowering access thresholds and potentially providing stability longer term. It also, however, opens ethical debates: an Oculus Quest at the time required a mandatory Facebook integration and is thus linked to a personal Facebook account (at time of writing requires an Oculus account) with known issues around data tracking (Bujlow *et al*, 2017). The DISTANCE project circumvented this by setting up a project Facebook account thereby avoiding linking to individuals' accounts which was shared across multiple headsets. With changes linked to the transition from Facebook to Meta, this approach is no longer possible.

The loan model of the VR headset fits within a sharing economy model where the upfront costs of technical equipment, including software is taken on by a third party, in this case AAS on behalf of its members. The sharing economy grew from DDI in the economy using digitised platforms (Belk, 2014) including Libraries of Things (Ameli, 2017). This sharing model supports not only a change in consumer behaviour by reducing resources (Edinburgh Tool Library, 2020), but critically also supports access to tools and specialist equipment for marginalised groups, those on lower incomes or with lesser means to invest in technology (Hamari *et al*, 2016: Hellwig *et al*, 2015) and fits with AAS' ethos of supporting sustainable making practices of and for its members.

The DISTANCE project was a collective learning project which occurred within a safe and trusted peer-led space that enhanced risk taking and exploration within digital space (Jaramillo *et al*, 2019). It evidenced that working remotely collaboratively can take place in both synchronous and asynchronous ways: collaborators could work on joint projects in shared digital space at separate times or they could work on it together, at the same time, in the same digital space. This enabled those with non-normative working patterns to fit around caring responsibilities or enabled those for whom travel was perhaps difficult for health reasons or with career responsibilities elsewhere, to be flexible in their collaboration. Regular scheduled sharing sessions meant that issues - technical or creative- were shared and addressed in near-real time.

Skills

Learning to use and understand this new technology required completely new skills, both haptic skills in terms of acquiring the tactile skills of handling the handsets and headset but also the mental challenge of different ways of working and thinking. Learning these skills did not come naturally to all the makers: some were "struggling" or "frustrated" with

the technology, with a reluctance to fully engage with the VR experience: "always more interested in the real world" whilst for some the physical experience of wearing a VR headset for a prolonged time confronted them with nausea and headaches, thus limiting their time in VR. Others, however, took to it easily. All makers were transferring existing skills into VR: from drawing to making skills such as weaving or throwing ceramics. It was notable that the more experimental adopters of the technology were willing to abandon their tacit knowledge of making and materials to play and explore.

The rationale for the makers to opt into DISTANCE ranged from simply wanting to explore this new technology as part of their ongoing professional development "to challenge myself" or "take me out of my comfort zone". All makers specifically explored how experimentation in a virtual environment would inform their analogue practice. Some makers who had prior experience of working with digital technology had specific aims in mind: "Discover and exploit the main advantages that working in VR with [Gravity Sketch] GS-VR has over other 3D modelling programmes". This mix of knowledge proved valuable to the collective learning experience during both the online collaborative sessions and the formal workshop exchanges facilitated by AAS. Access to the technical expert proved a key asset in the success of the DISTANCE project and enabled the makers to explore and solve practical problems, often relating to how to integrate their analogue practice into their VR. This maker led approach to making proved an equally fruitful learning experience for the technical expert as different questions emerged from maker queries than perhaps VR content developers might ask.

Whilst there are other technologies that enable remote collaboration, through file sharing of digital drawings for example, VR enabled creation and collaboration in a three-dimensional virtual space both in real time and asynchronous time. But unlike other creative technology, such as CAD, the immersive virtual reality tools offered a *playfulness* perhaps hitherto not experienced but which belies its origin in the gaming industry: "When I am in the headset I am not on the clock – I am playing". It was clear that the ability to play and experiment with this technology with low financial risk (headsets loan) did require an extensive investment of time to develop the necessary skills required: "Being able to deal with new stuff needs time to be digested and help each other". Furthermore, VR enabled craft makers to explore making without the usual physical boundaries of a material practice: no gravity, scale limitations, mess or carbon footprint of materials (acknowledging of course the digital carbon footprint): "immersive technology allows you to break the rules". This "limitlessness" was considered both an opportunity and a barrier when constraints can be useful as a framework to work against. Transferring haptic skills to a virtual environment required a fundamental understanding of what haptic skills each maker possessed: what were the actions which constitute their daily making practice? And how did these actions translate into bodily movement? Transferring these haptic skills to a VR hand controller with little haptic feedback proved challenging. The tactile setting in the hand controller enabled the weaver to successfully receive haptic feedback on the use of virtual materials in VR: "that feedback 'rumble' really supports the feeling of touching something". This was, however, not experienced by the other makers.

Augmented craftsmanship

The COVID-19 pandemic highlighted the need for digital literacy as more activities migrated to online, but this shift was part of a longstanding process. This digital transformation trend is disruptive, and it is changing the way that designers and artists create and distribute their work and influencing how audiences and clients access these creative outputs (Cavalheiro, 2020). Consequently, acquiring and improving digital skills is becoming more necessary for creative practitioners (Helgason *et al*, 2023). Digital technologies have pushed craft practice to new boundaries, enabling new ways of making work and creating new visual vocabularies (Cutler, 2012; Shillito, 2013) and VR is another in the toolbox. The exploration of material qualities in VR relied on the capacity of the software to mimic materials in a three-dimensional virtual world. Some materials were easily translated. Others, such as the drape of fabric, the fluidity of thread or the transparency of glass, required more exploration and experimentation with a limited palette. A weaver tried to emulate the woven textile. Only once the actual weaving action was abandoned and instead images of prior constructed woven fabric were imported, did the ability to construct or disregard components quickly become apparent. The ability to repeat knitted samples in an exploratory fashion would not be possible in real life without physically knitting them: "Gravitysketch helped me to visualise the things that are possible in real life". Furthermore, being able to walk around the constructed assemblages at different scales enabled her to envision her work on a scale hitherto not possible. The scalability in VR proved a key asset to most makers and supported the element of play. The liberty to "play" required a change of mindset. A potter consciously had to "forget" his tacit and material knowledge so as not to preclude experimentation in VR as the experiment "won't' work" in the analogue studio. A furniture designer was "making all these things that I cannot make in reality". A glass maker was experimenting with fluid 3D forms "that would be almost impossible to make at this scale and in this form as it defies gravity". In other words, experiments in VR might not be easily translatable in studio production: one maker felt a "responsibility to make work that is not possible in any other way". The experimentation in Gravitysketch had a freedom of expression that was "mindblowing", not easily found in material practice. It was noted by several makers that whilst tacit knowledge is critical for designing objects and products which will "live in the real world", this inherent knowledge can stymie the playfulness to which VR lends itself and which proved valuable for exploration and experimentation. For some makers, the playfulness generated in VR space was then taken back into the physical studio, generating a shift in process.

The interaction between the virtual and analogue proved to require some flexibility of mind. Some makers found the amount of time required "disproportionate to the results" to create something in VR "to then bring it back out into the real space to then make it". Those most adapted were those who had an ability to "start with nothing". One potter produced a multifaceted form in VR. This was translated into a 3D printed form from which a negative multi-part casting mould was made from which a ceramics form was slipcast and fired. The use of VR and 3D printing "took four steps out of the mould making process" so here too VR facilitated both time and ma-

terial saving contributions. This 3D object was brought back into the virtual environment by minting it as bitcoin. These different processes, outputs and learning were presented as an exhibition in a 3D environment, Frame V, that could be viewed and navigated via web browser on any compatible device, including immersive versions in the VR headset (Fig 1.)

Figure 1. Frame V digital immersive exhibition space of DISTANCE II, Applied Arts Scotland, with work by Chris Donnelly showcasing glaze testing of 3D printed form created in VR created slipcast and glazed before being turned back into digital through NFT mining. Source: https://framevr.io/distancechrisgallery. With kind permission from the artist.

The space included the opportunity to embed film, audio and 360-degree photo collages alongside 3D models, and for the viewer to take self-directed virtual walk-abouts. Linked spaces exhibited the work of individual makers and collaborative groups. This offered "a guided tour of everything that is possible in a virtual space" in terms of making practices. Furthermore, social media supported these collaborations to be shared and enabled immediate feedback on the processes and work made. This exploration between the virtual and analogue revealed different opportunities to interact with the initial form and transform it into different immaterial and material iterations, each with their constituent feedback to the maker (Spence et al, 2020 & 2022). The ability to import analogue works through photography and film into VR which could then be manipulated, 3D printed or made in the studio and then brought back in the VR made some makers question: "What is reality? Am I looking at x in VR or in VR looking at x?".

Conclusion

In DISTANCE the VR studio became not only a site of individual experimentation but a shared learning environment. Once basic VR skills were acquired, the virtual studio offered a creative place that offered limitless options in terms of scale, and material exploration, unhindered by physical or financial limitations, it enabled a certain amount of risk taking and exploration that would be prohibitive if executed in real terms. It is notable that the pandemic gave unprecedented "licence to play" as other commitments and responsibilities had temporarily been removed. Both the socially and environmental *inclusivity* of the technology make this a potential *sustainable* option. This is however, potentially offset by the rapid changes in software development, making investment in soon-to-be-obsolete hard- and software a non-viable option for creatives for whom training in new technology requires an upfront investment of time, even when hardware costs can be shared through a loan model. Furthermore, obsolete hardware, unless recycled in closed loop, wastes materials and resources. The barriers to adopting a virtual studio practice using VR were either physical (nausea and headaches), limited time to experiment and learn the necessary skills, inability to let go of innate material knowledge to facilitate playful learning and experimental making, and the limited material palette in the existing software. Conversely, the tacit knowledge of the makers can be used to arguably improve the experience of the tool itself. The facilitating factors were access to R&D funding, access to specialist equipment (sharing economy model), expert advice and support and an extended period within which to experiment. The funded R&D interventions are highlighting DDI in the creative industries that are worth paying attention to and are a model that deserves investment going forward. It is also worth reflecting on the value of a community of practice in a physical studio space, where *haptic* skills are paramount. If we consider the community of practice to be composed of shared experience, expertise and meaning (Jaramillo *et al*, 2019), then VR can replicate much of the intellectual and emotional aspects of experience, expertise and meaning but still falls short of the physical, at least whilst the VR studio is limited to a headset. A question going forward might be how immersive technology can integrate the embodied experience of making when the current focus is mostly audio and visual senses rather than haptic ones. However, technology is developing fast to include resistance and feedback loops to make the sensory experience more complete. What might this mean for material practices such as craft, design and architecture, where embodied material and haptic knowledge are fundamental to learning and acquiring skills? And what implication would this have on the 'playfulness' of VR?

Notions of hybrid craft production: conversations and small-scale experiments in digital fabrication

Abstract

Since the advent of 3-D printing as a form of additive manufacturing technology in the early 1980s, digital fabrication has made many inroads in craft and production. The 'digital fabrication revolution' (Gershenfeld 2012) has also presented us with opportunities for hybrid craft production, or situating craft practices at the intersection of traditional and digital modes of production. In spite of the burgeoning opportunities, there is still hesitation amongst traditional craftsmen and makers when it comes to adopting or integrating digital modes of production into their workflow. With contemporary Singapore and evolving ideas of 'craft' as the backdrop, this research unpacks possibilities for production through conversations with local craftsmen engaged in traditional and digital fabrication. The conversations primarily revolve around two pottery artists (with an emphasis on functional ware) and a makerspace located in a public library. The conversations and experiments reveal three key observations. First, notions of expediency and precision can play a role in how we come to appreciate and appraise 'skill' or more specifically 'hand skills'. This has implications for how we understand 'direct experience' (McCullough 2018; Cardoso 2018) in the context of craft objects. Second, when assessing quality, conversations around 'failure' reveal differing opinions about benchmarking and quality control between artists engaged in traditional pottery and digital fabrication respectively. Third, asking more open-ended questions about what a 'tool' is and how we can shape our own tools and workflows will reveal more opportunities for hybrid craft production. Lastly, through the aforementioned research, two potential barriers to entry were identified in the form of economic barriers, and time and education barriers.

hybrid craft production, digital fabrication, workmanship

Introduction

Since the advent of 3-D printing as a form of additive manufacturing technology in the early 1980s, digital fabrication has opened possibilities for makers and manufacturers alike. One can gain a sense of the techno-optimism via Neil Gershenfeld's (director of MIT's Center for Bits and Atoms) (2012) proclamation of this technological phenomenon as the "digital fabrication revolution". Chris Anderson, a former editor-in-chief of Wired magazine, elaborated on what this meant for individuals and communities by tracing the boom of the 'maker movement' and 'makerspaces' in his 2013 book, 'Makers: The New Industrial Revolution'.

3-D printing presents us with opportunities for hybrid craft production, or situating craft practices at the intersection of traditional and digital modes of production. At a time of "postdisciplinary flux", we can observe that the "categories of making are increasingly intermingled and hybridised" (Adamson 2013). While the market potential of 3-D printing for industrial manufacturers has been growing, this paper is more interested in the possibilities afforded to individuals, from "mass personalisation" (Deloitte 2015) to the boom of the "makerspace phenomenon" (Sherlock 2021). In particular, we are interested in individuals who consider themselves to be hobbyists, enthusiasts or amateurs in the realms of traditional and digital crafts.

The "hybridization of traditional and digital processes" (Treadaway 2016) can be found in a range of disciplines, from ceramics to textiles. However, in spite of the burgeoning opportunities, there is still hesitation amongst traditional makers in Singapore when it comes to adopting or integrating digital modes of production into their workflow. Various researchers working at the crossroads of computational methods and traditional craft have provided inspiration for this research, including Zoran's 'hybrid reassemblage' (in the context of "digital fabrication to restore broken ceramic objects") and Zheng and Nitsche's 'crafter-designer collaboration' model (discussed against the backdrop of a collaboration between design technologist Clement Zheng and ceramic artist Amy Roberson leading to experiments involving pottery and interaction design).

Singapore as context

Sherlock (2021) stated in her survey of the makerspace phenomenon covering San Francisco, Berlin and Calgary in Canada, that the "critical discourse around what is being made and why is often lacking". The same could be said of the digital

craft scene in Singapore, especially when looking for opportunities to rethink traditional crafts. In this spirit, we began our inquiry with one guiding question: how will digital fabrication tools open possibilities for hybrid craft production? In attempting to answer the aforementioned question, we conducted interviewees and studio tours with three research participants based in Singapore. In this spirit, one aim of this research was to explore the receptivity of craftsmen largely engaged in hand work to integrating digital fabrication into their workflow.

The criteria for selecting research participants was twofold: [1] craftsmen that made functional household craft objects, or, [2] craftsmen that employed either traditional, digital (such as 3-D printing) or hybrid craft production methods. The interviews enriched our appreciation for the role(s) played by traditional and digital craftsmen and possibilities for hybrid craft production.

Three craftsmen

Before we dive into our findings, it would help to better understand the profiles of our three research participants: Jolyn Ong, Goh Sing Hong and Muhammad Ismadi.

Ong is a hobbyist and pottery artist who has spent three years honing her skills in ceramics, with the goal of opening a pottery cafe one day, one that allowed patrons to find peace and relaxation. At age 25, she took up pottery classes at Toa Payoh Community Centre in Singapore before practising at shared studios and self-learning through online tutorials. Ong's motivation is driven by the endless wealth of knowledge that ceramics craft has to offer, which she believes could take her a lifetime to learn.

Goh is one of the youngest pottery artists in Singapore and spent two years learning ceramics at various studios, including Mud Rock Ceramics, Common Touch Craft and Ves Studio, before continuing her practice at her home-based studio and developing her own style. During this learning journey, she realised that she had a few decent pieces to sell and began marketing her wares through Instagram.

Muhammad is a maker coach at MakeIT at Tampines, a makerspace that is part of a National Library Board (NLB) initiative, and specialises in digital tools such as 3-D printing technologies. With a background in applied physics, Muhammad spent three years building a 3-D printer from scratch using scrap materials in 2013, a time when 3-D printers were not as affordable to the public. As a maker who now owns multiple consumer 3-D printers, he finds joy in DIY projects and customising everyday objects like wearables (e.g. watch straps).

'Direct experience' and making

Architectural professor McCullough took a production-based approach when he located the essence of craft in the digital realm as one that is based on the "direct experience, personal vision and mastery of a medium" of a maker (McCullough qtd. in Cardoso 2018), while Cardoso (2018) argued that the direct experience is not limited to makers, as it "stands alongside the experience of users" and that it is a 'collective' and 'open-ended' process.

When asked about their preferences regarding pottery craft, Ong shared that she has never been swayed by user or consumer preferences, explaining that "the whole point I'm doing ceramics is so I listen to myself". Rather than trying to find a fixed style, Ong envisions having dynamic styles that will speak of her different personalities and preferences that she has as a pottery artist. On the other hand, Goh is clear about her own style, as she is particularly interested in curvy forms and describes her style as "wacky". While a style can be perceived in her works, Goh mentions that consumer preferences such as cups being more popular as compared to vases tends to influence her production decisions when planning upcoming collections.

Despite having different tastes and preferences in their practice, both Ong and Goh highlight the importance of making artefacts by hand, and do not see a need to incorporate digital fabrication technologies such as CAD (computer-aided design) modelling and 3-D printing into their production process at this moment. After some years of practice, they have both learned techniques such as handbuilding and wheel-throwing to create pottery with their hands and therefore, the need to incorporate digital processes did not arise.

While Ong and Goh emphasised 'direct experience' (McCullough) and making things by hand, Muhammad explored using a 3-D printer as a tool to make his artefacts, rather than building or sculpting them *only* with his hands. Utilising the materials readily available in his makerspace, such as wax, concrete and air clay, he experimented with various casting techniques while relying on 3-D printed moulds. His casting experiments were an attempt to expand his palette of materials beyond plastics commonly associated with 3-D printing.

Immediacy and production

Pottery is a relatively long process, from hand-building or wheel-throwing, to glazing and firing. Ong and Goh mainly practiced the wheel-throwing technique to create their forms [see Table 2].

Table 2. Steps for making pottery, as shared by Ong and Goh

	Step	Description
1	Sketching Ideas	Drawing inspiration from online sources, and sketching ideas on paper.
2	Wheel-Throwing	Execute ideas on the wheel-throwing machine by perfecting the clay forms while ensuring that measurements are consistent. Perfecting the form alone takes a lot of practice (in order to get even thickness and reduce cracks during the firing process later on). It is important to note that the clay will shrink by 20% during the firing process, thus they have to compensate by making their items bigger than the finished size at this stage.
3	Glazing	The next two steps (glazing and firing) have to be done carefully as they are irreversible. Glazing itself is a whole different art form. If the compounds are inaccurate, it will affect the results during the firing phase.
4	Firing	Lastly, the glazed item is brought into the kiln to fire at above 1000°C. Once the clay is fired, it can no longer be recycled again.

Ong (2022) shared her opinion on the tedium of pottery:

> *A lot of people think a simple mug on the table is something you can get in a day, but it is not. If you are into the knowledge of it, you realise a piece of mug, bowl, or plate takes a month. The drying process, trimming it whilst it is just dry enough but not too dry... all these little things that you have to take note of adds to the whole length of the duration of making.*

To illustrate the point further, the final steps are irreversible—once a pottery piece is fired, the clay can no longer be recycled and the potter will have to destroy the piece or start over again. In comparison, Muhammad shared his experience with 3-D printing, while making a smartwatch strap from scratch [see Table 3].

Table 3. Steps for making a smartwatch strap, as shared by Muhammad

	Step	Description
1	3-D Modelling	Create a 3-D model of the strap using TinkerCAD, a 3D-modelling software.
2	Preparing for 3-D Printing	Convert the 3-D model file (.stl) into a 3-D printable format (.gx) using FlashPrint.
3	3-D Printing	During the 3D Printing process, several iterations can be made based on the measurements and prototypes in order to get the strap size and fitting right.

While pottery has irreversible steps (especially after glazing and firing), digital fabrication allows multiple iterations even after the initial 3-D printing. It is also clear that 3-D Printing is not an instantaneous process that allows you to see results or output immediately. Unless one downloads ready-to-print 3-D files from open-source portals such as Thingiverse.com, 3-D modelling requires time to refine and render; the step of 3-D modelling being a crucial one.

Quality benchmarking and defining 'failures'

When analysing how different craftsmen benchmark their craft pieces, it would help to understand how they define a 'good' or 'failed' piece. For Ong, she still considers herself an amateur and student after three years of practice, as she is constantly trying to hone her skills to the reach the level of a master ceramist before launching her own collection. On the other hand, Goh launched her first collection after about a year of practice. When asked how they each defined a failed ceramic piece, Goh described pieces that were "too thick, heavy, uneven [the opening is off centre], random holes" while Ong focussed on "cracks, patchy glazes".

To Ong, uneven forms can be seen as expressions of 'wabi-sabi', or the idea of intentional imperfections, and that the beauty of ceramics is that "there is no right, bad, good or wrong art". Goh believes that as a pottery artist, it is necessary to experience failures, while Ong thinks that "there's no such thing as failures, just lessons in pottery". For example, Ong usually slices her failed pieces in half to analyse what went wrong before recycling the clay. Both Ong and Goh agree that it was only after making progress over time, that they began to see their initial pieces as failed attempts. While different craftsmen have differing ideas of a good quality craft object, and the definition of failure is also equally subjective or deeply personal.

While Ong and Goh mainly described failures in terms of the physical characteristics of pottery pieces such as uneven forms and cracks, Muhammad experiences failures either during or after the 3-D printing process (e.g. during a casting process). With digital fabrication, iterations originate from the 3-D modelling process leading to an existing 3-D file that allows repeatability.

Possibilities for hybrid craft production

When presented with the possibilities of incorporating 3-D Printing into her process, Ong saw an opportunity to make a chuck using 3-D printing. A chuck is a tool that Ong often used to help trim her vases with narrow or uneven rims during the wheel-throwing process. Currently, Ong has been making chucks out of clay, but believes that there might be an opportunity to make her own tools using 3-D printing. Rather than relying solely on hand skills to achieve a certain form, pottery artists can make use of additional jigs when working with unusual or complex geometries.

Muhammad, on the other hand, has been experimenting with building his own tools since 2013. Rather than wait for 3-D printing to become more affordable and widespread, Muhammad spent three years experimenting and building his own first 3-D printer in 2013. Later, he purchased a Creality Ender-3 Pro, a beginner-friendly and relatively affordable 3-D printer suitable for makers. Muhammad prefers the Ender over competing models due to its flexibility. He is able to customise or upgrade different parts on his own, and print custom parts if required.

Many digital craftsmen have been experimenting with building their own 3-D printers for ceramics in recent years. Ong added that she thinks it is "quite exciting" and that she "will personally try it, in future" and she "might even include it if [she sees] some value in it... [and she sees herself] selling 3D printed ceramics because it's a series that is interesting and people might be interested". Digital fabrication can be used in a 'tool-making role', in addition to directly fabricating of end products (Jorgensen qtd. in Zoran et al. 2015).

Barriers to entry

Having discussed the potential for hybrid craft production, we cannot overlook barriers to entry.

Firstly, there is an economic barrier as pottery is considered an expensive craft to learn. Although Ong was keen on learning ceramics from a young age, she was only able to commit to learning pottery after having a stable personal income at the age of 25. Goh mentioned she is one of the youngest potters in her studios, where most potters are aged 30 and above. An average five-week pottery course can cost between SGD300 to 400 (USD 226 to 302) and Goh mentioned that she bought a second-hand wheel-throwing machine for around SGD300 (USD 226). On the other hand, the makerspaces (MakeIT) at public libraries in Singapore offers free usage of 3-D Printers to public users (age 13 and above), as long as they have a registered National Library Board account and completed a free three-hour starter course. In addition, visitors can receive guidance from maker coaches.

Secondly, there are also time and education barriers. When Ong and Goh first began learning pottery, they had to attend at least five physical lessons in order to learn the fundamentals of clay. Goh spent three weeks learning hand-building and two weeks on wheel-throwing, while Ong spent ten weeks learning wheel-throwing. With the basic skills acquired, they were then able to progress to self-practice or self-learning via online video tutorials. On the other hand, there are many free online resources that encourage self-learning about digital fabrication. For example, there are free 3-D modelling softwares such as TinkerCAD.com and Blender and many websites share user-generated content such as digital design files hosted on Thingiverse.com. In addition, studio space and overheads are a concern. While pottery artists who do not own a wheel-throwing machine have to rent spaces in pottery studios, one can do 3-D modelling relatively inexpensively.

Conclusion

In Gershenfeld's (2012) words, "personalisation, producing products for a market of one person" is what makes digital fabrication a 'killer app'. By being directly involved in the process of making, craftsmen can develop an emotional and personal attachment to the product as they feel less alienated in the course of making (physical or digital). Digital fabrication will not replace traditional crafts but opens opportunities for hybrid craft production, and new paths for customisation and personalisation in the today's consumer and craft landscape. While much attention has been given to 3-D printing for industry, the craft scene in Singapore can also reap benefits from advances made in additive manufacturing.

Abstract

The paper explores the possibilities of presenting quantitative information in qualitative, expressive, engaging, and entertaining ways. To do so, experiments focus on a range of sporting activities, where numeric performance data tends to be prevalent, but there is also an aspect of self-awareness and community that can benefit from a connection enriched by carefully expressed data. In this context, through three design workshops, we examine the sensory and semiotic quality of the interactions, leveraging outputs in the form of haptic actuators, as well as subtle uses of lighting and kinematics. The exercises challenged participants to transform raw data into novel sensorial experiences through commonly available hardware (sensors and actuators) and software, constituting a meta-medium to be valorized with the same agility as conventional materials, albeit with an obviously shifting set of skills. Based on the scientific literature and experimental results, this contribution offers a mapping of possible values between individual and shared experiences, working towards a new vocabulary of tactile and kinetic experiences that may be useful for the creative industries.

Author keywords

sensorial quality; haptics; kinematic objects; experimentations.

Introduction

The boundaries between digital and physical reality are becoming increasingly blurred, paving the way for new forms of hybrid interactions and opening up new meanings in perception. While eXtended Reality strives for a socially interconnected "metaverse" via VR and MR visors, this contribution tackles with interactions that often bypass the visual channel in order to connect people to (or through) data in more sensory ways, considering also haptic actuators (a growing communication channel, Zannoni et al., 2021).

In many fields of application, including those outside of sports, tracking and monitoring technologies have entered the daily lives of people through various wearable devices for observing the physical, mental, and emotional states of individuals (Mukhopadhyay, 2015). This phenomenon of self-tracking via technological devices relates to the concept of the Quantified Self (QS) (Wolf et al., 2010), and can be considered a cultural movement dedicated to the collection of body data with the goal of assessing and improving one's own physical, mental, and emotional performance. But going beyond the technical possibilities, the QS phenomenon has generated debate around its sociological and ethical implications in terms of privacy (Thuraisingham et al., 2018) and equality (Lupton, 2015). In fact, while measuring specific body parameters offers objective data for evaluation and personal improvement, it also implies the continuous confrontation of a user's health and performance indicators with extraneous standards that may be above (or below) their realistic possibilities, leading to a potentially conflictual relationship between the QS and the sensitivity (Qualified Self?) of the users.

In contrast to human behaviour, which is based on perceptions and sensations, the data-driven approach to the self is capable of reconfiguring actions and responses that rely on objective measurements of data from devices, enacting a manipulation that "could result in loss of human free agency and autonomy and even deceptions of humans" (Stephanidis et al., 2019). As stated by Wiener (1950), technology has the power of influencing and changing human key values and behaviours, which is becoming increasingly evident in this era of rapid technological advancement and permeation in human society. This leads the research towards a more symbiotic relationship (Licklider, 1960) between devices and people, close to the concept of Human-Computer Confluence (Ferscha, 2016) and Human-Computer Integration (HCInt) (Farooq & Grudin, 2016; Mueller et al., 2020), leading to data-based communication through new forms of sensing, blurring the barriers between the physical body and the digital self.

Computational Thinking and sensorial interactions

This work is based on the assumption that Computational Thinking (the ability to define a step-by-step solution to complex problems; Wing, 2006) acquired through the practice of Learning by Doing (Bruce & Bloch, 2012) should be a part of every student's curriculum in order to better understand technology and develop a proactive approach to using technology for improving everyday life. The relevance of Computational Thinking (CT) is widely recognised and it is taught at various levels of general education or STEM-focused, from el-

ementary schools to universities (Sabitzer et al., 2014; Mannila, 2014; García-Peñalvo & Cruz-Benito, 2016).
At the elementary school level, for example, an innovative education approach grounded in project-based teaching is proposed by Lyu (2021),tackling the children's problem solving skills while assisted by the teachers. Another didactic approach by Rossano (2020), consists of teaching middle school students the basics of Arduino and coding through simple exercises and applying the newly acquired knowledge to real-life situations, like the management of a wooden rail crossing model. At the high school level, Yin (2022) uses a didactic process with four steps to show how using Arduino-based activities can improve CT and engineering learning.

On the level of higher education for the Design Profession, the ambitions of a CT-focused course can be more advanced, not only teaching but also inquiring about the possibility of turning digital, quantitative data into qualitative, sensorial feedback, and evaluating whether these can become an actual framework. Beyond innovative functionalities, Design has a particular responsibility for finding appropriate semantic associations. New sensory qualities and gestures may follow analogue metaphors or pure abstraction, based on the intrinsic nature of the information being communicated or controlled. This paper presents the findings of a series of workshops, carried out with students of (industrial/product) design, with the goal of experimenting with such new sensory qualities.

In particular, the general theme of sports has been chosen, as this provides wide opportunities for experimentation. Physical activity is already one of the main targets of self-tracking, and sports are mostly quantitative, measurable, while also including various layers of social interactions between players, trainers, and fans. Indeed, past research works have shown interesting experimental augmentations of sporting activities, both within the boundaries of existing sports and reinventing them altogether. An interesting example by Hribernik (2022) developed a haptic feedback interface specifically for water sports, which pose obvious challenges, in order to effectively communicate data during a physical activity session. Another take on the haptic approach is tackled in the creation of a superhuman sport, "DubHap," with the intention to redesign existing sports and adapt them to the new era (Chernyshov et al., 2018). With a design-driven approach, technology can also help to invent completely new "superhuman sports" for the AR/VR and sensing gloves, engaging citizens through a series of "ideathons" (participative design workshops) in order to pull in ideas, such as interacting with a virtual energy projectile that can only be sensed and not seen (Orikasa et al., 2017).
Taking inspiration from the above mentioned research, our workshops' participants started experimenting with isolated sensorial aspects of various sports, then proposed smart objects that highlight a range of possibilities, analysed in the last section of the paper.

Workshop structure

The workshop format, called "Smart Design Pills", has been developed for design students in the third BSc year, therefore with a solid background of creative exercises, modelling and presentation skills, but without any knowledge of interactive hardware & software prototyping or coding. The programme comprises three workshops that cover the fundamentals of prototyping, beginning with the simplest actuator and gradually increasing difficulty: LEDs and light signals are the theme for the first workshop, "Shiny Rhythms"; vibrating signals and tactile perceptions are studied during the second workshop, "Touching Signals"; while movement and kinetics are explored through the third workshop, "and Yet it Moves."

Each workshop is three weeks long and begins with an introductory exercise focused on computational thinking skills without digital hardware and software, by substituting and simulating the sensors/actuators with readily available tools and materials: the phone's flash and vibration motor are used for role playing, cardboard and clay for stop motion animation. Later during the first week, students learn about the sensors, actuators, and code necessary for the workshop, as well as studying relevant case studies of smart objects. The second step concentrates on defining a concept and developing a rough prototype of the group's interactive product in view of the third and final step, which is committed to creating a final prototype while also taking aesthetic factors into account.

For the purposes of this course, students were divided into 17 groups of two or three, and each was assigned a random sport. Numerous factors were considered in order to create a collection as diverse as possible, including the potential need for equipment, the degree of interaction (individual or team-based), and the settings in which the sports could be practised (gyms, particular outdoor settings, settings irrelevant to the practice). Based on their technical characteristics, the sports were divided into six macro-groups (water sports, balance sports, ball sports, racket sports, urban sports, and martial arts) to facilitate planning and review processes and the sharing of useful information between groups within the same macro-group.

Workshop 1 - "Shiny Rhythms," was based on the use of light signals via white LEDs. A couple of evocative images were selected for each sport, specifically drawing from visual, kinetic, and acoustic aspects, as inspiration or reference. The students were required to recreate each of these concepts using an animated light signal that included timing, rhythm, and intensity as variables, with the aid of particular apps that allowed them to control and modify the values. Sketches, notes, and illustrative graphs showing the intensity of the signal over time were required to document the brainstorming and design phases. Afterward, a brief video showcasing the three final performances had to be created.

Students were then asked to apply the knowledge they had acquired to a product that would incorporate the use of LEDs into their assigned sports activities as the actual exercise for the first workshop, proceeding in the three weeks process as described above. The final goal was to elaborate digital signals into a light performance that could visually express the qualities of the sport.

Workshop 2 - "Touching Signals", focused on experimenting with the perception of haptic signals using vibrating actuators. The materials provided for the introductive exercise were an illustration of the emotion spectrum (Plutchik, Robert, 1980) as well as a map of emotions perceived by the human body (Nummenmaa et al., 2013) that helped them identify the areas of the body where sensors and actuators should be placed. The introductory activity focused on the representation of a designated emotion through vibrating sequences. The purpose of the activity was to find haptic feedback for conveying information that is typically processed through visual or auditory channels during the training processes, athletic performance, and communication with other participants (fans, teammates,

coach). The actual three weeks long activity of this workshop requested the students to design a product that incorporated haptic actuators in sports activities.

Workshop 3 - "And Yet it Moves", requested to design a kinetic smart object capable of interacting with the athletes, the audience, or the sporting environment. To familiarise students with the concept of movement, they were asked to identify some key aspects of sport (e.g., strength, coordination, acceleration) and represent them through a stop-motion video, using clay. Subsequently, they were asked to focus on three categories (objects for training, for sport execution, and for communication), elaborating a concept for each situation, rough prototyping and physically simulating the interaction of their products. Based on the findings from this exercise, students designed the project for the third workshop.

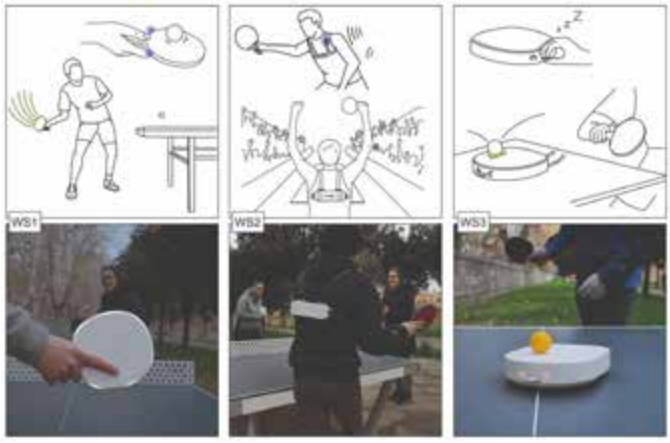

Figure 1. Top row: a storyboard for each project; bottom row: the prototypes resulted from the workshops.
Designed by: Barberis Lorenzo, Ciubotaru Gabriel Cosmin, Guarnieri Elena.

Results can be illustrated through the projects of the table tennis group (FIgure 1). The interactive table tennis racket designed for the first workshop features built-in LED lights that react to the ball's stroke through a shock sensor and the racket's movement through an accelerometer, providing a visually appealing indicator for the most spectacular (quickest, strongest) moves during the game. The product from the second workshop is a wearable harness for the player, equipped with vibration actuators on each shoulder. Each vibrating actuator responds to the audience's cheers on its respective side, giving the player haptic feedback on their surroundings without distraction from the game. Training the player with a small wheeled robot is the aim of the final movement-themed project. The robot is designed to run in random directions and it must be hit with the ball to raise the speed and therefore difficulty.

Interactive approaches

The 51 interactive projects developed across the three workshops lend themselves to a categorisation that can identify various aspects along which the projects are diversified. Prior to analysing our case studies, it's worth noting that past research has examined and theorised on qualitative design values in a variety of ways. Some of the methodologies that emerged from the research have been applied to the projects as a first step to approaching a more fitting system of values for this subject. Among the pioneers of Design for IoT, Rose (2014) categorised projects according to 7 possible characteristics: Glanceability (43% of the 51 projects fall under this characteristic), Gestureability (41%), Affordability (59%), Wearability (47%), Indestructibility (43%), Usability (56%), Loveability (33%). According to Rose, designing a product that exhibits all seven characteristics is quite difficult. In fact, only 10% of the 51 projects displayed one or two of the traits; around 30% displayed three or four; barely 15% displayed five out of seven; and only 4.5% presented six out of the seven characteristics. On the other hand, a more generic categorization such as the well-known "three levels of design" (Norman, 2004) - Reflective, Behavioural and Visceral - may be (even more) useful to better understand the product.

Beyond pre-existing categories, the traits of each student project were analysed separately, thus identifying a set of connotation parameters that were common to all of the projects. Each parameter presents two dualistic and mutually exclusive values: one that leans on a "personal" and "closed" aspect and one on a "shared" and "open" side. The parameters that have been identified are as follows, naming the "personal" value first and the "shared" value second:

P.1 - Instinctive / New language: Products marked "instinctive" appeal to the immediacy of human instincts and common knowledge, whereas products marked "new language" present a new vocabulary of symbols that the user must learn in order to interact with the device. An example of an instinctive project is a parkour-specific leg band that vibrates in the event of a violent landing, simulating the wave of impact from the ground upwards. A rotating and portable basketball hoop that can be attached to any vertical pole is a project that introduces a new language, revolutionising the traditional game of basketball.

P.2 - Individual / Collective: Products marked "Individual" are defined by a single user, whereas "collective" projects rely on the participation of multiple users who contribute to the device's functioning. The climbing belt is an example of an individual product that, through vibration, "pushes" and accompanies the climber towards the wall, correcting the position without the help of instructors. The floats that confine the water polo field demonstrate the collective aspect. These light up to show the intensity of the fans' cheers for the players in the water.

P.3 - Performance / Entertainment: The projects that present the value of "performance" are those focused on pure sports execution (competitive or training). Instead, "entertainment" indicates the projects that highlight the visual or spectacular aspect for those who are watching. The fencing target that moves to dodge the shots of the fencer is an example of a product for sports performance and training. The kinetic sculpture in the centre of the skateboard arena, which reacts to the noise of the fans, effectively expresses the concept of entertainment.

P.4 - Human-driven/ Device-driven: Products marked "Human-driven" react to user input, detecting human interaction and then providing feedback. On the other hand, the "device-driven" products are the first to provide an indication to the users to guide them through the practice. A bracelet designed for boxing fans is a "human-driven" product that provides vibrant feedback to the wearer based on the power of the boxer's blows. Whereas, a small wheeled robot equipped with a chalk that traces a random path on the floor for the skater to follow is an example of a "device-driven" approach.

P.5 - Wearable/ Tangible: These two values indicate the product's location in relation to the user: "Wearable" projects are products that are actually worn by the user and remain in direct contact with the body; "tangible" products are physical devices that can be either individual objects or applied to sports equipment. An example of a "wearable" device is composed of two leg bands designed for paddle tennis that vibrate alternately to indicate to the player the correct rebound to keep during the game. A "tangible" device applied to the hockey stick warns the player by vibrating when the disc moves too far, allowing them to maintain control.

The visualisation of the data (Figure 2) has made it evident that the majority of the products that resulted from the course tend to place in the "personal" sphere (65%) rather than the "shared" sphere (35%). In fact, the majority of the projects displayed characteristics that were considered personal (instinctive, individual, performative, human-driven, wearable). The third workshop marked a high point for wearable product design, which is one of the main causes of this result. This outcome demonstrates that the interaction between humans and devices is mostly viewed as a private experience, but on the other hand, the tendency to involve the collectivity is relevant. Perhaps as human-machine contact advances, it will become more diverse and inclusive to the point where it serves as a tool for strengthening human unity.

Figure 2. Result of the systematisation of projects through the "personal" and "shared" parameters.

Conclusions

The research conducted to date has made it possible to test the "Smart Design Pills" didactic format with the goal of refining and verifying it in the future also in other fields. The programme includes the formulation of three workshops that focus on the human-device symbiosis, in this specific case in the field of sports, with the aim of transforming quantitative digital signals into sensory and qualitative interactions. Each workshop focuses on a fundamental concept and is approached through introductory activities giving the participants an alternative perspective before tackling the actual project. The products obtained from the workshops confirmed the ability of the participants to start from a basic level of interactive prototyping, but still achieve meaningful results, developing significantly their skill of computational thinking in the meantime. Five versatile parameters with polarised values that lean either to a "personal" sphere or to a "social" sphere have been developed based on the evaluation of the projects that resulted from the course. The outcome of this distinction shows a propensity to view human-machine connection as an individual experience, however the encouraging quantity of collective interactions may provide an opening to a more expansive definition of "human-device" interaction.

From the perspective of the Cumulus community, it would be interesting to see whether and how such principles can be applied by students (and professionals) of different cultural backgrounds (compared to Rome, Italy) and in different fields of activity. Finally, the research confirms the value of Quantified Self as a tool to "reflect, learn, remember and improve" (Wolf, 2010) on the individual's performance, but also confirms a possible "qualified self" approach by treating raw numerical data as a design material, that can lead to engaging experiences and ultimately a more a symbiotic experience between people and data.

Abstract

Presently, many people are listening to music through streaming services. Though listening to music in such a way is convenient, we feel it lacks the anticipation of encountering unknown music like we felt by looking at the album covers. In addition, listening to a vinyl record requires some errands; however, the effort yields a rich and immersive musical experience. In this paper, we design an alternative way to appreciate music that would provide a similar anticipation and immersive experience to encounter music. In the proposed experience, users perceive multiple 3D objects as crystallized music and select a song from them. When an object is submerged in water, bubbles are generated as part of the object dissolves, and music begins to flow. We developed an interactive system that realizes such an experience by creating objects, each with an IC tag inside, and preparing a water tank with a tag reader on the bottom to identify the object. Music objects are created from the sound source and molded by using 3D printer. We tested the interaction and confirmed that the system functions well as expected. We also ran a questionnaire to acquire users' feedback for designing a better experience. Our objective with this research is to design a novel way to appreciate music. The experience consists of listening to music and appreciating it also by sight, by materializing the tune as a 3D object. Digital technology has generally been used to achieve fast and convenient functions. In contrast, this work attempts to design a "slow" experience in which one is confronted with music more carefully.

Introduction

We have encountered musical compositions in many different ways. When listening to vinyl records, we have sometimes chosen a song based on a preference for its cover. Presently, people encounter new music through a streaming service by selecting a tune directly or following suggestions and playlists created by someone else. The latter seems to reduce the number of unexpected encounters with unknown music. We think there was the pleasure of collecting music before, by possessing the records and discs. However, such pleasure also seemed lost as people began to listen to music through streaming. Observing such situations, we devised an idea to conceptualize music as a tangible entity when we generally regard them as digital data now. We decided to design music as a crystalized object that produces sound when dipped in water and dissolving. We expect users to feel the music melting out of the object. We aim here to design an alternative experience of appreciating music and develop a system to realize it. We produce an object of music tune by analyzing the sound source and converting the music to a 3D shape as per a specific rule. The crystal's appearance helps in imagining music, as the shape represents the characteristic of music. In addition, we think one could feel like possessing music more directly than owning it as a digital file. We expect this system to offer a novel experience for encountering music, not only providing entertainment. This research can also be regarded as an attempt to design a new experience by giving different attributes from its original perception, allowing the viewer to appreciate the subject from a different perspective.

To realize the idea, we develop a system that identifies music tunes by objects. The system equips a water bowl into which a user throws the object. The object is molded by 3D printer, and an IC tag is installed inside it. The tag is read by a tag reader at the bottom of the bowl, which lets the system match the object with specific music. To make a representation of music melting out, we insert a material like dry ice into the object and let it produce bubbles when submerged in water. We examined the interaction with the developed system and multiple objects, each materializing different music, and confirmed that specific music is played by the corresponding object. To evaluate the experience provided by this study, we conducted a survey and administered a questionnaire to examine whether the system offered an engaging approach to music.

Experience with Crystalized Music

We considered what if we could crystalize a piece of music so one can take it by hand. Since the crystallized object is

music, we should be able to expect to listen to the tune by dissolving it. As it would be natural to expect a different shape from different music (Figure 1), you will have fun imagining the original music from its shape. To make it happen, we designed a mechanism for the interaction. We also prepared a method to transform a music tune into 3D geometry for creating crystalized music objects.

Figure 1. Concept of crystalized music.

We expect a user would have the experience shown in Figure 2. First, the experience begins with viewing multiple music objects. Each object represents a different music. As the shapes represent certain musical features, they are generally different in their looks; some are spiky, whereas others are smooth. Therefore, the user can imagine the tune from the object's shape. A user would choose one to listen, not knowing what music it is. Once chosen, one can throw the object into the water to dissolve it. The user will see the bubbles forming as the object dissolves, and the music starts to play with a lighting effect appearing simultaneously. When it is resolved entirely, the sound will cease.

We aim with this research to propose a different perspective of being involved with music. First, we want to provide a sensation of feeling music crystalized as an object. This expression realizes the transformation of music, a temporary phenomenon, into something static and tangible that one can appreciate before listening to the sound. In addition, users can feel the music by watching and touching the object. That would allow users to select a tune to listen to in a different approach than generally practiced. We expect this interaction would lead to emphasizing the music's transient nature because users will observe the event also by sight.

To establish an immersive experience with our approach, we wish to have the shapes somewhat reflect the music's characteristics. However, we do not want to create an object referring to a personal impression that would differ for each individual. Therefore, we need a method that automatically transforms the music into the sculpture design according to a particular rule or algorithm. We started by employing a simple transformation rule that converts the sound wave pattern to a 3D object. By finding an appropriate transformation rule, people could envisage music by browsing the objects' shapes. One could find similar music by sight but not through recommendations provided by a streaming service. That would be another different experience this approach would provide. Seeking an ideal algorithm is a topic for future work.

Figure 2. Entire process of the experience.

Related Research and Works

Various ways of interacting with music have been proposed. Some make the experience an installation that facilitates a specific space to appreciate listening to and interacting with the music. The Intelligent Street is an installation work that designs a space for interactively listening to music, where people can affect the music by sending text commands via smartphone (Lörstad, 2004). Sound Forest is another installation work, a room with numerous illuminating interactive strings (Frid, 2019). Multiple people can play with a string simultaneously to emit a sound and share the experience. Mayer et al. (2014) have developed a system in which two users collaborate to create music and visual effects by interacting with two-sized semi-sphere domes. While these works and ours share the objective of attempting to design a novel experience of interacting with music, theirs also aim to provide interaction among the individuals entertaining the experience.

From an interaction design perspective, our approach can be considered a variation of designing a tangible user interface (TUI). A first of that kind happens to take a theme related to music (Ishii, 2004). Our work shares the concept of providing an alternative experience relating to music. However, with Ishii's Music Bottle, music is still the same sound phenomenon, though the interaction with music differs from regular listening practices. Our approach is different in making music a tangible entity to interact with. reacTable (Kaltenbrunner, 2006) is a synthesizer system employing a tangible user interface (TUI) to create sound. The user synthesizes a sound by putting circular and cubic objects on a circular table. The visual effects of the objects appear on the table when they are placed on the table. When positioning multiple objects in a neighborhood, their effects link in creating a sound. There is still other research on designing specific tangible interfaces. "The Table is The Score" (Levin, 2006) proposes to use spectrogram shapes formed by a rubber or felt and place them on the table to play sound. In adopting TUI, many approaches seem to treat objects as interfaces. In the case of Ishii's Music Bottle, the interaction is designed by fitting music into the metaphor of a bottle, as a thing to keep something in it. We believe that the interactions with a TUI must be designed so that the object is well integrated with the context of the content, rather than simply being used as an interface. We conducted this study considering this concept.

In realizing this work, we have sculpted the music as a three-dimensional object. Similarly, several attempts have been made to transform music into a visual representation. Narratives 2.0 (Dittrich, 2008) is an example of music visualization. It uses the frequency of a music channel to determine the turns of lines and colors in creating a visual representation. Another visualization work created for a poster (Bremer, 2020) utilizes the music's data and includes information on how the tune has been listened to at a streaming service. In addition, var-

ious methods have been proposed for converting music into visual representation (Lima, 2021, Khulusi, 2020). Macrogroove (Chable, 2019) attempts to interactively convert sound into 3D shapes. A common approach among these studies and ours is that the shapes and colors are automatically generated from the music data according to a specific rule rather than through individual tastes. The resulting expression may not conform to human senses; however, it may lead to discoveries about a tune, providing a different perspective on appreciating music.

Implementation

System for Playing Sound

The system equips a water bowl where users can drop the object. To realize the experience explained in the previous section, we need to implement the following functions for building the system.

1. Identification of objects
2. Detection of an object submerged in water
3. Control of playing sound
4. Illuminating effect (optional)

First, the system should be able to identify the object chosen for playing music. Several approaches can be used to identify the object. In this study, we inserted an IC tag into the objects. We employed this method because the system can simultaneously detect an object's immersion in the water by placing a tag reader at the bottom of the water bowl.

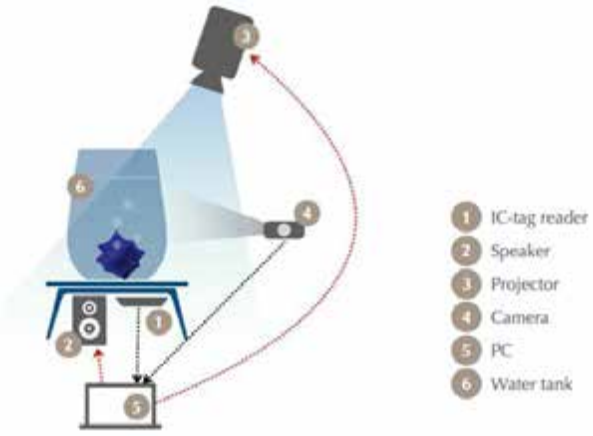

Figure 3. System overview

When the system detects an object submerged in water and identifies the corresponding music tunes, the system starts playing the sound via a speaker at the bottom of the system. Simultaneously, the system projects a visual effect onto the surrounding plane as a supplemental representation of sound. An extra function is required to stop the music by observing the melting progress. However, we have not implemented it yet. It is a topic for future work. Figure 3 illustrates an overview of the system.

Crafting of Music Objects

We need the followings for preparing the music object.

1. Conversion of sound data to a 3D shape
2. A mechanism to identify an object
3. A mechanism to make the object look soluble in water

We do not want to manually design a 3D shape of each music by relying on individual sensitivity and preference. It would be ideal to have an automatic translating rule to create the objects of many different musical tunes. We are currently adopting a method that transforms the sound volume and pitch changes into a 3D object. The objects are then fabricated using a 3D printer (Figure 4). We make a hole in the object for placing an IC tag, as shown in Figure 5. We also place a soluble material in that space. This mechanism generates bubbles, creating the appearance that the object is dissolving in water. The object itself remains unaltered even after the bubbles subside with the current setup, though. We also attempt to prepare molds and create objects out of meltable materials. However, placing an IC tag inside an object created this way is awkward because the tag remains after it melts. Therefore, we need to design another system for object identification, which we have not implemented yet.

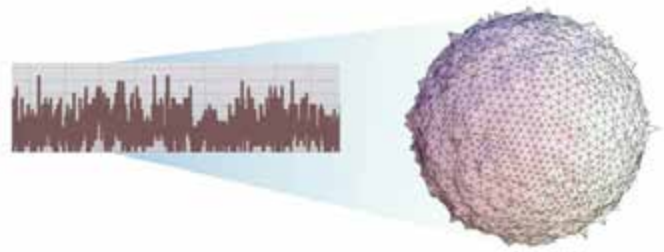

Figure 4. Conversion of music data to a 3D shape.

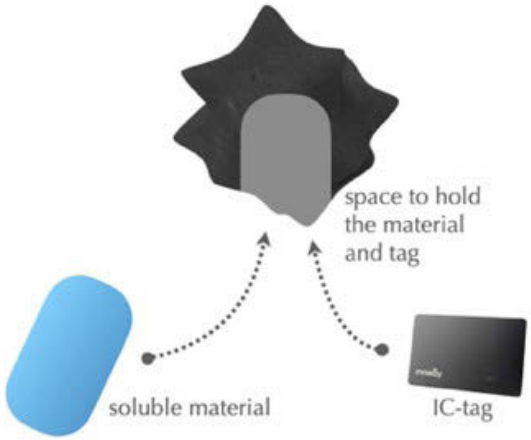

Figure 5. Structure of the music object

Evaluation and Discussion

To verify that the system functions properly, we threw the objects into the water to examine if it correctly identified them. We threw three different objects into the tank in random order 20 times, with 16 times success. The failures were not due to misrecognition but because the function to recognize them was not activated properly. We interviewed 11 persons on their experience with the system. 10 answered that it was an entertaining and impressive experience, and eight answered that they felt music was melted out from the object. The results suggested that the intention of the experience was conveyed to the participants, though we consider further improvements are necessary to provide the experience more realistic.

This work offers the users largely two different experiences. One is choosing an object by imagining the music by its shape, as shown on the left image of Figure 6. The other is to feel the music as if it is melting from a solid object (Figure 6, right, Figure 7). To make the first experience more affluent, we believe the object's shape should reflect the music's characteristics more. It would be possible to extract various other attributes that give the music its characteristics, such as the length of notes and the frequency of specific scale changes on the score. In this study, we only considered shapes to represent a piece of music; however, attributes like color, tactility, and weight could also be regarded as representational elements. Reflecting these in the model is an issue for future research.

We have added some small interaction designs to reinforce the feeling of listening to crystallized music. After the system detects an object is submerged, an interval is inserted before the music begins, making the sound start at a low volume and increase in volume over time to match the amount of bubbles. Another design is applied to the music's sound. If the sound is clearly audible, users cannot feel the music is playing underwater. Therefore, in addition to placing the speaker at the bottom of the water tank, we have digitally converted the music so that it sounds like it is playing underwater. These small designs are not necessary to achieve functionality. However, when creating an experience, we believe it essential to mind these small details. Currently, the object remains after the bubble and music ceased because it is plastic. However, we want the object to disappear to express the one-time nature of crystallized music. We consider this would alter the experience further.

Conclusion

To design a new experience of appreciating music, we devised the concept of listening to music by melting a crystalized object. The innovation of this study is designing music

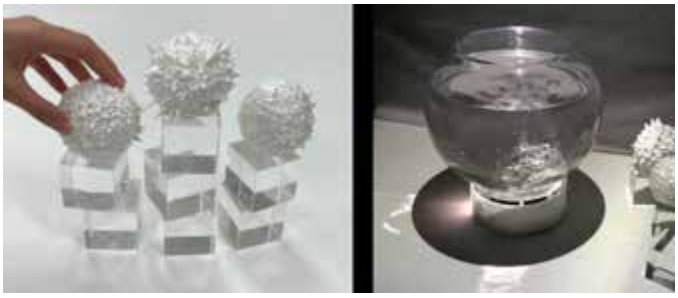

Figure 6. Choosing a music (left), music and light are coming out from object (right)

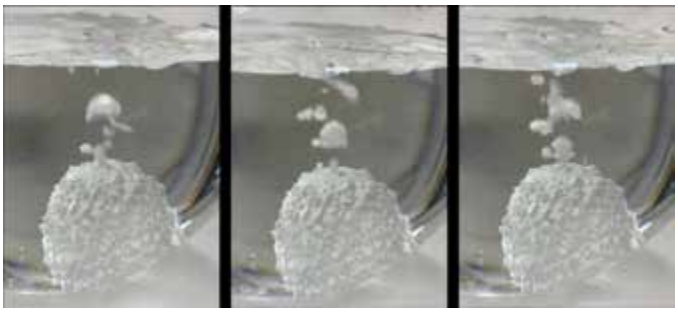

Figure 7. Bubbles coming out of the object

itself as a tangible entity. Further modifications are required to make the user's experience of listening to the crystallized music melted out more natural. Having reviewed the result of the user experiment's feedback, we became aware of the need to reconsider the design method for the object's appearance. However, we believe we succeeded in demonstrating this idea's feasibility. In the future, we would like to revisit the molding of objects and formulate conversion rules that will produce many variations in object design. We did not design this system for listening to music in daily use. The experience would be one that users would encounter in exhibitions. The experience must also be evaluated from such a viewpoint in future work.

Abstract

This paper explores the intersection of Human-Computer Integration (HInt) and Critical Disability Studies (CDS) to explore how a posthumanistic epistemology in design can produce knowledge and know-how for the application domains of Health and Well-being. To use disability as a catalyst for innovation, a rethinking in the philosophy of sciences is necessary to establish knowledge production that emerges from new fluid politics that operate in 'composition' instead of 'organization'. By placing an emphasis on nomadic practices that move beyond fixed borders, the encounters between Disability Studies or Human-Computer Integration can produce situated, embodied and contingent design knowledge that study deviant and complex embodiment, and the kinds of alterations of human characteristics and abilities through technology. The first section of this paper explores the rethinking in the philosophy of sciences. The second section argues for a posthumanistic epistemology in design, which can be seen as the perfect way to produce situated, embodied and contingent design knowledge on the intersection of HInt and CDS. The final section of this paper highlights the potential for the disciplines of Somatechnics and Soma Design to engage in each other's body of knowledge to produce transformative knowledge through a shared focus on deviant embodiment and disability. The takeaway message of this paper is that the intersection of HInt and CDS potentially leads to new – otherwise overlooked - insights on the human-technology relationship, and therefore can take part in the historical strive for man-machine symbiosis. The posthumanist epistemology allows for alternative ways of thinking that move beyond the current Humanist perspective, and builds on a plural, relational and expansive foundation for the development of design practices that catalyze innovation in the application domains of Health and Well-being.

Introduction

Current developments in the field of Human-Computer Integration (HInt) (Mueller et al, 2020) shift the focus away from the 'stimulus-response' model of HCI towards integral relationships between humans and computers (Danry et al., 2021), that have the potential to fundamentally alter human characteristics and abilities through computing systems (Andres, 2023). The paradigm shift towards HInt can be seen as a continuum from interaction to integration, which extends but does not replace the HCI field (Farooq & Grudin, 2017). HInt operates from a different worldview than the often traditionally narrated stories on the progression of man, which are rooted in ideas on Enlightenment embodiment (Mitchell et al., 2019). This worldview 'proclaims to the Renaissance parameters of Vitruvian symmetry and aesthetic perfection' (Braidotti, 2013). In Human-Computer Integration, which is part of the historical strive for man-machine symbiosis (Licklider, 1960), provides an opportunity to question, collapse, or even eliminate traditional perspectives on what it means to be 'human'. These relationships between humans and computers revolve around symbiotic partnerships between humans and computers (Semertzidis et al., 2022), which means that the relationships exist upon interdependence, focusing on 'complex relations of trust, respect, dependence and communication' (Wolfe, 2010), rather than putting the emphasis on values of agency, ownership, and autonomy. An example of such a scenario is the bodily integration with 'computing systems that can sense, interpret, and automatically act to body-based and contextual signals' (Andres, 2023). Designing for the 'webs of asymmetrical relationships' (Shildrick, 2022)

in bodily integrated systems (Mueller et al., 2021) requires a deep understanding of micro-biologies, (bio)assemblages, or phenomenology of organ and tissue (Shildrick, 2022). Alternative ways of thinking about embodiment are necessary to move beyond the separate disciplinary structures that exist in scientific organization. Critical Disability Studies (CDS) historically has required alternative ways of thinking as it has always been 'about the kind of complex relationship between the body and the machine' (Braidotti, 2006), and 'has always contravened the traditional, classical Humanist conception of what it means to be a human being' (Goodley, 2017). Therefore, Critical Disability Studies can be seen as a well-established body of knowledge, that starts from traditionally narrated divisive and pathologized bodies to uncover alternative materialities to bring bodies and minds into being (Mitchell et al., 2019). In this paper we highlight a posthumanist epistemology for design at the intersection of Human-Computer Integration and Critical Disability Studies, to allow us to move beyond the current Humanist perspective. A posthumanist epistemology builds on the development of design practice through a plural, relational and expansive foundation, aimed at the potential catalyzation of innovation in the application domains of Health and Well-being. The *first* section of the paper starts with a rethinking of the philosophy of science, moving away from rationality-oriented (humanistic) philosophy towards a relationality-oriented (posthumanistic) philosophy. The *second* section explains our ideas on posthumanist design practice further in depth and emphasizes a compatible connection between HInt and CDS. The final section highlights the potential for the disciplines of Somatechnics and Soma Design to produce transformative knowledge for both Critical Disability Studies and Human-Computer Integration through a shared focus on deviant embodiment. We *conclude* with a short reflection on the intersection of HInt and CDS, and how this potentially leads to new – otherwise overlooked - insights on the human-technology relationship.

CONFLICT – Paradigm shift from rationality to relationality

As this emerging paradigm shift in Human-Computer Integration has more to do with 'becoming-in-the-world' (Shildrick, 2022) than with 'being-in-the-world', the contingency of its existential-ontological evaluation (Keane, 2015) requires a rethinking in the philosophy of sciences to establish alternative modes of knowledge production which are able to integrate the disciplines of Critical Disability Studies with Human-Computer Integration.

Philosophy of Science

The ongoing debate regarding the potential meanings of technology in the application domains of Health and Well-being often draws upon 'models of explanation in medicine, concepts of health and disease, clinical judgment, as well as the meaning of human dignity, the definition of death, or the significance of beneficence, virtue, and consensus' (Meacham, 2015). However, these debates often start reasoning from out of the medical, or the social model of disability, which emphasize the context of 'human enhancement' (medical model) or 'corporeal surroundings' (social model) (Retief & Letšosa, 2018) of the disabled body. These models regard the disabled body as being inferior (medical model) or as something to be ignored (social model; Barnes et al., 2010)). The disabled body has been studied for centuries through a Humanistic perspective, which poses rationality to the forefront of the scientific process. This work, influenced by Anglo-American thinkers, such as Popper (falsifiability), Kuhn (paradigms) and Lakatos (research programs) rely on objectivist viewpoints to produce knowledge and work from a disciplinary perspective (Chimisso, 2006; Darwin, 2010; Walker, 2010). In the Humanist worldview, disciplinary structures are operating separately, and researchers are often driven towards choosing one of these structures to move forward in the scientific process. This could potentially have supported the objectification and further pathology of the disabled body, since the influential medical model emphasized on determining law & principles (Major Science) rather than questioning and investigating the relationship that these disciplines have to themselves (Minor Science). However, knowledge production in the 21st century can no longer be created only through one disciplinary structure. In contrast to the search for objectivity and universality in the scientific process, the deployment of the posthumanistic worldview, as described in French philosophy of science by famous philosophers Deleuze, Guattari, and Foucault, bases its worldview on relationality rather than rationality. This paves the way for a pluralistic, relational, and expansive way of thinking in design and design practices (Marenko & Brassett, 2015). For the intersection of HInt and CDS, this can be translated towards a design epistemology that emphasizes nomadic design practice without fixed borders. Design practices on the intersection of HInt and CDS revolve around 'making hacks into reality' (Von Busch et al., 2022), and make use of a kind of 'designerly realism' (Von Busch & Palmås, 2023) to explore, unveil and excavate power relations shaping the production and dissemination of knowledge, and vice versa, knowledge production in turn shapes and reinforces those power relations as well. These design practices look like a intertwined spectacle of 'competitor, allied, non-allied, collaborative, competitive, contradictory or aligned practices of design' (Wakkary, 2020), that result in new fluid politics which operate 'in composition' rather than 'organization'.

CONNECTIVITY – Posthumanist epistemology in design

The posthumanistic epistemology in design (Wakkary, 2020) emphasizes nomadic practices that move beyond the fixed borders of the disciplines of Disability Studies or Human-Computer Integration, and situate in specific places, dealing with embodied encounters and unexpected contingencies.

Posthumanistic epistemology in design

Bodies matter, in 'the fleshiness of the world which inhabits us and is inhabited by us' (Merleau-Ponty, 2012). The experience of partnership in the fragile, sensitive, and intimate characteristics of deviant embodiment with its technological instrument 'constitutes the self' (Shildrick, 1997, 2009; Shildrick & Söffner, 2017). To comprehend the kinds of qualities that can be found in the paradigm shift from Interaction towards Integration, we need to think about different ways of looking at knowledge, practices, techniques, design tools and methods - the 'dispositifs' (Deleuze, 1992; Marenko & Brassett, 2015) - through which our bodily 'becoming-in-the-world' (Shildrick, 2009) is formed. In short, *how* we come to 'matter'. This 'matter(ing)' - represented in the 'active forms

and repertoire for how it plays' (Mitchell et al., 2019) - can be seen as a body of knowledge - 'learned by doing' - that is already well-developed in Critical Disability Studies. The daily encounters of resistance to power and dependency, as well as the daily grappling with the gritty (painful, (Siebers, 2015)) and messy (pleasurable, (Shildrick, 2009)) materiality of the disabled body can be seen as knowledge about the relation of human *difference* to social organization and human perception (Siebers, 2015; Mitchell et al., 2019). A society that wants the disabled person to 'pass' (through playing roles) or 'masquerade' (through disguising the disability) their difference (Mitchell et al., 2019) potentially does not shy away from the same mechanisms when Human-Computer Integration becomes part of everyday life. The institutional, physical, and administrative mechanisms (Deleuze, 1992) are important because our bodies become part of the systematic assemblages that affect how our bodies and minds develop. Rather than pursuing design to be just about the physical world around us, it also encounters the way we interact with that world through language and ideas. New politics of fluidity could come out of the possible question how deviant embodiment – meaning the alteration of human characteristics and capabilities - is treated in relation to 'complex embodiment' – meaning disability materiality and its 'the fruits of the interaction between body, mind and environment' (Siebers, 2015).

CREATIVITY – Somatechnics and Soma Design

Although Somatechnics is not directly linked to its pragmatic counter half Soma Design in HCI, these disciplines do relate. Therefore, we state that these disciplines should move beyond their own existences and get involved in each other's body of knowledge, assemblage, and reality-making to embrace the high-end potential for knowledge production that can result out this.

Deviant and complex embodiment in Somatechnics and Soma Design

Somatechnics, as explored in Critical Disability Studies, is used to re-imagine the embodiment of technobodies (Verhoeff & Van Der Tuin, 2020) through 'multifarious ways in which embodiment exceeds established boundaries and meshes with non-human entities' (Shildrick, 2022). 'Tekné' refers to ways of seeing, knowing, feeling, moving, being, and acting in situated contexts through the body structures and 'active forms of interplay' (Easterling, 2012) of the embodied subject, including practices such as politeness, elegance, poetry, and language. Somatechnics critically engages with the ethico-political implications of a wide range of practices and techniques (Shildrick, 2022) and emphasizes the importance of understanding the body in relation to the materialities of the world. It calls for 'a recognition of the body in the world as an artifact wrapped up, entangled and produced by the materialities of that world' (Sullivan, 2012). In HCI, the design practices of Soma Design (Höök, 2018), 'soma' can be recognized as the unity of mind and body, intellect and experience, and Soma Design Theory engages in experimental activities that 'will always depend on the affordances of the technologies and materials used to shape the designs (Höök, 2018). Soma Design has interaction design at its base, meaning that 'it is always the study of the socio-digital material: the coming together of people with designed interactive artifacts and the behaviors and experiences generated in the combined material of people, practices, tools and design.' Both Somatechnics and Soma Design emphasize the transformative relationships between the body, environment, and materiality, and exemplifies the unique knowledge that arises from interactions in the 'enmeshment of body-material and environment-material' (Mitchell et al., 2019). A shared focus on the complexities in deviant embodiment, whether represented in Critical Disability Studies or Human-Computer Integration, could potentially teach us how to design for artefacts that bring something new to the world that may otherwise go unrecognized (Mitchell et al., 2019).

Conclusion

In this paper we explored the intersection of Human-Computer Integration (HInt) and Critical Disability Studies (CDS), to learn how this intersection can become a catalyst for innovation in Health and Well-being. Human-Computer Integration (HInt) shifts the focus away from the 'stimulus-response' model of HCI towards integral relationships between humans and computers. As this emerging paradigm shift has more to do with 'becoming-in-the-world' than with 'being-in-the-world', the contingency of its existential-ontological evaluation, requires a rethinking in the philosophy of sciences is necessary to establish alternative ways of knowledge production which move away from the Enlightenment perspective and engage with a posthumanistic epistemology in design, which produces knowledge and know-how through nomadic practice beyond the fixed borders of the disciplines of Disability Studies or Human-Computer Integration. The body of knowledge that emerges from the interconnected disciplines potentially results in new fluid politics operating with situatedness and embodied repertoires and contingency. The symbiotic partnerships of humans and computers, which is embedded in Human-Computer Integration, will be studied in design practices, and be intertwined with the matter and 'mattering' of disability materiality. The compatibility of HInt and Critical Disability Studies is further explored in the disciplines of Somatechnics and Soma Design which can produce transformative knowledge for both Critical Disability Studies and Human-Computer Integration through a shared focus on deviant embodiment.

Acknowledgments

This project is a joint-PhD project (2022 – 2027) at the University of Amsterdam and University of Antwerp. It is funded by the Dutch Research Council and supported by the Amsterdam University of Applied Sciences as part of a doctoral grant for teachers.

Did you know that... the many traumatized and disabled veterans returning from WWI resulted in more acceptance of disabled people participating in the workforce? Also, the famous Bauhaus model (Otto & Rössler, 2019) originated from the idea that this educational model would make it possible for a heterogenous group of artists, designers, craft-makers to learn together, despite their different backgrounds and WWI traumas. Bauhaus' emphasis on 'making' and materiality redefined what design can do for society amidst the leftover anxieties and revolts of the past.

Metaphysical instruments: prototypes for hybrid and live music-making

Abstract

We present a series of musical instrument prototypes that inquire about how live music can be produced simultaneously in the tangible world and within the metaverse. Our study is centred around a workshop with seven young Interaction Design students and follows a Research-through-Design approach. We invited participants to ask what musical instruments for the metaverse should look like? how they are played? and what affordances do they provide for both tangible and virtual audiences and performers? Participants prototyped working electronic musical instruments that can be played and listened to in both the real world and in virtual space. We took a Critical Design stance and followed a vision-driven design process, foregrounding the non-existent rather than problem-solving or market demands.

The resulting physical prototypes deviate from existing musical instruments and offer novel interactions that affect how music is performed and listened to. Our findings show that hybrid music-making provides possibilities for collaboration, explorations of scale between tangible and virtual worlds, and notions that challenge who is in control of the music-making process. We also analyse how mapping between senses and feedback drive experiences for performers and audiences alike.

Introduction

The digitisation of sound dramatically transformed music, its production, distribution, and consumption. Since the disappearance of the mix-tape in favour of mp3 players and the usage of samples from online files in live performances, digitality has blurred the roles of musicians, distributors and consumers (De Notaris & Savonardo, 2022). As Internet connections grew faster, mobile and broadly available our lives became mediated by online services and social media platforms. Our tangible world is increasingly interwoven with software and the idea of inhabiting virtual environments -the metaverse- has gained momentum with attempts to turn it into reality (Ball, 2021; van der Merwe, 2021). In this work we explore how music can simultaneously be performed and listened to both in-person and within the metaverse. We focus on musical instruments as tangible and virtual objects that emit sound in both of these environments.

With the metaverse beginning to be recognized as a space for musical opportunity, we ask ourselves how live music can be performed and experienced within it. There has been some research around networked music performance (e.g. (Rottondi et al., 2016)) and some companies (e.g. Sensorium Galaxy, Mizic.io) are starting to offer virtual reality (VR) and hybrid concerts, with some of these happening within video game environments (Groux, 2020). Attention has also been placed on how networked music enables collaboration between musicians and enhances audience participation (Carot et al., 2009; Xambó et al., 2017; Yamchareon & Herkenrath, 2005). These studies focus mostly on the technicalities of synchronization or on the social aspects of collaboration and how they exist online. There is however little work around the design of musical instruments for online and VR performance with Serafin and colleagues (Serafin et al., 2016) and Turchet (Turchet, 2019) presenting some ideas and guidelines. The instruments described for VR and networked performances in these works resemble traditional instruments such as guitars, xylophones and assorted percussion instruments. We therefore centre our research on what novel instruments for hybrid performance look like, how they are played, and how they sound; trying to distance our work from existing instruments.

Focusing on instruments as objects allowed us to follow a Research-Through-Design methodology (RtD). Taking ideas from Frayling (Frayling, 1993), Gaver (Gaver, 2012), Andersen (Andersen, 2014) and, Wensveen and Matthews (Stephan Wensveen & Ben Matthews, 2015) we consider the process of discussing and developing prototypes as a form of inquiry. Since our research questions revolve around objects which do not yet exist we find Critical Design (Dunne & Raby, 2001) to be a useful frame for our design activities as its vision-driven approach allowed us to consider possibilities that are neither problem-solving nor market-driven.

Metaphysical instruments

Using prototypes as objects of inquiry invited us to write a brief guiding the research and development of musical instruments for hybrid performance. We named the brief *Meta-*

physical Instruments, a combination of the words *Metaverse* and *physical* that also references philosophical metaphysics. Metaphysics' ideas of *being* were useful for exploring how reality and experience differ within the Metaverse and outside, however our engagement with metaphysics was superficial as an in-depth analysis was beyond the scope of this work.

Our brief considered the divergent experiences of performing and listening to live music within the metaverse versus tangible space and prompted the following questions: How should instruments for hybrid performance be played? how should they sound? What social opportunities are there for live music in VR? And what novel experiences can VR provide for live music? These questions were broad and ambiguous allowing participants to project and use their own definitions of music, instruments, and live performance.

Workshop

Given the complex skillset involved in making electronics and VR we took inspiration from Bowers and colleagues (Bowers et al., 2016) in organizing an open-ended workshop that leveraged participants' existing knowledge. We invited interaction design students to a 12-week workshop. Seven undergraduate students (authors four to eleven) joined and divided themselves into three groups. Participants were in the second year of the Design for Digital Media and Technology programme at CENTRO University and had knowledge in programming, 3D modelling, animation and digital drawing. The first four weeks of the workshop were spent developing skills in electronics, microcontroller programming (ESP-32 and the Arduino IDE), digital manufacturing (3D printing, CNC mills and lasers) and VR development using the Unity game engine. The final eight weeks were devoted to prototype production.

The workshop started with a launch presentation explaining the brief and an outline of existing experimental musical instruments was provided. We wanted to distance ourselves from stablished categories of instruments such as (Temilola, 2020; Turchet et al., 2022) and encourage participants' definitions of what an instrument is and can be. Following our Critical Design perspective they were also introduced to vision-driven design processes. A short description of each of the resulting prototypes follows.

CQNC: Community in Quest for Noise Connection

Patricio Pous-Pierson, Alejandro Lobo-Barrera, and Jordi Fragoso-Terreros developed CQNC (pronounced sequence). It bridges the metaverse and tangible reality through real-time sound recording. CQNC uses field recordings to produce music and explores how these can work as an instrument. It requires at least two players, one using a VR headset while the other physically carries a device (Fig.1, left) capable of recording sounds and uploading them to a server.

When a recording is made it is downloaded into VR and represented as a ball. Users can then place sounds into a playback area (Fig.1, right). Sounds in this area are looped and mixed into a single output. A sound's volume is modified by moving it up and down in space and its playback speed and pitch are controlled by rotating the sphere. New recordings increase the samples available for mixing. In VR players compose complex soundscapes from samples recorded live in distant environments.

Figure 1. The CQNC sound recording controller (left) and its VR environment (right) showing the playback area and the sounds it contains.
Video documentation can be found at https://en.centro.edu.mx/3JC4yd1

Conditioned Freedom (CF)

In CF Paola Ferrari-García and Ximena Peña-Rios present an interactive sound installation. It provides contrasting experiences for tangible and VR users by placing one of them within a woven structure (Fig 2, left) filled with light beams and annoying sounds. Blocking a light mutes one of the sound channels and makes the space more bearable. Within VR users experience an open landscape (Fig 2, right), an opposite environment to that of the physical installation. Each time a light is covered in the installation a relaxing sound is played in VR accompanied by a visual effect.

Figure 2. The Conditional Freedom installation (left) within which the performer interacts with light to control sounds both in tangible space and within a VR landscape (right)

CF's driving concept was that art is experienced through its end result but we seldom see the struggle of making it. Their title links this struggle with constrains in creative freedom and places the physical user in the role of a creator and the VR audience as spectators of a finished work. In their view the greater the struggles in the tangible world the more beauty is produced in VR.

Llum

The instrument made by Fabiola Toledo-Galindo and Julio Torres-Cazares is played and listened to both from the outside and from within. Llum is a handheld tangible instrument and a large virtual space at the same time. The project explores how the functionality of a tangible object can change when its scale is altered.

The instrument is a 3D-printed cracked sphere that emits light from within (Fig 3, left). Each piece works as a key that synthesizes sound and light in both tangible space and VR. Its virtual counterpart is an enlarged version of the same sphere (Fig 3, right) within which the VR audience exists. The walls of

this space match the object's keys in shape and functionality; That is, if a user touches a wall, it will synthesize the matching sound both physically and virtually. The nature of the instrument blurs the line between audience and performer as they are all capable of contributing to the composition. For this collaboration to work sounds from each key are added together when they are played simultaneously, either physically or virtually. The sounds produced in VR therefore match those emitted by the instrument in tangible space.

Figure 2. Llum, an instrument that is played both physically (left) and virtually (right). VR users experience and play the instrument form the inside while tangible ones hear the sound coming from within the object. Video documentation can be found at https://en.centro.edu.mx/3YSY65z

Findings

The following subsections analyse how the prototypes function as musical instruments, how they approach liveness, and how scale and control were used in driving users' experiences.

Mapping and feedback

Serafin and colleagues (Serafin et al., 2016) highlight the importance of feedback and a clear mapping between senses in VR musical instruments. We base our initial analysis on these features. Both Llum and CF map gestures to sound with visual and auditory feedback. In Llum's case, the single sound output that amalgamates inputs from all participants breaks the auditory feedback, as performers increase in number it becomes difficult to recognize sounds triggered by individual users. This collective feedback makes players respond to one another's actions rather than focusing on individual composition, turning the metaverse and live-music into social spaces. This suggests that communal feedback can favour collaborative and improvisational practices.

The CF installation also has a direct mapping between visible rays of light and sound but contrary to other instruments, gestures remove sound rather than creating it. The sounds produced in VR do not provide feedback to the performer to whom the resulting composition is unknown. The contradictory interactions arising from this multiplicity of experiences resonate with Dunne's view that objects working contrary to established logic can be very engaging (Dunne, 2008). In CF the instrument's feedback also takes a narrative role in a story, the performer's attempts to silence the whole installation are contextualised as a creative struggle.

CQNC challenges views of what an instrument and its music are. There has been research presenting field recordings as music (Shaw & Bowers, 2020). However, CQNC provides a novel perspective as it is difficult to decide what the instrument is: Is it the sound recorder as an object or is it the spheres sounding in virtual reality? This difficulty in assessing where the music-making happens and who the performer is suggests that it is truly collaborative and explores musicality in a way only made possible through networked co-creation. Referring back at Serafin and his team's principles for VR instruments we find that CQNC breaks some of these: it has no direct feedback or mapping, it embraces latency and provides no visualization of a player's body. It is yet engaging and rewarding to use, suggesting that current definitions of instruments for VR and the metaverse should be questioned in the field's early days.

Virtual and Live

Liveness is central to the resulting prototypes. Not only in the technicalities of device-metaverse communication, but also in overcoming the lacking senses of unity and unexpectedness inherent to remote emulations of live-music as described by Tarumi an co-authors (Tarumi et al., 2017).

Llum's collaborative nature demands that tangible performer and VR audience co-exist. This temporality gains depth when seen from a social perspective. As the virtual audience shares the same space, they must also synchronise their actions in order to drive their portion of the composition. We believe that implementing communication between audience members in a future version would further enhance this social coordination.

In CQNC liveness is less straightforward. Tim Shaw describes field recording as "a practical activity that often requires one to spend long periods of time outdoors hunting for sound" (Shaw & Bowers, 2020). This is seemingly contrary to live performance, waiting for sound samples to arrive could frustrate players in VR. However, receiving a new sample provides an exciting element of unexpectedness. Users were found to restart compositions when a good sample appeared. Simulating this with pre-recorded sounds could be done but knowing that they are being recorded live adds a sense of complicity between tangible and virtual players.

Control

The prototypes revealed issues of power and control that were not built-in by design. By control we mean people having power over one another and not interface features. In most performances musicians have complete control over what to play, how to play it and when. Our work suggests that the distribution of control is central to the metaverse but difficult to define.

In CF control is approached from an unusual angle, the person within the installation has complete control over sound production but that control is unpleasant to wield and must be endured for the pleasure of the virtual audience. This creates a dynamic in which the person in the installation controls the content but is emotionally subordinated to those in the metaverse.

CQNC and Llum show a different form of control, one in which users react to sounds provided by others. These instruments

allow adversarial or collaborative interactions between participants, where players will conform to what is being provided or try and subvert it. Llum distributes control amongst participants: If few people are attending in VR control shifts towards the person playing physically. In contrast, with tens of VR participants, the notes from the tangible instrument are quickly outnumbered by collective online behaviours. The distribution of control in CQNC is slightly simpler, every player ultimately controls their own composition but VR players have no agency over the received sound and must work within the constraints created by the person recording. It is also possible that the recorder feels pressure to provide adequate samples, despite not knowing what each player is doing, resulting in a self-constrained curation of sounds.

Scale

All three prototypes incorporate aspects of scale. The digital flexibility of scale has been extensively explored within design; however, we see value in presenting it from a music-making perspective. Llum incorporates shifts in scale by making the tangible instrument inhabitable within VR space. This shows that VR can not only place users in otherwise inaccessible spaces but also alter our reading of tangible objects: The instrument ceases to be to a standalone object and becomes a model of the VR space, therefore containing its audience. This illusion of containment is further reinforced by making the tangible instrument emit sound and light from within while in VR it is spatially emitted from the key that was pressed.

CF uses scale to drive its concepts. The installation as a constrained space is designed to overwhelm the user. Its virtual counterpart is a large, well lit, and calming landscape. The interplay of scales between VR and installation provides an entry-point to the project's ideas, appreciating this difference in scale is sufficient to understand the project.

Both CF and Llum present VR worlds much larger than their physical counterparts. Contrastingly, in CQNC the scale of VR space is fairly small, with minimal movement and interactions restricted to a sphere in the middle. This limited space serves as an interface for an instrument that could be of global scale. Reducing sounds gathered over a large area to such a small space suggests that the metaverse could be not only an alternative world but also a container for parts of our tangible reality.

Conclusion

Designing, developing and using our musical instruments provoked many questions that were not originally foreseen. We set out to make prototypes that questioned the ontology of instruments in the metaverse, outlining what they are and how they exist. This starting point was however greatly expanded through our process.

Our findings around feedback and mapping do contribute to characterising our prototypes as instruments but they also promted questions about collaboration and improvisation that emerge from the instruments' online nature. When discussing liveness, we were surprised to be focusing on feelings of unity and the unexpected rather than the technicalities of internet communication protocols. The themes of scale and control were not initially identified in our research and were prompted by the prototypes, we find them very relevant when discussing the metaverse and see their emergence as an indicator of how open-ended and protype driven processes can elucidate unidentified questions that contribute to research. We would like to expand on this inquiry in future work by further exploring our prototypes through live performances with a breath of different audiences and performers from various musical backgrounds.

Abstract

Humans explore the world around us using our able senses. Numerous studies have suggested that the greater the number of sensory modalities stimulated at any one time, the richer our experiences will be, in that the experiences may have a higher level of impact and be more memorable across a variety of our senses. (e.g. Bahrick & Lickliter, 2000; Spence,2002; Stein & Meredith, 1993). This is becoming increasingly important and relevant as we enter the AI-generated virtual worlds where our visual perception should have a certain resemblance to our analog world experiences. If human perception is a cross-experiential phenomenon, how could we enrich artificial intelligence with multisensory creative abilities to support the same processes and outcomes for material interaction?

The ability to perceive correspondences across sensory modalities resembles the phenomenon of synaesthesia (Cytowic, 1989). Synesthesia is the combination of several senses simultaneously. It is an unusual condition which gives rise to a merging of the senses. For example, smells may trigger the experience of shapes, or letters may give rise to the perceptual experience of colour or may cause the experience of any combination of tastes, smells, shapes or sensations (Simner, 2012). These misunderstandings may be why the phenomenon was considered unreliable for over a century after its discovery by Francis Galton (1883; Sachs 1812). In the last decade, we can trace an increased interest in cross-sensory experiences signalling synaesthesia as its correlated phenomena (Dixon, Smilek, Cudahy, & Merikle, 2001; Mattingley, Rich, & Bradshaw, 2005; Ramachandran & Hubbard, 2001a, 2003). While for most, mental imagery may be most vivid in the case of visual images (Kosslyn, 1994), it is of keen interest to note that rich mental images can be generated via the sense of smell, touch, taste, and sound (e.g. Klatzky, Lederman and Matula, 1991; Reisberg, 1992; Stevenson and Case, 2005).

Through the intersection of two disciplines, User Experience Design (UXD) and Color and Materials Design (CMD), we aim to explore the possibilities of employing an intelligent agent to generate 3D materials based on merged multisensory inputs rather than relying on existing algorithms, visual styles, and previously constructed patterns. The exploration will be in the form of an experiment and workshop conducted with a trans-disciplinary group of graduate students from the User Experience Design and Colour and Material Design disciplines. We will use customised text to engage a 3D scene AI generator trained with available sensory data sets enriched with multi-perceptive input from the workshop participants. Our key novelty is the use of artificial intelligence trained with multi-sensory material properties to generate AI-generated 3D materials for virtual and potentially hybrid products and environments.

Introduction

In this paper, we aim to investigate opportunities for involving artificial intelligence in the design process of creating 3D virtual worlds. Our focus will be on the AI generation of 3D digital materials and their potential to arouse sufficient sensory and emotional stimuli. Several studies have suggested that the greater the number of sensory modalities stimulated at any one time, the richer our experiences will be, in that the experiences may have a higher level of impact and be more memorable across a variety of our senses. (e.g. Nikolic & Russo, 2019; Bahrick & Lickliter, 2000; Spence,2002; Stein & Meredith, 1993). Accordingly, In the AI-generated virtual worlds, our sensory and cognitive expectations lead us to search for resemblance from our analogue world experiences. Hence, if human perception is a cross-experiential phenomenon, how could we enrich artificial intelligence with multisensory creative abilities to support the same processes and outcomes for material interaction?

Through the intersection of two disciplines, User Experience Design (UXD) and Color and Materials Design (CMD), we aim to explore the possibilities of employing an intelligent agent to generate 3D virtual materials based on merged multisensory inputs rather than relying on existing algorithms, visual styles, and previously constructed patterns.

Our approach is hybrid and includes several methods applied in different research stages. In the first phase, we conducted a single case experiment, which we will describe in detail and present the findings. This led us to the second phase, where we prototyped and experimented with the AI-driven text-to-image platform for generating and rendering virtual materials on 3D objects. The whole process and the framework used are described in this paper's Synesthetic Artificial Intelligence Generation chapter. Lastly, we plan to conduct contextual interviews in a workshop with a mixed group of students selected from the User Experience Design (UXD) and Color and Materials Design (CMD) majors.

Our key innovation is using artificial intelligence trained with multi-sensory material properties to generate AI-generated 3D virtual materials for meta – and potentially hybrid – products and environments.

Background

In our conceptual approach, synesthesia plays an important role in designing multi-sensory meta-perception beyond the physical world. Synesthesia is a psychological phenomenon related to the human brain's capability to combine several senses simultaneously. In particular, stimuli on one particular physical sensory can produce additional sensory experiences for which sensory inputs do not exist (van Leeuwen, Singer & Nikolić, 2015). It is an unusual condition that gives rise to a merging of the senses. For example, smells may trigger the experience of shapes, or letters may give rise to the perceptual experience of colour or may cause the experience of any combination of tastes, smells, shapes, or sensations (Simner, 2021). One of the most reported types of synesthesia is audio-visual (AVS)(Afra, Anderson, Funke et al, 2012), where sound stimuli can evoke the visual experience and vice versa. In particular, sounds such as the middle note 'C' can induce a red colour experience, but the same note three octaves higher can become green (Ginsberg, 1923). Likewise, we can have different varieties of sense responses to sensory stimulation, such as; the taste of a particular food (gustatory) can associate us with the visual appearance of the food (Cytowic, 1989); when we hear a particular sound (auditory) can induce smell of a specific food (olfactory) (Beeli, Esslen & Jäncke, 2006). Therefore, despite early scepticism, contemporary research in the field proves that synesthesia exists.

Furthermore, the interaction with materials in regard to a product, space, or environment is essential for a completely holistic multi-sensory user experience. Hence, from the perspective of colour and material design, "texture is an essential component of materiality that evokes the sense of tactility," often translated through a flat, 2D image that is applied onto the surface of a 3D object to define its colour, gloss, transparency, roughness, and other key physical attributes (Lefteri, 2014). A texture in 3D rendering engines like Photoshop, Substance Painter, Substance Designer, Blender, and Keyshot require inputs whose details must be specified unambiguously. These tools make use of generating textures in a *procedural material workflow*. (Jantunen, 2017). Procedural materials are created using mathematical models instead of pre-stored data, reducing the storage needed for these materials and thus creating texture maps to be applied to models in an actual runtime. Dong et al., 2019).

As an example case study, *Procedural Material Generation* (Jantunen, 2017) delves into the steps to create a procedural material in five steps with a focus on different material properties such as texture, patterns, micro-surfaces, colour, and lastly, defines the *procedural aspect* of the material to identify the properties which can be changed while still retaining the essence of the material. Our *workflow* (Figure 1) combines the aspects of synesthetic modalities with procedural material workflows to generate multi-sensorial materials, unlike a 3D rendering engine, whose inputs must be specified unambiguously and in complete detail, without further sensory extension when it comes to no explicitly stated properties (Ramesh, et al., 2021). The design of products and experiences are typically the result of many fine-meshed and complex processes (Jongerius, 2010); and our proposed workflow uses the sensory nature of synesthetic procedurality when designing multi-sensory meta-perceptions.

This multi-sensory, layered approach is based on an archival collection of information sourced through 1) scent, 2) sound, 3) emotion, 4) taste, and 5) movement. The sensory experiences are categorised as layers that, when combined together, compose a unique material outcome.

Figure 1. Multi-sensory layered approach

During the first phase, digital prototypes of 3D virtual materials were created using Open AI's text-image generation AI system DALL.E. Over 150 unique samples were created through prompts that described various material attributes regarding colour, texture, finish, and form. For the experiment, fifteen samples of visual distinction were short-listed (Figure 2).

Figure 2. Virtual material samples created on DALL.E with prompts (left to right) beige green exploding fuzzy fluidic sphere, black white eternal colliding amorphous sphere, and high gloss stretchy blob slime beige sphere

Experiment

A single-case experiment research was employed to initiate the first phase of the 3D virtual materials generation. We invited six graduate students to participate in the experiment from two graduate design programs, User Experience Design (three participants) and Color and Materials Design (three participants). The participants included three females, two males, and one non-binary, of American, Indian and Mexican origins, and in an age range of 23-27 years old.

The experiment was conducted in a controlled lab environment with a defined layout, ambient temperature, sound,

light, and projected image control (Figure 3). The AI-generated digital material samples were displayed on the screen for a period of three minutes, during which the participants observed the sample and noted their sensorial responses in a provided worksheet. (Table 1). The experiment lasted 45 minutes, followed by 15 minutes of guided discussion.

Figure 3. Single-case experiment set-up

Findings

Upon the completion of the first phase, participants revealed directives toward sensory modalities in regard to a series of AI-generated materials. The results from the experiment revealed the ability of the participants to look beyond the aesthetic attributes of the virtual materials. With this in consideration, it should be noted that half of the participants stated had it not been for the structure of the worksheet, they would not have related the visual with all of the senses. Four out of six participants stated that they found associations to be made quicker with certain senses than others. The sensorial responses experienced by the participants were then used as inputs to generate the synesthetic AI-generated virtual skin.

Table 1. Example of worksheet and responses from the experiment

	Touch	Smell	Taste	Sound	Visual	Emotions
Sample 1 	Tender Soft	Soft scent of a mother	Delicate sweetness	Lullaby	Baby's skin	When pressed will release the flow of milk
Sample 2 	Fuzzy Soft	Wet grass	Fresh taste of blooming spring time	Soft breeze	A planet with unknown biome	A walk through paddy fields in the morning

Synesthetic Artificial Intelligence Generation

Starting from text descriptions, we used DALL-E to generate the image of a sphere texturized according to the initial prompt – as demonstrated in the single-case experiment – and then we extracted the corresponding texture. The procedure to fit the bump map and the texture was then refined using the Stable Diffusion model to progressively refine the starting template mesh, which in our case, is a sphere.

A neural network generates an RGB texture and predicts the magnitude of the movement along the normal direction for each vertex. To compute the displacement, we encode the position of the vertex $x \in R^{Nx3}$ using Multiresolution Hash Encoding (MHE). We parsed the features obtained $h \in R^{NxF}$ to a SirenNet, an MLP (MultiLayer Perceptron) with sinusoidal activation function:

$$\bar{x} = \bar{x} + \bar{n} \cdot d \cdot SirenNet(MHE(\bar{x}))$$

where $\bar{n} \in R^{Nx3}$ are the vertices normal and d the maximum displacement. The texture is computed in a similar way by mapping the positions of the pixels to the range $[-1,+1]$,

$$RGB_{i,j} = SirenNet(\sin\sin((2i/(H-1)-1)\,\pi), \sin\sin((\,2j/(W-1)-1)\pi))$$

where H, W are the texture dimensions. This initial transformation ensures periodical textures. Using a sinusoidal activation function makes the training shorter and more stable for this task. During the generation, we optimise the material gloss level to reduce artefacts, like light reflection included in the texture.

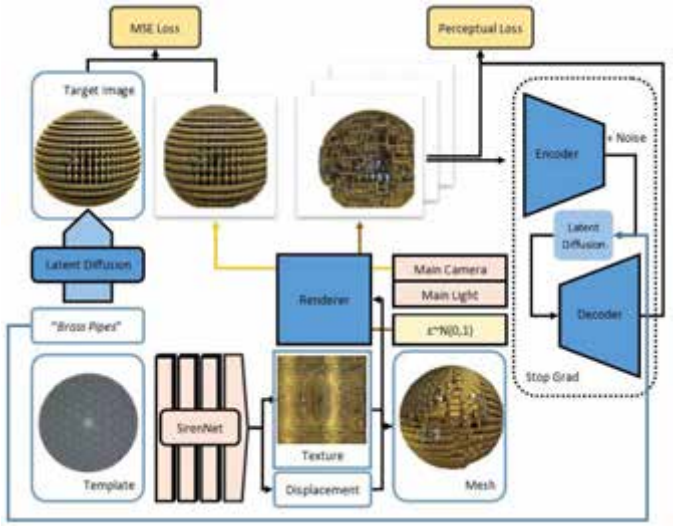

Figure 4. AI Synesthetic Virtual Materials Generation Procedure

For each training step, we start with generating the texture and the displacement along the normal for each vertex, then we produce a refined version of each render using the Stable Diffusion Img2Img pipeline conditioned on the text prompt. Finally, we compute the MSE (Mean Square Error) between the main render and the target image, then compare the renders from the cameras sampled uniformly around the sphere and their refined version using a perceptual loss based on a pre-trained VGG19 net.

This solution led to faster convergence and better quality than using a loss based on CLIP embeddings, moreover the refining procedure must be executed without the gradient computation, allowing to reduce the memory occupancy and increasing the training speed if compared to the SDS (Score Distillation Sampling) used in Magic3D, because it does not require backpropagation through the encoder network at the cost of having to decode the denoised latent vector. In this way, we produce textures with 712 pixels of resolution. To enforce a more coherent bump map, we follow the same procedure with a uniform texture. To guarantee stability during the training, we must ensure semantic consistency between the refined images and the corresponding renderer. For this reason, we set a low strength (around 20%) and a not too high guidance scale (we used 12.5).

Conclusion

We aim to explore the possibilities of using AI for 3D virtual material generation, with the potential to arouse sufficient sensory and emotional stimuli. Hence, we have collected and designed multi-sensory material properties to generate AI-generated 3D materials for virtual – and potentially hybrid – application to products and environments through User Experience Design and Color and Material Design (CMF) workflows.

In the first of several on-going experiments, we have investigated procedural approaches to collect sensory data to train our neural network model toward enabling its synesthetic reasoning and virtual material rendering based on multi-sensory data inputs. By increasing the number of sensory modalities stimulated in the multi-layered, procedural material approach, the sensorial experiences related by the observer have an increased impact in regard to their virtual material experience.

While we seek to find a balance between our real and virtual worlds, in turn, the expectations of our senses have linked our findings to human perception within the collaborative environment where User Experience Design and Color and Material Design enrich the ability to support synesthetic material interaction.

Cabinets of curiosities for the postcolony II: tokens: collections I-V

Jacqueline Deirdre Pretorius

Graphic Design Department, Faculty of Art, Design and Architecture, University of Johannesburg, South Africa
dpretorius@uj.ac.za

Abstract

This paper offers a discussion and reflection on my work titled "Cabinets of Curiosities for the Postcolony II: Tokens, Collections I-V" (hereafter referred to as "Tokens") which was exhibited in 2022 both physically in a gallery in Johannesburg, South Africa, and virtually on the non-fungible token (NFT) marketplace OpenSea. The physical component of "Tokens" consists of five entomology cases, each displaying a collection of unique, handmade objects, and an artists' book, and the digital component takes the form of 51 NFTs. I describe the origin, development and nature of the project and explain the reasoning behind the creative decisions that I made. Initially the project was driven by my need for tactility and experimenting and crafting with physical materials, but it evolved into an exploration of the question of what is considered "new knowledge" in creative practice. This exploration eventually led me to the world of NFTs and resulted in a final creative project that engages with further questions around uniqueness, the aura of physical and digital art, and value.

I propose that by making and naming new objects, I created new knowledge, which I then attempted to validate by minting the objects as NFTs. However, I realised that by digitally reproducing the physical objects I ran the risk of destroying their "aura" as postulated by Walter Benjamin in his 1935 essay "The Work of Art in the Age of Mechanical Reproduction". I consider Benjamin's concept of "aura" in relation to physical and digital art and highlight more contemporary views that refute his claim. This leads to a brief discussion of the financial value of NFTs and the importance of community in creating value in the NFT world. I conclude by noting that many questions remain on what blockchain technology can do and become for artists and the study contributes one such perspective and experience. Creative practitioners are encouraged to become acquainted with this technology.

Introduction

In this paper I discuss and reflect on my work titled "Cabinets of Curiosities for the Postcolony II: Tokens, Collections I-V" (hereafter referred to as "Tokens") which was exhibited from 20 September to 26 October 2022 in real life (IRL) at the Art Gallery of the Faculty of Art, Design and Architecture (FADA) at the University of Johannesburg (UJ) in Johannesburg, South Africa, as well as virtually on OpenSea, the largest marketplace for non-fungible tokens (NFT) (Fries 2021).

The physical component of Tokens consists of five Iroko wood and perspex entomology cases, accompanied by an artists' book digitally printed on ILFORD Fine Art Textured Silk paper and folded into a leporello format (figure 1).

Figure 1. Physical display of "Tokens", FADA Gallery (picture by author)

Each entomology case displays a collection of unique, handmade objects organised according to formal qualities such as colour or material. The objects are small, ranging in size from approximately one to ten centimeters and were created through the combination of existing things, or the manipulation of natural and found materials. Figure 2 shows a close-up of one of the collections of objects, Collection I. The objects in Collection I were made from a variety of materials, including air dry paper clay, acrylic paint, felt, beads, plastic animals and figures, safety pins, a rose thorn and bra components. Their creation was prompted in 2020 by my need for experimentation and crafting with physical materials as I missed the tactility of making following decades of primarily creating art and design with digital media. I was inspired by developments in art jewellery design and interested in applying various traditional and non-traditional jewellery making techniques and materials to craft beautiful and intriguing objects which blurred the boundaries between sculpture and jewellery.

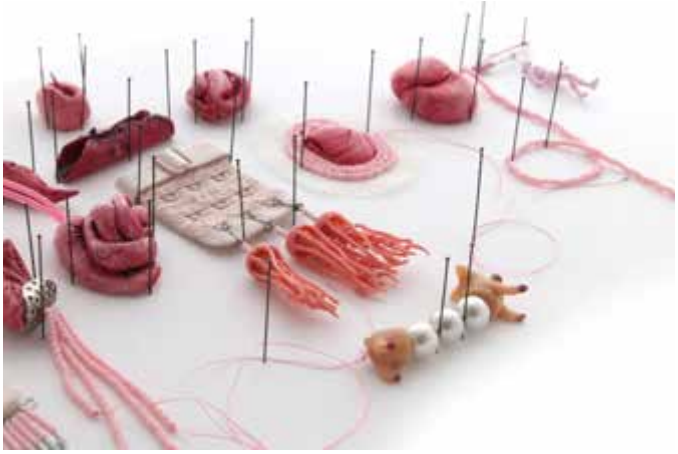

Figure 2. Close-up of Collection I (picture by author)

The objects contained in the collections are documented in the artists' book by way of 51 photographs captioned with the object's name (figure 3). The word tokens in the title refers to both the dictionary definition of token, which is "...a thing that you give someone, that expresses your feelings or intention, although it might have little practical effect" (Cambridge Dictionary) and the NFT component of the work.

Figure 3. Page from artists' book

Figure 4. NFT "card"

Each object was minted as an NFT in the form of a "collectable card" containing, within a frame, a photograph of the object captioned with its name and the title of the artwork at the top (figure 4). The collection of 51 NFTs comprises the virtual component of the exhibition and each token was available for purchase on OpenSea (figure 5) for the duration of the exhibition at https://opensea.io/collection/tokensi-v. The NFTs can be viewed on OpenSea where they have been given, in the words of Friedman and Hawkes (2021) an "afterlife where it is no longer subject to mortal decay" because, as Betancourt (2006) observes "[t]he limit for a digital work is not based on its physical demise, but rather on its availability within contemporary technology." In minting the NFT on OpenSea a unique token ID number was generated providing proof of the uniqueness of the NFT and therefore I exhibited a list of these numbers in the FADA Gallery alongside the physical work.

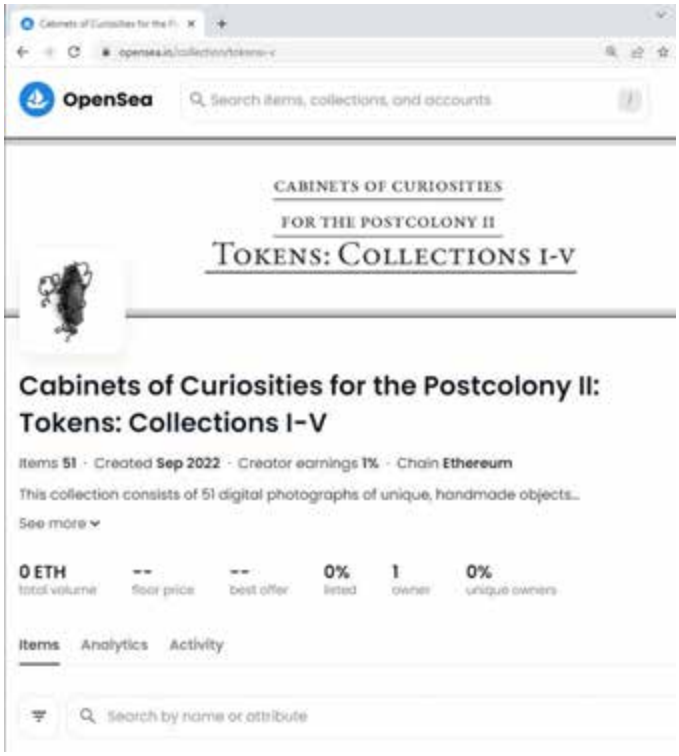

Figure 5. Collection of 51 NFTs on OpenSea

While creating the physical objects during 2020 I considered a variety of display methods, including entomology display cases and creating a cabinet of curiosities. These experiments would eventually lead to a project named "Dead Living Things: A Cabinet of Curiosities in the Postcolony" (hereafter "Dead Living Things") (Pretorius, 2023) which was exhibited at the FADA Gallery as part of the 2021 staff exhibition "Interventions in Practice". While the objects served as a starting point for "Dead Living Things", I did eventually move away from creating new and unique objects, to collecting and displaying existing objects in a cabinet of curiosities (Pretorius 2023). "Dead Living Things" aimed, amongst other things, to understand the role of colonial collection practices in constructing knowledge and to show how our understanding of the world is mediated through existing objects, text and language. "Tokens" builds on this interest, but in addition, explores the question of what is considered "new knowledge" in creative practice and how objects can help us to understand this question. The process of working on this question led me to the world of NFTs and resulted in a final art work that engages with further questions around uniqueness, the aura of physical and digital art and their value.

Creative practice and new knowledge

Exploration of the question "what is new knowledge in creative output" was prompted by the purpose of the 2021 and 2022 FADA staff exhibitions, which aimed at creating opportunities for FADA academics to exhibit creative work with the purpose of applying for creative output as research production. Since 2019 the South African Department of Higher Education and Training (DHET) has acknowledged, through policy implementation, that creative work can be formally recognised as research output through a process of peer review, as is the case with textual research (Pretorius 2023). As part of the required documentation for peer review the crea-

tive practitioner must "demonstrate the contribution to new knowledge" which the creative output makes (DHET 2017:9).

Therefore, in preparation for the 2022 exhibition I revisited the objects I had made in 2020, and then, working from the belief that the existence of things IRL and in our minds are understood and expressed through naming and language, I named each thing with a pseudoscientific name in Latin using the binomial naming system used to name living organisms. I chose the binomial naming system as the process of collecting, naming and classification of living organisms is linked to the scientific project of new knowledge creation, which in the past was linked to the tradition of cabinets of curiosities and colonialist collection practices. Incidentally, entomology, the study of insects, and etymology, the study of a word's history, are words that appear somewhat similar, a pleasing coincidence which I thought appropriate for the project.

In the binomial naming system, living organisms are given a two-part name, where the first part refers to the genus, which the species belongs to, while the species name constitutes the second part (Amateur Entomologists' Society 2023). I assigned each object to a genus based on a similar material or colour as follows: Rubisco (pink) (Collection I), Margarita (pearl) (Collection II), Lignum (wood) (Collection III), Cuprum (copper) (Collection IV) and Tenebris (dark) (Collection V). The species was identified more broadly based on a characteristic of the object, such as medium, symbol, association, shape, or material. In cases where this resulted in two objects having the same name, I added a variety name. I included an x between the names to indicate that the object is a hybrid of materials, objects and techniques. I used Google translate to create the names by way of literal translation, therefore, Rubisco x polypus (figure 5), literally translated means pink octopus. I selected the translation for octopus as Google translate did not provide a Latin translation for jellyfish. My reasoning was that by creating objects and naming them, I had created new knowledge, although of questionable value. To ensure that this knowledge was validated as new and unique, led me to the decision to mint each object as an NFT.

The blockchain and NFTs

An NFT is "a unique digital item stored on a blockchain" and "can represent almost anything", for example art, collectibles, profile pictures, and event tickets for events, and "serve as a digital record of ownership" (OpenSea 2022a). The difference between fungibility and non-fungibility is that fungible items are "interchangeable with another of the same item", such as a $1, whereas non-fungible items "has its own unique value" because the item is "totally unique" (OpenSea 2022a). On OpenSea minting "is the process of writing a digital item to the blockchain" through which "its immutable record of authenticity and ownership" is established (OpenSea 2022b).

The blockchain is a generic technology which, like the web, allows developers to "build almost any kind of workable system on top of it" (Vinay Gupta in Catlow 2017, p. 23). It is a powerful, disruptive technology which some argue has the ability to "change everything forever" (Catlow 2017, p. 31) due to its inherent features that include "decentralization, immutability, anonymity, traceability and transparency" (Del Vacchio and Bifulco 2022 2-3). Jones and Skinner (2017, p. 9) aptly refer to the blockchain as "Janus-faced", with one side holding the promise of "fairness and accountability" due to "its traits of transparency and decentralization", whereas "on the other its monetary roots born as a financial payment system … mean its implementations are often stridently capitalistic." This duality between "art as currency and art as socio-political arena" (Jones and Skinner 2017, p. 13) runs through the literature on art and blockchain.

The literature on the blockchain, including NFTs, is vast and rapidly growing (Casino, Dasaklis and Patsakis, 2019). Del Vacchio and Bifulco (2022) provide insight into the impact of blockchain on art and cultural heritage by identifying three themes through a review of literature. The first is provenance and authenticity (Gipp et al 2017, Anagnostakis 2018, Angelova 2019, Ch'ng 2019, Whitaker et al 2020, Wang et al 2021); the second tokenization and fractional equity (Whitaker 2019, Whitaker et al 2020, Franceschet et al 2020) and the last, rights management and digital protection (Zeilinger 2018, O'Dwyer 2020, Ch'ng 2019, Huang and Dai 2019).

De Vacchio and Bifulco (2022, p. 6) define tokenization as "the process of converting a right on an asset (usually owned) into a token, digital information, which is then issued on a blockchain platform for its exchange between users." Tokens may originate as a physical object IRL or be "digital-born" as is the case with "crypto art". Franceschet et al (2020, p. 402) refers to "crypto art" as "a recent artistic movement in which the artist produces works of art, typically still or animated images, and distributes them via a crypto art gallery or their own digital channel using blockchain technology." The tokenization process as explained by Franceschet et al (2020, p. 402-3), in which an artwork is uploaded to a crypto art marketplace and a transaction created on the Ethereum blockchain resulting in an NFT, is similar to the process I followed to create my NFTs on OpenSea. However, whereas crypto artists tokenize their work to create proof of uniqueness, ownership and authenticity with the aim of encouraging sales (Franceschet et al 2020, p. 402-3), my interest was less in selling work than using the blockchain to record and validate the creation of new knowledge.

To be able to mint my NFTs, the physical objects which I created needed to be digitally reproduced, in this case into jpeg format by way of digital photography. I found it very ironic that in the NFT marketplace the act of placing a digital copy of my original object, and assigning a unique token ID to the copy, renders the copy unique. The infinitely reproducible digital image of the original object, with its accompanying ID, becomes the "original" work of art which accrues value in the digital space, whereas the true original, the physical object IRL is arguably of less value. The implications of the reproduction of a physical work of art in relation to its value was explored by Walter Benjamin in his influential essay "The Work of Art in the Age of Mechanical Reproduction", first published in 1935.

Aura and physical and digital art

Benjamin (1969) argued that the reproduction of an original physical work of art, such as a painting or sculpture, by mechanical means, for example photography, robbed the artwork of its "aura" thereby diminishing the value of the work. According to Benjamin (1969, p. 3) "[e]ven the most perfect

reproduction of a work of art is lacking in one element: its presence in time and space, its unique existence at the place where it happens to be." It is this existence that determines the artwork's history, including changes over time in its physical condition and ownership. For Benjamin (1969, p. 3) authenticity is dependent on the "presence of the original" and authenticity cannot be reproduced through technical means. Benjamin (1969, p. 4) describes authenticity as an art work's "most sensitive nucleus... the essence of all that is transmissible from its beginning, ranging from its substantive duration to its testimony to the history which it has experienced". The element which is lost in reproducing a work of art is termed "aura" by Benjamin, and, as Betancourt (2006) observes, it is logical to assume that aura is lost not only with mechanical reproduction, but also digital reproduction.

Friedman and Hawkes (2021) state that aura is linked to the "viewer's visceral reaction to the physical traits of the work" such as the "variable pressure of the crayon on paper, the thickness of impasto brushstrokes or their glossy translucency, the weave of the canvas showing through the loosely applied imprimatura, the mutable effects of light playing on the surface at different times of day." Such tactile qualities resulting from physical making was what I particularly craved when I initially started creating the objects, and it was these qualities that was remarked on and appreciated by visitors to the FADA Gallery exhibition in their comments to me.

A review of the literature examining digital art in relation to Benjamin's concept of aura shows that several researchers have concluded that digital art does not lose aura through mechanical reproduction, but instead, a new type of aura emerges which some ascribe to the difference between digital and physical objects (Bozkanat 2022:3, Emison 2021:13, Friedman & Hawkes 2021, Trice 2020:5, Bakker 2018, Betancourt 2006). Betancourt (2006) argues that digital and non-digital art objects are fundamentally different due to all digital objects consisting only of binary code, while physical objects take on many different and unique forms. Therefore, Betancourt (2006) argues, digital objects "constitute a new class of object" that contains the "aura of information", which refers to "the separation of the meaning present in a work from the physical representation of that work". Betancourt (2006) explains that "[b]ecause the material aspects of digital works are ephemeral, lasting no longer than the phenomenological encounter with the presentation of the digital object, (typically on a screen of some type), the 'aura of information' suggests that the digital itself transcends physical form. This illusion defines the 'aura of information'".

Similarly, Friedman and Hawkes (2021) argue that "NFTs simultaneously embody two kinds of abstraction: financial value and the aesthetic aura". They formulate this argument by referring to the controversy surrounding the burning of a Banksy print by its owner in 2021. The print was purchased for $95,000 and after a reproduction in the form of an NFT was sold for $380,000 the original was incinerated. Friedman and Hawkes (2021) maintain that when the original is destroyed "it becomes possible to package, market and sell the aura in the absence of the original. The destruction of the original allows the NFT to monetize the aura, imposing on it the form of financial value". The financial value of NFTs has been a prominent preoccupation since the emergence of blockchain technology and cryptocurrencies and as Friedman and Hawkes (2021) observe, because financial value and the aesthetic aura are collapsed into "the same symbol at the same time ... they have become functionally identical. And if identical, then interchangeable."

The entanglement of these two types of abstractions have led to NFTs being considered both a "craze" and "the future of digital art" with sales skyrocketing from an estimated $12 million in December 2020 to $340 million in February 2021, with collectors being prepared to pay millions of American dollars for a single NFT (Chohan 2021, p. 1). Chohan (2021, p. 1) rightly observes that "despite in essence representing little more than code" NFTs sell for millions because "a buyer has ascribed 'value' to the code". Chohan (2021:6) notes that this leads to the ultimate question raised by NFTs: "how valuable is an NFT in reality?" The answer, according to Chohan (2021, p. 6), is that "[i]t is as valuable as people express a willingness to pay for it".

NFTs and value

I put my NFTs up for sale on 22 September 2022 for the duration of the Interventions in Practice exhibition priced at 0.510 "wrapped ether" (WETH), a decision based on a cursory analysis of the pricing of NFTs on OpenSea, and symbolically on the fact that I was minting 51 tokens. WETH is a cryptocurrency and at the time of minting my NFTs 1 WETH, at closing, equated to $1,267.87. Therefore, at that point in time, the price of one of my NFTs was $647 US dollars, which I thought was quite a substantial amount.

However, this price was nothing compared to the oft cited example of $69 million paid for the work "Everydays: The First 5000 Days" created by Mike Winkelmann (Kastrenakes 2021). Winkelmann, an American graphic designer working under the name Beeple, started creating an image every day from May 2007—a practice which he continues at the time of writing this paper—and posting the image to his Instagram account "beeple_crap". "Everydays" is a composite of the images which he created over the course of thirteen years and was auctioned off by Christie's (Gompertz 2021). Kastrenakes (2021) notes a development in Winkelmann's work from "somewhat crude sketches" to "evolving digital shapes and sceneries" while Gompertz (2021), in his review of "Everydays," grudgingly concedes "I won't pretend to have viewed each and every image, but I have seen enough to know it is of artistic and documentary merit".

Kastrenakes (2021) ascribes the value of Winkelmann's work to his "large fan base, with around 2.5 million followers across social channels", his productiveness, the staggering growth of the NFT market, and collectors and investors belief that digital art will continue to be traded in this way into the future thereby promising large returns for early investors. In addition, Christie's involvement in the sale legitimized "both Winkelmann's art and NFTs as a technology".

Winckelmann's enormous following—2.4 million on Instagram alone—indicates the importance of what Franceschet et al. (2021, p. 404) identify as engagement and community in the "Crypto-Artistic Movement". Participating in and building NFT

communities are considered essential for NFT artists (Lisa 2022) indicating the importance of connectivity between artists, collectors and other role players in the NFT world.

It is therefore not surprising that with my mere 482 Instagram followers and 301 posts—compared to Beeple's 3181 posts—and no presence on Telegram, Twitter, Reddit or Discord, I did not sell a single NFT. But then, selling art was not my intention when venturing into the world of NFTs and neither is it for many other artists who are exploring the possibilities offered by Blockchain in interesting ways. The publication Artists Re:Thinking the Blockchain presents a diverse range of such projects from the speculative to the playful exploring the "meanings, possibilities and implementations" offered by the blockchain" (Jones and Skinner 2017, p. 12).

Chohan (2021, p. 9) laments the fact that the focus on making "a quick buck" through NFTs has "detract[ed] from the genuinely interesting idea that a decentralized mechanism can offer a public recognition of the specialty of an encoded object." Chohan (2021, p. 9) observes the presence of "an exploratory, counter-hegemonic element to virtual participants engaging with NFTs" and it is this space which I believe is the more interesting area for exploration and creative work involving NFTs and the blockchain.

Conclusion

I set out in this paper to reflect on my work Tokens and how in engaging with the question of what is considered "new knowledge" in creative practice I entered the world of NFTs, which resulted in further questions around uniqueness, the aura of physical and digital art, and value. In addressing Benjamin's view on the "aura" in relation to digital reproduction, current arguments refuting his claim were raised and I touched on the financial value of NFTs and the importance of community in creating value in the NFT world. As my reflection progressed, the questions proliferated, and these could, unfortunately, only be addressed in a limited way by providing my perspective and experience of venturing into the NFT arena. What did become clear to me is that blockchain technology cannot be ignored by creative practitioners. As Catlow (2017, p. 21-22) notes, "blockchain technologies are here to stay. They are overtaking the WWW as the next big network technology for speculation and disruption ...artist have a crucial part to play here".

Acknowledgments

Thank you to Daniel Erasmus for building the entomology cases, providing insight into using cryptocurrencies and advising on the pricing of my NFTs, Lana Strydom for advice on minting NFTs and Eugene Hön for curating both FADA staff exhibitions.

Speculating futures in an age of nostalgia

Michael Smyth

Edinburgh Napier University, UK
m.smyth@napier.ac.uk

Abstract

This paper will present an exploration of the relationship between the past and the present and how that interaction influences design thinking when speculating about possible futures. It will argue that the growing influence of nostalgia, supported by the exponential growth of data creation and consumption, together with the democratisation of sophisticated tools, has the potential to introduce the unintended effect of flattening the very creativity that is central to design. The key argument is that design is influenced by visions of futures from the past, either intentionally or unintentionally.

The concept of Hauntology will be introduced as a way of framing how visions of possible futures are continually bound up with the concerns of the present which are, in turn, connected to the past through the "spectres of lost futures". More recently, critics have discussed Hauntology in the context of describing contemporary culture's persistent re-cycling of retro aesthetics and the subsequent inability to escape old social forms.

In the time that it takes to attempt to recall the name of a TV programme from our past, it is now possible to view original footage on a myriad of different platforms and services. These tools have the effect of making time plastic and stretchable, where the past has never been more accessible. The paper will argue that slowly and imperceptibly we have become beguiled by the increasing capacity to store, organise, access, and share vast amounts of cultural data and that this could lead to a dampening of creativity.

Introduction

In the city of Bristol UK, during the summer of 2020 a bronze statue was toppled by protesters, dragged through the streets to the harbour and thrown into the sea. In the grand scheme of things, this might seem like a small local disturbance, but what it raised were much more fundamental questions about our relationships with the past and how these are affected by the present and possible futures. The statue was of Edward Colston, a 17th century merchant and slave trader who was born in Bristol. Colston's memory had been divisive for years, with some thinking history can't be changed and others campaigning successfully for his name to be erased from streets, schools, and venues. The toppling of the statue served as a powerful reminder that the past is intimately bound up with futures and critically that the past is also a contested space (Stead & Coulton, 2022). It is subject to many different interpretations when viewed through the lens of the present.

Like so many people, I have been working from home for most of 2020 and 2021 but now I move between home and the office as I engage in what has become known as hybrid working. On a daily basis, I navigate the technology landscape moving between Webex, Teams and Zoom to communicate with colleagues. I am living the 1990s dream of Computer Supported Co-operative Working (CSCW) (Grudin, 1988). Moving seamlessly between meetings comprised of people who are having similar experiences, while all the time I remain physically in the same location. Paradoxically I seem to have caught up with a technological view from the past. From this perspective, the idea of what a future or indeed futures, might hold has become increasingly difficult to imagine. In response to this dilemma, I found myself looking more to the past. Imperceptibly my social media feeds became populated with terms such as retro, vintage, and redux and these curated images from the past provided a sense of nostalgia in uncertain times.

What is the appeal of nostalgia and why does something that is impossible to achieve continue to have such a hold on us? As our lives push forward, seemingly ever faster doesn't it feel natural that we should sometimes stop and wish that we could have some part of it back. Nostalgia keeps happening, even though it is impossible, and it is in that duality that part of the appeal resides (Berry, 2020).

In season 1 of the TV series Madmen in an episode entitled The Wheel (2007), directed by Matthew Weiner. The anti-hero Don Draper during a pitch to Kodak, describes nostalgia as delicate but potent. He continues that it literally means the pain from an old wound, it's a twinge in your heart far more powerful than memory alone. Just like Don, we are constantly looking forward and as designers we are always wondering how to improve our futures when we don't always realise that true power comes from the past. The past can offer nostalgia, and, like Don, it is only when we accept the past that we can properly move forward. Speculative design (Dunne & Raby, 2013), in many ways is as much about understanding the past as it is about imagining futures.

Hauntology — How futures are connected to the past

As with the case of the statue of Edward Colston, what these stories illustrate is that our visions of futures continue to be intimately connected to our past. Raising the question of whether that relationship is intentionally acknowledged or is the past an ever-present but perhaps unseen backdrop as we consider our futures? The nature of this relationship between the past and the future was articulated by the French philosopher Jacques Derrida who coined the phrase Hauntol-

ogy (Derrida, 1994). What he meant by this term is that the present is haunted by the metaphorical "ghosts" of lost futures. The concept raises the question of how "spectres" of alternative futures influence current and historical discourse and if "haunting" has real effects on how we conceive possible futures. In short, our visions of possible futures are always bound up with our concerns of the present which are, in turn connected to the past through these "spectres".

More recently, critics such as Mark Fisher have discussed Hauntology in the context of describing contemporary culture's persistent re-cycling of retro aesthetics and what he considered to be an inability to escape old social forms (Fisher, 2012). His position is captured in his characterisation of 21st century culture as being "20th century culture distributed over high-speed networks" (Fisher, 2014). For Fisher, creative and cultural production needs to either explicitly reference the techniques of the past in the means of production or risk being implicitly tethered to the past. In his 2012 paper entitled What is Hauntology?, Fisher frames an argument that there is no leading edge of innovation anymore and that we are living in what Franco 'Biffo' Berardi referred to as "after the future" (Berardi 2011). Fisher states that "what haunts the digital cul-de-sacs of the 21st century is not so much the past as all the lost futures that the 20th century taught us to anticipate" (Fisher 2012). From the perspective of Speculative Design, Anthony Dunne has discussed the idea of "broken futures" which I suspect refers to the promises of past futures and how these have failed to be delivered or, what was in fact delivered was a pale shadow of the original concept. In a similar way James Auger (Auger, 2013) refers to Alternate Presents or Lost Futures when considering different development paths, so rather that asking the question "what if?" it is reframed into asking "why are things the way they are?".

These ideas echo the position of Berardi who, when discussing the influences of the 1960s on the speculation of futures described this effect as "the slow cancelation of the future" in the context of being unable to break free from the shackles of these decades (2011). The horizons of the future seem tethered to ideas that emanate from this period of "peak future" (Smyth, 2021). We are seemingly bound to these spectre's of the past, for example the utopian ideals born in the 1960s and forged in the "white heat" of science. An imagined world of flying cars and jet packs for all, each somehow encapsulating the promise of a future so far removed from the everyday reality and so beloved of fictional secret agents of the time.

Influential Spectres in Uncertain Times

But fast forward to today, as we come to terms with the experiences of various lockdowns, what has become increasingly apparent is that the spectres of lost futures are ever more present as the uncertainties of the present begin to reshape our desires and dreams for the future. These are perhaps not best represented by the canonical visions of futures mentioned earlier, but rather by a gradual shift to a more holistic view of where humans fit in the wider ecology. The impact of climate change is being felt across the globe, sustainability and the circular economy have become a central part of any discussion about production and consumption. The Royal Society for arts, manufactures and commerce (RSA) in the UK refines this conversation when it talks about re-generation, with the twin focus of repair and improve. Meanwhile, the emergence of vintage, up cycling and re-use reflects one of the few growth areas of the high street. This is typified by Waste! a relatively new addition to the growing number of vintage shops in London. What makes Waste! stand out is its deliberate reaction to the modernist aesthetic of many shops. In the shop the owners have created the experience of a teenage bedroom from the past as it foregrounds the work of local designers to a wider public. Our relationship with the past is bound up in the pre-loved world of vintage and recycling both creating sustainability and a direct link to the past. Magnified by the uncertainties in society, economics and the environment, nostalgia provides the balm for this triple bottom line itch. From the perspective of technology, specifically Human Computer Interaction (HCI) and Interaction Design (IxD), the increased interest in Artificial Intelligence (AI) and More than Human Design (Giaccardi & Redström 2020) considers our place as humans in these eco-systems. These nascent entanglements of human and non-human agency pose significant challenges for human centred design processes. Just as we get used to Human Centred Design, the ground shifts again, which could indicate a desire to return to a more symbiotic relationship with nature and the environment. Hauntology extends the concept of action taking place over multiple sites and actors to consider how participation happens across multiple temporalities, to not only consider the present but also what was the past and what might be possible futures (Gatehouse, 2020).

The pressure is coming from technological change or perhaps more accurately the application of existing techniques but manifest in new forms. AI is a verdant ground for the ghosts of lost technological futures and much of the rhetoric associated with the Expert Systems of the 1980s and 90s is echoed in the current discourse around AI that pervades the discourse concerning interaction and its wider impact on society. These mysterious algorithms make selections and predictions that effect our lives. From the relatively trivial, such as choosing where we are placed in the phone queues based on our location and previous behaviours, to the selection of job applicants and the prediction of academic grades. The unconscious bias somehow one step removed as it permeates the code, distancing responsibility from the human actors. Does the promise of AI somehow speak to our lost futures, its vagueness adding to the allure and promise as this particular ghost in the machine quietly monitors in the background, making unseen decisions? This is set against a backdrop of an increased deployment of AI into industry (Industry 4.0) and the environment (Internet of Things) that has re-cast the role of technological artefacts and their relationships with humans.

We are living in times of seemingly constant change, but the direction of travel is uncertain. Technology fuels this illusion of progress, where change seems to equate to ever faster iterations off the same products, services and experiences. The spectre of Berardi looms large. But this is not the whole story, behind the technological tools lies the resource of data. Year on year the amount stored data grows exponentially, as we create and consume ever more amounts. The devices we use to traverse the datascape require more memory capacity to cope with the scale of data. This, coupled with the next generation of data hungry apps that harvest our data on an industrial scale, is a vicious circle that far from trying to avoid, we seem intent to run headlong towards as we upload, comment and retweet, creating vast data sets for third party vendors.

Nostalgia and Technology

The role of data, particularly from the perspective of innovation and skills has been a topic of interest for some years now. Technology lies at the heart of such innovation, but the situation has been further complicated by the growth of media data sets and the diversity of tools available to search such repositories.

In the time that it takes to attempt to recall the name of a TV programme from our past, it is now possible to view original footage on a myriad of different platforms and services. These tools have the effect of making time plastic and stretchable, where the past has never been more accessible. Fisher (2013) refers to this as "technologised" time, where the past and the future are subject to ceaseless de and re-composition. Time becomes compressed and, in effect begins to disappear much in the same way as Marc Augé (2009) talks about "non-place" when referring to airports, retail parks and chain stores as places that have become generic and have lost their meaning and connection to us. Now we can add "non-time" into that discourse.

In a recent article by Lauren Cochrane she describes a similar situation in terms of how we are experiencing an acceleration of nostalgia, which she characterises as being "trapped in what we might call a Revival Spiral" (Cochrane, 2022). She describes the current retro culture as "anemoia", a nostalgia for an era that a person has not actually lived through, whereas the Revival Spiral is perhaps better characterised by a seemingly increased longing for the recent past. This could be because of the rate of change in digital culture, resulting in a nostalgia for eras that we have just left and accelerated by the plentiful data that documents that last ten years. The situation has been compounded, Cochrane argues, by the turbulent times that we are living through. Pre 2016 might only be eight years ago, but it feels like a lifetime: Trump; Brexit and a global pandemic. The effect has been the tendency to romanticise the cultural signifiers from 2019 or earlier.

The article describes how Sarah Lloyd from University of the Arts (UoA) London, considers the revival culture as a way of gaining a sense of control over the ever-shifting cultural landscape and relocating oneself in the past to better understand the present. The accompanying technological tools are crucial to this relationship. With so many data resources available to us, we can create experiences of the past without the need for newness. A situation that mirrors the concerns of both Berardi and Fisher. With the same search engines and algorithms available to everyone, the effect has been to "flatten the zeitgeist" (Cochrane, 2022) leading to a monoculture across the generations. This view was similar to that explored by Superstudio who were one of the key exponents of the Radical Design Movement that emerged from Florence, Italy in the 1960s. By adopting a speculative approach Superstudio sought to give voice to a new generation of architects who wanted to critique the traditional methods of planning and question the very nature of what cities might become in the future. The Continuous Monument (Figure 1) imagined cities as anonymous megastructures where the last vestiges of local cultures would be removed. Though never intended to be built, their aim was to act as a catalyst for discussion and reflection on the lived experience associated with such a future. There can be little doubt that the spectres of Superstudio haunt the glossy renders of many visions of future cities but perhaps most strikingly in the case of The Line the Saudi governments plan for a 170

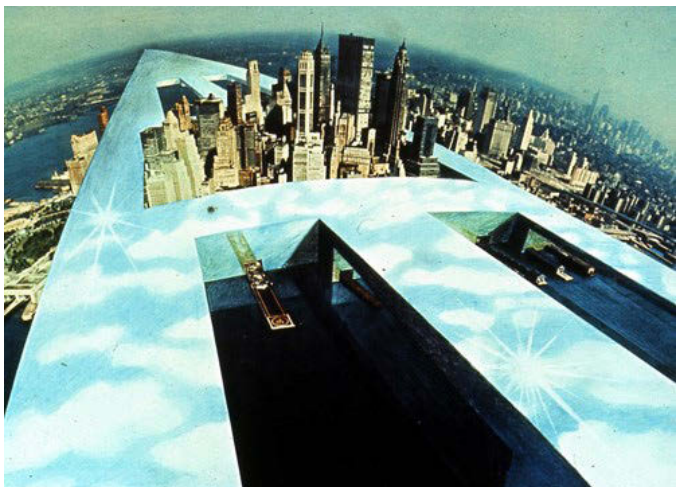

Figure 1. The Continuous Monument, Superstudio (1969-70) image courtesy of C.Toraldo di Francia Archive

kilometre long structure to be built near the Red Sea, complete with 500 metre tall mirrored facades.

But let's return to the idea of nostalgia and how the past continues to exert influence and beguile our imagination of futures. Simon Reynolds coined the phrase "retromania" to describe what he saw as the growing influence of nostalgia on popular culture and the commodification of the past (Reynolds, 2011). Coverley (2020) cites the impact of digital technology on cultural memory, in particular the internet and its power to democratise and make accessible vast resources of data that were once in limited supply and are now available for manipulation and nostalgia. He summarises the 21st centuries' obsessive curating of the past as a "symptomatic yet futile attempt to control time which has only intensified as new technologies become a facilitator for nostalgia, providing instantaneous access to endless new swathes of the past" (Coverley, 2020).

The remix culture continues to pervade many aspects of creative and cultural production, from the "cut-up" techniques favoured by authors and musicians, from Burroughs to Bowie. The technique of "cut-up" refers to the process of literally cutting up existing texts to generate new meanings with the rearranged pieces. There is now a new generation of artificial Generative Adversarial Networks (GANs). These employ neural network architectures to generate new data based on learned patterns. As well as generating images of human

Figure 2. The Zizi Project: 7-channel installation at Inspace City Screen, Edinburgh Fringe Festival 2019, image courtesy of Jake Elwes

faces and creating images from text, GANs can generate entirely new data making them core too many leading-edge AI systems. An example of this approach is the work of Jake Elwes, who in the Zizi Project (2019) used films of drag artists to train a neural network to enable audiences to create a synthetic facsimile that could dance to particular songs. The work was exhibited as part of the Edinburgh International Festival in 2019 (Figure 2). Part of the appeal is the capability of seemingly endless recombination of images of the past based on the promise of insight through serendipity. In short, an automated cut up for a new generation.

So, what is the effect of the exponential growth of searchable and retrievable data; the growth of publicly available AI based tools that can manipulate and endlessly re-purpose such data into new forms and the allure of nostalgia? This paper has argued that slowly and imperceptibly we have become beguiled by the increasing capacity to store, organise, access, and share vast amounts of cultural data. The laudable aim of data driven innovation needs to explicitly take on board the prophetic words of Berardi and Fisher and, what these mean for the design and development of technological tools for the creative industries, as these tools might have the unintended effect of dampening the very creativity that is central to the endeavour.

Computational thinking in design and fabrication for augmented and accessible museums

Marco Verde
IED- Istituto Europeo di Design, Italy
info@alo-architettura.com

Abstract

The attention to the universal accessibility of spaces and culture is rapidly growing, and both computational thinking and emerging technologies are fostering the proliferation of innovative strategies and processes, from design to management, to facilitate the inclusiveness of museum spaces and the dissemination of cultural heritage.

In this context, starting from the small scale of museum devices and installations, computational design strategies, new digital fabrication technologies and advanced multimedia narratives are gaining ground in the design-research and original development of immersive and rewarding inclusive experiences.

Our research work on this subject started in 2019, tackling the design and prototyping of an accessible device for the multimedia and tactile exploration of pictorial works for people with visual impairments. The brief had the potential to tackle the historic debate on the concept of the frame, a debate based on a visual fruition of the artworks that totally loses its value from the perspective of a visually impaired person. A new question emerged: Can we reformulate the role of the frame and envision a new model that encourages alternative cognitive processes and facilitates the tactile exploration of pictorial artworks?

Lately, in 2021, ALO was commissioned the design and prototyping of a larger multisensory and accessible installation for the Lazzaretto Cultural Art Centre in Cagliari, the Digital Story Explorer. The DSE was originally conceived as an adaptable system to tell the story of historic buildings, cities and territories through a hybrid multisensory narrative strategy, physical, digital and tactile at the same time.

The search for a strategic combination of advanced design, digital fabrication techniques and uncommon building materials (such as composite materials) carried out so far has led to identifying both current critical issues and potential directions for rethinking the role of museum exhibition devices as nodal to the creation of accessible cultural spaces of immersion for active involvement of visitors. Through a sample of projects realised within ALO's current architectural practice, the paper will illustrate this ongoing design research on contemporary strategies, processes and new materiality aimed at an accessible and experiential museality.

Introduction

In the field of design research on accessible spaces and culture, starting from the small scale of museum devices and exhibition systems to the full scale of museum buildings, computational design and digital fabrication technologies together with advanced multimedia strategies have a special potential to engage visitors in inclusive, immersive and rewarding experiences. From the designers' point of view, one of the most significant aspects of a direct access to digital fabrication technologies is the ease and speed of in-house prototyping and self-production of final designs. A significant added value is given by the ability to produce complex solutions not feasible with traditional manufacturing techniques. This allow to deliver fully customized projects that are strictly adhered to the specific content, design scenarios and physical spaces which are all ever different case by case, as well as to implement specific strategies to address accessibility requirements and target visitors for a social but more individual experience.

In this sense, conventional products and exhibition systems and space design can no longer provide a fully contemporary experience, so that the visitor is not a passive spectator, but an active agent of the narrative(Hall, 1987). Hereby emerges the need for new strategies based on the integration of multisensory storytelling to intercept the expectations of visitors who are becoming, most of them unconsciously, increasingly demanding due to the ubiquitous exposure to multimedia, sensing, interactions, interconnections and automations that are pervading all spheres of human life(Bekele et al., 2018). In this sense, advanced design techniques and digital fabrication, understood as inextricably intertwined constituents of a holistic thinking, take on a new value. Design innovation and non-serial production become critical towards creating inclusive and experiential landscapes for visitors' engagement.

Then, furniture, podiums and content display elements might acquire a new role and design dignity as means of communication and involvement of the public in a physical and architectural experience. If we no longer simply observe, but we are forced to move by the experience(Manning, 2012), museum spaces can become landscapes for active immersion. Hence, from a utilitarian approach, which started leading the design of museum spaces and displays starting in the XX century (Desvallées & Mairesse, 2010), we might shift to the design of immersive museum installations to encourage a complete multisensory experience of contents.

This article will showcase two projects (Aptica and DSE) framing our R&D agenda and take on the subject from a design studio practice point of view.

Our research agenda on this subject started in 2019, thanks to the collaboration with CRS4, Sardinia's Centre for Research, Development and Advanced Studies, which commissioned ALO the design and prototyping of a functional device for the multimedia and tactile exploration of pictorial works. Lately, in 2022, we completed the development of the DSE, an accessible storytelling system to tell the histories of historical buildings, cities, and territories that has been commissioned by the Lazzaretto Art Cultural Centre in Cagliari.

The DSE represents a new milestone as it provided the opportunity to deepen our research with respect to the conception of exhibition systems as agents to trigger a physical and multisensory experience of cultural content.

Aptica. A multisensory interface for museum accessibility

Our work stems from the initial studies developed by CRS4 researchers as part of the 'Over the View' research project. CRS4 initiated the development of software and hardware infrastructure to transform pictorial works of art into scaled 3D representations suitable for tactile exploration. The simplified miniatures were to be equipped with sensors to enable the playback of multimedia content describing the area being touched. Hence, ALO prototyped a new complete and functional physical interface called APTICA (fig.1), which gave he systems the integrity of a complete and finished product.

Figure 1. The APTICA interface with 3D miniature of the artwork. The touch feelers sensing surfaces enable the multimedia tactile navigation of contents.

Accessibility by design

Museum experiences and art exhibitions are undergoing a transformation(Allen & MInnion, 2020): from passive viewing of exhibitions and exhibits, there is a shift to entirely new ways of offering imaginative tours that stimulate viewers and offer accessible, rewarding and memorable experiences. As summarised by A. Marras (Mameli et al., 2021), museum accessibility emerges at the intersection of physical aspects of museum spaces and displays with cognitive, sensory, cultural, economic and digital aspects.

Zooming on the process of tactile experiences from a practical point of view, it requires training and preparation(Galati, 1996); this was a critical observation that emerged also during the meetings with the CRS4 research team including Andrea Ferrero, a visually impaired researcher and artist; as Ferrero pointed out, a strategy is needed to see objects with the hand. From the perspective of a designer, there are certain drive criteria that should be taken into consideration in order to facilitate the process of tactile recognition and achieve the most effective results (Levi & Rolli, 1994).

In this regard, in addition to the relevant utilitarian aspects, the brief from CRS4 showed the possibility of opening a new chapter within philosophical, historical and semiological discussions about the frame, an object that has so far assumed the status of a theoretical object as observed by Pinotti (2018) (Daniela Ferrari & Pinotti, 2018). Pinotti illustrates the story of the frame, which appeared in a context that intended art as a reality detached from the one we live in. The frame was a boundary between the representation and real space which purpose ranged from intensifying the perception of the depth of the field or projecting the movement outwards.

The historical evolution of the role of the frame went through various phases until its denial. However, the whole debate starts from the assumption of a visual fruition of the artworks; therefore for people with severe visual impairment, the frame in its traditional conception loses its value. This raised a new question: Can we reformulate the role of the frame and imagine a new model that perhaps supports alternative cognitive processes and facilitates a tactile exploration of pictorial artworks?

Moving from the concept of the frame as a boundary for the eye to that of an intensifier of the senses was a critical challenge of the project. For this purpose, the research agenda explored the design of an interface that would serve to prepare the hands for the tactile experience.

Preparing for the tactile exploration

Figure 2. Global view of Aptica interfcace.

Aptica was designed as a tabletop object which body seems floating over the supporting surface. The aim was to isolate it from the surrounding physical world and stimulate the perception of a suspended, autonomous object on which to focus one's senses.

Following the instructions of a tour guide, the first part a visitor should come into contact with is the perimeter of Aptica: a fragmented edge consisting of a sequence of thin ribs that point towards the centre of the 3D touch tablet. The fragmentation aims to provide an initial intense tactile transition from the surrounding solid objects to the sensory space. (fig.2)

Then the hands meet the skin: a continuous and smooth surface that finishes the top of Aptica body and surrounds the tactile tablets. It is a neutral transition zone intended to evoke new feelings in contrast to the previous one to familiarise the touch with a smooth and continuous surface. The goal is to prepare the touch for the perception of three-dimensional figures which edges are necessarily more complex. The concave shape of the skin guides the hands towards its deepest part, suggesting an immersion into the sensory space of the 3D miniature. To achieve a smooth and sturdy surface, the skin was made of composite material and cast in a mould fabricated at ALO's workshop by CNC robot milling.

Finally, at the centre of the skin there is a platform featuring a set of spring-loaded electrical connectors ready to plug the interchangeable tactile tablets (fig.3). These are automatically recognised by the system via an embedded RFID card that recalls the respective audio and video descriptions. All software and system data are stored on a PC in a technical compartment integrated into the body of the Aptica. (fig.3a)

The tactile tablets are produced according to the subjects to be represented. On the top of each figure there is the touch feeler, a sensing inductive surface consisting of a sophisticated design that is generated through a computational process to meet project brief requirements.

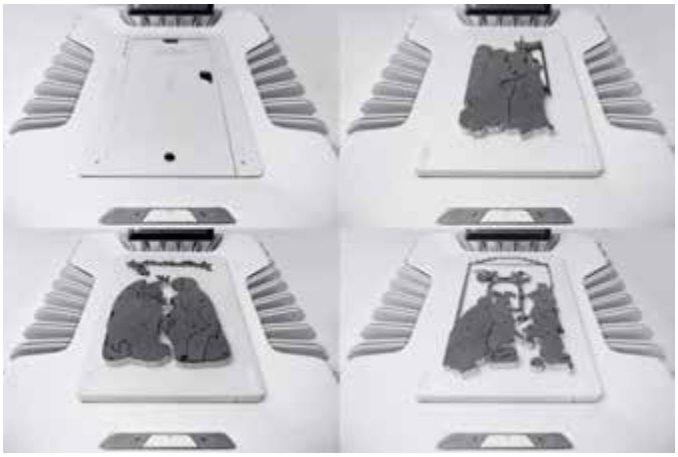

Figure 3. The APTICA interface features a technical compartment (3a) and it is designed to host interchangeable 3D tactile boards that can be swapped without the need for any technical intervention.

The computational design of single line touch feelers

As illustrated by L. Lanzi (Mameli et al., 2021), the realisation of the prototype involved a preliminary careful study of the artworks selected for the project from an iconographic point of view, with the consequent choice of the main elements to be reproduced and arranged as 3D figures of different height, so as to make them easier to read through touch. This initial work was carried out by CRS4 research team and experts involved in the Over the view project.

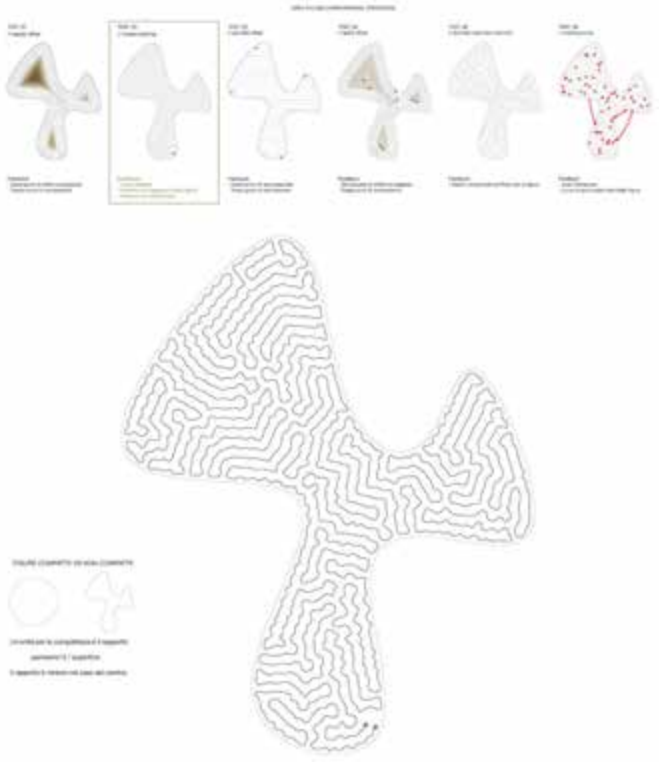

Figure 4. On the top a catalogue of attempts for a single-line filled surface with the points for electrical connection. The diagram on the bottom shows a final sample generated by the computational process.

The top-layer of each figure has been developed as a sensing surface, the touch feeler, which perceives visitor's touch and activate an audio narrative dedicated to the user, also with the possibility of asking specific questions. The development of the touch feelers was the second major design-research topic indeed.

ALO was asked to develop a sensing system based on two electrical connections (positive and ground) that would work without bracelets or additional connections involving the user. The main goal was to finds a system that could adapt to every kind of figure with minimum amount of electrical connections. Various geometric approaches were explored (fig. 4) to design conductive traces that could even detect the touch of a single finger anywhere on the surface of the figure.

However, in the case of non-compact figures, most of them failed to produce single-curve occupancy, which was very important in order to avoid over-complicated wiring and ensure system stability and scalability. Moreover a non-directional pattern appeared to be beneficial to avoid confusing the tactile exploration. Hence, we decided to investigate a computational method to generate an occupation pattern consisting of a single curve filling any kind geometric figure, compact or non-compact.

The studies of D. Hilbert or W. Sierpinski on space-filling curves(Sagan, 2013) showed a possible way forward, so we researched a computational protocol that, starting from a given boundary condition (the edge of the figure) and a set of genotypic parameters and constraints, modulates and folds

back the edge on itself up to fully occupy the figure with a single complex curve.

Figure 5. Detail of the conductive graphite pattern of the touch feelers prototype.

Through this procedure, which combines physical-computing methodologies and parametric-associative design strategies, we obtained a generative system that fills the space of the figure, while still matching production and functional constraints. The graphite based touch feelers were then prototyped in our laboratory by fine-tuning a fabrication protocol combining painting, cutting and laser engraving as to achieve repeatable and stable results.

Aptica prototype has proven the viability of the solutions researched and developed. Moreover, as the entire object and all its part has been designed as a parametric system, it is adaptable to every artwork, independently of shape and size and it is ready for immediate digital fabrication with basic CNC machinery.

Digital Story Explorer (DSE). Digital technologies for museum accessibility

The Digital Story Explorer (DSE) is the prototype of a multisensory museum accessibility system designed to tell the story of historic architecture, cities and territories in a contemporary, immersive and accessible way. In its first implementation (DSE 1.0), the system was customised for the permanent exhibition "Lazzaretto ieri e oggi" (open at the Lazzaretto in Cagliari since 13/2022) curated by the Cooperativa Sant'Elia 2003, to tell to tell the story of the Lazzaretto in Cagliari (Italy) and the life of doctors, quarantined, and people hosted and working in the building at the time of the plague (1830).

The DSE project continues the design-research undertaken during the Aptica project and the design of the tactile and interactive models of the Genna Maria and Serri Nuragic archaeological sites (also developed as part of CRS4's Over the View project in 2020) toward the larger scale of the exhibition space and its constituent elements.

Thanks to a renewed design and production approach, the agenda aims to establish a deeper relationship with the specificity of the exhibition spaces and content, and even the display podiums and structures acquire a pivotal role in the experience. Design research thus expands from the field of museum devices to that of immersive spaces, intending to amplify and awaken the sensory engagement of visitors by combining the very architecture of installations with more exploratory and trans-modal storytelling.

Hereby, digital design and fabrication techniques, including 3D printing and robotic fabrication processes, become strategic to personalize museum experiences by perfectly adapting them to the content and exhibition spaces and offering rewarding one-off experiences.

Design for all. A matter of form at the intersection of space and media.

The agenda is to blur the boundaries between the visitor's senses through the very materiality of exhibition elements and multimedia. The very design of the exhibition architecture and its constituent elements, such as display podiums, can play a central role in creating an inclusive and immersive atmosphere, in establishing immediate engagement with visitors, evoking feelings of curiosity and encouraging them to imagine themselves in other times and places, guiding them in a subtle manner through an active experience of the contents. (Waern & Løvlie, 2022)

The DSE 1.0 provides that the narrative about the Lazzaretto is unfolded through the support of a scale model. The structure of the building was reproduced following the plans of the 1830 from Alberti stored at the State Archive of Cagliari. However, telling non-experts the story of a building as a whole, its internal organization and life, with a static model is particularly limiting. Therefore, the challenge was to build a fine dynamic model with a hidden mechanical system. Finally, the ground floor opens up by sliding under the first floor according to the visitor's actions on the graphic navigation interface.

The entire 3D model was optimized for 3D printing with photo polymeric resin combining transparent resins for the facades and roofs and opaque ones for the structures and interior partitions to maximize the final efficacy. In addition, a dynamic lighting system accompanies the exploration by following visitor's actions down to the interior of the individual rooms which story is told. The rooms themselves come to life through the reproduction of animations from the graphic novel "Bartolomeo Salazar, the Last Plague Doctor," created by artist Stefano Obino, which are played back on the display of the navigation station and the wall in front of the DSE accompanied by a narrator's voice telling the story of those spaces among historical facts and memories passed down from generation to generation.

An advanced design of exhibition devices can provide new opportunities for a more immersive and pleasant cultural dissemination. With this goal, the podium displaying the dynamic model and the trans-modal navigation station (fig.6) were designed as a single entity. Even though they are two separate objects, their spatial relationship and shape are inextricably entwined (fig.7).

The design of the two elements pays special attention to younger visitors and those with visual and physical impairments. The intersection of their needs was made possible by an integrated parametric design approach that relays on a non-serial production approach to digital fabrication. This synthesis, guided by a humanistic approach to technology, helps to fulfil multiple requirements through formal articulation.

The wooden structure of the podium prevents the youngest and most exuberant visitors from touching the moving 3D-printed parts, while it also favours total enjoyment from above and below. It was also a deliberate decision to eliminate

Figure 6. Close-up view of the transmodal navigation interface with touch displays and touches tablets representing the two floors of the Lazaretto building with built-in touch sensors.

any protective cover to avoid barriers between visitors and the main subject of the narrative. As an alternative, an integrated sensor system activates an acoustic alarm signal to warn visitors in case of need.

The navigation station features a touch screen and an integrated tactile interface, consisting of two 3D-printed tablets representing the plans of the two-storey building and incorporating sensors for navigation. Finally, both the screen and the sensors, in a complementary manner, activate both the navigation through a 3D digital simulation of the building, the dynamics of the physical scale model and the multimedia content related to each room explored by the visitor.

The supporting structure of the navigation station is especially dedicated to wheelchair users, who can use the monitor or touch tablets (fig.6) while maintaining almost total visibility of the model and the rooms in which the narrative takes place without having to move.

The DSE features an embedded custom-made brain taking care of its behaviour. DSE mechatronics, both software and hardware, was custom-made by ALO team to allow communication between the digital graphic navigation system, touch screen, sensors and the physical model, controlling at the same time the synchronized payback of all multimedia contents, the dynamic lighting and the actuation system the makes the ground floor of the model opening to show the interior structure. All graphic effects, animations and lighting behaviours are generated through code and executed by an integrated mini-pc; the control engineering relays on the open-source Arduino platform to allow maximum flexibility and adaptability of the system to future, unexpected developments.

3D printing and digital fabrication for museum accessibility

Providing a contemporary and rewarding experience is perhaps one of the challenges with the most significant impact on the material and construction aspects of an exhibition, its structures and devices and, at a larger scale, on the museum space itself. In this regard, Digital fabrication fosters the realisation of effective interventions that require, by their very nature, unconventional and deeply customized solutions(Scopigno et al., 2015).

Only a few years ago, neither Aptica nor DSE would have been feasible with the same final quality as well as in a reasonable time and cost-effective manner.

Today, thanks to the democratisation of digital fabrication processes, coupled with the research-oriented approach that characterises ALO's transdisciplinary agenda on non-serial production, the basic research, design and prototyping phases come together to address accessibility with innovative solutions quickly and with reliable results, starting with clean and functional details such as those of touch tablets (fig.6) with embedded sensors.(Dellantonio, 1993).

For the DSE, in particular, all the technologies directly accessible at the ALO laboratory were strategically combined: the wooden display structures were manufactured using six-axis robotic milling, as was the complex 3D mould for the fibreglass finishes of the upper part of the podium. All the parts of Lazaretto's dynamic model, on the other hand, were produced by large-scale stereolithographic 3D printing allowing high quality and fine details. Finally, DSE 1.0 is a prototype but has all the characteristics of a finished product.

Conclusion

Digital technologies for design, production and interaction are proving to be excellent instruments for high-impact storytelling and dissemination of cultural heritage. Perhaps, for an inclusive and emotional engagement, technology alone is not enough.

Figure 7. The podium with the 3D printed dynamic model and the navigation station

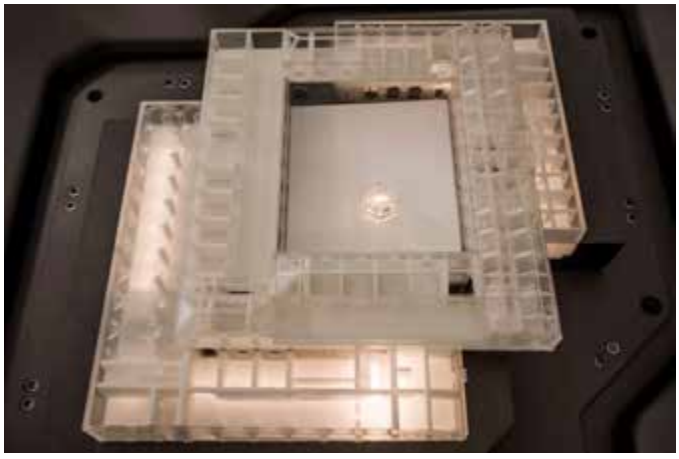

Figure 8. View of the ground and first floor of the 3D printed dynamic model. Ground floor lighting is on as this is the floor currently selected for the exploration.

Rather, it seems that it is particularly necessary to adopt technology from a humanistic and creative perspective as much as to engage with a holistic, interdisciplinary practice to rethink museums' space and equipment design.
The search for novel strategies and modalities to establish more dynamic and evoking connections between visitors and contents might pass by the materiality itself of the display elements and spaces and the embedded digital technologies as a whole.

Both Aptica and DSE are an applied and functioning expression of an original take on the subject by addressing design and production as inextricably interwoven aspects. The two projects proceed from an interdisciplinary approach whereby computation, matter and fabrication actively merge in the pursuit of a physical and emotional involvement of visitors, as to prompt them to move and explore contents and museum space as a whole, with curiosity and in a more personal and intimate way.

Hence, devices and exhibition infrastructure are no longer solely intended to be functional furniture to display content, but they are conceived as agents themselves for a complete, accessible and satisfying experience. These take on a new role with a significant dignity that requires renewed design intensity. Hereby, they become suggestive subjects of research and expression for practitioners to address universal accessibility and the design of rewarding experiences beyond already acquainted models.

Acknowledgments

Special thanks are due to CRS4, the Over the View project head Gavino Paddeu, Andrea Ferrero and the research team, as well as to the Cooperativa Sant'Elia 2003 - Lazzaretto di Cagliari for having challenged ALO for the Aptica and DSE projects respectively with an open mind, giving confidence to the experimental work presented in the initial conceptual proposals.

Special thanks also go to Sardegna Ricerche for having granted the Cooperativa Sant'Elia 2003 - Lazzaretto di Cagliari for the development of the DSE system.

Marco Verde would also like to thank Josh Terranova for his tireless collaboration in the development of the DSE software and the collaborators who contributed to the final quality of both projects.

Abstract

Clinical placements are an essential component of the education provision for students of medicine and other health professions. However, opportunities to achieve learning outcomes cannot be consistent across students due to the very nature of their exposure to different patients in different timeframes and settings. In addition, the unpredictability of attendance of patients and the impact of the COVID-19 pandemic has resulted in few opportunities to experience more than one point in a patient journey. An innovative online virtual environment named Wales' Virtual Hospital (WVH) was developed using agile software development and User-Centred Design approach. This research paper presents the comprehensive usability and user experience (UX) studies that were conducted to evaluate all aspects of WVH by end-users and experts. The main contribution of this research is in the case study of evaluating a newly developed innovative online virtual environment, where behavioural and subjective feedback were collected to test the usability and the effectiveness of the learning experience. For this paper not all the outcomes of the evaluation process are reported, instead a key outcome of each iterative cycle is given as an example. The evaluation approach developed and used in this research could be adopted by other researchers to evaluate similar systems.

Keywords

VR, Educational Challenges, Usability, User Evaluation, Expert Evaluation.

Introduction

Medical learning requires a multimodal approach, with the need to offer students up-to-date evidence-based knowledge and the explanation of processes and key procedures (Philippe et al., 2020). Alongside scientific theory and the use of multimedia or online-resources, a core part of supporting medical students involves practical elements, such as placements in clinical settings. Clinical placements are considered an essential component of the education provision for students of medicine and other health professions. It enables the vital and unique experience of applying textbook knowledge to 'real' patients and the demands of an often-evolving clinical situation.

However, in clinical placements opportunities to achieve learning outcomes cannot be consistent across students due to the very nature of their exposure to different patients in different timeframes and settings. Hence, not all students will have the chance to experience a variety of specialisms, departments, and see the vast number of presenting complaints and patients (Life Sciences Hub Wales, 2022). As a result, students often see only one point of the patient's journey. Furthermore, the COVID-19 pandemic has brought a more critical challenge to experiential learning with face-to-face interaction becoming limited (Pears et al., 2020; Chan et al., 2021). Simulation can be used to augment clinical placements (Schiza et al., 2020, Macnamara et al., 2021). This learning technique provides strong engagement and offers students many technical skills. It offers the chance to learn from situational awareness, making judgements, and implementing practical processes (e.g., fitting a catheter) without affecting the safety of a real patient, and the opportunity to receive feedback and a debrief on their performance (Chao et al., 2022).

Immersive technologies such as Virtual Reality (VR) have received a lot of positive attention in the fields of medical education, with evidence to show that it creates realistic and interactive simulations; supporting the transmission of knowledge; instilling emotional engagement; role expectation and learning by doing (Dubovi, 2022). This should complement other forms of teaching and training and not be used as a substitution (Bruno, et al., 2020).

However, creating medical scenarios, such as 3D-modelled wards featuring virtual patients and colleagues using computer-generated environments, can be quite expensive to produce, especially when creating multiple scenarios for different types of clinical situations. Using 360° video, which is sometimes referred to as VR because it can be viewed in a VR Headset, gives the students an omnidirectional field of view simply by moving their head to look around, providing a passive sense of immersion (Snelson & Hsu, 2020). The limitation is that they cannot interact in the same way as the computer-generated environments where they can walk around,

interact with objects, and feel more present in the experience (Huang, et al., 2020; Witmer & Singer, 1998).

To address some of the limitations of clinical placements and to develop an inexpensive VR content creation platform that would allow clinicians to generate bespoke content, an innovative online virtual environment named Wales' Virtual Hospital (WVH) was developed. The design of the virtual environment allows clinicians or academics to create three types of interactive learning experience framed around a patient presentation in three formats: 360° still environment, 360° video environment, and fully immersive 360° VR environment. The goal is to build a library of medical case studies from a range of specialisms and to deliver more experiential learning of healthcare, with opportunities for interactivity in the form of answering questions as the content progresses. Clinicians or academics can use an online toolkit named the "Creator Mode" (CM) to create the different types of interactive learning experiences. This can be done by recording 360° video content which is currently very inexpensive, available to a consumer market, and easy to set-up and capture (Harrington et al., 2018). Students would be able to access the "Viewer Mode" (VM) portal to view the content and interact with it on their mobile, computer, or VR Head Mounted Display (HMD). As part of the WVH system, students would also be able to answer key questions as the scenario progressed, allowing them to make judgement calls at different stages through a graphical interface, which would appear within the 360° environment. Clinicians or academics can view students' engagement data using "Data Mode" (DM) toolkit (e.g., number of correct or wrong answers).

The development of WVH was carried out by integrating Agile software development approach and User-Centred Design approach (UCD). This resulted in more frequent usability evaluation iterations and a systematic way to examine and confirm end-user needs (Jurca, et al., 2014). Research shows that iterative evaluation and refinement cycles are essential to develop an educational intervention (Sandars & Lafferty, 2010). As the WVH system relies on collaboration between the academics, recording and uploading 360° videos and creating the interactive content and then the students engaging with it, it is important to make the system user-friendly, with intuitive functionality, for both types of users (Fisher and Wright, 2010). This would encourage its adoption into the course pedagogy and ensure learning opportunities are effective and optimised. In this paper, we present the comprehensive usability and UX studies that were conducted to evaluate all aspects of WVH system by end-users and experts. The aim was to ensure that the system design adhere to design principles and meet users' needs, across the WVH system modes, and making the delivery of the interactive virtual learning content more streamlined and engaging for the users.

Evaluation Method

Figure 1 illustrates the experimental approach that was adopted to critically evaluate the usability of the different types of modes and interactive learning experiences created using the WVH system, and to measure the effectiveness of these learning experiences. An iterative development cycle and testing with both experts and end-users were conducted while working closely with the WVH development team. The expert evaluation technique is typically conducted by professionals who have a high level of expertise in a particular field or subject matter (Ghaoui, 2005), in the case of this project Human-Computer Interaction and Design specialists. Experts used their knowledge and skills to assess the usability of the system and user learning experience. Whereas end-user evaluation technique involves collecting feedback from actual users of a product or service (Ghaoui, 2005). This approach allowed for a more practical and realistic assessment of WVH system, as it is based on the experiences and needs of the users (i.e., students, lecturers, and clinicians).

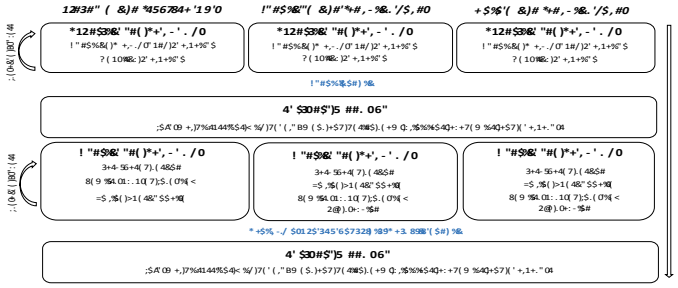

Figure 1. Evaluation Approach

Expert-based Evaluation:

Three expert evaluators evaluated the system's three different modes with the different level of interactions. This evaluation process was iterative starting with early conceptual prototypes and finishing with a high-fidelity prototype. Two expert evaluation techniques were followed, this included:

- Cognitive walkthrough (CW): This rigorous expert analysis technique was used to check through the system design and logic of steps in user interaction (Lewis & Wharton, 1997). The focus of this technique was on evaluating the learnability of the system from the perspective of new or infrequent users. The evaluation was structured around three design principles: visibility, affordance, and feedback (Donald, 2013). During the evaluation process the expert evaluators went through the user tasks provided by the development team and discussed the four key questions cited by Wharton and his colleagues (1994).
- Heuristic Evaluation (HE): This usability engineering technique allowed the expert evaluators to go through the system design looking for usability problems, guided by Jakob Nielsen's standard usability heuristics (Nielsen and Molich, 1990; Nielsen 1994) and visual-design principles (Gordon, 2020). At the end of the session evaluators rated the identified usability problems using the severity rating scales for impact by Nielsen (1994). The severity ratings created a priority list for the development team to work on to improve the system. Nielsen's standard usability heuristics were chosen as they are relevant when evaluating the different modes of interaction (Joyce, 2021) and for educational systems (Mohamed & Jaafar, 2010).

The expert-based evaluation techniques were regarded as a first pass of evaluation to identify as many usability problems as possible. This was followed by user-based evaluation to focus the evaluation further.

User-based Evaluation:

A total of 12 medical students evaluated the VM using the different levels of interactions. Individual testing sessions were conducted at ATiC's laboratory on the high-fidelity prototype of the system with five students (VR mode) and remotely with seven students (other modes). The CM and DM of the system were evaluated by five professionals (clinicians and academics). Research shows that 85% of usability problems can be identified with five participants (Asarbakhsh & Sandras, 2013).

Task scenario-based sessions using thinking aloud protocol: Participants were invited to complete a series of tasks related to the key activities they need to complete to use the system. Participants were provided with scenarios to give them an explanation and context (Dumas & Redish, 1999). As participants move through the system to complete the tasks, they were asked to verbalise their thoughts, feelings, and *opinions.*

Behavioural observation: To avoid the observer effect (Blalock & Blalock, 1982; Bloombaum 1983), the user-based evaluation sessions were video recorded using Noldus Viso system and screen capturing software for tracing and recording participants' actions and navigation. Allowing the researchers to analyse the participants' system interaction retrospectively. Observations were made on the key metrics of *Effectiveness* (were participants able to complete the tasks with a high degree of accuracy), *Efficiency* (how fast can participants complete a task) and *Errors* (how many errors do participants make and how easy it is to recover from those errors). To allow for a more visual presentation of the user interaction (Andrade, 2018), Tobii eye tracking was used to capture users' unconscious behavior, preference, and to understand their decision-making.

Post-session interviews: Semi-structured interview sessions aimed to collect more detailed feedback from participants on the following aspects:

- Likelihood of use: thoughts on the likelihood of themselves and other students using the system.
- Content and learning experience: the quality of the educational content available and what could be added; how effective and efficient this type of experience on learning; thoughts on the feedback they get from interacting with the system; and finally explore if the multiple-choice question is the best way to test students' knowledge and learning.
- Utility: does the system offer the functions that end-users need.
- Overall experience and usability: aesthetics; typography; learnability (ease of learning); ease of use; memorability (ease of remembering), and overall satisfaction.

Post- session online questionnaire: The online questionnaire consisted of three sections:

- System Usability Scale (SUS): a simple and reliable standard 10 item questionnaire with 5-point Likert scale used to collect participants' subjective feedback. The SUS was chosen as it is a well-researched and widely used to evaluate similar systems (Brooke, 2013; Orfanou, Tselios, & Katsanos, 2015; Renaut, et al., 2006).
- Look and feel of the design, consisted of four statements with 5-point Likert scale, which investigated participants' thoughts on different aspects of the design.
- Satisfaction: a statement with 5-point Likert scale about how satisfied participants are with the overall experience using the system.

Implementation & Results:

For this paper, an example of each iterative evaluation study will be discussed to highlight a key finding of that evaluation study and to illustrate how the evaluation method presented in this paper was implemented. Hence, not all the detailed feedback from the expert and user evaluation which has been shared with the development team is discussed here.

The first round of the iterative process was carried out with early WVH prototype of the VM using CW technique, the objective of this study was to evaluate two scenarios using the different level of interaction. The evaluators walked through the system thoroughly inspecting the two scenarios several times and completing a series of tasks. The outcome of each task was presented in the format illustrated in Table 1. A representative task of this study was to locate and enter the bay number 06. Once the participant was in the bay, they were required to check some important information about the patient (e.g., patient history, ECG; Figure 2).

Table 1. The outcome of a cognitive walkthrough

CW questions	CW Answers
Will users try to achieve the right effect?	**Yes.** Users will be able to attempt to enter the bay and find the key patient information.
Will users notice that the correct action is available?	**No**. Not everyone will look around naturally. Users should be provided with information on how to navigate the 360 environment and what actions will take place all around them or what interactive elements will appear.
Will users associate the correct action with the result they're trying to achieve?	**No.** Important interface components, or actionable items should not be placed too far from each other.
After the action is performed, will users see that progress is made toward the goal?	**Yes.** When the users click on the white dot to enter the bay the user is taken to inside the bay. Every time the user click on the actionable items inside the bay the user is presented with the related information.

Figure 2. Screen shots of the WVH viewer mode in a Shift Scenario

All the problems encountered in this study were categorised under four themes: (1) navigation; (2) interactivity; (3) feedback given to users; (4) visual communication. The problems were shared with the development team with a list of recommendations to improve on the design. The improved prototype was then tested with medical students using the user-based evaluation method discussed previously.

In this study participants evaluated a scenario using Oculus Quest VR headset. All participants said they could see themselves and other students using the system. Overall, participants found the experience engaging and fun. The immersive environment as participants noted gave them the experience of 'being there', which supports memory and practice-based learning. All participants commented on how it may benefit the way they learn best – by being in the role and in the hospital (such as on a clinical work-placement). They could see potential as to how this platform could support practice-based learning – or used as a library for extending their knowledge. They also said it may better develop their experiences for areas where they may not have had the opportunity first-hand. Two participants thought the video quality was not 'crisp', and that they felt they were 'floating' within the VR environment. However, this did not present a large problem towards overall UX. Unfortunately, none of the participants were able to complete all the tasks as the system kept crashing before reaching the end of the scenario. However, if we considered the number of tasks they completed before the system crashes, then all participants were able to complete all the tasks with a high degree of accuracy. On average efficiency level was 14 minutes (SD=0.7), and no errors were made (getting a question wrong was not counted as an error).

In the follow-up interviews, three participants said that they did not realise that answers were behind them, with one participant wondering whether they could be brought forward, but then became undecided because they recognised that having to search the environment for answers suits the immersive format. Participants suggested that having a fixed number of answer options would encourage them to look around for them. Participants commented on the quality of the production of the scenarios (e.g., quality of acting skills) which could be improved based on the content created by clinicians. Generally, participants found the structure of the scenarios very useful to test their knowledge and learn from any mistakes. Participants found the multiple-choice format useful for both learning and testing.

In this version of the prototype, SUS mean score was 78 (Grade B, Good) with a standard deviation (SD) of 6.2. Participants thought the system offered the functions that they need, and they were happy with its look and feel. Overall, all participants were very satisfied with the system.

Table 2. The outcome of heuristic evaluation

Heuristic	Ratings	Problems encountered
Visibility of system status	2	It is not clear which of the text fields are optional and which are compulsory. The appropriate feedback is presented, however, the display time of the error message is too short to read.
Match between system and the real world	1	'Preview Image' does not indicate upload image. Consider clearer labelling.
User control and freedom	4	Unable to upload a video making it hard to complete the task of creating a marked scenario.
Consistency and standards	1	Inconsistency in labelling, when selecting an image from the "Images Library" the dialog box labelled 'Select Media' and then you are presented with 'Select Images'.
Error prevention	1	You are allowed to select two images as scenario cover even though you only need one. Users should be constrained from selecting more than one image.

The iterative process of evaluating each design cycle continued with another round of expert evaluation of the re-designed VM, and the newly developed CM and DM. For each mode a series of tasks were tested. For the purpose of this paper, one example of a representative task from evaluating the CM will be used to illustrate the process (See Table 2). The task was to create a marked scenario, adding a stopping point at 30 seconds with one correct and two wrong answers. The evaluator should then move and place these answers in a location in the 360° environment. The outcome of the CM evaluation uncovered some violation of the design principles. As shown in Table 2, one of the encountered problems prevented the evaluators from completing the task. In contrast, both the VM and DM insights were mostly positive, where most of Nielsen's Heuristics were adhered to. After fixing the problems identified by the experts another round of user-based evaluation was conducted. Where medical students evaluated the VM, and professionals evaluated the CM and DM.

The updated version of the VM scored 84 (SD=13) (Grade A, Excellent) on SUS an improvement from the last round of evaluation. The system, as participants noted, was user-friendly, easy to access with clear graphic design, navigation, and interactivity. However, the audio quality during part of the scenario was reported as "poor" by some participants. Answers placed spatially around the scene were still causing some confusion to several participants. Participants were generally satisfied with the learning experience.

CM and DM were evaluated by clinicians and academics. In the CM, participants were tasked to create new learning content using the platform. The task involved building a 360° virtual scenario: inputting information, uploading videos and images, and then creating questions and answers and placing them within the 360° virtual space. All users had no prior experience and were still able to complete the task effectively, with some commenting that they would have no problems reprising the task now they had completed it once, adding that an initial demonstration video would have better prepared them. Two key challenges users encountered were (1) understanding how to move (or look) around the 360° content within the preview windows; (2) the choice of symbols and their placement in the interface.

Users began by setting up their scenario content by inputting basic information and uploading media. Following typing a title and description, many users were hesitant regarding two buttons, "Show to Users" and "3D Video", before progressing. This can be seen in the eye tracking data in Figure 3, where they fixated on these elements overall. It was not clear to us-

Figure 3. A heat-map of scenario information page

ers that these buttons were in fact switches, and by clicking them it would toggle on/off different options for the scenario.

Following uploading 360° video content, users were presented with a window titled "Camera Centre" displaying a preview image of the video with a symbol of a target in the centre. Upon hovering, the cursor would change from an arrow to a hand icon, which indicated to users they could interact or move this element. All users tried to click and drag the target symbol first to move the 360° video, which had no effect, rather than clicking the background or the image to move the perspective. This can be seen in eye tracking data in Figure 4.

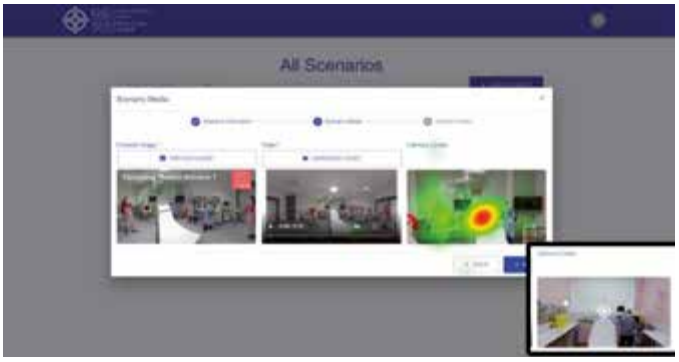

Figure 4. A heat-map of scenario media page

In the final screen, users can input questions and answers into their 360° scenario at any moment during the playback of video. There were specific challenges when placing answer boxes within the 360° environment. Each answer box had three symbols, a target, a pencil, and a tick or cross to denote if it was created as a right or wrong answer. Users assumed the pencil would allow them to 'edit' and move the answer box, instead this sent their cursor to the text entry box on the right. Upon clicking the target, it changed to a green computer disk icon, this would save the location of the answer in the 360° environment. However, it wasn't clear that users had to now move the background video by clicking and dragging, and instead users tried to drag the answer box. Once this process was finally worked out, users tried to click the green tick (representing 'correct answer') instead of the disk symbol. The eye-tracking heat-map reveals a definite focus on the green tick symbol (Figure 5).

CM and DM scored 69 (SD=10) and 71 (SD=13) on SUS respectively (Grade B, Good). Overall participants were somewhat satisfied with both modes, with all participants suggesting that having a demo instruction video for first time users would have increased their satisfaction rate.

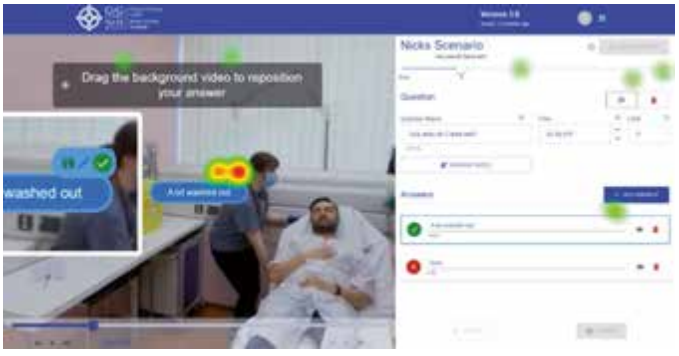

Figure 5. A heat-map of the final page where users can add questions and answers

At the end of each design and evaluation cycle, all project partners and stakeholders were invited for an informal evaluation testing session. The outcome of these sessions feedback to the next design cycle with all the data collected via expert and user evaluation.

Discussion and Recommendations

Conducting the evaluation in this thorough and rigorous manner allowed for a more comprehensive and well-rounded understanding of the designed system and led to better decision-making and improvements to the system.

The paper offers insights on how to evaluate an interactive educational system using the different interactions levels. Designers and project teams should take in consideration the following:

- It is crucial to start validating design ideas at the early design stage and continue evaluating the system throughout the whole development process.
- The findings from the expert-based and user-based evaluation complemented each other as they provided different perspectives. The expert-based evaluation can be regarded as a first pass of evaluation to identify as many usability, design, and technical problems as possible. While the user-based evaluation highlighted user-experience issues and areas where the system did not meet the needs of the users.
- By combining the two approaches and collecting both subjective and behavioral data, it is possible to validate and confirm findings from both approaches. This helps ensure that the findings of the evaluation process are accurate and reliable.

The case study of evaluating the newly developed innovative online virtual environment contributes to research in this field by demonstrating how this evaluation methodology, where iterative collection of behavioural and subjective feedback is undertaken, can be used to test the usability and effectiveness of similar systems. However, there are some limitations of this research that need to be addressed, especially regarding evaluating the effectiveness of the learning experience. This research has only collected subjective feedback from students. Further research is planned to investigate the effect of VR simulation teaching prior to in-person simulation training. The research will involve 300 medical students using the Randomised Control Trial (RCT) method. In addition, there was no comparison between different levels of interaction to understand which students preferred or found more engaging. Lastly, future evaluations could be further strengthened by increasing the sample size.

Acknowledgments

We would like to thank the development company VirtusTech for their assistance with this research. We also thank all the core collaborators in this project; Clinical Innovation Accelerator (CIA), Cardiff University; Cwm Taf Morgannwg University Health Board; Emergency Department, Aneurin Bevan University Health Board; and Swansea University. The research was undertaken as part of the Accelerate programme, co-funded by the European Regional Development Fund and the Welsh European Funding Office.

Design perspectives for the future of work in industry 5.0 environment: the digital and physical space in augmented reality uses

Sara Muscolo, Viktor Malakuczi

Sapienza University of Rome, Italy
sara.muscolo@uniroma1.it, viktor.malakuczi@uniroma1.it

Abstract

The advent of Industry 4.0 has introduced into the manufacturing environment a new level of interconnection between machines, operations and sensors that have been able to automate entire processes. Along with this decentralization of the workforce, the new concept of Industry 5.0 aspires to elevate humans to the focal point of cognitive, physical and digital activities, by bringing advanced technologies that autonomously work beside humans in a human-centered perspective.

This is proposed to go beyond the productive purpose by enhancing the experience and quality of work itself, generating questions about how design could intervene to foster effective communication (by limiting misunderstanding and conflict between the technology and the operator) especially in situations where digital and physical are blended.

The object of study is the manipulation of the operator's work environment through the use of Augmented Reality (AR), investigating how it can be integrated into the work experience in terms of performance and psychological response, with particular attention to the type of interface placed in the worker's own spatial reality.

After an overview of the use of eXtended Reality (XR) modes and how such technology can support human work, the focus will be placed on the category of Spatial Augmented Reality (SAR) aimed at operator training and assistance during production routine, which will then be analyzed from a design perspective involving reflections on how the discipline could intervene to enhance learning and use. These definitions point to raising the human factor above the task of assembly and the related operations, therefore the experience over the process, supporting the concept of human-centered manufacturing.

From a design point of view, this becomes subject of exploration not only regarding the configuration of the interface itself, but how its functionality can be manipulated to make the experience engaging in terms of tasks to be performed and human cognitive response, to arrive at considerations derived from a literature review with observations about possible ways in which the figure of the designer could act in such a typically engineering context.

Author keywords

human-centered manufacturing; spatial augmented reality; industry 5.0; interaction design; user experience design.

Introduction

The industrial sector is the protagonist of a current technological evolution characterized by an increasingly close interconnection between digital and physical systems, resulting in a loss of the human component in relation to ever more autonomous and sophisticated technologies. Hence the advent of a new stage of Industry, the 5.0: a vision that intends to implement a human-centric evolution that places operators and their well-being at the center of the production process (European Commission, 2021a).

The ways to achieve this goal will define the "work of the future" which, as cited in the thematic area of Cluster 4 that constitutes Horizon Europe's interventions, is intended to increase understanding of the human-machine relationship (European Commission, 2021b).

This concerns in particular the coexistence of the intangible digital and tangible physical reality that ever more often meet in working scenarios, opening new views of experimentation connecting those two worlds by using eXtended Reality (XR) as a tool: an evidence is the programme 2021-2022 of the Digital, Industry and Space cluster of Horizon Europe, which comprehends "eXtended Reality Modelling (RIA)" (CORDIS, European Commission, 2022a) and "eXtended Reality Learning - Engage and Interact (IA)" (CORDIS, European Commission, 2022b).

In this scenario, design is interpellated as a tool capable of elaborating new ways of relating humans and technologies around their workspace, so that two different but collaborative worlds can be merged. Indeed, if that of humans is unpredictable and subject to emotions, that of machines is predictable and automatic, but lacking human judgment, adaptability, and logic (Haight and Kecojevic, 2005). The goal of this intervention is to establish fluid communication that fosters and accommodates progress in favor of optimized processes for production and those who work in it, combining the skills of both.

The article takes eXtended Reality technology as its object of study, observing how its use is able to meet the goals

of the new industry of the future and how it promotes inclusiveness and involvement of the human component.

The exploration is articulated in a literature review focusing on the uses and limitations for which design needs to be involved, so that new development hypotheses can emerge in which the discipline is integrated into the design process of such technologies.

The aim is to be able to define a vision in which future industry grows naturally around humans, so that they can evolve spontaneously in circumstances in which they are now alienated: in front of machines and processes whose operations do not take into account human comprehensibility and presence. This with particular focus then not only on production, but on those circumstances in which cognitive capabilities (such as during learning and assistance) take center stage for the optimal performance of operations.

In the next chapters, the dimensions touched by XR in the factory will be investigated, starting with new work scenarios in the industrial 5.0 context and its current use, and then arriving at Spatial Augmented Reality (SAR) and how it can be designed to optimize the course of work without devices acting as intermediaries between humans and processes.

The evolution of industrial work and the XR

Industry 4.0 has introduced a new level of interconnection between machines, operations and sensors, ensuring that operators have technological support at their side, designed however to be primarily performance-centric, opening opportunities for possible human replacement in favor of automation (Coronado et al., 2022). The 5.0 view, on the other hand, opposes this probability by considering the machine only as a tool to complement/enhance human work (without replacing it) while also improving its quality.

We thus move away from the sole purpose of production and closer to a more experiential conception of work itself, which is currently instead focused on a dehumanization that worries not only operators but also society and governments (Grabowska et al., 2022). Indeed, the same authors state how the term "human-centric" classifies a still narrow segment of research that needs to become a key area of it.

The human factor is therefore a fundamental requirement in the design of Industry 5.0, which places it no longer as an element to be discarded but rather in a position of understanding the technological complexity through a clear dialogue with it, suitable preparation, and a directional openness to development (İşcan, 2021).

It is evident how as technologies and operations within the factory progress, work is destined to evolve, opening new possibilities for work performance and well-being, and defining new figures and duties: the use of cognitive skills in tasks, is capable to increase engagement and interest while working, making individuals more flexible. This evolution toward more cognitive rather than mechanical contributions is the result of adaptation to an increasingly digital environment, that makes the operator of the future able to dialogue with and be assisted by machines.

The recent production methodologies open up new possibilities for increasing human capabilities: Romero et. al (2016) classifies various typologies in which humans are combined with specific technologies, describing their figure in relation to how they are assisted by them. Specific examples may be the "Augmented Operator," the result of the combination of the operator and Augmented Reality, or the "Virtual Operator," derived from the combination of the operator and Virtual Reality. Both types describe an operator whose skills are enhanced, whether in mobility, vision, or processing, and refer to a type of cognitive interaction between humans and the mechanisms of the workspace. The latter is included in an industrial context characterized by Cyber-Physical Systems (CPS), in which information is transmitted by physical and virtual elements, that through feedback and data acquisition generate automated operational decisions. A new dimension of human-machine interface is able to place humans between cyber systems and the physical world, through an enhancement of the human: it is the concept of Human Cyber-Physical Systems (H-CPS) elaborated by Romero et. al (2016) that aims precisely at a dynamic interaction with machines in the cyber and physical worlds, enhancing human skills and senses through the technologies themselves.

Indeed, industry is following the current technological trend toward immaterial universes, as evidenced by the report of Accenture Technology Vision 2022, which states that "the most ambitious companies will bring to life new physical and digital worlds, populated by both people and artificial intelligences [...] gathering not only advantages over automation, but experimenting with new forms of collaboration between humans and machines" (Daugherty et al., 2022). This evidence is closely related to the use and development of eXtended Reality technologies, whose work is to reduce the distance between humans and the virtual through different manipulations and representations of reality, in this case intended as the work environment.

As described by Rauschnabel et al. (2022), the main definitions of XR, namely Augmented Reality (AR) and Virtual Reality (VR) can be easily distinguished based on the presence of the physical environment as part of the experience: if there is a local presence, it is referred to as AR. The latter can be declined into types such as Mixed Reality (MR), Tangible Augmented Reality (TAR), and Spatial Augmented Reality (SAR) that will be discussed later.

In industrial settings, the most widely used XRs are MR and AR. They, once integrated, are capable of improving several aspects of the industrial system, in particular:

- Time management: AR is leveraged for long and advanced tasks in manufacturing, such as "complex setups, operations with many tasks/long cycle time and advanced maintenance" (Fast-Berglund et al., 2018), and the same authors state how connecting digital/cyber/virtual and physical worlds can lead to significant time savings in that application area. Doolani et al. (2020) also call XR technologies into question, introducing new features such as increasing time-room flexibility.
- Personnel training: one of the major applications of augmented reality concerns the training of operators, who today need to be prepared and resilient precisely as a response to increasingly advanced technologies. Doolani et al. (2020) define how AR can be used in this regard, especially for tasks that include "monitoring assembly line, sorting, picking, keeping, assembling, installation, inspection, packing, cleaning routines (process, shovel, sweep, clean work areas) and using hand tools, power tools and machinery". Werrlich et al. (2018) testify how a virtual assembly phase, tested before going physical, can improve the training transfer.

- Communication with machines: scope of use can include the communication between workers and technologies in the industrial environment, as mentioned by Materna et al. (2018) regarding the programming of collaborative robots, in which workers were able to program, collaborate and readjust the cobot to new uses with a reasonable time.
- Cognitive load on workers: the experiment by Hou et al. (2013) demonstrates how animated AR systems cause a positive effect of cognitive facilitation on workers in training, no longer having to rely solely on their memory to complete an assembly, and therefore reducing errors.

SAR design for the workplace

Augmented reality applications help increase human presence in a clear dialogue with the surrounding digital and intangible environment, especially when it comes to Spatial Augmented Reality (SAR). In fact, Doyle Kent and Kopacek (2021) among the categories of intervention to foster efficient collaboration between operators and machines, include confidence in the use of surrounding technologies and an exploitation of them that, however, do not make the human figure redundant.

This type of Augmented Reality under consideration is capable of enhancing the user's visible scenario and influencing the operator's involvement by offering the real and virtual worlds in the same view, and promoting autonomous workflow by impacting on usability and cognitive workload (Rupprecht et al., 2021).

Such technology moves beyond traditional eye-worn or hand-held displays (Figure 1), exploiting "large spatially-aligned optical elements, such as mirror beam combiners, transparent screens, or holograms, as well as video projectors" (Bimber and Raskar, 2005).

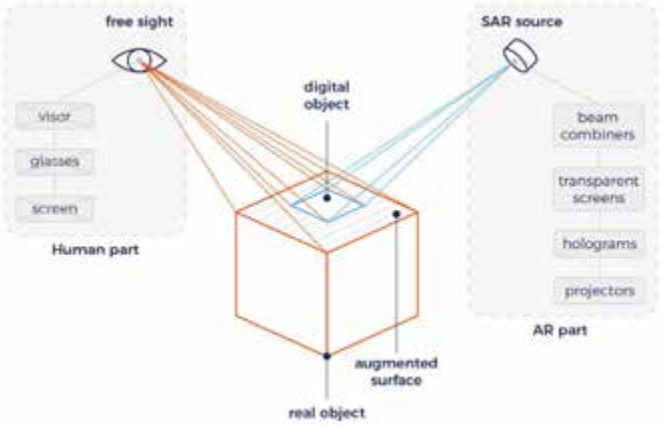

Figure 1. Principal elements for a SAR configuration.

This typology is the most ubiquitous form of AR currently in use (Giunta et al., 2018), in fact it increases the actual visible environment, influencing, in the case of the workstation, the involvement of the operator, who is present between the real and virtual worlds, improving the performance and experience (Uva et al., 2018).

In fact, wearable tools for augmented reality have limitations like those listed by Siltanen and Heinonen (2020), such as the difficulty in seeing the real environment through glasses or visors, or their battery life leading to complicating their use when connected to external power sources. In addition, weight and comfort are also relevant factors for dynamic use such as at work. SAR on one hand offers a solution to such limitations, but it also has disadvantages related to the environment on which it operates such as visibility, surface-based distortions, object relationships, brightness, contrast (Kruijff et al., 2010).

In the work environment it is supportive already from the design phase, Porter et al. (2010) in fact employ it as a means of iterative design, in which the design is projected onto the surface of the physical object and modified in real time, making the idea of the physical prototype and product much clearer and more direct than from the 3D model on a computer screen.

Regarding its purely industrial use, the benefits are evident particularly in assembly and production work tasks. In particular, Bosch et al. (2020) state how less experienced operators are able to operate without or with little supervision, with increased flexibility, employment and reduced training time, leading to an acceptance of the technology by most workers.

In the case of assembly, Uva et al. (2018) compared the instructions viewable by Head-Mounted Display (HMD), tablet, paper, and projections on the work surface. The result was that the latter method proved to be the fastest of the assembly times, with greater reduction of errors and lower cognitive load, collecting positive testimonies especially about having hands free during practice. Such use has proven successful particularly in those situations where even experienced operators are faced with assembling products that are different from each other or modified (e.g., resulting from mass customization), being able to follow the operations without relying only on their memory.

Funk et al. (2016) conducted a similar experiment, comparing the same types of instructions and demonstrating how direct projection to the work location leads to faster assemblies, fewer errors and cognitive load, while also appreciating the freedom in not wearing devices and having free hands.
The increase in productivity and quality given by projected instructions improves not only performance levels, but also the workload itself on the operator (Bosch et al., 2017).

Applications, limitations and opportunities

Analogous experiences related to SAR can be gathered in work domains different from industry, such as in medicine (Bin et al., 2020) or collaborative design (Ben Rajeb and Leclercq, 2013) with related activities such as prototyping (Morosi et al., 2018). Scenarios then extend by investing in wellness (Mousavi Hondori et al., 2013) and culture (Ridel et al., 2014) such as the exhibition and museum domain, where the authors' past experiences show how SAR can give not only contextual information, but also an immersive three-dimensional view, providing an immediate and shared experience, as the visitor's gaze remain free while interacting.

Despite the wide variety of uses and purposes, however, as of today there is no consolidated UI language that could help both designing and understanding the possible interactions, even though there are promising experiments, e.g. Schmidt et al. (2018) have performed studies on User Interface (UI) and user response to interaction. Although the SAR paradigm allows for immediate interaction and does not require learning a new device, it still remains necessary to learn a new way of interacting with projected digital content, which

in 2023 does not yet have a widely shared gestural and cognitive identification.
This is a relative disadvantage compared to HMDs that, promoted by powerful industry players, have vocabularies, toolkits and guidelines at their disposal, such as Microsoft's Design Checkpoints (Microsoft Learn, 2022) in which interaction models, gestures and physical inputs, along with UX Elements and visual rules are well defined and distinguished.

However, there is no common line or framework among the SAR case studies , making the design process of SAR experiences rather challenging.

In the particular field of industrial SAR, effective experience design means not only gains of productivity, but also a facilitated state of mind for operators.

This can be achieved not only by optimizing the hardware part for greater adaptability and adoptability, but by exploiting the role of software often integrated into the systems, configured by the workers themselves on the factory floor.

Such intervention should be performed and studied following User Experience Design concepts (Figure 2) such as those classified by Hillmann (2021) for XR Design: comfort and safety, interaction (affordance, signifiers, feedback), environment and spatial components, sensory input (visual, audio, haptics), engagement (storytelling, gamification), constraints and inclusion, diversity, accessibility.

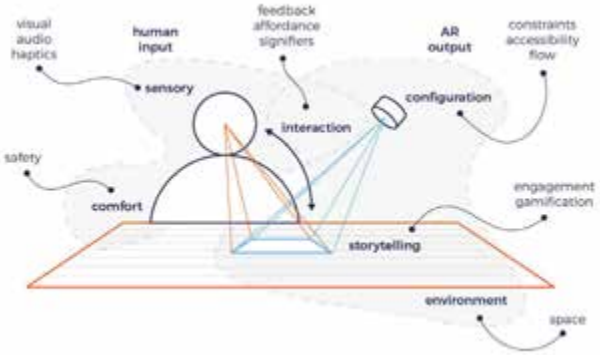

Figure 2. User Experience Design concepts for SAP configuration.

Indeed, authoring tools can be useful in configuring the activities to be followed by the operator, aiming for optimal use derived from a routine that is engaging, simple and not monotonous. The same ease must be present for those who program or modify the experience itself, whether they are the designer, engineer, or line manager. A practical example is the Arkite [1] system that provides both the hardware workstation and the software setup for operators' manual assembly guidance and training.

While there are multiple generic purpose AR authoring tools (e.g. Adobe Aero, Audodesk Forge, Vuforia Studio, Areeka Studio), for the purposes of industrial SAR these services will need to evolve by integrating domain-specific UX Design concepts in order to build an optimal process that takes into account not only the functioning of the various stages, but also the experience in its use, introducing more direct feedback concepts, rewarding systems and gamification.

Conclusion

As we have seen, SAR is capable of enhancing the user's visible scenario and influencing the operator's experience, despite being affected by the number and type of interactions within the augmented space and its positioning.

In order to ensure the optimal use of (S)AR in the industrial context, the presented desk research highlights the need of future research regarding (1) a design methodology that can be applied taking into account who will have to use or configure this technology, since "to advance the use of XR technologies in industrial maintenance and other similar hands-busy type of professional use, there is a need to develop an explicit list of UI and usability heuristics for XR context" (Siltanen and Heinonen, 2020), (2) the human engagement in monotonous workflows such as on assembly line, through the concept of gamification by investigating the design of motivational elements (also employed in the training beneficially influencing the learning process, as stated by Schuldt and Friedemann, 2017), (3) the elements of interaction from human/digital inputs and outputs, specifically investing graphical interfaces, physical interfaces, supporting devices, tasks to be performed, human response and feedbacks received by operators while performing tasks.

In particular, an upcoming experimental research of the authors will focus on how to reach a direct and natural gesture communication with projected and digital objects in order to develop a clearer interaction with the augmented interface, investing visual navigation and kinesthetics studies.

In the increasingly complex factory of the future, design research is fundamental for exploring and enhancing the operator's own senses, making them meaningful and augmented through technologies such as SAR: these could have the power to increase the level of human integration in the factory, especially in such an automated environment.

From the perspective of the Cumulus community of worldwide design schools, it would be particularly interesting to explore the differences between geographical regions and hence different cultures of factory work, which would influence the transversal applicability of new SAR solutions. On the other hand, design education might be influenced as well, preparing future designers to possible new branches of specialization, either by focusing on the technological medium, such as Design for XR experiences, or Design for the intelligent factory, focusing on the industrial domain as an area for systemic design interventions.

Abstract

The digital transition towards the Metaverse deeply permeated by digital technologies is the core of current debates. In this shift, fashion emerges as a relevant context for analyzing the implications of the Metaverse, with fashion companies being among the first industries to implement projects in this persistent virtual space. Today, with fashion being such a relevant global business, but one of the most polluting industries, its transition towards "hybrid" experience modes can produce significant impacts in terms of more efficient and sustainable modes of production.

Also, in the existing spectrum of digital technologies, Virtual Reality (VR) represents an opportunity and a tool from which the fashion industry can benefit. However, although VR has proven its effectiveness in fashion retail, the scientific literature still presents limited studies; yet there is plenty of scope for its potential use in the fashion industry. Also, there is a lack of studies comparing Immersive VR (IVR) to non-immersive shopping experiences, such as Desktop Virtual Reality (DVR). Therefore, researchers must identify the differences between IVR and DVR systems since they may affect users during their evaluation. For this reason, further research is needed to assess how VR technology can improve the shopping experience towards the Metaverse.

The aim of the research is to compare the experience of buying an accessory (i.e., a luxury handbag) on a desktop computer, DVR, with that in IVR, assessing the impact in terms of system usability. To test the differences in terms of usability, we developed two versions of the application. The first is developed as a traditional desktop application and the second is developed for the IVR Head-Mounted Display (Oculus Quest 2).

We hypothesized that IVR modes can be more easily used and accessed by the user. To this aim, we conducted a within-subject experiment with 60 participants by administering the System Usability Scale (SUS) questionnaire to compare the DVR and IVR applications.

Thus, the paper shows that display, interaction, and locomotion in the design of shopping experiences can generate different feedback on the system usability, and therefore IVR could be a more suitable tool for novel shopping modes in the fashion industry towards the Metaverse.

Introduction

In recent years, the retail industry has witnessed an unprecedented acceleration of digitization, where Covid-19 has been the main driver (McKinsey, 2020; Shankar et al., 2021). In this transition scenario, companies have been looking for fast and alternative ways to innovate while adapting to government-issued restrictions (i.e., the isolation and closure of physical shops).

Therefore, companies have started to make exponential use of the new technologies available to make production systems more responsive, flexible, sustainable, and efficient, and to improve sales processes (Bisson et al., 2021; Fiorentino et al., 2022).

Due to this digital transition, the physical reality made of "things" has gradually started to evolve towards a less tangible dimension, characterized by relations between people and immaterial, digital, and "metaphysical" objects.

Among the rising technologies, we focus on Mixed Reality (MR) as the continuum of Virtual and Augmented Reality (VR, AR), (Milgram & Kishino, 1994), which contributes to the development and diffusion of the Metaverse, a persistent virtual space that users can use for work, entertainment and for other activities, such as shopping experiences. Within this emerging space, a new form of 'immersive' interaction between users and services is shaping (M. Park et al., 2018; S. M. Park & Kim, 2022), especially using VR and Head-Mounted Displays (HMDs).

Although the Metaverse does not necessarily require the use of VR technology, recent studies state that it will be an open challenge from a future-oriented perspective (Babu & Mohan, 2022; S. M. Park & Kim, 2022)

But while the general frameworks describing the Metaverse are becoming increasingly accessible, the implementation strategies and their implications on specific industrial systems are largely unexplored.

In this regard, our paper focuses on the fashion industry, one of the industries that can certainly benefit from this ongoing transition towards the Metaverse (Bertola & Teunissen,

2018; Cappellieri et al., 2021; McKinsey, 2023), for several reasons.

First, the fashion industry, traditionally based on physical and material interactions, had to face the consequences of the Covid-19 pandemic, one of the major challenges so far. Since 2020, many companies - both luxury and fast fashion - have closed their manufacturing factories and physical shops, laid off employees, and canceled fashion shows and events due to the severe restrictions in place. The natural consequence of this was a sudden decrease in sales.

Moreover, after the first lockdown, companies had to adapt to the rapid change in consumer behavior caused by social distancing and isolation. Therefore, consumers - especially Generation Z - developed a new approach to fashion shopping experiences. This is because the lockdown has shown how it is possible to replicate our daily lives in the digital world. In fact, almost all the activities we do daily, from study to work, from sports to socialization, can now be accomplished digitally. This is very relevant because it has given digital spaces a whole new meaning for consumers, changing their purchasing behavior and expectations.

Meanwhile, Covid-19 raised a new level of awareness with respect to the planet. Sustainability became a priority in the minds of consumers, who demand different production processes, especially avoiding waste that is difficult to dispose of in the environment.

The fashion industry is widely recognized as one of the most polluting, with a long history of established wasteful practices that increased with the rise of fast fashion. The need to speed up time-to-market and reduce market costs resulted in the use of toxic textile dyes that made fashion second only to the oil industry in terms of global pollution damage (Dhir, 2021).

As a result, the fashion industry is surprisingly one of the keenest to adopt digitization strategies using digital technologies such as VR to transform its business model, motivated by the apparent plethora of options and benefits it offers (Bertola & Teunissen, 2018; Boardman et al., 2020; Ricci, 2022). Indeed, considering the importance of fashion as a global business today, the transition to 'hybrid' modes of experience can have a huge impact also in terms of more efficient and sustainable modes of production (Bulovic & Covic, 2020).

One of the biggest benefits that digital fashion is bound to bring is the promotion of sustainability, helping brands target environmentally conscious consumers. Virtual fashion prototyping allows a company to have a series of products visualized and configured in real-time before the physical product is made. Digital and virtual clothing can save 3,300 liters of water per garment and emit 97% fewer carbon emissions (DressX, 2021).

However, the literature concerning the fashion industry and the use of VR is scarce (Xi & Hamari, 2021) and, therefore, also about its implications in the emerging Metaverse. Thus, although VR has proven its effectiveness in the field of fashion retail, there are only limited experimental studies (Xi & Hamari, 2021). On this basis, this paper aims to provide insights into the use of digital VR technology to improve the shopping experience in the fashion industry towards the Metaverse, by expanding the previous study of Ricci (2022), and by presenting the results of an experimental design.

The objective of the research is to compare the shopping experience of an accessory (i.e., a luxury handbag) on a desktop computer - Desktop Virtual Reality (DVR) - with that in Immersive VR (IVR), evaluating the impact from the point of view of system usability. To test the differences in terms of usability, we developed two versions of the application. The first was developed as a traditional desktop application, while the second was developed for Oculus Quest 2.

To this end, we conducted an in-subject experiment with 60 participants, administering the System Usability Scale (SUS) questionnaire to compare DVR and IVR applications.

The research question is: "Can an IVR shopping application be more usable than a DVR application?"

Background

When investigating the use of VR in the fashion industry, two rather different approaches can be identified (Morotti et al., 2020). The first originates in the fashion industry and the second in the academic field. We will focus on the contributions from academia, as they present the results of experimental studies.

Namely, the Metaverse can be enjoyed with both non-immersive and immersive virtual technologies (Dwivedi et al., 2022). Yet, there are no studies in the field of fashion that clarify the differences between immersive and non-immersive VR experiences. In fact, such comparative studies only exist in one other product area (i.e., groceries) (Lombart et al., 2020; Peukert et al., 2019; Schnack et al., 2019).

In the area of fashion, the present studies are rather concerned with analyzing the implications of VR for enhancing the shopping experience through specific metrics.

For example, Lau et al. (2014) researched how interactivity can enhance consumers' shopping experiences. To do this, they designed an IVR shop in which participants were instructed to look around and explore fashion products within the virtual environment. Subsequent interviews revealed that participants engaged with and enjoyed the experience, demonstrating how interactive design can enhance consumers' shopping experiences (Lau et al., 2014).

Similarly, Jang et al. (2019) studied the role of interactivity along with vividness in consumers' intentions to approach an IVR shop. The results showed that participants who perceived greater interactivity and vividness also tended to show stronger purchase intentions. Furthermore, these positive influences were mediated by perceived telepresence and the value of experiential shopping (Jang et al., 2019). In contrast, Lau and Lee (2019) validated that VR could improve interactive shopping, consumer purchase intention, and hedonic user experience within consumer shopping experiences (Lau et al., 2019).

However, designing an IVR shop may also be useful to measure the dimensions of the user experience within virtual shops and how it affects the shopping results. In this regard, Park et al. (2018) designed an IVR shop, addressing a female target group. During a one-hour individual session, all participants were asked to enter the shop and freely explore it as much as they wanted. Preliminary results showed that the immersive VR experience is positively correlated with pleasure, attitude towards virtual shops, and purchase intention. Therefore, the researchers concluded that IVR could be used as a new shopping tool to improve consumer experience and engagement (M. Park et al., 2018).

Moes and Van Vliet (2017) analyzed to what extent a shopping experience can take place using online material (e.g., a normal shop photo, a 360-degree photo, or a VR photo) and to

what extent these different materials create different effects in an online or physical shop. The main result is that presenting the experience of a physical shop on an online platform is more effective with the help of VR than with a normal or 360-degree photo. In addition, the use of VR seemed very suitable to achieve other positive effects, such as increasing the consumer's intention to visit the physical shop. Therefore, in a society where online shopping is on the rise and physical shops are under pressure, "the use of VR seems a logical step"(Moes & Vliet, 2017).

In terms of interactivity in relation to the hearing sense within the virtual shopping experience, Morotti et al. (2020) discussed the potential of using voice commands in an IVR fashion shop, exploring the benefits of speaking and interacting verbally with a VR assistant embodying a salesperson. Preliminary results suggested that VR could provide effective experiences, and the integration of the voice assistant could help make the virtual experience more natural and easier (Morotti et al., 2020).

In summary, the results of this research provide a strong initial statement on the positive effects of VR for retailers, with respect to the metrics investigated (Moes & Vliet, 2017). However, further research in the fashion industry is still needed to establish the effects of different experience modes. Furthermore, although all contributions address the improvement of the shopping experience in the fashion context, there are no studies comparing IVR and non-immersive VR experiences.

Only Ricci (2022) presented a future agenda about the design and development of VR and haptic applications with the aim of improving the fashion shopping experience.

Therefore, we aim to extend this work by presenting an experimental design, conducting a comparative study, and formulating the following hypothesis:

H1: Users perceive the IVR shopping application as more usable and accessible than the DVR.

Methods

We conducted a within-subjects experiment with two conditions: IVR mode and DVR mode. Both conditions provided the same shopping experience but differ in terms of display and interaction systems within the applications. To balance the treatment orders, a Latin square was used.

Participants

At the Polytechnic University of Bari, sixty volunteers (35 male and 24 female) aged 22 to 58 (M=30,5, SD=10.23) were recruited for this study. Nobody had ever used VR for a shopping experience, although most of them (n=41) had previous experience with VR before the experiment, with a level of familiarity with this technology equal to 4 on a 7-Points Likert scale.

Task

We designed a virtual fashion showroom using the Unity 3D engine. The case study is a luxury handbag, as accessories compared to clothes (such as t-shirts, shirts, etc.) have simpler physics and are much easier to render in the 3D engine.
Subsequently, the task of the experiment assigned to the users was to find a luxury handbag in the virtual shop and explore its features freely until they were ready to buy it.
The features of the handbag user interface included:

- Zoom in or out of the product.
- Display detailed information about the handbag (e.g., brand, history, production process, size guide, washing method, and reviews).
- Call up an attributes window to change the color and finishings.
- When finished, click on the handbag to add it to the shopping cart.

Setup

This experiment was carried out in a university laboratory that included a workstation with a seat, a Zotac ZBOX MAGNUS ONE i7-10400, an Oculus Quest 2 HMD, and two wireless controllers. We designed two versions of the applications: DVR and IVR. The first was a traditional desktop application, while the second was designed for Oculus Quest 2 (See Figure 1).

Figure 1. User testing the IVR shopping application.

Both versions presented the same functionalities but differed in terms of interaction and display devices. The keyboard and mouse were used to interact within the DVR application, and the display was on the computer monitor. However, interaction occurred with the controllers in the IVR application, and the scene was seen through the HMD. In this case, we implemented the standard metaphor of raycasting (Lee et al., 2003), a group of interactive techniques used in IVR for selecting distant targets. We implemented a raycasting-based virtual pointer as a laser pointer that, when intersecting a target object, selects it (See Figure 2).

Furthermore, the locomotion technique also differed between the two versions. Whereas in DVR, locomotion took place using arrows on the keyboard, in IVR we implemented a natural navigation metaphor, i.e., teleportation (Bozgeyikli et al., 2016). Specifically, point & teleport is a locomotion technique that overcomes the problem of limited tracking areas by allowing users to teleport to selected target positions using either controller. Furthermore, teleportation was the most suitable

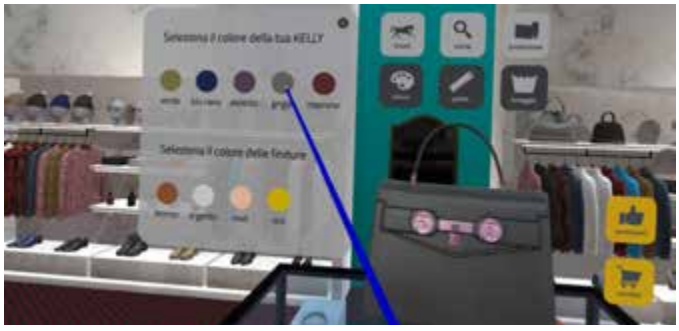

Figure 2. Raycasting technique for the interaction mode in the IVR application.

technique for our application, as the designed virtual shop was very large in terms of spatial extension.

Procedure

We welcomed the participants when they arrived and asked them to sit in a designated position and to provide informed consent. First, we described the purpose and tasks of the experiment to all 60 participants through a PowerPoint presentation. Afterward, we showed the participants how to interact and move in both DVR and IVR modes. We administered the pre-experience questionnaire to the subjects when they were ready to start. Next, participants had to go through the DVR and IVR training sequences, performing tasks like the real experiment, in a cube training environment. Then, once they were ready, they tested the experimental scenario to complete the task.

Measures

Finally, we invited participants to complete a questionnaire at the end of the experiment, both for DVR and immersive VR modes. To test our hypothesis, we assessed the subjective measurement of system usability. As a result, we requested that participants fill out the System Usability Scale questionnaire (SUS). The SUS is a ten-item standardized questionnaire used to assess perceived usability (Lewis, 2018) (See Table 1). To interpret the SUS results, we used the curved rating scale (Lewis & Sauro, 2016) ranging from rating A (Best Imaginable) to rating F (Worst Imaginable).

Table 1. SUS assessment method

Questionnaire	Number of items	Type of rating scale	Time of the administration	Application(s)
System Usability Scale (SUS)	10	5-point Likert Scale	Assessment of the perceived usability at the end of a study	Subjective assessments of perceived usability of products

Results and Discussion

All participants completed the task and answered the questionnaire, returning valid results without outliers. The score returned by the SUS questionnaire for the IVR mode is 81 (Excellent, See Figure 3), corresponding to an A rating, on Lewis and Sauro curved rating scale, while the score returned for the DVR mode is 54.50 (Poor, See Figure 3), corresponding to a D rating. Confirming our hypothesis, the IVR application results in being easier to use than the DVR.

The perceived usability may depend on how the IVR system is implemented compared to the DVR system. Thus, we can suppose that the explanation for this is in the display, interaction, and locomotion systems. The effects of IVR versus DVR display modalities on usability have been investigated by numerous studies but not for retail and, particularly, for the fashion industry.

For instance, in the case of the DVR application, the display system was on a 2D screen and returned flat images with a low degree of immersiveness. In the case of the IVR, instead, users could be fully immersed in a virtual environment that surrounds them at 360°.

Recent literature reports that IVR displays have been shown to positively affect performance in a visual search task (Pallavicini & Pepe, 2019), such as finding the handbag in our experiment. Also, users feel more naturally immersed in the IVR scenario, showing a more intense emotional response in IVR versus after DVR (Othman et al., 2022). Additionally, users commented to feel a greater sense of presence in IVR as opposed to DVR condition, probably due to the higher degree of immersiveness. Interaction could also be a contributing factor. Indeed, interaction in the DVR took place with the mouse, which, regardless of how familiar users were with this tool, was probably not suited to the visual search task compared to the raycasting technique (Pallavicini & Pepe, 2019). The same is true for locomotion, which in the DVR was accomplished using the arrow keys on the keyboard and was limited in comparison to the ability for users to project themselves anywhere via teleportation in IVR. These results regarding the usability of the IVR compared to the DVR are encouraging for further applications in the fashion industry.

Figure 3. On the left: Box-and-Whisker plot of the scores of the ten SUS statements for the DVR mode; On the right: Box-and-Whisker plot of the scores of the ten SUS statements for the IVR mode.

Conclusion

We are currently living in an ever-expanding digital reality, which has affected every part of our lives, including the way we experience shopping. Indeed, the Covid-19 pandemic has accelerated digitization through the spread of technologies such as VR, assumed as one of the elected tools for experiencing the Metaverse. In this transition, the fashion industry can take advantage of this technology to become more sustainable, by reducing its pollution impact.

Nonetheless, the literature concerning VR adoption within the fashion industry is very limited. And, clearly, there is a lack of studies comparing IVR versus non-immersive shopping experiences, i.e., DVR. Indeed, researchers should acknowledge the differences between IVR and DVR applications because this could affect the users during the evaluation. As a result, more experimental research is needed to determine how VR technology may improve the fashion shopping experience in the Metaverse.

We, therefore, extended the work of Ricci (2022) by performing a comparative study between an IVR and a DVR shopping experience and assuming a luxury handbag as a case study. The aim was to test the usability of the applications to assess which of the two was the more usable.

To this aim, we conducted a within-subject experiment with 60 participants, administering the SUS questionnaire to compare the DVR and IVR applications. As a result, the study demonstrated that higher immersion in the design of shopping experiences can provide different feedback on system usability, showing that the IVR application (A rating) is more usable than the DVR (D rating). The explanations for this may be found in the implementation of IVR and DVR systems and their differences in display, interaction, and locomotion systems.

One of the main outcomes of this study is that IVR has the potential to create new shopping modalities for the fashion industry. Indeed, as users find IVR applications more usable than DVR, it is possible to think that in the emerging Metaverse applications, IVR could play a fundamental role among all the technologies involved, being potentially accepted among users.

Also, further research is needed in order to assess other measures such as user experience, customer engagement, and purchase intention, and analyze their implications in the Metaverse.

To conclude, this research may also have potential implications regarding sustainability. In fact, it would also be interesting to analyze in depth what benefits it could bring from a sustainable perspective, quantifying the reduction of waste and product returns.

Abstract

Augmented fabrication is an upcoming technology which combines digital design with physical manufacturing. Since there is a lack of experimental data on the benefits and experiences of augmented fabrication, a pilot study was done with the Shape Origin, a spatially aware manual CNC cutter. The experiment consisted of engraving a set of boards with circular 2mm groove. As a pilot test, the co-authors participated in the experiment and engraved five boards each.

We concluded that the quality and elapsed time improved significantly after repetition. As participants, we ended up with more confidence in operating the machine and growing more knowledgeable about the wood as a material during the engraving, resulting in cleaner cutting results with a flat learning curve.

Introduction

Today, evolving technology allows us to design and manufacture automatically (Weigert et al., 2019). Yet because of this, the creative input of the designer and the experience gained during the process vanishes more and more (Zoran & Paradiso, 2013). The experience a designer feels during the process of making the product, will provide insights about the material and applicable fabrication methods. Once it is completely digitally done by machines, the designer is not able to adjust during the process (Loh, Burry, & Wagenfeld, 2016).

With the use of augmented fabrication tools and digital manufacturing, it is possible for people to do the fabrication process themselves, assisted through digital fabrication means (Verlinden & Bekker, 2017;Mahapatra, Jensen, McQuaid, & Ashbrook, 2019; Yung, Li, & Ashbrook, 2018). In this way, the designer of the product can make small adjustments during this process. Also, most augmented fabrication-tools are very mobile (Yung et al., 2018). Due to this high level of mobility, the person can easily transport the fabrication tool from one location to another. This makes switching between workplaces or different contexts possible. A couple examples of such mobile augmented tools are the FreeD, a handheld digital milling device that is monitored by a computer but still preserves the makers gestural freedom (Zoran & Paradiso, 2013), the augmented airbrush an airbrush that allows novices to experience the art of spray painting (Shilkrot, Maes, Paradiso, & Zoran, 2015), and the D-Coil: a 3D modelling approach that uses wax coiling to bring tangibility to the design of digital models (Peng, Zoran, & Guimbretiere, 2015). Each of these devices assist the user in developing a skill that would otherwise be very difficult and would take a long time to learn.

The concept of augmented fabrication is still new in product development and manufacturing, a structured approach to investigate its benefits requires design inclusive research (Verlinden & Horvath, 2009). Most of such systems are still in development while no experimental data is found on its influence on design. This study represents a pilot study of using the Shaper Origin, a commercially available augmented milling machine (Shaper Tools Inc, 2023). The focus is on the learning curve and quality of the resulting workpieces.

Method

In this pilot study, the Shaper Origin will be our practical testing tool (Shaper tools inc., 2023). The research question was formulated as *to what extend (time) does working with the Origin Shaper tool as an augmented fabrication machine improve custom board cutting?* Furthermore, by fabricating a design several times we want to see if the fabrication process is getting faster and easier (i.e., learning effect).

To verify if a learning curve can be flattened by using augmented fabrication tools, practical research is the best option. As Nielsen stated, an estimation of usability requires only 5 participants (Nielsen, 2000), while a subjective verification of the use of such tools is still lacking.

Workpiece design

In this experiment a set of wooden plates were engraved with a circle contour (figure 1).

Since this was a simple design, the engraving design was made on the machine - it comes with a basic toolset in which we could model the contour. This made the start of the process quicker and easier. Figure 2 left shows how the milling path is being mapped in the centre (concentric).

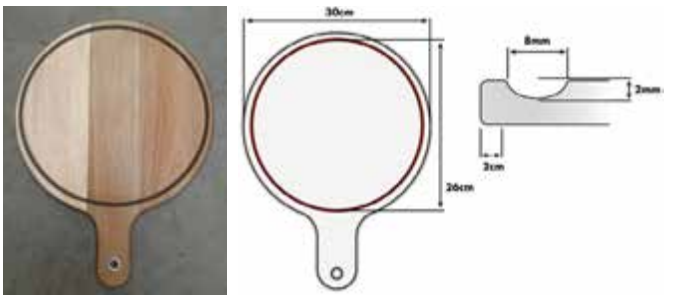

Figure 1. Workpiece and its dimensions.

Figure 2. Left: Shaper Origin display with engraving design, right: finished workpieces.

Each of the participants was tasked to engrave five wooden plates. From a functional perspective, a circular groove/split with a diameter of 26 cm was determined to prevent juices from draining of the plate when dinner is served onto it, as indicated in red in figure 1. Apart from measuring the time to complete the workpieces, the quality of each contour was rated.

Pre-test with Shaper Origin

The shaper origin is a commercially available handheld milling machine that is spatially aware using a specific tracker tape on the work surface, which is observed through a camera by the internal computing unit. The interface guides you by showing a path you need to follow. When you deviate from the milling path, the tool adjusts itself in time to prevent any minor mistakes.

To check if our experiment setup was appropriate, we did a pre-test with a test plate. This way we could make sure the machine was set up correctly, specifically the engraving pattern and depth.

The engraving was designed to be 2 mm deep, this required two milling phases: the first time one millimetre and the second time two millimetres with a ball-end mill (Ø8 millimetre). Thus, the full milling path is 163 cm.

We immediately noticed that the elevated surroundings were not wide and high enough to support the Shaper. We needed to add more of support surface to prevent the Shaper from getting out of balance when moving around the wooden plate.

Furthermore, the tracking stickers required careful planning. Since the elevated surface(s) of the jig had a small surface, these were not usable for placing the stickers. As seen Figure 2 on the right, we ended up using a lower surface as no inaccuracies were noticed by this hight difference.

During our setup and pre-test, we experienced several unexpected challenges, for example the need for more tracking stickers on the board. This caused the Shaper to lose track of its position. Secondly, due to a height difference between the working surface and the support blocks, The Shaper often lost balance. The pre-test findings can be found in the Appendix.

Figure 3. Placement of tracking tape - left: initial, right: final.

Determining engraving quality and flaws

In Table 1, a visual categorisation of flaws is provided. When moving the miller too slow, black spots/burn marks appeared on the edges. This was due to the heat caused by the rpm or because the mill was due for replacement (flaw 1). Another flaw that appeared when going too fast, was these frayed edges (tear-out). These were very visible, so we did our best to avoid them (flaw 2). Not deep enough only shows white marking (flaw 3). Some of the boards had an uneven surface, causing uneven groove depths (flaw 4). This was a flaw we did initially not take into consideration when calculating the quality scores, yet it influenced the overall look of the engraving. Where the starting point and the endpoint met, the lines not always connect perfectly. This was due to starting and ending the milling process abruptly.

The occurrence of flaws determined the quality score for each workpiece. No flaws are represented as a 10 out of 10. Each flaw is subtracted, ranging between -3 (very visible) and -1 (minimal).

Table 1. Categorisation of milling flaws.

Flaw 1 – burns

Flaw 2 - frayed edges

Flaw 3 - insufficient depth

Flaw 4 - uneven surfaces

Results

The participants all are 4th year product development students at the University of Antwerp, ranging between 21-24 years old with no formal training on manual milling/wood-

working. Before the experiment, the participants gave a confidence value they felt about working with the Shaper tool. Afterwards they were asked to rate their confidence working with the Shaper tool again.

For each participant, the time to finish one workpiece was captured. The five measurements were be put on a timeline, shown in Figure 4.

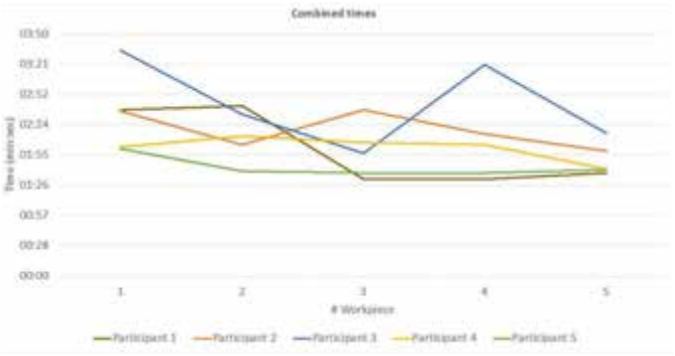

Figure 4. Times per participant.

In most cases, the initial workpiece took most time and there is a gradual decrease of approx. 30-45 seconds to complete each workpiece between first and last plate per participant. Time drops over time occurred for multiple participants, suggesting an increase in efficiency. Secondly, several mentioned the feeling that handling the machine. However, in some cases exceptions happened (like participant 3 in workpiece #4 where tracking was lost) while overall times stayed below 3 minutes – which translates to a minimum speed of 0,9 cm/s and a typical speed of 1,4 cm/s.

Figure 5, the quality plot, reveals increasing scores of each consecutive workpiece in comparison to the initial board. This is due to the fact that the participants found a comfortable tempo of following the contour and operating the machine. The roughness differences between some of the plates were negligible.

In subjective feedback, the nature of guidance and correction felt natural to the participants. Lastly, with more practice, not only the time, but also the quality of the engraving was improving. This became noticeable through the understanding of which groove shape was desired, but also getting used to the manner of operation with the Shaper Origin had an influence across the participants, which resulted in overall better results. There were deviations in the workpiece thickness

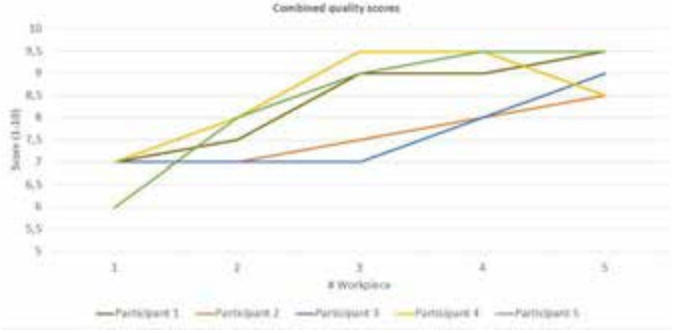

Figure 5. Quality scores per participant.

which on close inspection influenced the performance (flaw #4). The tracking tape should be put on the same level as the milling surface.

Figure 6 shows that the more plates an individual participant cuts, the higher their overall efficiency scored. Even with the difficulties through the middle ground of the plates (2nd plate 2 to 4th plate), the comparison from the 1st plate to the 5th plate all participants scored higher.

Figure 6. Efficiency per participant.

Conclusion

Augmented fabrication tools can potentially greatly reduce the amount of skill that is needed to operate certain machines, this way the steep learning curve might suddenly become much flatter.

This study involved engraving a set of plates, performed by participants that had little experience with carpentry. As the collection of 25 workpieces could be manufactured and objectively tested on quality, this pilot study is a first of a series on the performance of digital craftmanship.

Both by time measurements and subjective evaluation, we can conclude that the augmented fabrication with the Shaper Origin does add sufficient guidance to engrave a continuous curved contour in relatively little time (less than 3 minutes per workpiece). Repeated operation decreases the manufacturing time, while the quality of the engraving was the same during the experiments, while some improvements were certainly visible. Furthermore, the subjective feedback and the confidence score of the participants grew along the executing of the experiment. This all establishes to a small learning curve to operate and design engraving with augmented fabrication – both in performance (time and quality) as well as confidence.

Of course, improvements in small series manufacturing do not necessarily influence the ideation/prototyping process, and specifically with carpentry, more consideration of the material (macro structure, grain, warping) is required to improve quality and creative expression.

Acknowledgement

The authors would like to thank Danny Stoop for the technical support and expertise on carpentry.

Appendix Pre-test timings and challenges

1st setup	7:17	scanning
Preperation	1:47	Programming circle and dept
Milling 2mm	3:26	Milled to deep, not complete, Too few stickers
2st setup	4:43	Extra stickers, new scan
Preperaton	2:48	Programming circle and dept
Milling depth 1mm	8:26	Lost orientation, no clean groove
Milling depth 2mm	4:02	Lost orientation again, new scan
Milling new supportive blocks, adding extra sticker		
setup 3	2:58	Adding extra stickers and adding support for the shaper
Preparation	1:00	Programming circle and dept
Milling depth 1mm	1:39	No problems, everyhting went good
Milling depth 2mm	1:27	
final test		
Milling depth 1mm	1:23	
Milling depth 2mm	1:15	

Introducing the material experience concept in the metaverse and in virtual environments

Luca Alessandrini, Valentina Rognoli

Design Department, Politecnico di Milano, Milan, Italy
luca.alessandrini@polimi.it, valentina.rognoli@polimi.it

Abstract

Metaverse consists of a set of virtual spaces populated by avatars and allows humans to move from the commonly known detached browsing interaction to inhabiting what is now called the immersive internet or spatial web. Here another dimension is added to interactivity by merging the virtual and real worlds. MetaverseIt is creating new interaction possibilities in content consumption for various fields: health, mobility, architecture, fashion, art, social, retail, etc., improving user engagement.

Material experience plays a key role in how human beings perceive and interact with the world through their senses. While in physical artefacts, material perception is intrinsic to what they are made of, in the case of virtual objects can simulate materials with existing behaviours or even have the potential to create modes of material interaction without precedents.

The Metaverse's technological ecosystem can directly affect how we interact with objects in real, virtual, and mixed environments. However, it still requires intensive research and development to reach its full potential.

This article aims to investigate how material experience is approached in Metaverse ecosystems and in virtual environments in general from two main perspectives: by the users who populate these virtual dimensions interacting with virtual materials and by the designers who take part in their creation and development.

To do so, a framework has been created to classify all the possible characteristics that virtual materials can have in the virtual environments, hence in the Metaverse, following the five senses and in the meantime, a correlation has been traced with the related virtual output defined by the designer who develops material experiences for virtual environments.

This analysis highlighted that it becomes vital for the designer developing material experiences for virtual environments to be aware of the possible hardware devices available stimulating the virtual material experience in the user; that a balance needs to be created between the richness of details and the performance to ensure fluid experiences in relation to energy consumption and the speed of the connection; that, especially nowadays, living in times of conflict, designers should develop more inclusive virtual material experiences opting for a multi-modals experience stimulating multiple sensorial channels fostering connectivity and creativity.

Introduction

Mixed reality (MR) is the merging of physical and virtual worlds, where virtual stimuli are overlaid with a real scene in real-time. It allows us to create a fluid and interactive interconnection between the virtual and the real world and potentially become the next big change in the media world (Mott et al. 2019).

The enhancement of MR creates new possibilities of interaction in content consumption in various fields: health, mobility, architecture, fashion, art, social and retail. It creates unprecedented ways to interact with products, from improving customer involvement in the purchasing phase (Grewal et al., 2017) to enriching the product usage experience. The current content is mainly based on visual cues complemented by some audio integration. In this virtual and mixed environment, material experience (MX) plays a key role in how people perceive and interact with physical and virtual objects (Bardt, 2019). While in physical artefacts, the material perception is intrinsic to what it is made of, the processes used in the manufacturing and with respect to the laws of physics, virtual objects have the potential to explore new laws to create unprecedented ways of interaction (Milgram and Kishino, 1995). However, interaction with virtual materials can only be related to the means, tools and devices available to enhance that. MR technologies have been explored for decades and are already available through different devices. It will be possible to consider MR as a continuous between physical and virtual in the very near future (Peddie, 2017). However, it still requires intensive research and development to reach its full potential as the next breakthrough media.

In this paper, the concept of MX is not related only to the physical dimensions but also to the digital ones. Furthermore, the digital dimension is not referring to the actual materiality of the medium (e.g. computer, smartphone, VR glasses), but also to the digital representation of materials in virtual spaces, such as their aesthetics and interactive qualities. Considering the metaverse as a space web (Accenture, 2022), all representations of its elements, objects and environments

displayed need to be manifested somehow to the user called to occupy a virtual space and to interact with their contents. Objects and environments need to be addressed with a visual appearance (e.g. colour, glossiness, texture, etc.) and/or designed to give responses and feedback when the user interacts with them. Therefore, looking at the Metaverse and virtual spaces in general from this perspective makes emerges how MX plays a central role in how users experience them and what the designers need to take into account to create a meaningful experience.

The Metaverse and its challenges

Metaverse is an evolution of the current internet that allows people to move from browsing interaction to inhabiting (Accenture, 2022). It is also defined as the immersive Internet or space web, the spectrum between merging the virtual and real world where the 3D dimension is added to the interactivity. We can see the *"Metaverse not as virtual space but as the junction or nexus of our physical and virtual worlds"* (Smart et al., 2007). In this sense, the metaverse is not necessarily something detached from our reality, a virtual place to escape, but rather it can be integrated into our reality, an evolution in content consumption in a more immersive, natural and interactive way (Giang Barrera & Shah, 2023).

One of the clearest limits of the Metaverse's user experience is that, for the majority of cases, it happens only through two sensorial modalities: vision and sound. Users are still using their old devices (e.g. computers, mobiles, etc.) to navigate in it, so the Metaverse is being designed e developed to respond only to those types of interfaces. This contributes unequivocally to creating poor experiences, even causing some users exclusion in case they have some disabilities (Zhao et al. 2018). The near future of MR technologies is to explore multi-sensorial experiences enabling the construction of a 3D Web (Heller et al., 2019), having the potential to reduce the gap between disabled or regular users by improving mental imagery and the *sense of presence* (Sun et al., 2022). The term *presence* is used because it offers a broad perspective of phenomena and doesn't limit the interaction to certain technologies enabling the users to both *be there* (immersion in a virtual environment) and *be here* (the virtual contents are displayed in your current physical environment). In the context of the Metaverse, the *sense of presence* can be defined as "a psychological state in which virtual (para-authentic or artificial) physical objects are experienced as actual physical objects in either sensory or nonsensory ways." (Lee, 2004).

Material experience in virtual environments

Through the latest decades of technological advancements, people rely heavily on screens to conduct digital interaction. TVs, computers, smartphones and tablets are the dominant technologies to access data, communicate or produce content. However, while on one side, there is a great development in image processing, creation and representation, the other typologies of stimuli have been slowly developed. For this reason, digital interaction has become less and less tangible (Jung & Stolterman, 2010). It was partially caused by the slow technological developments in this area but mainly because the content characteristics developed for web 1 and 2 are characterized by interactions happening in 2D displays (Heller et al., 2019). With the advances done and the expectation of Web 3 spreading, the Metaverse opens wide new possibilities of interactions in three-dimensional environments and richer multi-sensorial experiences. The new generation's powerful processors allow the renderisation of better images, sounds and haptic feedback with more quality and richness at high rates. Faster connections allow exchanging data faster than ever. Hardware sensors are able to make experiences more aware of our surroundings and adapt the content to make us experience the *sense of presence* in digital environments. AI not only assist in performing faster and smarter tasks but also curate meaningful content and create experiences more personal to each user (Huynh-The et al., 2022). All this converges to new levels of interactions and contents. In this way, inhabiting a virtual environment means adopting new rules *augmenting* physical objects and environments or even creating representations of new ones. To this end, the digital materials experience (MX) comes on stage, which means, for designers, designing the MX of new virtual artefacts and environments.

Virtual materials and the Metaverse: cases from the contemporary phenomenology

The number of users spending more time in virtual environments is rising, a trend that has evolved since the beginning of the internet but that intensively increased in the last 3 years of the pandemic with the wide migration of activities and interactions performed in the physical world to a virtual environment (Mott et al. 2019). This creates the need for virtual environments to allow people to express themselves through virtual features such as avatars' appearance, avatars' clothes and accessories, private virtual spaces, virtual artefacts and art (Giang Barrera & Shah, 2023). These push design practitioners to go beyond the laws of the physical world, allowing themselves to design speculative new aesthetics, interactive modalities, narratives, experiences and even identities. The merging of physical and virtual dimensions has been one of the sparkles to the rise of some of the most significant speculative design case studies in the last decades, touching materials as part of their themes. Among them, we can mention the work done by Antony Dunne in the Hertzian *Tales: Electronic Products, Aesthetic Experience and Critical Design*, where the author questions the relevance of materials perception in the perspective of progressive virtualization of electronic products (Dunne, 2008). Still, Dunne, together with Fiona Raby in *Speculative Everything: Design, Fiction, and Social Dreaming*, imagines solutions were treating alternatives to the current dynamic (imagining how things might be) and operating outside reality, proposing radical solutions that affect current society, politics, and economy, thus challenging the building system. Thus, virtual worlds create critical, alternative realities that challenge the real world by contrast (Dunne & Raby, 2013). In this context, Virtual designs emerge from the real and shape the unreal; they are re-individualized spaces where the boundaries of identity are constantly reshaped, as are meeting places hosting new communities and generating new networks (Koozarch, 2022).

As we become more reliant on technology, the speculative design will most likely become more focused on how we interact with devices and virtuality (Chakrabarty, 2023). A contemporary speculative design case study is the work developed by the designer and creative technologist Billy Kwok called *Metaverse Design Manifesto, Undystopianizing the Metaverse*.

The designer developed an artwork including an interactive augmented reality experience that serves as a cautionary tale for the Metaverse and a design manifesto that lays out ten principles to make the Metaverse a positive evolution rather than a potential dystopia. Among his *Metaverse Design Manifesto*'s 10 principles, we can find pr point n°9 *Embrace digital materialism*. Billy suggests to designers to add a bit of physicality and substance to virtual objects to avoid pure photorealism or minimalism, embracing a balanced mediation between digital augmentation and digital augmentation (Billy Kwok, 2023).

Figure 1. Metaverse Design Manifesto, Undystopianizing the Metaverse

The Metaverse is creating endless possibilities to make speculative design cases virtually or hybridly experienceable by users worldwide; on the other hand, it is possible to see that, as a reflection of our physical reality dominated by capitalistic logic, it is possible to provocatively say that the kind of speculation widely spread in it is also the economical one (Giang Barrera & Shah, 2023). In this regard, some designers have been able to lean on the MX to create new virtual artefacts and environments, generating revenues and interesting case studies.

Andrés Reisinger explored the new possibilities of virtual materials in his furniture pieces. He raised US$450.000 on auction with his furniture collection "impossibles" in 2021 (Dezeen, 2021). As the name suggests, the pieces are surreal, looking and behaving in unconventional ways if compared to physical laws. On the Tangled chair (Figure 2), he played with the perception of structured softness by breaking users' expectations when they saw the armchair collapsing, revealing the empty core. Similarly, the Deep Space sofa (Figure 2) presents similar initial characteristics of softness built by exterior fabric texturing and emptying over time, however, there are incongruences between the initial volume movement, the emptying speed, and the final volume. At first glance, it is possible to imply the sofa back is filled with some liquid inside due to the swinging weaving. However, as it starts emptying, the speed is faster than an actual liquid would flow out the volume, remitting to air behave as the final volume also indicates. In both cases, it's primordial the time dimension of the experience. The material and object performed to bring the surprise effect increase the distinction and value attributed to the virtual product.

Figure 2. Impossible sofa collection by Andrés Reisinger

The opportunity to play with materials and interactions has not only been applied to artefacts but also to proper environments designed to generate experience in the user through their virtual materials. The designer/artist Krista Kim designed Mars House, an NFT 3D house. It reached the price of 288 Ether (equivalent to $512,000). It was described by SuperRare (2021) as "the first NFT digital house in the world". The owner Has access to this digital space through VR technology. The aim was to create a zen environment, an escape place to relax. To this, it applied colour gradients on the floor and ceiling similar to sunset pallets, Kwon, to promote relaxation in users. The dichroic effect on the furniture surfaces also creates the gradient to reach the same effect. The use of translucent material emphasizes the environment's lightness avoiding creating solid visual barriers. On the upholstered furniture objects such as sofas and armchairs, it was applied a texture mimicking velvet. It improves the perception of softness, smoothness and worminess strangely related to the idea of comfort and comfortable seating. Even if the cues are strictly visual, we link the visual information to our previous knowledge and past experiences and attribute the idea of comfort and relaxation to the Mars House (Figure 3).

Figure 2. Mars House by Krista Kim

Material experience introduction

Material experience (MX) is usually inherent to the design process of physical goods, and since the early design schools materials have been involved in the creative process. Bauhaus design schools introduced MX by studying materials, advocating that thinking, knowing and exploring materials were fundamental for good design practice.

The designed physical artefact exists in volume, represented by an outer surface and an inner core. An object only exists if it's made of something (Ashby & Johnson, 2013). With the digital revolution, the conception of existence evolved from physical products with physical features to a blurred border between physical and digital until encountering virtual objects built by bits. However, even purely virtual artefacts are still manifested by the representation of substances. Before jumping into how MX occur in virtual experiences is vital to understand its nature briefly. The designed physical artefact made by its essence (matter) is a medium to arise an experience, and MX are those experiences generated with and through the product's materials (Karana et al. 2008). MX consists of four main experiences that users can encounter interacting with materials:

1. *sensorial experience*, those coming from appraisals inspired by material sources, such as smoothness/hardness, warmness/coldness, glossy/matt, deep/shallow sound, etc.;
2. *meaning experiences*, thank the contact with the material, the user can project ad introject a series of meaningful connections with his/her own experience;
3. *emotional experiences* generated on users that are able to create make the MX recall some emotional content inspired by the material;
4. *performative*, how people would interact and how materials can guide them to certain actions.

Designing physical objects means transforming materials into desired artefacts. The materials' proprieties and characteristics directly affect the creative process and final result. It determines possible shapes, functions, interactions, durability, value and sensorial stimulus. Aesthetic shapes, which stimulations we receive according to the *human five senses*. The received inputs will be processed by the person and judged into meanings according to personal standards, raising the question of what the material means to us. It's a cognitive process based on association, situation, memories, past experiences and symbolic significances to objects. It's highly influenced by personal characteristics, cultural differences and actual psychological state (Rognoli, 2010).

Translating physical to digital

This section intends to present an analysis of how the designers are often called to understand the correlation between the envisioned MX, the qualities of the material they want to design and their virtual representations. Consequently, it will be presented as an in dept exploration of the tools, aspects and commands at the disposal of designers working for digital environments. To do so, a framework (Figure 1) has been created to classify the possible interactions (passive and active) doable by the users with the materials present in virtual environments (also the Metaverse) following the five senses. Meanwhile, a correlation has been drawn with the related virtual cues defined by the designers developing material experiences for the virtual environments.

In Figure 1, the lines are divided according to the five human senses, while the columns represent the different subjects divided into:

- *material qualities:* are the characteristics that materials in the physical world can have, e.g. surface, volume, rigidity/elasticity, weight, etc. These are the starting point for giving and designing the qualities of virtual materials.
- *material proprieties:* are those to be designed by the designers for the virtual environments; they can be passive or active.
- *virtual correspondence cues:* are properties and characteristics that the designers use to obtain the desired MX. They can be commands present in software or parameters controlled by the designers to obtain a certain effect.

The *material proprieties* column is divided into *passive* and *active*. *Passive proprieties* are those that do not require an active response, effect or animation. On the other hand, *active proprieties* require something to be performed by the object or the environment made of the designed material. This can be a variation of the original shape, appearance change, displacement, sound, etc. It was chosen to make this clear distinction because it influences how the designer will develop and envision those virtual materials. During the process of designing the MX, it is required to define the materials' qualities to improve the material performance and so the user experience in interacting with them. These aspects are particularly important when we deal with *active material proprieties* that have an important role in the virtual MX. This is because they are designing materials in an environment where they can decide their own reality, with new laws of physics and impossible phenomena. To do so, designers should first understand how the user will actively interact with the object and which device will mediate the experience (screen, mouse,

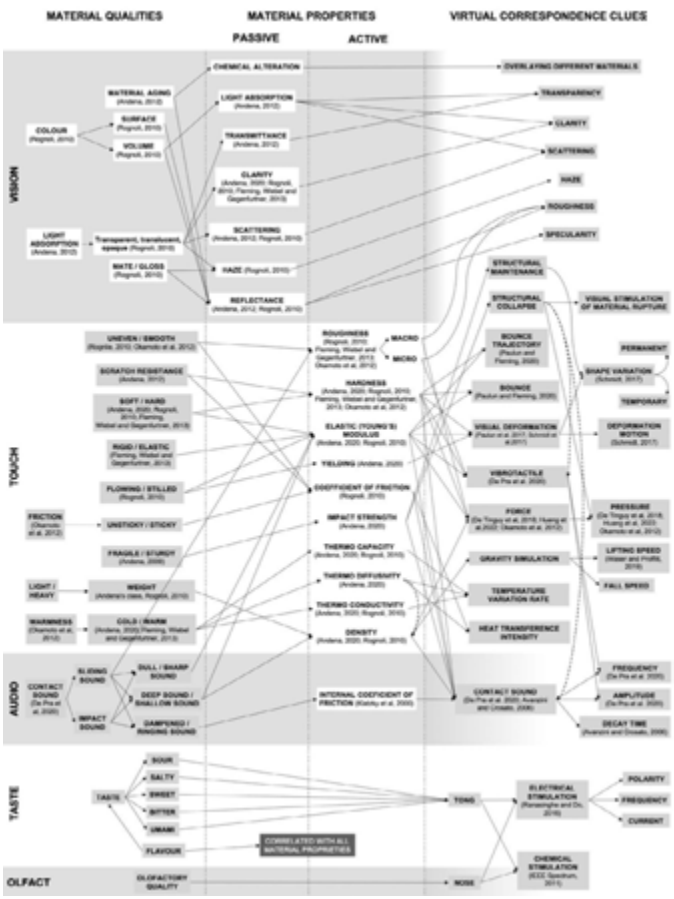

Figure 3. Virtual material experience framework

mobile, VR set, etc.). This is vital to understand which stimuli can be generated and which types of input users will give during the interaction generating virtual correspondences cues as consequent outputs feedback. In the case of *passive material proprieties*, the object would not require any active performance; the object would exist on the scene and react to the environment proprieties (such as global illumination and light interferences from other objects).

Here following, we raised some considerations and mentioned some case studies that have been analysed following our framework (Figure 1). This one has been put together through a rich literature review on MX, materials-related design methodologies, physical materials properties and design for virtual, augmented and mixed reality.

A first consideration observing Figure 1, is that, in general, visual material qualities have a more linear and direct correlation to the virtual correspondence cues. The main explanation for this link is that most of the graphic rendering software uses the PBR technique to render. The PBR means Physically Based Rendering; it is based on real-life surface properties to generate a visual representation being represented by pixels screes. This approach creates a more intuitive and accurate workflow by making analogies with our physical world materials (Souza & Mota, 2021). It calculates the rays of light received in one specific point (referred to as cameras on rendering software) from the light scene. Since the physics phenomena are consolidated, well studied and defined, rendering software programs represent virtually those characteristics.

Physical-virtual perception

Applying a force to an object's body shape influences how people perceive its mechanical properties. Hardness and elasticity are basic mechanical proprieties and are perceived mainly through physical interaction by the users, therefore, they also can be inferred by visual cues. When objects are shown deforming by the action of an external force in dynamic images, people can imply a level of stiffness by comparing the initial shape with the final one when the force is applied to it. Effects such as light, self shadows and surface texture displacement can indicate the deformation of a surface, creating the illusion of deformation and softness during the interaction. As much the texture deforms, and the differences between highlight and darker the self-shadow areas are, the softer the material is perceived. The visual motion of the process of deformation is a key stimulus to perceive the softness/hardness otherwise observer could lose this correlation when presented just with a static image mode of the initial and final shape. Another factor that collaborates with people correctly perceiving hardness and stiffness is knowing the applied force. For example, users who are extremely familiar with this kind of force can easily perceive an object suffering gravity's action effect. Another example related to the perception of stiffness can be given when an object is in free fall and hits the ground, users are able to judge the bouncing and bouncing motion trajectory to estimate hardness and elasticity (Paulman and Falming, 2020). Material density also can be communicated through visual correspondence cues by, for example, controlling the object's lifting speed. In this case, users associate their notion/perception of weight with the fact that the slower the object moves up, the heavier the object is perceived. Moreover, by presenting objects with the same lifting speed but different volumes, the object with the smaller dimension could be perceived as heavier and denser. It indicates that users bring their notion of real-world behaviour to virtual environments (Lv et al., 2022).

Haptic interactions

Haptics cues also can contribute to stiffness perception. De Tinguy et al. (2018) developed a wearable haptic device that simulates the pressure on the finger. They tested the haptic device in combination with VR and AR, simulating interactive objects, such as buttons, balloons and the human body itself. The study revealed that users better perceived stiffness when combining visual stimulation with haptics, even if the force was not applied directly on the user's fingertip. The interaction was better obtained in AR mode when users interacted with tangible objects layering the haptic stimulus on top of the physical surface rather than in VR, where no actual object was handled (Billinghurst et al., 2015).

Auditory interactions

Haptics-auditory can also improve the perception of materials and improve the object's *sense of presence*. De Pra et al. (2020) conducted an experiment recording the vibration and sound from the contact sound of a ping-pong ball with three different materials: wood, plastic and metal. Those recordings were then reproduced through high-fidelity headphones and a low-quality haptic display on a glass surface which users could interact with. The result demonstrated that people can distinguish clusters of materials by vibrotactile and auditory stimuli with more assertiveness on metal (by its characteristic sharp waving sound), followed by plastic and the less recognizable wood sound. The author deduced that more precision on the stimuli could contribute to a more engaging and realistic experience. The same findings were pointed out by Avanzini and Crosato (2006) that said that in *cross-modal haptic-auditory* interactions, audio could compensate for the lack of high definition on haptic devices. Moreover, Avanzini and Crosato (2006) stated that the buttons perception of virtual buttons is improved when sound feedback is added.

Virtually tasty

Our perceived experience with food and beverages is very complex and can involve all 5 human senses. Let's take as an example the experience of eating a triangle of nachos. The crunchiness can be elicited by visual cues of how the piece of food collapses, by audio presenting the sound of crumpling, haptics from the breaking, the corny smell released and by taste with stimulation of salty and sweet in the mouth. One of the main challenges in many explored areas of virtual experiences is taste (Ranasinghe & Do, 2016). While some research areas try to recreate artificial taste and flavour sensation by the use of chemicals, others seek to stimulate it by electro stimulations. Using chemical substances can indeed create rich experiences, but it raises several issues, such as manageability, transferability and scalability of these applications due to the need to have several chemical compounds involved. Electro-stimulation, on the other hand, is presented as an alternative to solve most of these problems. Ranasinghe and Do (2016) proposed a Digital Lollipop, where a wearable device was placed on the user's tong and electro-stimulated. The experiment was able to manipulate the sour taste on users' tongs similarly to lemon juice just by manipulating the electric current, frequency and polarization. Furthermore,

taste perception also can be influenced by other factors, such as the context where the taste experience is perceived. Narumi et al. (2010) conducted a study in this context, proposing that a possible solution would be improving the scene definition, stimulating the perception of different states in the user's mind through scanning and automatically generating a 3D scene in real-time.

Conclusions

Metaverse is not a novel concept; however, its market application, widespread and naturalness in the interaction are constantly evolving. Over the past two decades, there was a great development in technologies that enabled the Metaverse to activate its next application level. The current 2D web interactions are evolving into 3D content awareness. This virtual content can be accessed through different devices able to render stimuli over the five human senses.

We are seeing that mixed-reality technologies initially focused on visual-audio experiences for ludic interaction such as video games (Karis & Epic Cames, 2013). In the meantime, tech companies are developing their products for professional applications in the Metaverse due to the economic potential generated by it.

MX in the Metaverse can improve the realism of virtual experiences and improve the *sense of presence*. It directly impacts how we interact and act in mixed physical-virtual environments. It can improve the comprehension and enjoyment of physical products' digital representations. It allows new interactive levels between actual objects and virtual information, for example, changing the visual aesthetic of certain product surfaces by applying an unexpected texture and colour or perhaps adding haptic feedback exploring tactile experiences on materials to enhance some of their characteristics (Baumgartner et al., 2013). Furthermore, MX can improve the experiences in virtual environments and objects, adding new self-expression possibilities by representing the users' personality through virtual customised characteristics allowing a better *sense of presence* and ownership over virtual objects such as NFT-certified artworks.

To better understand what the factors to be taken into account by the designers developing MX in virtual environments are, It has been essential to create a framework (Figure 1) linking the actual physical materials' attributes to virtual ones involved in the MX. In this way, this current work presents an effective correlation between *material physical qualities* in the physical world, *material proprieties* that could potentially be defined by the designers in the virtual one, and *virtual cues* to be set to obtain the desired MX. However, human perceptions are extremely complex and could be stimulated not only by the cues listed among the presented cues and the relative case studies or, as we could see in the above-mentioned examples, but cross-modal (stimulating more senses at the same time) interactions could also blur sensorial perceptions suggesting more effective stimuli (Huang et al., 2021). These could be, tasting colours or haptically feeling an image (Baumgartner et al., 2013).

Adopting the point of view of the designers, we can affirm that to create a meaningful MX in the virtual environments, the following aspects need to be taken into account:

- designers need to be aware of the hardware devices to stimulate the MX possibly used by the users and its processing capabilities.
- the designer needs to great balance between detail richness and performance to ensure fluid experiences taking into consideration the required consumption of energy efficiency and connectivity.
- design for the Metaverse, particularly, involves constantly thinking about accessibility and easy usage. At the present time, we are seeing the chance to define primordial standards for interface interactions and feedback, taking into consideration a more inclusive perspective and so the needs of users not able to adopt all the five senses (Baumgartner et al., 2013). Therefore, designing cross-modals MX can produce more inclusive solutions by stimulating different sensorial channels. In this manner, some stimuli can compensate in case of users' sensibility deficit.
- the convergence of technologies we are witnessing creates an environment that allows new levels of interactions through which designers can trigger MXs. In this context, Designers need to make several choices in the virtual MX design, for example, which method and equipment to use to discover material proprieties, which device to use to render the experiences, which software to use to create them, which sensorial channel to stimulate during the experience and so on.

The focus of this article wasn't to explain in detail particular software or technologies because it is highly variable, and only designers can take into consideration their available resources to define possible paths. This condition is quickly evolving, having novel technologies rapidly spreading, such as neural rendering and 3D scanning on personal devices combined with the intensive use of AI to automatize time-consuming and highly-skilled processes, which are making the production of virtual materials and objects more democratic and widespread. This can stimulate non-skilled users outside the professional environment making content creation more intuitive and faster, leading to additional ways for common users to express themselves on social networks, sharing not only images and audio, but sensations (through the 5 senses) through sharing objects and virtual artefacts.
In the end, we can firmly affirm that further studies need to be developed to understand the influences of sensing virtual materials possibly in the development of novel devices to fully simulate new and always more rich virtual MX.

Balancing authenticity and creativity: a VR system design for assisting ceramic creation

Haoxiang Fang, Baosheng Wang*, Qing Liang

School of design, Hunan University, Changsha, People's republic of China

Abstract

Culture-based product designers are facing the challenge of balancing authenticity and creativity: designers need to maintain tradition in materials, craftsmanship and cultural factors, while product design values innovation in form, function and user experience, which requires both indigenous knowledge and creative design methods. This paper describes our attempt to develop a VR system to help culture-based product designers learn indigenous knowledge and translate it into ceramic creation. The system includes a ceramic repository module, a design case library module, and a rapid prototyping module. The effectiveness of the VR system was assessed through a design workshop where eight participants were randomly divided into two groups, one working with the VR system and the other working with paper-based approach. Experts scored their design work by assessing authenticity through appearance, craftsmanship and culture, and creativity through aesthetics, technology and uses. Results showed that the VR group had a better general performance, specifically in terms of culture, and were more open to creative experimentation in terms of technology and uses.

Introduction

Cultural-based creative products support handcrafted, intangible cultural heritage tourism by attracting tourist interest and promoting the development of the tourism economy (Liyan, Xuanqi, Hesen, Yue, & Jian, 2019; Partarakis, Zabulis, Antona, & Stephanidis, 2020). To do so, designers must extract local design elements while avoiding deviation or stagnation to balance authenticity and creativity in the design process (Qiu, 2020; Wu, Zhang, & Xu, 2018), which means they need to maintain tradition in materials, craftsmanship and cultural factors, while product design values innovation in form, function and user experience. This requires a thorough understanding of both indigenous knowledge and creative design (Suib, Van Engelen, & Crul, 2020).

To meet this challenge, some studies have explored new ways of learning indigenous knowledge. Ch'Ng et al. (2020) investigated the process and method of using VR technology for cultural heritage learning and identified the positive significance of using VR technology for experiential learning. Zhang, Wan, Huang and Cao (2022) used VR technology to design a reading system for ancient Chinese books to help readers overcome cultural and language barriers through VR scenes. Some studies also explored new ways of creative design. Unfold design studio and Knapen (2010) create a ceramic design system working with AR named "l'artisan electrique" for users, even without ceramic creation knowledge, to create, influence or hack tools that further their design practice. Guan, Wang, Chen, Jin and Hwang (2021) created a VR-based pottery making system and found it enhanced student's creativity and learning engagement. Chen, Chang and Chuang (2021) used VR application for engineering design and found VR had marked effects on the novelty and usefulness aspects of creative performance on engineering design creativity. Yang et al. (2018) experimented with using VR drawing for design and explored the effects of VR on an individual's creativity and revealed VR's ability to boost creativity by maintaining stable focus or attention.

This research shows how we use VR technology to enhance cultural-based product design by immersing designers in a digital environment to learn about indigenous knowledge and creative design examples, using the example of Changsha Kiln ceramic creation in Changsha, China. The research aims to understand the potential of VR technology to support culture-based product design processes and revitalize intangible cultural heritage.

Design of the VR ceramic creation assistance system

The VR ceramic creation assistance system is designed based on the traditional ceramic creation skills of Changsha kiln in Changsha, China, which is a colored ceramic creation technique. The Changsha kiln ceramics were one of the main commodities traded along the maritime Silk Road during the Tang Dynasty. The system is developed using the Unreal Engine and is accessible through the Meta Quest2 , a VR headset, aims to provide an immersive and interactive experience in designing creative ceramic products from the Changsha kiln.

We reconstructed a virtual design studio scene in VR to provide a sense of familiarity, safety and privacy and eliminate negative experiences in VR environment, which contains three main modules (Figure 1.): a) *ceramic repository module*, which includes indigenous ceramic knowledge presented as scenes of appearance, techniques and cultures to clarify domain and relationship between each other to help designers use knowledge purposefully in the design process, (b) *case library module*, which contains design cases organ-

ized with narrative theory to enhance users' personal experience of the design process, and (c) *rapid prototyping module*, which is a modelling function in VR environment that makes it easier to review and modify design proposals. Users will be entrusted as a designer to help the Changsha kiln elf (a virtual character designed to guide the user) to finish its design by learning indigenous knowledge and creative design cases in ceramic repository module and design case library module, and further develop their own design attempts through the rapid prototype module.

Figure 1. Virtual design studio scene.

Ceramic repository module

The ceramic repository module includes a *virtual pattern scene* full of patterns from Changsha Kiln and *virtual roaming scenes* showing indigenous ceramic knowledge (Figure 2).

In the virtual pattern scene, each pattern contains knowledge related to Changsha Kiln. By clicking on a pattern, users can view the knowledge description it refers to in the form of text and pictures in the information panel. We organized and divided it into three layers for explanation to make the content of different knowledge more organized: (1) *appearance*, which includes the form properties of Changsha Kiln artifacts, such as material, decorative patterns, and shapes; (2) *craftsmanship*, which includes the techniques and production methods used in the ceramic creation of Changsha Kiln, such as underglaze painting, applique (applique involves adding low-relief clay forms to slurred, scored leather-hard surfaces for embellishment); (3) *culture*, which includes the local culture activities related to ceramic production in the Changsha Kiln, such as the custom of offering sacrifices to the kiln god and burning pagoda made with porcelain chip. We visualized the relationship between the knowledge it represents through the visual effects of the pattern, such as color coding for different layers and lighting effects that hint the connection between knowledge.

Virtual roaming scenes contains our reconstructed virtual environment of historical context related to the knowledge of Changsha Kiln. By clicking on a pattern in the virtual pattern scene with a shortcut key, users can explore and experience the scenarios it reflects and access more detailed information including indigenous cultural elements involved in Changsha Kiln-based design cases (one part of the design case library module). For example, users can observe how people build a pagoda out of porcelain chips, the way they scatter grains for good luck and the scene of people gathering around the pagoda to pray. Such immersive experience would help users gain an intuitive understanding of the knowledge related to Changsha Kiln.

Design case library module

The design case library module consists of four sets of case combinations. Each set contains existing cases and a Changsha Kiln-based design case. The existing cases include culture-based creative product design cases on the Internet, which are reviewed, classified and summarized by experts and presented in the form of text and pictures. They are used as design case references for users, and can be viewed at any time through the information panel (Figure 3).

The Changsha Kiln-based design cases were created by project team members according to inspiration from existing cases using the cultural elements of Changsha Kiln. They come with text explanations and interactive 3D models, but cannot be viewed at first. They are set in the story as the design that the Changsha Kiln elf wants to complete, which requires the user to follow the avatar's led to view existing design cases and to think and find out the indigenous cultural elements needed for product design in Ceramic repository module to unlock them. The indigenous cultural elements are hidden in specific virtual roaming scenes. In order to find it, users need to analyze existing cases and think from three layers (appearance, craftsmanship, culture, as indigenous cultural elements used to unlock the Changsha Kiln-based design case is set according to this structure), and actively explore in the Ceramic repository module. Each time a particular element is found, the user is prompted through the information panel. which makes the user clearly understand the selection of the Changsha kiln elements.

Figure 3. The existing cases (left), the Changsha Kiln-based design cases (middle), the user experience of ceramic repository module and design case library module (right).

Rapid prototyping module

The rapid prototyping module is a VR modeling system that allows users to quickly iterate and test their design prototypes. The system includes basic clay modeling, some basic shapes, and a variety of pre-designed components. Designers can shape ceramic products through clay modeling by mov-

Figure 2. Virtual pattern scene and information panel (left), Virtual roaming scene (middle), and the structure of ceramic repository module (right).

Figure 4. Rapid prototyping module.

ing the handle controller, and select the basic shapes and pre-designed components in the corresponding interface, and use the controller to place them in 3d space (Figure 4). Through the combination of shapes in space, the user can test their ideas about design.

Experimental design

We performed a one-day rapid design workshop to evaluate the feasibility and effectiveness of the VR ceramic creation assistance system. By analyzing design results, we were able to identify the effectiveness of the system in learning indigenous knowledge and promoting creative design.

Participant

The study recruited eight participants with similar design backgrounds, six with no prior knowledge of Changsha Kiln and two with basic ceramic creation experience. They were all students in cultural and creative design and were randomly divided into two groups (each group has one participant with basic ceramic creation experience): a control group that work with paper materials and an experimental group that work with the VR system (Figure 5).

Figure 5. Control group (left), and experimental group(right).

Experimental procedure

Both groups were asked to design creative ceramic products for tourists, based on the culture and techniques of Changsha Kiln. The designs were organized in a standardized format, including the name, function, and physicality (shape, color, and material) of the work, and presented in the participant's preferred method (sketching, modeling or physical prototype). The designs were then evaluated by three experts using an adapted scoring scale, to qualitatively and quantitatively assess the authenticity and creativity of the designs. The scale includes three terms used for authenticity and three terms used for creativity (Table 1.), adapted from the study of the authenticity of tourism crafts (Revilla & Dodd, 2003) and the research of creativity (Cropley & Cropley, 2008). Following the design activity, participants were invited to semi-structured interviews to gain insight into their creative process and to clarify experience with the VR system.

Result and discussion

The expert scores of the design outcomes (Table 1.) show that compared with the control group, the experiment group showed different preferences for product authenticity, the authenticity of the control group products was more reflected in the appearance and craftsmanship, while the experimental group focused more on the culture aspect of the product, especially the extraction of local ceramic customs and stories. The experimental group also had significantly better performance in creativity and were more willing to try new things in terms of technology and uses.

Table 1. Rating scale and scores (Full score of 5).

Dimensions	Factors	Interpretation	Control group	Experimental group
Authenticity	Appearance	Refers to the appearance of a product, such as shape, color.	3.5	3.5
	Craftsmanship	Refers to the crafts, materials used to create the product.	4.0	3.5
	Culture	Refers to the elements that reflect the local culture	2.25	3.75
Final score of authenticity		The mean of the three factors of authenticity.	3.25	3.58
Creativity	Aesthetics	Refers to the aesthetic effects on other people	3.25	4.0
	Technology	Refers to the technology used and how it is used	2.75	3.5
	Uses	Refers to the usage scenario and method of the product.	2.5	4.0
Final score of authenticity		The mean of the three factors of creativity.	2.83	3.83

Table 2. Design outcomes and explanations.

	Control group	Interpretation
1		This is a nail organizer for playing the lute, made with traditional Changsha kiln skills.
2		The refrigerator sticker made of Changsha Kiln skills and image.
3		The building blocks made of Changsha Kiln skills can be built freely to restore the shape and pattern of Changsha kiln products.
4		Changsha Kiln Capricorn fish image cup, trying to show the Capricorn fish in the water.
5		This is a kaleidoscope, can be customized Changsha kiln patterns, users can see the Changsha kiln patterns constantly changing.
6		The design of the coaster using heat transfer technology can present the brown spot pattern of Changsha kiln according to the temperature.
7		The pagoda shaped wind chime, which is composed of tiles from Changsha Kiln, which users can choose and place freely.
8		Changsha Kiln Capricorn fish image of tea bag, restore the legend of the Capricorn fish trying to swallow ships/

The VR scene enhanced the presentation of cultural activities, resulting in the experimental group paying more attention to culture aspect in authenticity than the control group. VR simulates highly detailed realistic environments through 3d perspective, which makes it easier to understand knowledge that is difficult to be transmitted in the form of pictures in paper documents (Yang et al., 2018), especially highly comprehensive knowledge such as cultural activities. For example, there is a local custom of using ceramic shards to build pagodas and burning them to pray for good luck. In VR environment, the construction method of pagoda is obvious, while it would have been confusingly complex in paper documents. It explains why the experimental group designed relevant schemes (Table 2, design No.7) while the control group ignored the extraction of such local customs.

Besides, learning in VR is more enjoyable and attractive to participants, which they concluded as "learning by roaming in an immersive environment". Compared with fragmented documents full of appearance and craftsmanship knowledge, exploring cultural activities in the VR environment is more impressive and contributes to the user's sense of discovery (Obeid & Demirkan, 2020), which made the control group more willing to do their design based on culture aspects of Changsha Kiln. In contrast, paper documents were regarded as materials to be used in the creative process by participants in the control group, which explained why the control group paid more attention to the extraction of appearance and craftsmanship.

The mechanism of unlocking design cases through exploration enhances participants' motivation and provides an opportunity for self-reflection and design critiques, which leads to a better creative performance. Participants in experimental group reported they tended to perceive surpassing existing design solutions as a challenge. In the process of gradually unlocking the design cases, they continue to criticize and reflect on the design cases, which promotes the construction of knowledge related to authenticity and the generation of new ideas. Strong motivation and self-reflection developed through design critiques was beneficial for enhancing creativity (Demirbas & Demirkan, 2007; Obeid & Demirkan, 2020).

The realistic restoration of space in VR environments enhances users' ability to understand space, and the introduction of rapid prototyping modules aids in the generation of more creative solutions (Pandey, Luthra, Yammiyavar, & Anita, 2015). Participants were able to test their solutions in 3D space more efficiently and were encouraged to try different structures, these extra bold attempts often gave birth to new ideas (Zhang, Wan, Huang, & Cao, 2022). For example, both groups used images of Capricorn fish for their designs (Table 2, design No.3 and No.7). The experimental group initially had similar ideas to the control group, but after many attempts through the VR system, he combined the legend of the Capricorn fish swallowing ships to design an interactive tea bag, rather than just extracting the image of Capricorn fish. The virtual pattern scene also directly stimulated one participant in the experimental group to design Changsha Kiln pattern themed kaleidoscopes (Table 2, design No.5). "The way you show patterns in the VR system reminds me of kaleidoscopes, that's why I made this design." As he claims.

Conclusion

This research explores the potential of VR technology in balancing authenticity and creativity in cultural-based product design process by enabling designers to immerse themselves in a digital environment to learn about indigenous knowledge and creative design cases. We developed a VR ceramic creation assistance system based on Changsha Kiln and conducted experiments to see how VR technology can help design ceramic creative product based on intangible heritage.

The results showed that the 3D perspective provided by VR enhanced the presentation of cultural activities, and the way of " learning by roaming in an immersive environment " changed designers' attitude towards indigenous ceramic knowledge, treating it as personal experience rather than material to be used in design process. Mechanisms that unlock design cases through exploration also promote original ideas by providing stronger motivation and opportunities for self-reflection and design critiques.

There are still some limitations to this study. The rapid prototyping module is too simple to enable more detailed visual effects, and better VR modeling methods have the opportunity to lead to stronger creativity. While our system is designed for a single user, the future should yield richer results through multi-user exploration and communication in VR environments. Incorporating an AI-based dialogue system is also a good way to generate more creative design.

What is furniture in the metaverse for?

Lucilla Grossi, Luca Guerrini

Politecnico di Milano, Italy
lucilla.grossi@mail.polimi.it, luca.guerrini@polimi.it

Abstract

Since its beginning in the science fiction field, the Metaverse has been presented as the digital copy of the world. Neal Stephenson in *Snow Crash* (1992) imagined it as a virtual planet twice the size of the Earth, organized around the Street, an equator-like ring on which the activities align and develop on the surface of the Planet. In the novel, the Metaverse is populated by the digital alter-egos - avatars - of a small élite who find the exacerbated rituals and contradictions of a consumerist post-industrial society.

Snow Crash's Metaverse is a powerful metaphor for urban sociality, but, at the same time, it is also a dystopia. Duplicating the real world digitally, in fact, means facing and solving all its contradictions.

The literary model has inspired many social platforms that have taken the concept of doubling reality literally. In the leading platforms born as metaverses for social gatherings, such as Second Life, Horizon, Decentraland, VRChat, virtual architecture and design frequently model themselves on the real ones. Similarly, actions performed by people mirror the real world's. Given that the virtual world has neither gravity nor climate influences and the users do not have a flesh body, the needs in space are inevitably different. From the design perspective, this approach seems to waste opportunities: it roots in the usual rather than fully exploiting the potential of the new.

On the contrary, in metaverses born as videogames, architecture and design are accurately conceived to evoke a precise narrative and induce gamers to specific actions.

Some of the reasons for the normalization of metaverse spaces can be found in the ease of fruition. The users can approach a space with similar connotations and functions to the real one effortlessly. Other reasons deal with the background of people who are building the metaverses. The creation of the virtual world is open to professionals from different fields: neither design is conceived by designers nor buildings built by architects. Therefore creators often ignore the architectural and design culture and its basic methods. These untrained professionals could bring fresh air to the virtual architecture field. The mimetic model, however, seems to limit creativity so far. The essay aims to analyze from a spatial design perspective the reasons that fueled the frequent tendency of the mimesis of reality in a context entirely different in needs and potentials. Through case studies and literature, the research delves into the correlation between spaces, technologies, and actions in the metaverses born as extensions of real-life phases.

In the virtual world, actions are reshaped according to the connotations of the space and the technology involved. The more technology includes the real body in the virtual movement, the more concrete the actions become. Therefore, the crucial question is: what is the point of recreating the world in an infinite-potential platform if it is lived the same way as the real one? In a context with different potentials, actions should have different connotations to give additional value to what they have in the real world.

Keywords

Metaverse; spatial design; virtual worlds; skeuomorphism

Introduction

Since its inception in science fiction, the metaverse depicts a digital copy of the world. Neal Stephenson, the novelist who first used the word in *Snow Crash* (1992), imagined the metaverse as a virtual planet twice, the of Earth's size, shaped around the Street, an equator-like ring on which activities aligned and developed. In this virtual world, the digital alter-egos – avatars – of a small élite live the exacerbated rituals and contradictions of a consumerist post-industrial society. Stephenson's metaverse is indeed a dystopia, but also a powerful metaphor for an urban lifestyle behind which it is easy to recognize Las Vegas and its Strip (Dionisio et al., 2013, p. 8).

For decades, the metaverse debate only occurred among experts, notably computer scientists, and engineers (Dionisio et al., 2013; Damar & Turkey, 2021). However, successful platforms reached a broader audience in the field of social gatherings, such as Active World (1995) and Second Life (2003), and gaming, such as Roblox (2006) and Fortnite (2011), which enlarged in number in recent years. The pandemic brought on these platforms an increasing mass of users. Finally, the decision of Mark Zuckerberg to reshape his 2 billion-user company into a metaverse in January 2021 skyrocketed the attention of the media (Narin, 2021). Metaverse websites proliferated accordingly.

We analyzed these platforms from a spatial design perspective, wondering whether the multiplicity of these metaverses may shed light on the features of spaces and places of our future virtual life. This study summarizes our findings and tries to highlight exploited and unexploited potentialities of virtual space.

Definitions and misunderstandings

Today, the noun "metaverse" usually refers to a freely accessible digital environment that allows social gathering, gaming, and trade. According to the Merriam-Webster dictionary, the word derives from the blend of "meta-" and "universe" ("Metaverse," n.d.), literally "beyond the universe."

The singular form "metaverse," which is frequently used, expresses the idea of a single platform suitable for developing all aspects of virtual life; this form is flanked by the plural, "metaverses," which, in fact, represents the current situation of the many existing platforms.

Today, having a single metaverse platform is a utopic vision; the potentially achievable system closest to this concept is the interconnection of the many existing platforms through a single account. Its advantage would be to access every service and web space with the same information. Consequently, all the account activities and online purchases could be accessed anywhere. The existing platforms, however, have long histories behind and consistently different purposes, which hinders the possibility of, and their interest in, interconnecting.

Since the major protagonists involved in web3 – the latest evolution of the web, based on decentralization, blockchain technologies, and token-based economy – have different ideas of how to shape the metaverse, it is a priority to provide the reader with a definition of "metaverse" adopted in this study, which is: a digital system that allows the *synchronous presence* of many users and their interactions. In other definitions, synchronous presence is frequently challenged, but the most relevant ambiguity lies in the structure of the platforms (Evans et al., 2022). In fact, in addition to the digital worlds accessible in *virtual reality*, some systems allow the synchronous co-presence of users through *mixed reality* while equally satisfying our definition.

Because of its mediatic relevance, the metaverse developed by Meta, *Horizon Worlds*, deserves to be mentioned first. Launched in December 2021, it is one of the youngest among the most famous metaverses (Rodriguez, 2021), but it is not notable for its innovativeness.

When Facebook changed its name to Meta on 28th October 2021 (Mac et al., 2022), the metaverse gained momentum, and definitively left its earlier condition of elitist web reality unknown to the general public. This massive mediatic move originated significant misunderstandings: everything dealing with the metaverse is often associated with the company, both in its functional and aesthetic setting. Instead, *Active Worlds* (1995) and *Second Life* (2003) are the first created platforms corresponding to our definition.

Second Life is the most renowned because, in its early age, it gained significant interest from visionary brands, such as Adidas (Siklos, 2006), universities, and even political entities, such as Swedish Embassy (Bengtsson, 2011), which built their headquarters there. Unlike Active Worlds, which in 2022 looks like a ghost town (*Active Worlds*, n.d.), Second Life has had a constant number of users, which has recently, even increased. In October 2022, it had about 200,000 active users daily and 500,000 active monthly (Signorelli, 2021), more than double the 200,000 monthly users of Horizon Worlds (Horwitz et al., 2022).

The concept of Horizon Worlds is very similar to Second Life's; they both consist of a social platform focused on people gathering and virtual purchases. They both have no ludic purpose but a video game-like aesthetic, and the access to the virtual world is through customizable anthropomorphic avatars. Therefore, compared to Second life's approach to virtual reality, Meta's doesn't seem to add much.

On Meta's website, Horizon Worlds is described as an "ever-expanding social universe" accessible using the *Meta Quest* headset – Meta's hardware device for Virtual Reality (VR) – which involves customers in an engaging experience better than a two-dimensional fruition on the screen. In this respect, Horizon Worlds confirms the general trend of many social metaverses to enhance their attractiveness through VR technology.

Today the limited diffusion of headsets, due to their high price and the side effects caused by their prolonged use (Lawson, 2014; Kemeny et al., 2020), hinders the immersive use of platforms by many people who access the platforms mostly in 2D from computers or consoles. Indeed, according to Anand Agarawala, CEO of the metaverse *Spatial*, 80% of its customers use a computer or mobile (Levy, 2022). Also, Meta Quest has faced criticism, especially from its employees, who declined the CEO's invitation to hold their meetings in VR (Mac et al., 2022) because of its cumbersomeness.

Headsets are an open battlefield for the biggest technology companies. In addition to the Meta Quest, Apple is developing a device able to switch between VR and Augmented Reality (AR) (Charlton, 2022), Google has been working on AR viewers (Wall Street Talks, 2021), and Microsoft is developing its version too, *HoloLens*, focusing on Mixed Reality (MR) (*HoloLens 2*, n.d.). Along with the big companies, many other firms are also launching new headsets, such as HTC, PlayStation, and Valve Corporation, whose Valve Index is at the top of Tech Radar's ranking (Benetti, 2022).

The intensity of this competition is strongly connected with the development of the metaverse because the type of access profoundly influences its shape. Therefore, winning

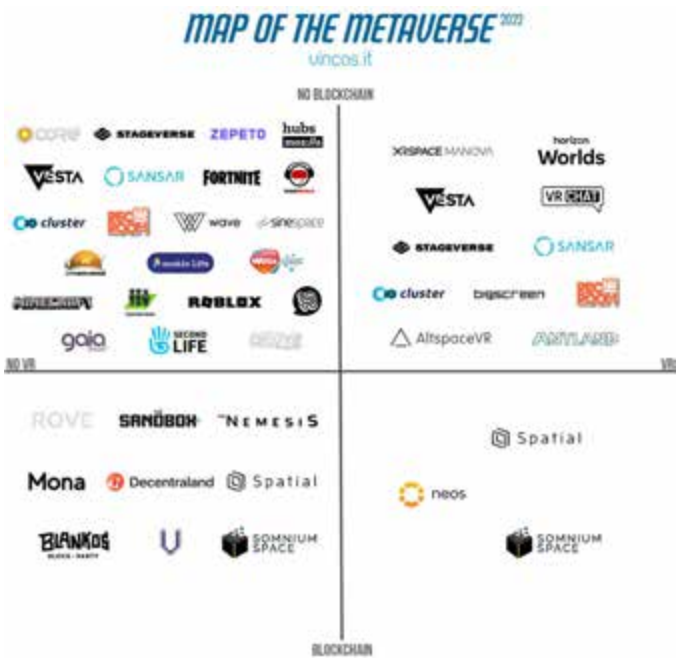

Figure 1. Map of the metaverse, Vincenzo Cosenza, 2022

the race guarantees dominance in a new market and the possibility to shape the users' experience of a new kind of web still under construction. The difference in approach between Meta and Microsoft may clarify the issues at stake: the former focused on VR devices and therefore is building a whole virtual world that allows the user to be isolated from his real surroundings and co-present with other users in the platform; the latter, which is working on MR, is designing a metaverse that preserves the direct experience of the physical environment while adding extra virtual elements in it, and developing the metaphor of teleportation technologically.

From games to social platforms

Matthew Ball, one of the greatest connoisseurs of the digital ecosystem and investor in the future of new technologies, identifies two main categories of metaverse: *game-like* and *non-game-like*. (Ball, 2022). *Game-like* metaverses are gaming platforms that developed thanks to an advantageous combination of user attendance, increased social purposes and decreased gaming reasons, and the farsighted response of the developers who intuited and accompanied the evolution.

Their primary purpose is to generate engagement through interactive narrative development; therefore, the narrative component of games lays the basis for all design choices. A notable example is *Fortnite*, which according to statistics, currently has 250.000.000 monthly active users, which makes it the most visited metaverse of all (Osservatorio Metaverso, n.d.).

Fortnite was launched in 2011 by Epic Games company, but began its exponential rise in 2017, the year in which a new game mode called *Battle Royale* was introduced; it allows the so-called Player versus Player (PvP) game instead of the traditional Player versus Environment (PvE) one (The Fortnite Team, 2017). This upgrade, brought many people to attend the platform to create communities rather than game-fighting each other. In this mode, Epic Games introduced live events, such as fight shows, movies, and concerts – emblematic cases were those of Marshmello, Travis Scott, and Ariana Grande – thus laying the foundations for an increase in engagement (Barbera, 2020).

Non-game-like metaverses are fundamentally social platforms, virtual spaces that allow people to meet and talk. They are frequently business-based and adopt both decentralized and centralized systems. This means that some are controlled by several figures, and some are owned and directed by a single company. Some relevant decentralized examples are Second Life (2003), Spatial.io (2016), Decentraland (2017); centralized ones are VRChat (2017) and Horizon Worlds (2021).

Gaming platforms and social platforms fundamentally differ in their aim. In the former platforms, architecture and design are accurately conceived to evoke a precise narrative and induce gamers to specific actions. In the latter ones, people can gather freely as if these virtual environments were a new contemporary cities. Therefore, the design of spaces focuses on the best conditions to induce social interaction. The challenge is shaping these new virtual meeting places effectively.

To study the spatial connotations of the platforms, we analyzed 55 popular metaverses, divided according to their immersiveness (VR or desktop view), belonging to a blockchain system, and primary purpose (gaming or sociality). Our survey focused on the spatial features of the sites, on their degree of adherence

Figure 2. Hoppin' World, https://hoppin.world

to the spatiality of the physical world (three-dimensionality, gravity, climate), with interest in understanding the reasons and purposes for their design choices and the exploited or non-exploited potential of virtual spaces. We identified three main subgroups: *copy-worlds*, generally called *mirror worlds* (Gelernter, 1991), *semi-copy worlds*, and *experimental worlds*.

Mirror worlds are virtual copies of Earth that could be envisioned as the immersive evolution of satellite mapping websites, but with the intent of a metaverse. Their structure and aesthetics is similar to *Google Earth* and its twin *Bing Maps*, but their primary aim is to be meeting places instead of documentarist 3D maps. Even if the photorealistic effect unites them all in a specific category, these metaverses have consistently different structures.

The most direct approach to mirror worlds is that of the blockchain-based *Earth2* (2020). This metaverse comprises a perfectly rendered terrestrial landscape where users can browse through different transportation. The platform replicates a land market. Users can buy a plot corresponding to a specific place on the Earth and build on it. Due to the absence of avatars, which will be introduced shortly following an agreement with Ready Player Me (A2Analyst, 2022), the aesthetic coherence is not compromised by any unrealistic element.

On the contrary, *Hoppin' World* (2020) is distinguishable for its cartoon-like avatars, similar to Horizon World's, contrasting with the realistic video environment in which they move. This platform allows users to explore places on earth through 360° videos uploaded by other users. Therefore, the landscape looks alive and populated by real people recorded on the clips. Unlike other metaverses, it is *not designed* from a technical point of view, as it does not stand on a geometric mesh.

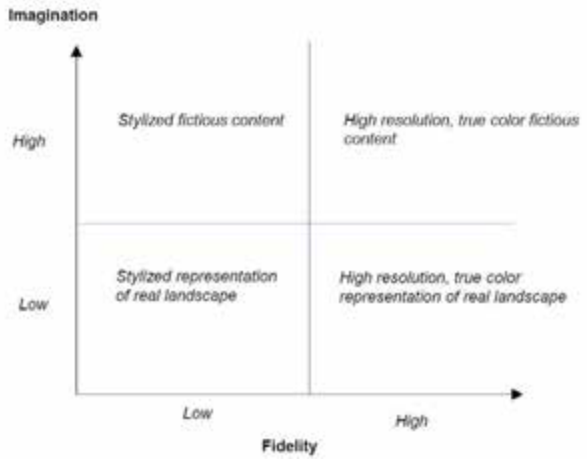

Figure 4. Designing Metaverse artifacts - Designing the Metaverse, Seidel et Al., 2022

Semi-copy worlds, instead, hold an intermediate position on design choices between mirror worlds and gaming metaverses. They are social platforms designed to recall some literal features of the real world but with a cartoon-like or video-game-like aesthetic. We can distinguish three main aesthetic threads: pixel art, Disney-like, and cyber-punk. The *pixel art* aesthetics derives from the first videogames design and has many examples in the gaming field; the most emblematic are Minecraft (2011) and Sandbox (2012). The *Disney-like* thread, instead, is based on a modification of archetypes typical of cartoons with very different levels of abstraction. Decentraland (2017), Spatial.io (2016), Cryptovoxels (2018), and ChatVR (2017) appertain to this aesthetic. *Cyberpunk* metaverses are instead hyper-realistic scenarios massively inspired by science-fiction literature and movies. Many platforms in this category make use of the powerful computer graphics engine Unreal Engine 5, such as Netvrk (2016), Bloktopia (2021), and Wilder World (2021).

Regardless of their aesthetics, semi-copy worlds host buildings with doors and windows, furnished with chairs, tables, and beds, as in real-life houses. In April 2022, even the first bathroom line for the metaverse was launched, "Meta-Loo," inevitably causing hilarity (Rowland-Dixon, 2022).

Each metaverse is clearly distinguishable aesthetic-wise. The following diagram illustrates the type of appearance through the parameters of *Imagination* and *Fidelity* (Seidel et al., 2022). Mirror worlds would be located in the lower right quadrant – low imagination, high fidelity – whereas semi-copy worlds would be located in the three other quadrants.

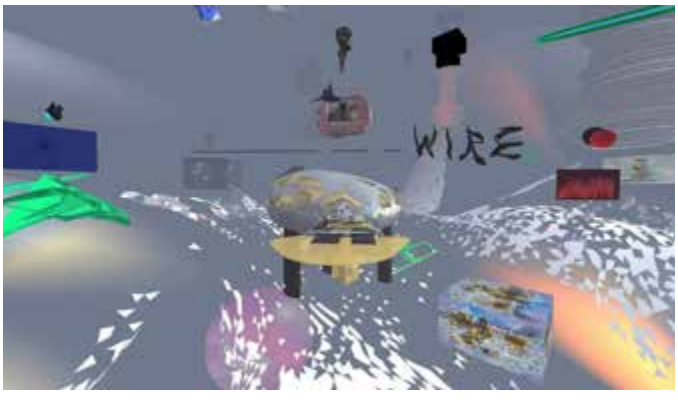

Figure 5. WIRE, Portrait XO, 2022, https://newart.city/

The third category of virtual environments we identified is *experimental worlds*. They constitute a small minority of non-game-like virtual worlds, designed without reality-mimicking, and experiencing virtual spatiality more radically. Unsurprisingly, these proposals challenging the physical world's limits deal with contemporary art and target people inclined to the unknown. For example, Bika Rebek from Some Place Studio, whose spaces look like extraterrestrial universes made of extra-large human-world elements and foams, put a different perspective on the design of virtual spaces (Rebek, 2022).

Similarly, Markéta Gebrian presents on NEOS VR platform the experimental project Bodily Metaverse of Lisbon, an artistic interpretation of Lisbon city center reshaped as an immersive virtual world. The VR environment enables "non-constructible and non-gravitational elements of architecture to be designed as floating floors, transposable elements, and teleportation features" and tests "the new opportunities that social VR brings to architecture design" (Gebrian, Florián, & Eloy, 2021, p. 133).

Frequently, virtual spaces corresponding to this category are not metaverses per se. Instead, they are worlds inside larger systems or independent platforms, such as New Art City, a brilliant example of a virtual space that doesn't mimic reality. It is a curated virtual gallery, whose exhibitions show free-floating elements in the space, with no perceivable limitation of distance nor connotations recalling the familiar human environment (*New Art City*, n.d.).

Skeuomorphism and comfortable habits

For decades, computer scientists and engineers have been working to produce a metaverse that could constitute "a compelling alternative realm for human sociocultural interaction." In a list of "four features that are considered central components of a viable metaverse," Dionisio and his colleagues put realism in the first place. The primary design effort – they state – should focus on shaping a "virtual space sufficiently realistic to enable users to feel psychologically and emotionally immersed" (Dionisio et al., 2013, p. 2). Therefore, from their perspective, there is no alternative to realism, as it provides effective foundations for the whole program.

The phenomenon of reality-mimicking is called skeuomorphism. The Oxford Dictionary defines it as "the use of symbols or other objects on a computer screen that look or sound like a physical object in order to suggest their purpose" ("Skeuomorphism," n.d.). While skeuomorphism is justified in video games by the presence of a narrative and gaming purpose, it becomes questionable in other metaverses as it shrinks the imaginative potential offered by technology.

Limitations that exist in the physical world do not exist in the digital one (Seidel et al., 2022). The metaverse is not subject to the rules of physics, therefore, devoid of gravity and climate problems. Natural phenomena do not obstacle construction, and there is no need to protect from rain: roofs are not needed, neither sheltering from cold or heat nor walls, if not as a visual limit. There is no need for furniture or urban and architectural elements to "live" in the metaverse.

In a world where the body does not feel fatigued, there is no need to sit or lay down to rest; food has no meaning, and no action is physically dangerous. From this point of view, the metaverse looks like the new paradise for advertising and sales: it is an audiovisual world in which the possibilities for action fall fundamentally on what you see, hear and possess; the only physical action allowed is moving in a certain direction, walking

or flying, and at most, in some metaverses, winking. In many platforms, much of the world can be reached by teleportation, a connotation that efficiently exploits the fluidity of the virtual, making the road connections ephemeral.

As much as one may use the metaphor of "living in the metaverse," it is hard to perceive its spaces as lively ones. As discussed in the book *Lost Zone. Hiking the dawn of the Metaverse*, some virtual worlds are likely to look – and be – abandoned since they don't respond to real needs (Belosi & Rafael, 2022). Exploring Active Worlds (AW), these authors moved across an abandoned land with all the connotations of a post-apocalyptic scenario, even with intact buildings. AW is the oldest metaverse, but the spaces that are currently visible, built in the last twenty-eight years, do not differ from the skeuomorphic design approaches of contemporary worlds. General users have built the urban structures; therefore, the scenario represents a non-curated accumulation of undefined and undefinable cultures. The authors encountered streets, cities, private and public constructions, cult buildings, and natural landscapes, an entire world that looks like a memorial of a lost society.

The continuous accumulation of these buildings recalls the *Junkspace* theorized by Rem Koolhaas (2006): a space resulting from careless planning that is transformed with the expansion of urban areas and characterizes contemporary cities. According to Koolhaas, Junkspace creates apparent unity but is actually a dividing space as it defines collectivity through the lack of well-defined shared rules; it is detached from the individual, an absent space which people can only perceive as an autonomous evolution: Man is only a witness, a "reluctant participant" (Koolhaas, 2006). In Koolhaas' opinion, Junkspace may transform the world into an immense public place without limits, language, and form. So it seems to have happened in the ruins of Active Worlds, and may happen to other metaverses built on the same approach.

Belosi & Rafael (2022) also raise the problem of the inconsistency of the metaverse, which looks, in their opinion, like a "literal simulacra of the real world." Although many professionals share this point of view, there is a general difficulty in implementing a more visionary approach. Bjarke Ingels, the founder of BIG Architects, showed an experimental method of conceiving architecture in the metaverse. He was the first to design a virtual building: Viceverse, the headquarter of the digital agency Vice Media in Decentraland. Ingels described as an "architect's dream" the absence of physical constraints, budget, and law regulations, which is verifiable in his virtual work that stretches the construction in an otherwise physically impossible way (Brandoli, 2022).

Virtual architecture is the ideal dimension also for Zaha Hadid Architects (ZHA) studio, which designed the general layout and all the buildings of the state of *Liberland* on Mytaverse as a meeting point for crypto companies and events. (Massoni, 2022) Both *Viceverse* and *Liberland* are architecture projects that look like IRL buildings in their concept phase, so before static and budget calculations, but they are still human-based buildings. Architects must still carry out a commission; consequently, experimentalism is limited by the client's vision. Moreover, even visionary studios like these seem resistant to abandoning the canons of architecture in favor of creating completely innovative experiences worthy of the possibilities of contemporary virtual technology.

Unlike BIG and ZHA, George Bileca, CEO of Voxelarchitects, a metaverse architecture studio, stated in *Domus* magazine that mimicking the real world gives newcomers "a chance to adapt to this space by offering them a reassuring environment" (Signorelli, 2022). In supporting the skeuomorphic trend in the metaverse, Bileca sounds more pragmatic and determined to favor a perspective of comfort for the users. But is comfort in the metaverse really given by chairs and bathrooms? And also, is comfort the best concept to pursue in designing it?

One main reason for the skeuomorphic approach is the ease of welcoming virtual people in an environment with known functions. Still, other factors could have influenced this process. The search for ease may come from the designers themselves, who are not trained to imagine non-human spaces and may find the mimic approach a more straightforward design method. Indeed, in web3, professionals from different fields approach art and design without appropriate education. The creative economy in the metaverse can provide equal opportunities for professional and emerging architects and people with entirely different backgrounds (Matoso, 2022). Therefore, coders or computer engineers can fill the role of urban planners and architects of the metaverse. Moreover, in many virtual platforms, such as Minecraft (a game-like metaverse), and Active Worlds (a non-game-like metaverse), the users are allowed to build structures on their own, which adds variety and stylistic indefiniteness (Matoso, 2022).

Lights in the cloud of troubles

The analysis conducted on the spatial features of the most popular active metaverses led us to understand that they depend on three main factors: the development of the technology adopted, the aim pursued, and the design culture of creators.

As far as technology is concerned, in addition to the constant development of computer graphics and programs, the choice of the technology of use is predominant for constructing these worlds. VR technology is one of the possible directions. For now, however, VR devices, as well as being prohibitive from an economic perspective, cause motion sickness (Lawson, 2012), so many users of the metaverse choose to enter screen mode. In our survey, 31 metaverses out of 55, more than half, are accessible only through the screen, which leads us to think that these platforms do not estimate VR as essential for development. The elitism and cumbersomeness of current headsets hinder projects based on immersive use, which can only grow by introducing lighter and more easy-to-use devices.

From a spatial point of view, the common thread of most of the investigated metaverses is the inclination to simulate the real world. Although the levels of interpretation and the aesthetics adopted vary substantially, the tendency toward realism is dominant. Not only have architecture and cityscape been replicated, but also the real estate market, which frequently leads the aim of many metaverses to speculation on lands and propriety prices (Schreier, 2011).

The aim of the single metaverses inevitably leads their design approach and justifies spatial choices. In game-like metaverses, whose purpose is creating involvement in the game, the design follows a specific narrative and fosters identification. Instead, in non-game-like worlds, which do not respond to any declared need, except social encounters and trade, the design of spaces becomes a unique tool to create value.

Figure 6. Wiami, Wilder World, https://www.wilderworld.com

Still, in many cases, spatial research is limited to trivializing archetypes and a set of clichés. In contrast, mimesis could be an inspiring approach to conjure up scenarios that lead to reflection as an exercise to visualize the future, for example, in the Solarpunk direction (Pintarelli, 2020). The metaverses we defined as cyberpunk have great potential to evoke science-fiction scenarios and make cinematographic environments experienceable.

Aside from experimental metaverses, whose approach exploits the absence of physical limits to create a spatiality detached from the real one and leads users to new cognitive experiences based on art and space research, the lack found in the most significant number of cases is that of references to visual culture. The opportunity of the variety of visual and design cultures, an enormous wealth of metaverses globality, often seems neglected.

Being the virtual worlds created by professionals from fields that often have nothing to do with the design culture, and given that architects and designers entered the sector after the creation of platforms, the methodologies and references typical of spatial design research still need to be integrated. Therefore, the creative potential that the virtual world allows, both for the absence of gravity and physical phenomena and its narrative and interpretative possibilities, could be exploited much more to add value to users' experience.

Craft in the age of robots

Sara Codarin

Lawrence Technological University, College of Architecture and Design, USA
scodarin@ltu.edu

Abstract

Through a series of robotically fabricated drawings, the work investigates the confluence of a creative analog medium like painting and the possibilities for custom production enabled by industrial automation. A six-axis tabletop robot is programmed to execute the toolpath of parametrically-designed linework using a 3D-printed actuator that holds a soft brush pen. Instead of working on a flat bidimensional target surface, the soft brush navigates the 2.5-D space dissolving the fully controlled digital inputs into unique ink marks. A bespoke Python script in Grasshopper is developed to optimize the digital-physical translation in which software variables push the brush on the paper incrementally in predetermined ways. As a result, the final appearance of the programmed paths remains uncertain due to ongoing negotiations between the digital procedural drawings and the robotic mark-making exploration in the physical space. Each drawing reflects an extent of craft practice as it represents the unique manifestation of non-repeatable digital and physical relationships in which two-dimensional marks on paper have three-dimensional implications. By adopting a digital fabrication tool traditionally rooted in delivering efficient repetitive tasks, it is possible to establish a culture of technology that empowers designers to deviate from the predictability of the outcomes and find space for debate.

Author keywords

Robotic mark-making; digital craft; robotic drawings; digital fabrication.

Introduction and scope of the work

The recent influx of digital manufacturing tools across various trades has set the stage for convergence between design and other industries. This opportunity to integrate creative professions with innovative implementation sequences allows makers, product designers, and architects to participate in a broader interdisciplinary context (Timberlake & Kieran, 2003). Similar file formats enable different possibilities in the realm of additive manufacturing, numerical control machining, and robotic execution of recursive tasks. However, in the design field, there is still a tendency to view technological development as an external factor, particularly in digital applications (Picon, 2022). To overcome this, designers should leverage the culture of technology to reframe their agency when working with adjacent disciplines.

The research featured in this paper is situated at the intersection of computational design, digital fabrication, automation, and craft, confronting an old form of analog expressions like painting and the opportunities for custom production afforded by industrial robotics.

Some argue that automated technologies can depersonalize the creation of objects, taking away the human element and transferring the necessary skills to machines (Boza, 2006). Rather, the project endeavors to investigate the concepts of technology and craft "getting the most out of the machines" (McCullough, 1996) by reorienting tools and processes through the bespoke materialization of digital media.

Painting is used as an application case since, traditionally, learning to paint has meant understanding how to hold the brush, test the pressure on the canvas, observe the resulting brush strokes, and build confidence in the dexterity of sequential gestures. The analog process relies on the maker's embodied skills to achieve consistent outcomes (Pye, 1968), and its success depends on their ability to craft the desired outcome. As a counterpoint, in this research context, a disembodied tool is used to extend the capabilities of human hands fostering a process of re-learning how to paint within a digital ecosystem using a retired automotive welding robot. The craft-oriented approach of the project aims at unbundle automation from the serial repetition of identical copies (Carpo, 2017) through the production of parametrically-designed linework drawings with a soft brush. The brush encompasses the 2.5-D space by retracting and pushing against the target sheet of paper, following a scripted set of rules. This procedure creates one-off ink marks that can only be loosely captured in the digital simulation. Drawing iterations are collected into a sketchbook (Figure 1), an everyday object deployed for annotations and hand sketches, as a learning device (Rowland & Howe, 2001) that

Figure 1. The sketchbook filled with robotic drawings and hand annotations describing the process.

conveys evidence of material iterations to discover unexpected insights into technique and materials (Sennett, 2008).

Elements of innovation: from machinery precision to craftwork

In the state-of-the-art of design representation, new disciplinary approaches are being explored in education and practice. One example is the use of robots or cartesian plotters for making digital drawings, which is becoming a common practice in technology-focused higher education institutions (Johnson & Vermillion, 2016). In the research field, Carl Lostritto has developed a custom Python-based workflow that effectively materializes the craft of hatching with computational lines using an automatic pen plotter (Lostritto, 2016). The Material Artifact Studio, led by Marcus Farr, also employs a similar tool for augmenting drawing processes (Farr, 2020). Rhett Russo has suggested the application of CNC tooling for transferring generative drawing information onto physical media such as textiles (Russo, 2010). Curime Batliner, in the exhibition *Drawing Codes*, displays a visual art project that uses an industrial robot to layer multiple line systems with ink on paper (California College of Art, 2017). Furthermore, a compelling point of view is offered by the multimedia artist Sougwen Chung, who works in conjunction with AI-enabled robotic arms trained to follow her drawing style and gestures to create collaborative outcomes (Chung, 2020).

The common thread of these experiments carries the qualities of materials, machine timing, data structure sequencing, and design accuracy, where the intricate complexity of the drawings challenges human abilities to produce comparable outcomes by hand. However, unlike the method discussed in this research, in these precedents every aspect of the line work is controlled with a predictable translation between concept and execution. Instead, the primary interest of the presented investigation lies in the uncertainty and unpredictability of each creative effort, giving digital data expressive capacity through materiality, with the potential to translate two-dimensional intelligent drawings into three-dimensional artifacts.

Methodology: robotic mark-making

The research process involves the definition of an experimental digital fabrication workflow consisting of the following routine: algorithms-aided digital modeling to develop the linework, geometry translation into a programming language, 6-axis robotic implementation of the exported toolpaths, procedural iterations, and evaluation of the outcomes.

Figure 2. The tooling setup with five tabletop ABB robots equipped with 3D-printed pen holders.

Five ABB tabletop robots are used to make the material drawings (Figure 2). Each robot is equipped with a simple actuator, a 3D-printed pen holder that keeps a soft brush in place perpendicular to the industrial arm's end, namely the sixth axis. A plywood board serves as a reference surface for the physical workspace and is leveled by taping clay underneath the four corners. The target drawing area is given by 96g square of paper in a 6″x6″ wire-bound sketchbook.

The design outcomes result from the mathematical re-sampling of data using Grasshopper, in which the generative rules are destructured into base elements of geometry and ultimately implemented with inkwork (Figure 3). Drawing types seek three-dimensional complexity inspired by phenomena in the physical world, such as those listed below.

Fillings

This method involves dividing two parallel spline curves into segments of equal length, then projecting points onto the outer side of the curves and parametrizing them by a polar rotation. The process generates a series of blended lines that can vary in density depending on the input values used.

Folds

The script is inspired by motion efficiency studies conducted by Frank and Lillian Gilbreth (Smithsonian Institution, n.d.). It creates line patterns that mimics the biomechanics of the arm, including straight segments, joints, and rotation nodes.

Fields

The software interprets the behavior of magnetic spin forces interacting in a particle field to compute field lines through points in space. It generates the drawing layout procedurally, starting from a set of vectors on a grid.

Flowlines

Looking at Durer's hatching techniques (Durer, 1973), the script simulates water flow on a double-curved topography using parametric controls. The topography is divided into a grid of points, and all the normal directions are extrapolated relative to the surface. The flow lines are calculated by comparing the normal vectors to the point projections along the z-axis. The steeper the topography gradient, the smaller the angle between the two vectors, and the shorter the flow line.

Before exporting an executable script, the three-dimensional parametrically-designed digital drawings are scaled within a bounding box described by the values (x, y, 0.25 mm). The x and y dimensions are the size of the destination paper template, while the fixed z value represents the maximum depth the physical brush will push onto it. This results in the soft brush navigating the 2.5D space, dissolving the precise digital inputs into unique ink marks. Every ink trace intelligently conveys meaning and multiple types of information, such as the subtle relationship between the digital 3D world and the physical 2D drawings. Since the digital lines do not lay on a flat surface, the robot's speed and directionality of each toolpath affect the lines' appearance. Dense linework can merge into blended ink patches, and overlapping lines enhance the readability of discernible surfaces without compromising the visual clarity of each individual layering sequence.

A bespoke Python-based Grasshopper plug-in is developed to optimize the translation from digital to physical. In addition

to generating cartesian machine language code with accurate robotic joint configuration, the script detects the point or line closest to the top surface of the drawings' bounding box. This approach allows for calibrating the workspace and adjusting the robot's tool center point (TCP), which is the brush tip. The initial TCP, or calibration depth corresponding to the pen's length, is 178.75 mm. At each drawing attempt, the teach pendant, or robot controller, prompts the option to regulate the TCP accurately to the tenth of a millimeter. Progressively, the input number is reduced, responding to the wear of the pen tip and ink discharge. The tool settings, number of iterations, and file information are annotated in the sketchbook after each drawing. This methodical approach adds layers of knowledge about the process and deducts speculative findings from such observations. The final work demonstrates the development of new forms of drawing conveyed by an industrial robotic arm, where data and custom digital scripting are a means to pursue the materialization of craft through automation.

The research underwent two stages of optimization and review, using students' outcomes to validate project intentions and results. Between the summer and fall of 2022, the possibility of producing robot-informed parametric drawings was offered in the context of the DigitalFUTURES consortium (DigitalFUTURES, 2022), an international group in education with a focus on computational design and digital fabrication, and the Association for Computer Aided Design in Architecture (ACADIA, 2022). Both experiences were an opportunity to share the idea of amplifying the meaning of data by translating matter into computational artifacts with a wider audience. Such artifacts engage the organization of linework in a painterly manner, using mathematical functions to construct new material wholes.

Results and discussion

Leonardo Da Vinci argued that the act of painting enables the mental conversation, *il discorso mentale*, in which an image formed in one's mind helps reflect on the details to be included or excluded in the final drawing. He believed that focusing on those visual elements was more important than practicing the technique. According to Leonardo, artists do not learn to paint, but they paint to learn (Neumeier, 2012). A similar approach comes to mind while generating drawings using computation. The outcomes document the various attempts, repetitions, parameters, and circumstantial variables such as ink level, paper texture, and environmental humidity that play concurrently with the designers' whim. Different tools and software settings are used to achieve each robotic iteration, which reflects the programmed lines' length, density of target points on the generated toolpath, and pattern overlays. The nuances between sequential implementations are captured by repeatedly executing the same script on different pages (Figure 4). These observations can only be made by actively engaging in actual making (Figure 5).

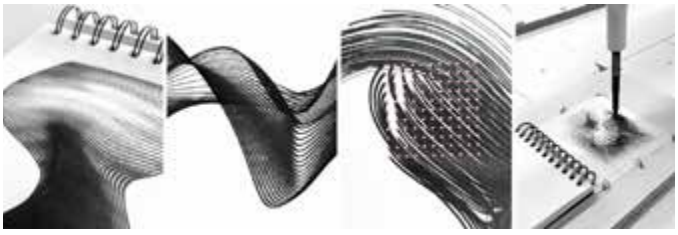

Figure 3. Sequence of linework-ink-based drawing types: Fillings, Folds, Fields, and Flowlines.

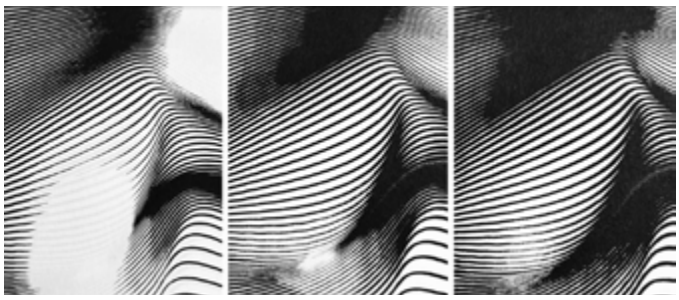

Figure 4. Drawings iterations obtained executing a script multiple times with different tool configurations.

The recurring theme of the geometric line is inspired by Tim Ingold's philosophical description of these kinds of entities. Unlike concluded objects like blobs, lines are a metaphor for interaction with the external world. They do not resolve the continuity of things or build a unified whole from disparate parts. Instead, their role is to foster a principle of movement where intricate connections form alliances of the base matter (Ingold, 2015). The dimension of motion, connected to the machine's run-time, in fact, pervades the drawings.

A methodical exploration is pursued to share different reflections on the successes and failures of this type of work.

Figure 5. Long exposure photo depicting the robotic mark-making process.

Procedural artists like Sor Lewitt, Vera Molnar, Bridget Riley, and Darel Carey are used as references to help build discipline toward a critical and diligent use of technology. Sol Lewitt's instructional wall drawings highlight the ambiguity of lines as fundamentals of geometry that exist vividly as mental constructs and less so as elements of nature. Exemplary works are the *Wall Drawing 86* (1971), in which ten thousand lines cover a wall surface evenly as an upfront conveyance for his ideas, and the etching on paper *Straight and not Straight Lines* (2003) that portrays lines as unique and individual manifestations of the human touch. This approach uses seriality and repetition as drivers to conceptualize geometric rules and relationships into base components of human thought. Vera Molnar's drawings' variations depict a pioneering agenda toward generative design aesthetics. Her collection of plotter drawings conveys a kinematic orchestration of lines controlled by rigorous arbitrary ordering systems. Among others, it is worth mentioning *Segments Inclinés A* (1984) and *Interruptions* (1968-69), where the artist begins with a grid of straight lines of equal length, and applies random rotations to each line, resulting in a densely complex pattern. The pattern suggests the presence of various forces that disrupt a regular structure, introducing an element of chaos. Bridget Riley's optical illusions, such as the paintings *Current* (1964) and *Winged Curve* (1966), require the viewers to shift their gaze across the canvas to understand the portrayed play of emotions within the abstract linework and, therefore, encourage them to think of 2D lines as an opportunity to build 3D spatiality. The robotic mark-making work also reflects contemporary visual artist Darel Carey's procedure to manipulate the perception of wall surfaces, as displayed in the art piece *Topographical Space No.1* (2016). The application of black tape to create large-scale line patterns determines a uniquely crafted experience of the space, which delivers an illusion of apparent motion.

Using a soft brush pen to negotiate agency with a robotic arm allows for finding a breakpoint between the upstream simulation and the downstream implementation. The work doesn't seek the manifestation of tooling precision but instead emphasizes subtle differences between iterations, drawing nuances, and variability of results. Additionally, zooming into the drawings augments the layers of readability of the pieces and accentuates a perceptible ink texture (Figure 6). A closer look outlines the individual ink traces, independently from the cohesive image, and brings attention to the directionality of the toolpath that generated them.

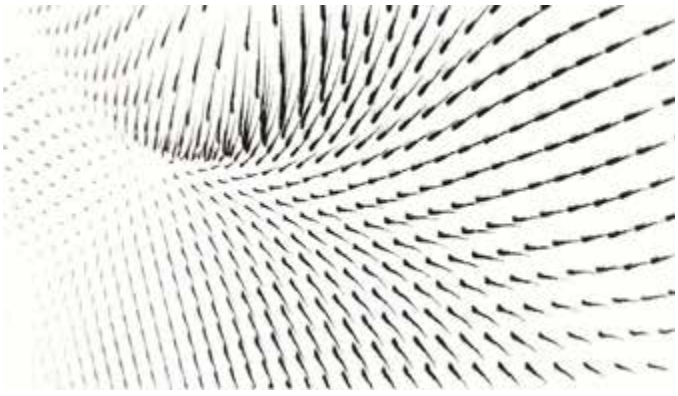

Figure 6. Zoomed in documentation into one of the robotically-implemented drawings using a soft brush.

The illustrated design tactics treat data, time, motion, actuators, and ink equally as materials.

Conclusions

In the robotic mark-making process, information gains expression through a custom workflow that merges computation and making in the presence of digital tools. Tension is discovered between the procedural aspect of the drawings and their visualization in the physical space that transcends technology itself. While the geometric control is manageable through input-output digital variables, the final appearance of the programmed paths remains uncertain. Through a planned loss of digital precision, each drawing is the unique manifestation of non-repeatable digital and physical relationships in which two-dimensional marks on a sheet of paper have three-dimensional implications.

While informed simulations offer a sense of determinacy, making physical iterations allows for exploring unknown domains and questioning established computational design rules. Recognizing their limitations and identifying gaps in their reach emphasizes material unpredictability. One intriguing realm of exploration for digital fabrication and intelligent making is understanding variations within the indeterminate regions of possibility, such as transitions, boundaries, and ink blends where points of shift occur. These conditions can be triggered by various factors, like circumstantial environmental forces, and reveal unexpected behaviors, leading to new knowledge.

Design customization involves fabrication tools, design variables, and material features. By adopting a precise fabrication technology, it is possible to diverge from the predictability of the outcomes and find space for debate. Robotics invites a sense of precision and control, but it also opens up new realms of exploration in the indeterminate areas given by temporal variability that interact with physical surfaces.

The potential to expand these processes to the third dimension and to the scale of larger components for interior design or architecture is a fascinating possibility that remains open for development. Ultimately, investigating the craft of robotically generated drawings represents an attempt to realign tools from other disciplines through the approach of designers in an advanced territory of making.

Acknowledgments

The work presented in this paper was conducted by Sara Codarin and Karl Daubmann with the equipment of the Lawrence Technological University, College of Architecture and Design. The setup and research contents were addressed to teach two workshops. The first workshop was taught for the DigitalFUTURES consortium (attendees: Nafez Maryam, Saman Keihanian, Arian Saghafifar, Secil Afsar, Tahmures Ghiyasi, Nadine Tarek, Roger Flores, Luisell Leon, Ronan Bolanos, and Romina Mehrbod). The second workshop was offered during the ACADIA annual conference at University of Pennsylvania, Stuart Weitzman School of Design (attendees: Namjoo Kim, Amir Mohammad Azizi, Seyedehgelareh Sanei, and Alec Naktin). Marisa Riley and Matthew DiMaggio participated as teaching assistants.

Light It Up: designing electronic textile with a light as a design material

Emmi Harjuniemi, Pradthana Jarusriboonchai, Jonna Häkkilä

University of Lapland, Finland
emmi.harjuniemi@ulapland.fi, p.jarusriboonchai@gmail.com, jonna.hakkila@ulapland.fi

Abstract

We are living in the era where digital futures are emerging and the technological development is rapid. Digital transformation is also happening in designing with soft materials, as the digital technology is integrated with fibers, yarns and fabrics. Therefore, the role of the textile and clothing designers changing and they are dealing with e-textiles and interactive materials. This paper explores a way to support textile designers in designing interactive artefacts. The aim of the research is to study and identify characteristics of technology as a tangible design material that designers could use along with other conventional materials, even if they are not technology experts. In this research, we are interested in developing better means for designers to prototype interactive and physical artefacts, allowing them to focus on their design vision, aesthetics, and normal practices used in their specific profession. Our goal is to identify characteristics of technology as a design material. We report of two workshops with altogether 17 design student participants using a fixed functionality electronics and a non-programmable microcontroller. We present the designers' overall experiences with the process as well as the resulting interactive prototypes. We discuss on the characteristics of ready-to-use technology that ideally would support the design, as well as integration of interactive technologies from the design education point of view. Our findings show that removing the need to do the actual programming allows the participants to focus on their design and to scope their concepts more tightly. Design students had positive opinion and experiences from the workshop as they managed to produce a functional porotype within three hours. The process forced them to work with the limitations of the technology and to process the idea how to integrate technology and light in their design. The paper contributes to the understanding of adoption of technology as a design material, and adds on to HCI education discourse which typically has emphasized the programming skills.

Introduction

We are living in the era of interactive technology, which is intertwining in our life in all sectors. The early days of technology development focused on exploring different solutions from the engineering perspective. In the last decades, the user experience viewpoint has gained more attention in the technology development. This has opened many different design opportunities in designing interactive products. For a long time, graphical user interfaces (GUIs) have been a standard interaction paradigm for people to interact with technology. However, new form factors and interactive materials are emerging. Materials are an important factor when designing and experiencing interactive artifacts (Fernaeus & Sundström, 2012). As interactive products take new physical and tangible forms, software and hardware can be perceived as a material for design instead of being just computational and processing units. This perception is argued to enable new opportunities towards designing interactive artefacts, including textiles (Hallnäs, Melin, & Redström, 2002). The familiar set of conventional gadgets, like smartphones and smartwatches, are being complemented with various different kinds of unconventional interactive products (Döring, Sylvester & Schmidt, 2013; Li, Häkkilä & Väänänen, 2018). Among these, textile interfaces are emerging (Cheng et al., 2017; Devendorf & Lauro, 2019; Freire, Honnet & Strohmeier, 2017; Häkkilä, Colley, Roinesalo, Lappalainen, Rantala, Väyrynen, 2017; Nilsson, Satomi, Vallgårda & Worbin, 2011; Perner-Wilson, Buechley & Satomi, 2010; Schneegass & Amft, 2017).

Electronic textiles, i.e. e-textiles, are made of textile materials with integrated electronic components. When e-textiles are developed, it is important to have knowledge on textile design process. However, to develop this further requires expertise from the field of human computer interaction (HCI) (Kettley, 2016). The designer needs to have at least some understanding of the programming and possibilities of the technology. When teaching the design of e-textiles, teachers with expertise on various fields are needed, as the domain falls in the intersection of design and technology. As a field, e-textiles need interdisciplinary development teams. Teachers with wide expertise can ideally share their methods and knowledge from applications, software and technologies, as well as learn from each other. This gives also the students a fruitful learning environment (Harjuniemi, Johansson & Pyrstöjärvi, 2019). De-

signing new form interactive devices requires more than just useful functions and intuitive interfaces. They need to have well-designed forms factors, be aesthetically pleasing, and fulfil cultural and social meanings (Devendorf et al., 2016).

In this research, we are interested in exploring the ways of teaching technology to textile designers. Our target was to 1) create positive experience on technology, 2) make it easy to present ideas via rapid prototyping, and 3) give the designers freedom to concentrate more on their design than to get stuck with coding problems. While we believe that learning to code could offer designers several benefits, in this paper, our focus is on enabling and supporting designers to follow their typical way of working when designing interactive artefacts, not in teaching coding to designers. We present design workshops with designers in training using microcontroller and electronics to prototype their design ideas. This paper marks the first stage in our research towards exploring technology as a design material for physical interactive artefacts.

Prototyping interactive products

The design process in a design discipline starts from researching the given problem, and then, generating concepts to solve the problem. A concept is chosen for the further development, where it matures to the production, and is finally launched to the market (Morris, 2016; Travers-Spencer & Zaman, 2008). During the recent years, we have witnessed a rapid growth in the number of microcontrollers in a form of physical and tangible computing toolkits. Microcontrollers such as Arduino or LilyPad Arduino come with an integrated development environment (IDE) and off-the-shelf electronic components, bypassing complex low-level electronic knowledge and lowering the barrier for integrating interactive technology into physical products. While designers can use these microcontrollers to create art pieces and prototypes of interactive products (e.g., Grant, 2019), it still requires skills and effort to create functional prototypes. For instance, the designer needs to consider how to embed and hide, or highlight, the conductive threads and microcontrollers in the designed object.

We have used Arduino and LilyPad in our previous courses and recognized these challenges. Because programming was new to the design students, they worried about learning and utilizing the skills which effected their ideation process. Also, the programming being an abstract, more mathematical task differs from working with the physical design materials the designers have used to, and may thus feel uncomfortable for them. In this research, we wished to further explore and identify characteristics of a prototyping technology that would allow the designers to perceive it as one material among other design materials they were working with during the design process.

Design Workshop with Design Students with Light Up board

In the workshop, we used Bare Conductive Light Up Board (Figure 1) as a probe to explore designers' preferred characteristics and expectations of technology as a design material. The Light Up Board is a microcontroller with six (6) built-in LEDs and six capacitive touch sensor electrodes. The board itself is not programmable. However, the board comes pre-programmed with six different light modes: touch on/off, dimmer, proximity, candle, spin, and dice. The behavior of the LEDs can be changed to different light modes by connecting different electrodes together.

Figure 1. From the left: 1) The Light Up Board is quite small. 2) Participant P3 testing the touch sensors on the Light Up Board using copper tapes. 3) Participant P6 testing her prototype after integrating the Light Up Board with her custom-made touch sensors and other components. 4) Participant P1 testing material to create a flame-like feeling from the Light Up Board.

We chose the Light Up Board for this design workshop for several reasons. The board includes both input and output elements, i.e., capacitive touch sensing and LED outputs, offering degrees of freedom for our participants to decide on interaction and feedback of the board. Light and LEDs are one of the most common output modalities in physical computing (Devendorf et al., 2016). Turning a single LED on/off is typically the first step in designing and building physical computing. We believed that the configurable light behavior would encourage our participants to focus on the material and the physical design and, at the same time, still offers a possibility to explore interactive aspects of the technology.

Methodology and analysis

Participants

We conducted two workshops with 17 participants (15 female and 2 men, aged 24-44 years) in total. Here, 13 participants (P1-P5, P7-P14) were Master students majoring in interior and textile design, the participant P6 was an experienced textile designer, and 3 participants (P15-P17) Master students in industrial design. The recruitment was done at an e-textile course, where the teacher distributed the advertisement to her students. Eight (8/17) of the participants had studied the basics of Arduino programming before, and responded that the programming was the most challenging part when they had to work on technology-related design projects.

Workshop setup

The two workshops were both three and a half hours long and were organized as part of an e-textile courses at the university. For the course, the participants' task was to design and build interactive prototypes with the theme of well-being and happiness (P1-P5), or a delightful item in the context of dinner party (P7-P18). The themes were given to the participants before the workshops. The participants had the freedom to use any technology for their final design. Only for the course´s first technology workshop, the participants had to explore and use the Light Up Board. Information about the workshop and used technology was sent to participants beforehand. We also had a short introduction about the board and capacitive touch sensors at the workshop. The participants were provided with plenty of Light Up Boards, soft design materials (e.g., plastic sheet, felt, fur, fabrics), different wiring components (conductive thread, copper tapes, conductive ink, crocodile clips, tin foil), and electronic tools.

Workshop procedure, data collection, and analysis

First, we asked the participants to fill in an ideation form by drawing and writing down the design ideas they were planning to create. After that, we introduced the Light Up Board

and gave introduction about the capacitive sensor: the techniques are as simple and straightforward as more crafty techniques of connecting conductive ink, conductive thread, or copper tape directly to the electrodes, as introduced by Strohmayer and Meissner (Strohmayer & Meissner, 2017a; Strohmayer & Meissner, 2017b). The participants were then asked to revisit the ideation form to describe how they planned to use the Light Up Board.

After the initial introductions, the participants had two hours to work on their prototypes. They had the freedom to use all materials and tools provided and as many Light Up Board as they wished (Figure 1). We observed and took notes of how the participants used the board and problems they encountered. The participants presented their prototypes to other participants at the end of the workshop. After that, we conducted a semi-structured group interview with the participants. The interviews were recorded, transcribed, and analyzed with an inductive thematic approach (Braun & Clarke, 2006). In addition to the workshop, we also did a follow-up study on how the workshop influenced the participants' final design (P1-P5, P7-P17) for the e-textile course, which they exhibited at the university in the end of the course.

Findings

Overall, the participants had a positive opinion and experience integrating the Light Up Board into their designs. Although the board had limited features, it still helped the participants to explore and demonstrate the interactive features in their designs and functioned nicely in the rapid prototyping workshop (Figure 2).

Figure 2. Interactive prototypes the participants created during the workshop.

It was a positive observation to see the participants enjoying the prototyping process. *"This was a fun experience for myself [...]. That was quite simple after getting to know it a bit. And I liked it, it was fun."* - P11. Positive experiences were regarded important for the e-textile studies and future projects. *"At the starting point I didn't have any experience for this kind of e-textile things, and I felt a bit nervous. But I realized that the user interface was quite a simple and even easy, and that gave me a little sparkle for the future. So I could call this as very well working package."* - P8. *"This might give a push for those people who otherwise would see this difficult."* - P7.

Material for ideation

The participants appreciated the simplicity of the Light Up Board. The plug-and-play feature allowed a prototype to be created quickly, which was important in the ideation phase in the design process when one explores and try-outs different ideas. The used time constrained forced designers to conduct fast prototyping. Having a working prototype after a half a day was also considered to be rewarding. *"I think it was easy and especially fun. I feel like it didn't make you feel like you used a shortcut even there were something done already for you. I think was, this kind um, nice, especially for fast prototyping... And we didn't have much time but still we experienced a lot, failures and successes."* - P14. However, the limited functionality of the board could restrict the idea generation. It was seen to work the best when the technology matched with the design. Participants also saw having a tangible prototype early in the process to ease the communication to others, and to be another benefit. The participants considered the Light Up Board and Arduino to complement each other.

Exploring materials and interaction possibilities

The participant P2 reported using the Light Up Board to test one of her ideas in practice. She also highlighted that the board helped her to realize where she should pay attention in her final design: *"I got to test my idea in practice with the board. I now know that in the final design, I need to have something to diffuse light to spread it to a wider area."* - P2. Furthermore, the board offered opportunities for the participants to explore different materials, e.g. conductive thread, and various interaction possibilities. Knowing that the board would always work allowed the participants to explore new materials to create touch sensors and to test whether they would work with the technology (Figure 1).

Focus on design and communicating the ideas

Bypassing the actual programming the Light Up Board allowed the participants to focus only on a few aspects when they created their prototype, particularly when developing a design concept and connecting the design with the board. This was considered as an advantage: *"for me, the coding part on a computer, then getting [the board] to work together with the code, put it into an actual prototype, and having functions work as they should and also [the design to] look good... this is a difficult combination of things. Working with [the Light Up Board] feels more certain. I don't have to focus on too many things... and it works more reliably"* - P1. Configuring the board to show the desired light pattern by using different wiring patterns was also considered simple and straightforward with the instructions.

The Light Up Board allowed the participants to communicate their design ideas in high fidelity, in a form that was close to a final product, without having to do any programming. The participant P2 show-cased a great example for using the board to communicate an interactive function in her design. P2 used two Light Up Boards to demonstrate remote touch between two *Secret Message Rocks* (Figure 3, left). Although the Light Up Board did not provide a wireless or a remote connection between the boards, a simple crossed wiring between two of them was enough to communicate the design idea and present the interactive feature of the rock.

Figure 3. Examples of the participants' final designs for the e-textile courses using the Light Up Board. Left: P2's Secret message. Right: P16's Spots of usage.

Problem solving

Although the Light Up Board did not require programming, it still helped if the participant had acquired knowledge and understanding about the technology. *"There was a problem with my prototype. I think the fabrics touched each other and created a short circuit. I moved it a bit and it's now working"* - P1. Thus, the participants knew how to fix the occurring problems. Our experience was that this was harder with programmable boards, where a teacher was needed more often.

Preferences for design

We observed that the participants first decided what function they would use or tested how it would looked like (Figure 1). The process then continued on to integrating the board with other materials and diving into the aesthetic details with the design (Figure 2). We also observed the participants spent a good amount of time choosing materials for their design, especially the materials to create the touch sensors, to cover the board, and to diffuse the light (Figure 1, right). The interview after the workshop revealed that it was important for the participants that their prototypes worked properly and were aesthetically pleasing. The participants discussed the properties of the Light Up Board as a material for design from two perspectives: physical properties and interactive functions, described in the following.

Physical properties

The participants considered electronic components in general to be *ugly*. Most of the participants' comments about physical properties of the Light Up Board were directly related to aesthetics, and in particular, how the board provided them freedom in design and allowed to create nice looking prototypes. The participants were fond of the *small size* of the board, which made it easier to hide. They also preferred an organic and conventional look and feel for their prototypes. They appreciated that the board allowed them to use different materials to create touch sensors in different form factors and to place them at various locations, depending on the design idea.

Interactive functions

The participants appreciated the different light modes the board offered. The configuration to select a light mode was simple and easy to understand. The participants would have preferred to have more interaction possibilities. Currently, the Light Up Board allowed one light mode to be active at a time. The participants wished to have multiple light modes (P2), movable LEDs (P5), different LED colors, and others sensors and output actuators (P1). However, the participants' preference was not to add more sensors or actuators to the existing Light Up board, as *"adding more [sensors and actuators] to the Light Up Board would make it to lose its simplicity. You already have Arduino if you want to do all those things"* - P1.
Final art pieces for the E-textile course

The participants continued developing their prototypes for the e-textile course, where they had to present their final prototypes that demonstrated the design concept and interactive features (Figure 3). In the exhibition piece by P2, one rock showed a hidden message when the other rock was touched. P16's piece was a scale model of an interactive table cloth that lighted up from below revealing decorative pattern of spots. In total, five designers used the Light Up Board in their final design piece.

Conclusion

In this paper, we have addressed the digital futures in the area of e-textiles and design education, and presented our exploration study of technology as a design material. We conducted two workshops with design students using the non-programmable but configurable Light Up Board as the ready-to-use technology. Our findings show that removing the need to program a microcontroller allowed the participants to focus more on their design. The board also facilitated the ideation and validation of design ideas in the rapid prototyping process. Overall, the designers liked the technology and got positive experiences in the very beginning of designing and making of e-textiles. We reported on the characteristics of ready-to-use technology that would be an ideal material for design. This research contributes in making technology more accessible to designers with limited technical background, and allowing them to start building prototypes of interactive artefacts. In this research paper, our studies were limited to textile designers. However, we believe that the results can generalize over other design disciplines where the designers work with physical material and do not have technology courses as part of their education. As future work, differences and similarities between different design disciplines in prototyping interactive products should be investigated.

Abstract

Additive Manufacturing (AM) has gained considerable footprint as one of the key components in making the 4th industrial revolution a reality. Unlike traditional subtractive manufacturing processes which account for ~ 95% waste of material, AM provides almost unchallenged and sustainable manufacturing capabilities to drastically improve manufacturing efficiency due to its nature of adding material as opposed to removing it. Thereby, reducing life-cycle material mass and energy consumed. The ability to produce functional 3D parts with customized and complex geometries directly from CAD model data is particularly attractive. While metal AM processes such as laser powder bed fusion (L-PBF) are already producing customized metal parts in applications such as dental implants, the full benefits of the technology have not been fully realized. This necessitates a global drive to learn best practices in AM towards new avenues for impact in teaching and learning, and in accelerated lab-to-market transition. The key to this is understanding inputs and outputs of fundamental AM process parameters. This knowledge will help designers and potential end-users of the technology to quickly identify parameters which are most influential to structural integrity of parts produced. Considering that very little research has been performed on knowledge transfer among AM researchers, business and higher education, this paper is aimed at capacity building in AM technology by helping inexperienced users in higher education understand the technology better. Thereby, contributing to the inclusive global drive for an accelerated transition from prototyping to commercialization. The method used involves a standard systematic triangulation of the literature to categorise and describe fundamental process parameters which influence structural integrity of parts produced by the L-PBF. The findings of this work yield new knowledge in three domains. Firstly, the influential input parameters of L-PBF are identified as powder-specific, laser-specific and machine specific parameters. Secondly, various post-processing solutions which are often used address the drawbacks associated with the technology are mapped out as thermodynamic, mechanical, and chemical post-processing treatments. Thirdly, the L-PBF is conceptualized into a framework which can help reshape the role of designers by identifying AM as a hybrid process and knowing what to look for when looking to make functional parts using technology. In this way, the paper contributes a novel skillset and attitude required to convert digital capabilities such as AM into valuable tools and methods.

Keywords

Additive manufacturing; Laser powder bed fusion; post-processing solutions; hybrid manufacturing.

Introduction

Broadly, additive manufacturing (AM) is defined as a canopy term of manufacturing technologies used to join material layer by layer to make three-dimensional (3D) products from computer aided design (CAD) models (Gibson et al., 2015; Sreenivasan et al., 2010; Wohlers & Gornet, 2014). The technologies were previously known as Rapid Prototyping or Rapid Manufacturing technologies (Atzeni & Salmi, 2012; D. L. D. Bourell et al., 2009; Doubrovski et al., 2011), because they were historically limited to production of prototypes and casting inserts. However, a more recent definition for AM according to the ASTM F2792 is "a process of joining materials to make objects from 3D model data, usually layer upon layer, as opposed to subtractive manufacturing methodologies" (ASTM International, 2013). In this way, the AM techniques remove traditional manufacturing constraints by enabling a range of benefits without the need for part-specific tooling to make customized parts with complex geometries in one piece. Thereby, providing almost unchallenged and sustainable manufacturing capabilities to drastically improve manufacturing efficiency.

The interest to optimise AM technologies has been growing exponentially over the past couple of decades. In particular, there is a growing interest in the potential of metal additive manufacturing (MAM) technologies such as laser powder bed fusion (L-PBF) (Costa et al., 2006; Rombouts et al., 2006). Hence, the focus of this work is on L-PBF. A typical L-PBF process starts with pre-processing at the control centre where a 3D CAD model of a part to be printed is well-defined, then sliced by a computer program into layers (20-100 µm thick), with a 2D image generated for each layer. The digital information is used to drive the movement of the laser inside the machine chamber with controlled atmosphere of inert gas, where the actual building takes place. In the chamber, the

building process is cyclical and consists of three steps which are repeated until the end of the construction process. Firstly, a re-coater (roller) applies an even coating of metal powder in line with the prescribed layer thickness. Secondly, the powder bed is exposed to a laser beam. The absorption of the laser radiation causes the metal powder to heat up above the melting temperature of the metal, forming a melt pool. This causes the fusion of the exposed areas of the current layer. Thirdly, the molten layer is rapidly cooled in the range of 12000 – 40000 °C/s (Chastand et al., 2016; Gokuldoss et al., 2017; Liu & Shin, 2019), depending on the amount of energy supplied. The process is then repeated with a new layer of powder coated on the previous layer until a desired part is built from thousands of individual layers in succession.

Although the AM technology has been around for over 30 years with functional parts already applied in industries such as the aerospace, automotive and biomedical, the full commercialisation has not been realized. The widespread implementation of AM technology is hindered by process inherent attributes that result in the as-built parts not meeting industry requirements. In this work, the as-built condition refers to parts as they come out of the AM machine. It is at this point where the consideration of AM as a hybrid process for making functional parts becomes critical due to the incorporation of conventional subtractive manufacturing technologies to obtain a part which can be regarded as qualified for application. The key towards meeting specific industry requirements is understanding the influential input parameters, attributes of the as-built condition and suitable post-processing solutions. In contributing towards a higher technology readiness level for metal AM, this paper is a knowledge transfer contribution which addresses three categories of AM as a hybrid process (inputs, outputs and the integrity engineering). Thereby, contributing to the inclusive global drive for capacity building in higher education towards an accelerated transition from prototyping to commercialisation of AM technology. Understanding the AM technology in line with the strategies presented in this paper will effectively help smaller companies and end-users develop their own innovative designs and products towards a successful participation in digital futures.

Approach

The first part of the strategy was to identify key focus areas of the AM process chain. The schematic diagram showing this approach is shown in Figure 1. The approach follows a standard systematic literature inclusion/exclusion criterion which according to (Tranfield et al., 2003) ensures quality and scientific reproducibility.

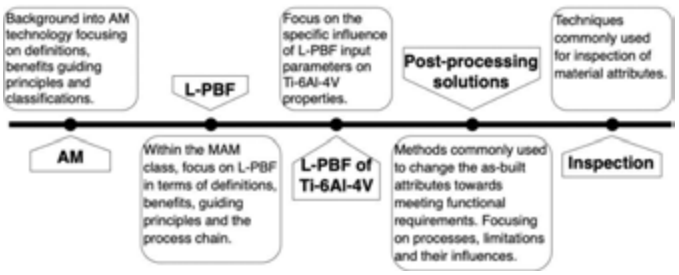

Figure 1. Schematic diagram showing strategy used to identify key aspects of AM for this work.

Since AM is broad and includes different techniques and materials, it was important to identify key areas in terms of definitions, classifications, foundations, and guiding principles. The second part of the strategy was to show the criterion in selecting the relevant literature. This meant identifying a combination of relevant keywords which were used as search terms. Table 1 shows these search terms and the reasoning behind each search term combination.

Table 1. List of chosen literature search terms and the respective reasons behind the choices.

Database search terms	Reasoning
Additive manufacturing (AM)	AM is a canopy term referring to a variety of techniques. It was important as a general broad understanding of the technology, particularly in comparison to subtractive manufacturing technologies.
Metal additive manufacturing (MAM)	AM is well-known for processing polymers. Hence, it was important to highlight focus on MAM.
Laser powder-bed fusion (L-PBF)	The focus of this project was on LPBF as one of many MAM techniques.
L-PBF/SLM and Ti-6Al-4V	L-PBF is used for processing many materials. Hence, this search term was important to specifically combine the technology with Ti-6Al-4V.
Ti-6Al-4V attributes (microstructure, porosity, residual stresses, and surface roughness) AND LPBF/SLM	These were the core search terms of this project. Combining each of the four attributes with the technology helped narrow and focus the research project into specific functional attributes.

The specific material chosen to explain the L-PBF is Ti-6Al-4V. The triangulation shown in Table 1 was intended to identify correlations in terms of the main structural aspects of the material, such as microstructure, porosity residual stress and surface roughness. This was done to understand what is known and established from the core contributions, highlight the extent to which consensus is shared, and provide a detailed audit trail back to the core contributions to justify the links between the correlations. A summary of the literature timeline and the types of literature contributions used in this work is shown in Figure 2 (a) and (b) respectively. The number of articles per year as shown in Figure 2 (a) is an indication of the database search output and not necessarily a reflection of the number of articles selected for this work. A significant number of these articles were excluded in this work following a successive screening by title, abstract and full article reading.

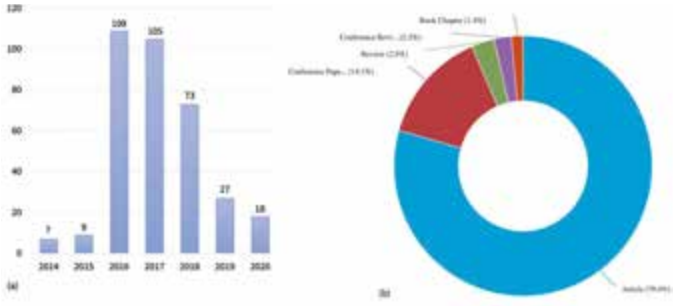

Figure 2. Literature timeline of articles which were screened for this study.

As shown in Figure 2 (b), majority of articles which contribute to the body of knowledge on AM are journal articles (roughly 79%). This can be seen as confidence boost in the quality of work presented in this paper. This is based on the high requirements for journal article publication.

Findings

Influential L-PBF input parameters

The influential L-PBF input parameters are classified as either powder specific (characterized in terms of particle-size and shape and powder flowability), laser parameters (characterized in terms of spot size, power, exposure strategy and scanning speed) and machine-specific parameters (characterized in terms of building path, layer thickness and system atmosphere) as shown in Figure 3. Although this is the case, it is important for the end-users of the technology to know that these parameters do not independently influence variables of L-PBF. This means there is no one possible set of processing parameters for a given material property. It is rather a collective influence of these parameters which needs to be considered. Generally, only about 10 % of L-PBF input parameters have about 90% impact (Schmidt et al., 2017).

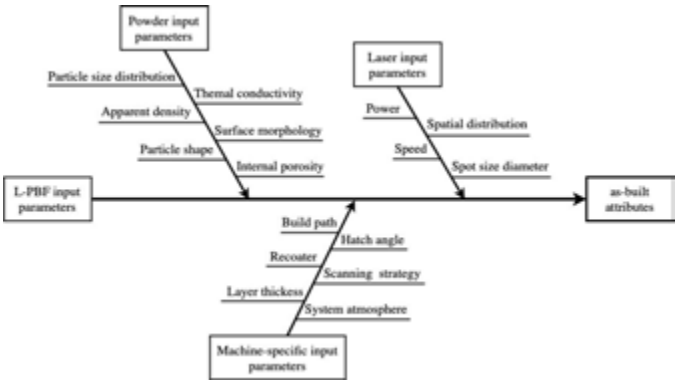

Figure 3. A schematic diagram showing a summary of L-PBF input parameters.

Different combinations of input parameters shown in Figure 3 have been widely explored to optimize the attributes of as-built parts. For instance, (Thijs et al., 2013) suggested optimum process parameter of 200W, 1400 mm/s, with scan spacing 105 µm for aluminium alloys. (Brandl et al., 2012) used 250W, 500 mm/s, 150 µm scan spacing, with 50 µm layer thickness to achieve defect-free parts. Table 2 gives an indication of how the optimized parameters for Ti-6Al-4V compare to the commonly used L-PBF input parameters.

Table 2. Summary of common process parameters compared to optimized process parameters for Ti-6Al-4V (Kasperovich et al., 2016; Kumar et al., 2018; Majumdar et al., 2019; Vilaro et al., 2011; Xu et al., 2015; Zhao et al., 2016).

Input parameter	Common usage range	Optimized
Laser power	80 – 280 W	~200 W
Laser scan speed	200 – 1200 mm/s	~500 mm/s
Layer thickness	20 – 50 µm	~30 µm
Particle size range	15 – 45 µm	~37 µm

With optimized process parameters, better L-PBF outputs can be expected such as global part density in the range of 99.0 – 99.9 % (Kasperovich et al., 2016; Kasperovich & Hausmann, 2015; Xu et al., 2015; Zhao et al., 2016). Additional process parameters shown to be effective include the preheating of the building platform to minimize residual stresses.

Output parameters of L-PBF

The L-PBF outputs refer to the characteristic aspects of a specific material in the as-built condition. The consensus of more than 90% of the selected literature studies reported that the L-PBF as-built Ti-6Al-4V inherently consists of martensitic microstructure, high porosity, high residual stresses and high surface roughness as shown schematically in Figure 4, and that these are not suitable for most industrial applications.

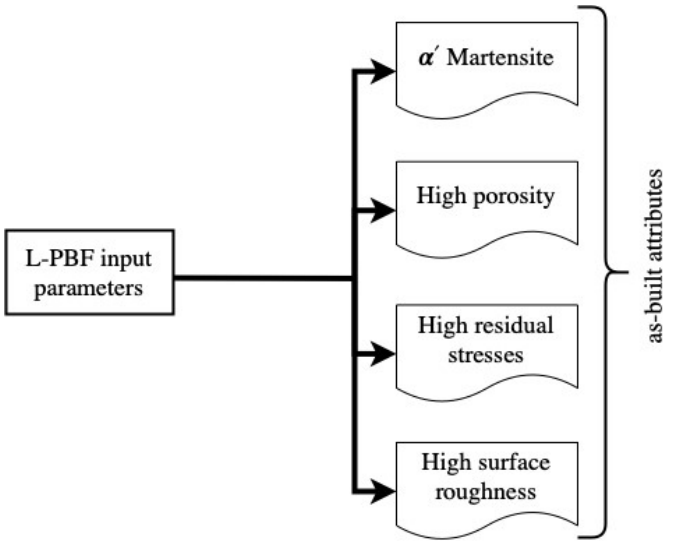

Figure 4. Schematic diagram showing typical L-PBF as-built attributes of Ti-6Al-4V.

The key when conceptualizing the L-PBF outputs is to understand the influential features of these attributes and how they affect material properties, which in turn determines whether the specific industry requirements are achieved or not.

Integrity engineering

Post-processing is inevitable for LPBF as-built Ti-6Al-4V parts because the minimum post-processing required to obtain the as-built part involves mandatory processes such as powder recover, stress relief heat-treatment, part removal from the build plate and the removal of support structures. Beyond the mandatory post-processing, the requirements for additional post-pro-

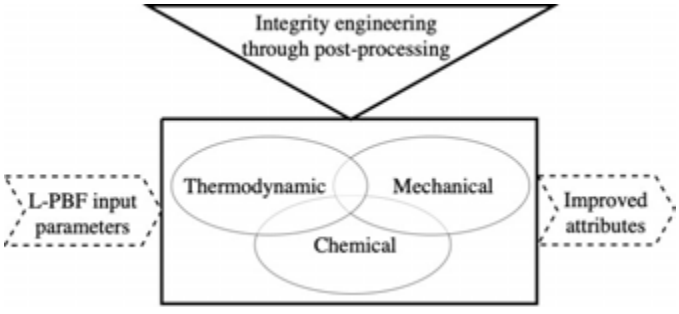

Figure 5. Schematic diagram showing where the integrity engineering fits within a typical AM process chain.

cessing solutions are material and industry specific. These can include a combination of thermodynamic, mechanical, and chemical treatments as shown schematically in Figure 5.

Thermodynamic processes are those that involve significant heat, such as heat-treatment strategies and Hot Isostatic Pressing (HIPing). Mechanical and chemical processes are surface treatments intended to improve surface finish and related properties. These categories are linked to each other through integrity engineering to emphasize that no single one is enough to achieve all material specific requirements for industry application. The choice and succession of application is often limited by availability and costs. The indication of how these solutions are used to address issues related to the four as-built attributes follows in the discussion section.

Discussion

Influential L-PBF input parameters

There is no consensus in terms of which parameters influence specific L-PBF as-built attributes. As such, the general recommendation is that a thorough optimization of L-PBF is the key to obtaining favourable as-built products. Such favourable products are dependent on specific industry requirements. This means designers would typically need to clearly define their design requirements and choose AM where it provides the most competitive advantage. Hence, understanding a proper balance of the input parameters shown in Figure 3 would need to be considered for each design requirement.

The paper brings awareness to designers to have some level of understanding of the impact of raw materials on their design requirements. In the current work, this means understanding for instance, the origin of influential parameters and be able to control such parameters to best fit the demands of their design requirements. For instance, it is important to understand that powder characteristics are a direct result of the technique used to produce that powder. Although there are several powder production techniques, the common ones include gas atomization (GA), rotary atomization (RA), plasma atomization (PA), water atomization (WA) and plasma rotating electrode process (PREP) (Anderson et al., 1991; DebRoy et al., 2018; Sames et al., 2016; Seki et al., 1990). All these powder production methods are capable of producing powder particle sizes in the range 10–60 µm (DebRoy et al., 2018), which is the size typically used in L-PBF. However, the quality of such particles is determined by characteristics such chemical composition, particle size distribution, shape, surface morphology, humidity, flowability, apparent density (packing density), melting temperature, thermal conductivity, and amount of internal porosity. Although the impact of each of these characteristics can be dissected further, ultimately, all powder characteristics determine the energy absorption characteristics of the powder-bed, porosity in parts and the surface morphology of final part. Generally, optimum properties are achieved as a result of good powder processability, which is in turn achieved by smooth particle surface morphology and uniform particle size distribution (DebRoy et al., 2018; Yadroitsev & Smurov, 2011). The main trade-off in the selection of powder size is cost vs surface finish. Smaller powder particles may cost more as a feedstock (than a larger size range) due to the cost of producing such particles.

The most influential of the laser-based inputs are scanning velocity and power input as they play the critical role in the degree of melting achieved, which can either be no melting, partial melting or complete melting (Hanzl et al., 2015; Mahamood et al., 2013; Zaeh & Ott, 2011). Understanding this offers designers an opportunity to select appropriate laser parameters to achieve optimum material properties. For instance, based on the study by (Shi et al., 2016), high velocity means low melt-pool temperature, while low velocity means the laser spends longer time at a specific spot, which means higher melt-pool temperature achieved. This trend was also shown by (Li & Gu, 2014), who observed a decrease in temperature of the melt-pool from ≈1500 to ≈1050 °C and a thermal gradient decrease from a maximum of ≈15 to ≈13.5 °C/µm, given an increase in scanning velocity from 100 to 400 mm/s during their study of parametric analysis of thermal behaviour during SLM processing of Al6061. (Li & Gu, 2014) also studied the influence of laser power on the melt-pool and reported that increasing laser power causes an increase in the size of the melt pool and the maximum temperature. The authors reported this after seeing an increase in the melt pool from 64.3 x 55.8 x 33.7 to 209.2 x 140.4 x 81.2 µm and an increase in maximum temperature from ≈60 to ≈1800 °C as well as temperature gradient from ≈10 to ≈22 °C / µm given an increase in power from 150 to 300 W (Li & Gu, 2014).

Machine-specific input parameters are perhaps the most influential on material properties of L-PBF parts (Seifi et al., 2016). Since there are so many L-PBF machines, the extent to which these characteristics influence material properties of L-PBF parts is machine-specific. The key is choosing the correct combination and understanding their influence on specific materials and the costs involved. For instance, different machines have specific patented scanning strategies associated with several advantages such as reduction of temperature gradient in the scan plane by distributing the process heat, which results in reduced residual stresses (Sames et al., 2016). Additionally, some scanning strategies have the advantage of having no major stress build up in one direction and so the anisotropy in fabricated components is reduced (Shipley et al., 2018).

Output parameters of L-PBF

The L-PBF outputs are often considered important if they play a significant role in determining the structural integrity of parts. For instance, two influential features of the martensitic microstructure are the acicular the α' laths (typically 300–500 nm thick) and the columnar prior-β grains (typically wide and long with the mid-length average width of about 103±32 µm) (Agius et al., 2018; Kumar & Ramamurty, 2019; Simonelli et al., 2014). Generally, the tensile properties associated with this type of microstructure are high ultimate tensile strength (UTS > 1000 MPa), high yield strength (YS > 900 MPa) and a low elongation at fracture ($\varepsilon < 8$ %). In terms of the influence, the acicular α' structure is responsible for retarding the movement of dislocations and cracks, thereby influencing strength associated with this microstructure. On the other hand, the prior-β grains are responsible for the anisotropic behaviour (in both tensile strength and elongation at fracture) usually associated with this type of microstructure.

Regarding porosity, the two types of pores common in L-PBF as-built Ti-6Al-4V are lack-of-fusion pores (typically 100-150

µm long and gas-entrapped pore (typically 10-100 µm) (Agius et al., 2018; D. Bourell et al., 2017). The global porosity in these parts typically ranges between 0.1–0.5 vol% (Agius et al., 2018). Considering that the requirement for global porosity in parts to qualify for application is less than 0.05 vol%, it is evident that porosity is higher in the as-built condition. Hence, the need for post-processing solutions.

Generally, residual stresses are classified according to the scale at which they occur, which can either be microscopic or macroscopic (Kandil et al., 2001). The microscopic residual stresses are usually more localized with minimal effect on mechanical properties. On the other hand, the macroscopic residual stresses typically vary over a very large distances (across the dimensions of the part) and as such, are typically associated with detrimental effects on material properties. The macroscopic residual stresses are inevitable in L-PBF processing due to high thermal gradients inherent to the process. The measure of how detrimental the residual stresses are is often depended on whether the stresses which occur in parts are either compressive or tensile residual stresses. Compressive residual stresses are generally beneficial, while tensile residual stresses are detrimental. The stresses referred to in this paper are the tensile residual stresses, as these are inevitable due to the temperature gradient mechanism (TGM) inherent to the L-PBF process. The residual stresses observed in the as-built parts are typically reported in the range 100 – 500 MPa (Vayssette et al., 2018). These stresses are higher than the maximum requirements in industries such as the aerospace for instance, which specifies a maximum of 100 MPa residual stresses for parts to qualify for application.

Surface roughness is commonly defined by mathematical parameters such as arithmetic average roughness (Ra), ten-point height roughness (Rz) and maximum height of the profile (Rt) (Gadelmawla et al., 2002). The Ra, calculated as the average value of several measurements carried out over a constant length, is the most universally accepted roughness parameter for general quality control. The Ra values of L-PBF as-built Ti-6Al-4V usually fall between 5–40 µm (Kasperovich & Hausmann, 2015; Palanivel et al., 2016; Townsend et al., 2016; Vaithilingam, Prina, et al., 2016), and this is too rough for most industrial applications. The detrimental effect of high surface roughness is an increased influence on fatigue crack initiation. Even though there is no consensus about the parameters which influence surface roughness the most, the poor surface quality of L-PBF parts is predominantly linked to three factors as, open pores and other defects on the surface, partially melted powder adhered onto the surface and the staircase effect.

Integrity engineering

Since the as-built microstructure does not always meet the industry requirements, the problem-solver of the martensitic microstructure is post-processing through annealing heat-treatments. These heat-treatments are usually carried out for two reasons; to decompose the α' martensitic microstructure into a dual-phase $\alpha + \beta$ matrix and to change the size and morphology of the prior-β grains. The common types of heat-treatments explored for this reason are sub-transus (≤ 980 °C), super-transus (≥ 980 °C) and duplex anneal heat-treatments. The latter which involves two annealing temperature stages combined with specific holding times followed by two stage cooling methods. An important consideration is that the heat-treatments carried out in AM are not typical. Therefore, depending on the type of heat-treatment, holding time and method of cooling, a variety of microstructures can be achieved.

If porosity is below the minimum specification, there is no detrimental effect on mechanical properties. This is because the smaller number of pores present in the part (microscopic) the denser a part is, which in turn means better quasi-static properties. However, if porosity is above the minimum specifications, the potential problem-solver is hot isostatic pressing (HIPing). Compared to the range of 0.1–0.5 vol% global porosity typically seen in the as-built conditions, a typical HIPing procedure can reduce porosity in parts produced by L-PBF to the range of 0.01–0.05 vol%, which is less than the minimum allowable global porosity of 0.05 vol%. A HIPing procedure is often specified along with functional requirements, but the procedure is alternatively available in standards such as the ASTM F2924-12A. The process has a combination effect whereby the pressure used enables the closure of internal pores and cracks to increase material density while the inherent heat-treatment effect influences microstructure refinement. Subsequently, both quasi-static and dynamic mechanical properties are improved.

Despite the efforts to reduce the residual stresses by input parameters such as base-plate pre-heating and re-scanning strategies, the residual stresses seen in the as-built parts still fall in the range of 100–500 MPa. Residual stresses in this range are a problem because they are still higher than the maximum allowable stresses of 100 MPa for most parts' application. Since residual stresses are a result of thermal gradients, the most effective way to reduce them is through high temperature stress-relief heat-treatments. In L-PBF parts, this is preferably carried out as a mandatory process before parts are removed from the baseplate to avoid the possibility of warping (Yang et al., 2017). These heat-treatments are specific to the material used and typically carried out at temperatures much lower than the recrystallization temperature so that the microstructure is not affected, but high enough to enable the desired atomic mobility. For instance, an effective reduction in residual stresses in Ti-6Al-4V produced by L-PBF is typically achieved after heat-treatments ranging between 480–650°C for 1–4 hours, followed by either furnace or air cooling.

The improvement of surface conditions of parts produced by L-PBF is crucial for most industry applications, particularly for parts designed for load-bearing applications because the crack initiation at the surface is minimized. Several surface treatment techniques in the literature have proven to be effective in reducing surface roughness (Vaithilingam, Goodridge, et al., 2016) thereby, improving the mechanical properties, in particular, improving dynamic properties. For instance, the reduction of surface roughness in L-PBF Ti-6Al-4V parts is typically achieved by mechanical and/or chemical polishing post-processing treatments. The operating principles and parameters of both treatments (mechanical and chemical) are widely known to the research and manufacturing communities and involve well-established standards and each with advantages and disadvantages towards achieving desired

surface finish. Overall, mechanical treatments such as machining work best on flat surfaces. For complex, high-quality near-net parts, the polishing and chemical milling treatments become the ideal post-processing solutions to achieve desired surface finishes and geometrical tolerances.

Understanding AM as a hybrid manufacturing process

The process using AM to produce functional parts which qualify for industrial application needs to be considered as a hybrid manufacturing process because the AM parts in the as-built condition fail to meet most industrial applications. Hence, post-processing solutions are deemed essential to link the as-built parts with industry specific functional requirements. This is achieved by integrity engineering through the post-processing solutions discussed in this paper. An overview of a typical L-PBF hybrid process chain is shown schematically in Figure 6 to show the process chain of how to get to an AM part which can be considered as qualified for application. In summary, the process starts with input parameters which include the actual building process to obtain the as-built parts. The as-built parts are then post-processed to improve material properties. This is followed by inspection and validation to check whether functional requirements are met or not. If met, the parts qualify for application and if not met, the process repeats from post-processing or with new parts printed from scratch.

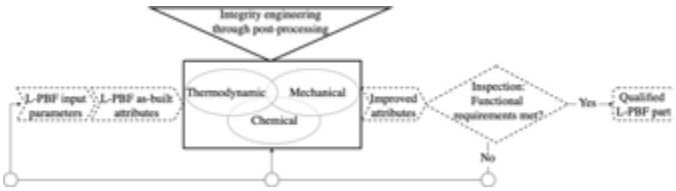

Figure 6. Schematic illustration of a typical L-PBF as a hybrid process chain to qualify parts.

Since there is a significant range of post-processing solutions available, some important considerations are as follows. The important parameters to consider when conducting thermodynamic processes include the type of heat-treatment, temperature, holding time, cooling method and pressure. The important parameters to consider when carrying out mechanical processes include operating speed, contact pressure and lubrication. The important parameters to consider when conducting chemical processes include the type of electrolyte concentration, applied voltage, temperature, and time of treatment. Authors in the field of AM have described and reported improved quality of L-PBF parts because of such post-processing approaches. The attempts have been successful in meeting specific functional material properties such as porosity (Fousová et al., 2017), tensile properties (Ter Haar & Becker, 2018), fatigue life (Chastand et al., 2016; Edwards & Ramulu, 2014; Kasperovich & Hausmann, 2015), surface finish (Kumbhar & Mulay, 2018; Strano et al., 2013; Townsend et al., 2016; Vaithilingam, Goodridge, et al., 2016) and geometrical accuracy (Umaras & Tsuzuki, 2017).

The importance of post-manufacture inspection included as part of Figure 6 is that it ensures the final, finished part meets all the required specifications. A variety of inspection methods exist and are often categorized as either destructive or non-destructive tests (NDT). Destructive methods are those which involve parts being destroyed to obtain material information and include standardized techniques such as tensile, compression, shear, metallography, hardness, fatigue, and fracture toughness tests. Since these tests are destructive, they are not performed directly on the finished parts. Instead, on representative test samples which are built and post-processed in the same conditions as the final part. Therefore, these types of tests are often regarded as precursors to the NDT as quality control techniques and statistical evaluations of product batches (Slotwinskic & Moylan, 2015). On the other hand, the NDTs are often used as inspection methods to detect and evaluate flaws (irregularities or discontinuities) in traditional manufacturing. While NDT techniques are well-developed and standardized for inspection of parts produced by traditional manufacturing processes, their inspection capabilities, and acceptance criteria for AM parts has not been fully established (Taylor et al., 2016). Nonetheless, some of the NDT methods have been investigated and shown to be applicable for inspection of AM parts. Although some of these methods have been widely investigated for inspection of metal AM parts in recent years, one of the major limitations of their use has to do with complex geometries typically produced by AM (Sharratt, 2015). Such geometries pose a challenge when it comes to the NDT techniques such as ultrasonic, eddy current, and radiographic test methods for instance. This is because accessibility to surfaces is not necessarily guaranteed for complex parts. Nonetheless, besides its limitations relating to detectability, sensitivity, accessibility and ease of use, x-ray computed tomography (XCT) remains the promising technology for examining parts of complex geometry (Sharratt, 2015). The key benefit of XCT is its ability to evaluate multiple criteria at once and to image the interior of samples or parts.

Conclusions

To give more insight and confidence in AM technology, quality assurance and life span of parts must be carefully investigated to understand the technology. This involves integration of three factors: technology, skills, and industry requirements. Currently, such understanding is not widely available and most of the time the focus on these factors is usually separated as opposed to being integrated. The work presented in this paper contributes to such understanding. Therefore, three conclusions can be drawn from the findings of this work. Firstly, it is important to consider the L-PBF as-built attributes as a collective that determines structural integrity of parts produced. Secondly, the paper summarises a body of knowledge through a technical review of the L-PBF processing of Ti-6Al-4V and highlights a definitive need for post-processing solutions to address the as-built issues predominantly seen in these parts. Thirdly, the paper proposes a strategy for understanding AM as a hybrid process instead of the common practice of using the technology as a prototyping procedure which ends with non-functional parts in most industries. The strategies presented in this paper are intended as knowledge transfer in higher education and aid the new end-users of the technology to quickly identify influential parameters of the various stages of AM as a hybrid process. Thereby, making it easy to know what to look for when designing for AM.

Abstract

Despite the spread of new circular materials and digital technologies, designers' awareness of how to practically implement them is not fully achieved yet. Therefore, new ways to foster digital craftsmanship skills and experiential knowledge should be implemented. This contribution aims to reflect on digital technologies, especially 3D printing, in speculative design approaches with circular materials through the development of the materials library from the FiberEUse research project. This "materials and product library system" is an adaptive experiential tool that goes beyond merely collecting physical materials samples. It also includes possible products, speculative applications, and non-textual content, merging physical and virtual learning experiences. Its physical section comprises a materials library with flat samples of the materials and a product library with applications or cut-offs of some meaningful details of products.

By analyzing the library's development path, three incremental phases emerge in terms of interaction with circular materials and 3D printing for speculative approaches: experiencing materials, technology, and products. The first phase aims to preliminary explore the potential and qualities of materials through traditional craftsmanship skills. The second phase deal with the first experimentations with the technology, understanding the limits and influence on the expressive-sensorial qualities. The third phase is oriented toward new applications, investigating the possible outcomes from a formal point of view. As a synthesis, the tinkering process emphasizes the active role of experiential tools in spreading the use of circular materials and digital technologies, helping acquire new skills through an experiential approach. It also adds a further level to the exploitation of materials libraries, paving the way for new possible uses, i.e., distributed replication, participation, and implementation. As a result, materials libraries assume a more active role in the experiential knowledge transfer even during their development, representing a practical path to building new skills. Hence, a new model of materials libraries may emerge as a replicative learning and speculative design tool.

Circular economy, Materials library, Additive Manufacturing, Materials experience, Experiential learning.

Introduction

Fostering new responsible ways of production and consumption is becoming increasingly important from an environmental, economic, and social point of view. Among those, Circular Economy (CE) models have demonstrated to help in encouraging sustainable practices by preserving the resource flows and values as long as possible (Reike et al., 2018). Considering the design and production of new goods and products, switching to sustainable materials and technologies is recognized as a possible strategy for implementing cleaner practices, as well as circular economy practices for design (Sumter et al., 2021). Among those, the use of new waste-based or recycled materials and digital technologies, i.e., 3D printing, is gaining attention within the design research and practice, helping to establish new bottom-up, collective, and practical design experimentations or tinkering activities with materials (Despeisse et al., 2017; García-Ruiz & Lena-Acebo, 2022; Parisi et al., 2017; Rayna & Striukova, 2021; Veelaert et al., 2020). Within this context, digital fabrication tools have mainly been studied at the intersection with CE, resulting in different strategies and approaches to put its principles into practice, i.e., through repairing, distributed economies, upcycling, and recycling initiatives from local waste streams (Colorado et al., 2020; Despeisse et al., 2017; Mikula et al., 2021; Oyinlola et al., 2023; Ponis et al., 2021; Sauerwein et al., 2019; van Oudheusden et al., 2023). Moreover, the discipline of material design is demonstrating its crucial contribution to spreading the use and knowledge of new materials linked with digital technologies, especially by experiencing materials and envisioning them into concrete artifacts through speculative design approaches (Clèries & Rognoli, 2021; Galloway & Caudwell, 2018; Kretzer, 2021; Pedgley et al., 2021). However, designers' awareness of using these new circular materials and sustainable technologies is not fully achieved yet (Pedgley et al., 2016; Romani et al., 2021). Therefore, new ways to foster digital craftsmanship skills and experiential knowledge should be

implemented in the next years. A possible way is represented by experiential tools, especially materials libraries, aiming to facilitate the knowledge transfer of unquantifiable practical contents, i.e., expressive-sensorial qualities and skills (Akın & Pedgley, 2016; Nimkulrat, 2021; Wilkes & Miodownik, 2018).

This work analyzes the use of digital technologies, such as 3D printing, in speculative design approaches linked to real exploitations of new circular materials. The analysis is based upon a reflective practice approach focused on the design and development path of a "materials and product library system", the materials library of FiberEUse, a research project on composite materials from recycled glass and carbon fibers. This new library merges a physical and a virtual learning experience through different media, i.e., physical samples, product cutoffs, and visual supports. It allows speculating on new possible applications by experiencing and tinkering with its different content. After introducing the case study, the work briefly detects three incremental phases of interaction and engagement with circular materials and 3D printing: (i) experiencing materials; (ii) experiencing technology; and (iii) experiencing products. Each of them is linked to a part of the materials library, as well as physical contents and possible interactions with the experiential knowledge. The experiential approach to the materials library helps in envisioning and speculating on new plausible applications through a practical approach. A fourth phase is then outlined as a possible way to foster the transfer of new digital skillsets and attitudes amongst designers and practitioners, which means (iv) experiencing the path to the materials library development. The tool assumes an active role in transferring these new digital craftsmanship skills as a participative learning and experiential tool to be locally replicated, modified, and implemented, including the development process in the learning activities.

Methodology

This work relies on the approach of Reflection-in-action, or reflective practice, in the research area of materials design (Clèries & Rognoli, 2021). Practical experimentations and projects are used as inquiry tools to reflect on practical issues and create new theoretical knowledge (Goldkuhl & Sjöström, 2018; Reich, 2017; Schön, 1992). As part of the Research Through Design (RTD) methodology, the role of design experimentations, artifacts, and products is to conceptualize and generalize through reflections to be collected during and after the practical inquiry itself (Friedman, 2008; Horváth, 2016). From literature, similar practical approaches in design research have been theorized by different scholars. Each approach usually emphasizes different aspects linked to the use of artifacts and practical inquiry tools within the design research discipline, i.e., as "designerly ways of knowing", tacit knowledge and reflective practice, or deriving embedded rules from prototyping (Cross, 1982; Friedman, 2008; Schön, 1992). In this work, the development of the Materials Library is considered a Reflection-in-action activity since it could be seen not only as a product to be properly developed and designed but also as a research path to be analyzed to build new knowledge. Hence, the whole design process of the tool may be seen as a practical inquiry that helps in understanding the use of speculative design approaches linked to the knowledge of digital technologies and new emerging materials, such as 3D printing and waste-based materials. Nowadays, Materials Libraries are seen as wider systems whose aim is not only to support materials selection by showcasing physical samples and sharing technical data.

In this work, Materials Libraries are intended in two different ways: as experiential tools to foster and speculate on the use and knowledge of emerging materials and technology or as practical design experimentations to generalize some theoretical knowledge. The first meaning is briefly resumed through the selected case study and represents the aim of this tool as a product and/or system. The second one corresponds to the methodology of this contribution, allowing for reflecting on the possible speculative experiences that may be encountered by interacting with Materials Libraries and digital technologies. The authors were directly involved in the design path of the library, resulting in a first-person approach to the design experimentation. In this way, the reflections during and after the inquiry were used to theorize on the topics of this contribution. In detail, reflections were collected by considering the structure and taxonomy of the tool during its use in a demo presented at the Milan Design Week 2021, as well as internal workshops to the project's partners, i.e., waste suppliers and designers of the products.

Speculative tinkering with materials

Using materials libraries creates a possible path to envision new applications and physical artifacts through an experiential approach. In other words, these tools represent a valuable option to foster speculative design approaches. According to Galloway and Caudwell, Speculative Design represents a meaningful way to ask new questions and generate plausible scenarios to tackle complex issues in design research (Galloway & Caudwell, 2018). In addition, speculative approaches may also be exploited in the research areas of materials design and Design for Additive Manufacturing, leading to practical experimentations and interactions with emerging materials (Bauer, 2019). To this end, designers and researchers are directly involved in the process of tinkering and experimenting with new materials formulations and process parameters, creating a range of physical output that materializes their practical work. From literature, this approach to materials is also known as Material Tinkering, a "practice of direct, creative, and iterative experimentation on materials" emphasizing the physical act of manipulating matter (Parisi et al., 2017; Rognoli & Parisi, 2021). During the experimentation process, the different material samples may foster the generation of new alternative scenarios and words, as well as applications, resulting in speculative actions (Rognoli et al., 2021; Rognoli & Ayala-Garcia, 2021). The tinkering activity is, therefore, embedded with speculative design approaches, defining proper "speculative tinkering" practices. Within this context, speculative tinkering is meant to envision new applications and scenarios through the iterative manipulation of emerging materials and technologies, often including other socio-ethical topics such as sustainability.

Case study: FiberEUse Materials and Product Library System

The case study focuses on designing a Materials Library to showcase materials and possible applications from the recycling and reuse of glass and carbon fibers from waste and products at their end-of-life, such as construction structures, wind blades, and aerospace components. The practical exploitations within the library also want to foster the integra-

tion of new waste-based materials through examples in real contexts, for instance, from industries or design practitioners. The new Materials Library is meant to spread the knowledge related to these new solutions, including different contents and materials samples. The experiential tool developed within FiberEUse widens the concept of materials libraries by including materials samples, new products, possible applications, textual and non-textual content. The "Materials and product library system" is divided into two main parts, the Physical Library and Virtual Library, merging the concepts of tangible/virtual fruition, as well as local/distributed use (Romani et al., 2022). This tool can be used during the different phases of the design process, making more accessible the knowledge of emerging materials and technologies through flat samples, cutoffs, pictures, renderings, and numerical data. The virtual part is visible at https://fibereuselibrary.com, while the physical one can be freely used on request. Only the physical part would be considered for the sake of this work, which is divided into two main parts. The first one, the Physical Materials Library, collects flat materials samples according to the finishing, kind of waste, and concentration (Fig. 1a). The second part, the Physical Product Library, showcases cutoffs and parts from physical products using the new materials. The Physical Product Library (Fig. 1b) was developed through a new spatial taxonomy, resulting in different three-dimensional tetrahedral structures, where each sample is defined by a position within a four-variable coordinate system. Each structure represents a different waste, material, and process, i.e., glass fibers, carbon fibers, and different 3D printing processes, and the vertexes are linked to the four selected variables of the structure. In this way, different variables, such as process parameters, finishing, or shape complexity, may be compared and experienced through the physical parts, which are linked to a specific position of the spatial system, allowing comparisons and qualitative assessment. Each sample of this section is then part of a specific tetrahedral structure, and it is represented by four different coordinates, one for each selected variable of the specific spatial structure. For instance, a sample of the structure "3D printed glass fibers" has a defined layer height, number of perimeters, surface finishing, and shape complexity, corresponding to the four variables at the tetrahedron vertex (Romani et al., 2022). Hence, the system allows to showcase and compare different combinations of the four variables, showing more possibilities in terms of new applications to envision.

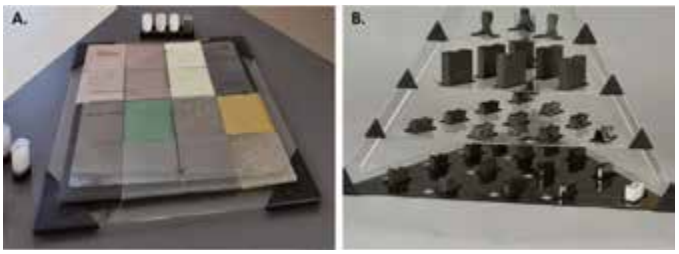

Figure 1. Tangible part of the materials library (physical part): (a) insight of some structures of the physical material library and (b) physical product library.

Experiencing Materials Libraries

Considering the interaction, tinkering with circular materials and 3D printing, three different incremental phases to foster speculative tinkering emerge from the analysis of the library's development path and final design. As shown in Fig. 2, tinkering with materials through 3D printing results in: (i) experiencing materials; (ii) experiencing technology; and (iii) experiencing products. Each phase is linked to a physical part of the materials library and specific technical and experiential knowledge, progressively envisioning new plausible applications.

Figure 2. Incremental phases in interacting, experiencing, and tinkering with circular materials and digital technologies through materials libraries.

Experiencing Materials

The first step in fostering speculative tinkering deals with materials and their preliminary exploration through tinkering activities. The phase of Experiencing Materials (Fig. 2, phase 1) aims to begin the exploration of their properties and qualities by interacting in an immediate way, trying to reduce the mediation and influence of external tools or processes. Hence, the first attempts to investigate their physical properties and expressive-sensorial qualities are usually performed by directly handling materials and tuning the first formulations. To this end, more traditional approaches and techniques from crafts are generally used. Although the influence of processes cannot be removed as a variable in shaping and interacting with materials, crafting helps in limiting their influence, focusing on the variations of the materials themselves. Experiencing materials also means interacting with them not only in structured ways but also encouraging fuzzy interactions, structuring the tinkering activity by narrowing down the practical activity, i.e., focusing on a specific material or a specific set of qualities. This phase helps in detecting some possible paths to organize iterative tinkering, as well as paving the way for the next steps. Considering the case study, this phase resulted in the production of some sets of flat samples, which were then selected to be part of the Physical Materials Library. Hence, this section of the Materials and Product Library system represents the final output of this phase, and their users can experience the results of this tinkering activity. They can also begin their path with these materials, starting their speculative path by understanding the materials as they are and acquiring some basic experiential knowledge to be used in their envisioning path.

Experiencing Technology

The second phase in fostering speculative tinkering focuses on the experimentations and practical trials with the technology, considering the impact of the process in shaping materials. The phase of Experiencing Technology (Fig. 2, phase 2) wants to continue the exploration of the previous step by experimenting with the influence of the manufacturing process through hands-on activities. The experimentation may be performed through sampling, trying to define some set of samples that highlight possible modifications on the qualities, either seen as opportunities or limits to their real implementation. In this case, digital processes can progressively replace traditional prototyping techniques, which can be used to support further investigation and tinkering, i.e., finishing and post-processing. In this case, tinkering with the

process by tuning the possible settings allows the practitioner to work in two different ways. First, it helps in defining the optimal parameters to obtain meaningful samples, which can then be used as a reference for developing new applications. Furthermore, they can also help detect different expressive-sensorial qualities that cannot be completely predicted by the user, usually experienced with a trial-and-error approach. Trials that are generally seen as errors have the great potential to foresee alternative ways to use the technology to reach new results, enlarging the ways to process the material and, consequently, the possible uses in real exploitations. Bearing in mind the case study, the first layers of the Physical Product Library represent the output of this phase, which means the biggest and simplest three-dimensional samples of that library section. They represent the synthesis of this tuning experimentation by showing the main combinations between process parameters, materials formulations, physical properties, and expressive-sensorial qualities. Also, in this case, the user directly handles the results of this practical activity, adding some experiential knowledge to what they previously experienced on materials.

Experiencing Products

The third step in fostering speculative tinkering is oriented toward speculative design and real implementations. The phase of Experiencing Products (Fig. 2, phase 3) aims not only to continue the previous tinkering and explorative paths but also to encourage possible experimentations, projects, and exploitations of the physical and experiential contents. At this point, the experimentation is mainly linked to digital technologies and tools by designing and developing possible applications and physical artifacts, representing the first trials of real implementations. New products, artifacts, or even some cutoffs or parts allow the designer to investigate the possible outcomes from a formal point of view, making tangible some crucial aspects to consider during the design process of new products. In detail, fields of application, technical features, possible geometries, and different aesthetics are analyzed by materializing them within plausible products. Showing some plausible examples, as well as some real products or work-in-progress concepts, should not be intended to limit the range of use and applications of the analyzed materials and technologies. Contrarily, it aims to further stimulate the development and design of different artifacts by materializing some ideas, which could then be considered as references for new projects. Furthermore, it aims to encourage the investigation of new possible features, geometries, and aesthetics to be achieved by exploiting the showcased materials and technologies. In this case, the final layers of the Physical Product Library resume the output of this final step, increasing the shape complexity and introducing some applications as a reference for future works and speculative approaches. The user can use them as a starting point for exploitations in real contexts through their design and professional activity.

Experiencing the Path

A possible fourth phase emerges as a potential experiential and speculative tool from the analysis of the case study, as shown in Fig. 3. As a matter of fact, the materials library of the case study helps in encouraging speculative approaches to sustainable materials and technologies by sharing the experiential knowledge to facilitate their use in real contexts. However, it also represents a way to showcase some results obtained using digital tools and skills, promoting their use. For this reason, the library may be used to foster the transfer of new digital skillsets and attitudes amongst designers and practitioners. According to the previous analysis, experiencing the path (Fig. 3, phase 4) for the materials library development allows the users to acquire these skills through a practical and experiential approach, which means taking part in the process of building the tool itself. From this perspective shifting, the tool acquires an active role in transferring new digital craftsmanship skills and is not just representing a passive knowledge transfer tool to be used in its final version. This approach paves the way for new possible uses of this tool, i.e., distributed replication, participation, and implementation, since experiencing the path adds a further level to experiential knowledge transfer. Moreover, first-person practical activity focused on the library helps in acquiring the skillset to pursue speculative tinkering on possible exploitations through hands-on activities, taking part in the process of envisioning new artifacts by directly participating in the fabrication path. Thinking about possible ways to replicate or create new versions of the library considered as a case study would be a possible way to foster this speculative hands-on approach amongst designers and practitioners.

Figure 3. Contribution of experiencing the path in developing a materials library in spreading digital tools and skills for speculative tinkering.

Conclusion

This contribution reflected on the use of digital technologies in speculative approaches linked to new circular materials from waste, fostering new projects and real exploitations. The analysis was performed through a reflective practice approach to the design and development of the materials library of FiberEUse. Three different incremental phases in fostering speculative tinkering emerged from the analysis, linked to a specific part of the library, which means: (i) experiencing materials with traditional crafting tools to explore physical properties and expressive-sensorial qualities (*tinkering with materials*); (ii) experiencing technology with hybrid approaches to understand its potential and limits (*process influence*); and (iii) experiencing products with digital crafting tools to envision new applications through tangible examples (*speculative design*). A further step was then added as a possible fourth phase, which means (iv) experiencing the path by transferring digital crafting skillsets through first-person hands-on activity in participating in the development of the tool (*knowledge transfer*). These reflections should be furtherly enriched by considering additional case studies, circular materials, digital technologies, and users. However, materials libraries may assume an active role in fostering speculative tinkering through digital technologies such as 3D printing and in transferring new digital craftsmanship skills thanks to its potential use as participative learning and experiential tool to be replicated, modified, and implemented. Their meaning is, therefore, also in experiencing the path

to obtain them, and not only in their final design, paving the way for a new way to interact with materials libraries, circular materials, and 3D printing. Further work should be done to assess the use of Materials Libraries in different contexts, i.e., in didactic activities, during the design process, or define how to evaluate the outputs from the speculative tinkering, for instance, the feasibility and technology readiness level of the envisioned applications and artifacts.

Acknowledgments

The development of the materials Library was funded by the European Union's Horizon 2020 research project FiberEUse "Large Scale Demonstration of New Circular Economy Value-chains based on the Reuse of End-of-life reinforced Composites" (GA. 730323-1).

Flaws as features: new perspectives for developing an additive manufacturing design language

Simian, Ricardo

AHO The Oslo School of Architecture and Design, Norway

ricardo.simian@aho.no

Abstract

In spite of some noteworthy niche-successes, many stakeholders would say that additive manufacturing (AM) has underperformed in relation to the early hype surrounding it (Wanke, 2019) or has lost its momentum (Killi & Morrison, 2020). The reasons for this underperformance are multiple: high costs per unit, unreliability when compared with established mass production methods and possibly a wrong understanding of the technology, amongst others.

In this paper I propose that the lack of analysis and the failure to grasp which are the real new possibilities at hand through AM are one of the main reasons behind the failed delivery of the 3D-printed utopia many announced at the beginning of the hype. In particular, I propose that the failure in developing a unique design language emerging from the actual properties of AM has stopped it from happening while trying to emulate mass production.

Manual and mass production are very well understood and established, to the point that they define our default tracks from conception to development to production. AM first entered the scene as a part of these tracks, being called "rapid prototyping" of an implicit mass production later down the line. Ever since, the new AM palette has struggled to define a space on its own as a method to deliver proper end products.

Some specific expensive niches were immediately successful in making use of 3D-printers, in what many expected to be no less than the start of the next industrial revolution (D'Aveni, 2013). Yet outside these niches AM is starting to resemble nuclear fusion, a promised all-success which somehow never arrives.

Every material combined with a production method will have qualities, properties, and limitations. Artisans have explored metal, clay, glass, and wood for millennia and developed design languages not only suited but emerging from them. Similarly, smart additive manufacturers should reflect both on the possibilities and flaws of the tools at their hands, developing a new, unique design language emanating from their materiality. Within this matrix, AM's "flaws" (filamented textures, rough and dusty surfaces, chaotic extrusion...) are possibly the most neglected aspects, still understood as elements to be ashamed of rather than creative possibilities.

Within this paper I analyse some notorious flaws of the AM palette and propose new perspectives to integrate them as possible features and advantages in this yet to be properly developed design language.

Additive manufacturing limitations

Step 1: buy a 3D printer
Step 2: print a 3D printer
Step 3: return the 3D printer

Popular meme text

This meme would make perfect sense if 3D printers were the almighty machines which some utopian visions would like us to believe are our near future. *"The smell of freshly baked whole wheat blueberry muffins wafts from the kitchen food printer. The cartridges to make these organic, low sugar muffins were marketed..."* (Lipson & Kurman, 2013).

In reality we are not only very far away from such a thing. Arguably, we will never have similar Star Trek technology in our kitchens.[1][2]

"Additive manufacturing" is an unusually self-explanatory name, but it wasn't the first baptism attempt for the technology. "3D printing" is catchy and intriguing but confuses more than clarifies regarding the method. "Rapid prototyping" clearly defines the proposed function without dealing with the technology itself. AM is a paradigm shift in relation to these iterations in terms of clarifying its goal (not only prototypes) and by describing how it works (by adding material). As opposed to casting, carving and material removal techniques, AM works in a step-by-step increasing manner, making non-microscopic layers or filament traces unavoidable almost by definition (Wanke, 2019).

Smooth surfaces have always been a proxy for craftsmanship and quality. Mass production democratised smooth

1 As far-fetched as it may seem, this is no strawman of some AM enthusiasts' line of argumentation. In 2014 Horizon, the EU research & innovation magazine, published an article called "What does the future hold for 3D printing?" quoting Marcel Slot stating that "the ultimate goal of 3D printing is a Star Trek-style replicator. Deighton, B. (2014). What does the future hold for 3D printing? *Horizon, the EU research & innovation magazine*. Retrieved 22.12.2022, from https://ec.europa.eu/research-and-innovation/en/horizon-magazine/what-does-future-hold-3d-printing

2 For a realistic overview of the 3D printed food landscape see Killi, S., & Morrison, A. (2020). Could the food market pull 3D printing appetites further? In (pp. 197-203). https://doi.org/10.1201/9780367823085-36

finishes, a parameter which otherwise required high skills and time dedication. Just imagine how devoted and skilled would you need to be to produce a smooth piece of wooden furniture with crude 18th century tooling, where even sandpaper would have been time saving science fiction.

AM has dramatically increased its quality, yet its filamented, hairy, support-structure scarred, layered roughness will remain one of its characteristics. No foreseeable technological development could provide casting or extruded-like surfaces and even if this occurred such technology would unlikely become a common, mainstream or desktop tool. No matter how optimistically utopian our 3D printed near future gets to be described in the opening chapter of "Fabricated: the new world of 3D printing" (Lipson & Kurman, 2013), AM's ugly duckling is here to stay. But is it truly ugly or have we failed to identify its species?

Material aesthetics in crafts

> *"By chance, a piece of titanium in the firm's material sample pile caught the team's eye. On an uncharacteristically overcast Los Angeles day the metal square was nailed to a telephone pole in the office parking lot; it went golden in the grey light and the team was smitten."*
>
> Guggenheim's Museum blog (Mendelsohn, 2017)

Aesthetics in crafts emerge from their materiality. Bilbao's Guggenheim architectural concept asked for an innovative curvy solution at large scale, but once titanium was serendipitously selected as the quotation tells, the novel material changed the original design as well. Material, shape, size, and light reflections became an inseparable entity.

Artists and craftsmen have gotten their hands dirty with the mediums at their disposal. Centuries of crafty experimentation have left us with virtuoso techniques which embrace their materiality. Being born with crafty techniques already established as "tradition", we may miss the fact that the different mediums and their belonging aesthetics may be very different, even contradictory, from one another. There is certainly no absolute good/bad in arts, but in art school the different techniques must be learned and more often than not will be criticised as poor. Even more interestingly, similar criteria could lead to "good oil" and "bad watercolour" technique evaluation. A classic critique almost every fresh art student will suffer comes from not deploying watercolour's fuzziness. There are plenty of counterexamples, yet classic academic watercolour technique is about learning to use its watery mess for the appropriate purpose. Wash, blending, backrun, tilting and almost every other watercolour technique makes reference to a somewhat chaotic possibility of the medium (Van Leuven, 2017). We learn these elements as academic craftsmanship and therefore will likely fail to realise that this is a fine example of using what could be considered a flaw (the messiness of watercolours) as a high-quality feature instead. We don't see a chaotic blend of uncontrolled, overlapping, dripping, watery blueish waves on paper. On the contrary, we enjoy a beautiful depiction of a cloudy sky, masterly achieved in three skilled strokes, some paper tilting and a sponge intervention.

Similarly, every other traditional crafting technique emerges from its materiality, developing an aesthetic on the way. Weavers, painters, sculpturers, potters and photographers have a language of their own. One of the latest additions to the family are the digital artists, who have seen their medium emerge and grow in a single lifetime. Yet even within this brief episode different schools and aesthetics were born and became aesthetically appreciated on their own. Early digital visuals were constrained by heavy pixelation, very limited colour palettes and short memory availability. Only 20 years later these technical limitations were a thing of the past yet "pixel art" became a thing, an established style, which some creators voluntarily use as an expressive tool, similar to the recent revival of stop motion animation (Costa, 2014).

Computer adventure games were very popular in the 90s and made extensive use of pixel art aesthetics (they didn't have any other choice). Ron Gilbert, the creator behind the popular "Monkey Island" game series, made phenomenal use of the comedic possibilities of clumsy pixelated imagery and animations. In the following decades his creations achieved cult status, which motivated him to create a new episode to his pirate saga. "Return to Monkey Island" became one of the most anticipated releases of 2022, yet Gilbert didn't deliver a nostalgic pixel art product, crafting a modern, smooth, cartoon-looking environment instead. Fans were divided about it, to put it mildly (Troughton, 2022). Pixelated, 256-colour graphics had become something emotional to defend, in a similar reactionary manner to Star Wars fans demanding unspoiled analogue versions of their childhood movies instead of the "digitally enhanced" versions George Lucas produced for the 25th anniversary re-release, a discussion which reached a religious tone (Lyden, 2012).

If you are a watercolour afficionado, pixel art connoisseur or Star Wars fan, the previous, crude descriptions of these aesthetics in terms of materiality and limitations almost certainly provoked an emotional reaction in you. This story and analysis are therefore not only about materials and aesthetics but also about the emotions they induce. We will come back to this topic later.

From prototypes to end-products

> *"A prototype is always more expensive than anything."*
>
> Wes Anderson (Anderson, 2009)

As previously mentioned, 3D printers were firstly known as "rapid prototyping" machines, and in many environments they are still called that way. This is a very senseful name since in most product development processes AM plays its most relevant role at the prototyping phase.

The answer to the question why didn't we start crafting end-products immediately when AM manufacturing technologies became available could require a whole book on its own. The factors which played (and still play) a role range from industrial patents, to technological limitations, to production economics, to plain cultural biases and tradition-based resistance to update our production methods (Killi, 2017). For the purpose of this paper economics, tradition and cultural biases are the most relevant parts of the matrix to analyse.

Regarding economics, in high-end projects where there are no budget constraints, quite often AM can provide unbeatable solutions. Boutique clients looking for an extra 0,1% efficiency regardless of the price tag are good AM customers. Accordingly, new generation rocket nozzles and customised, record-beating bicycles are now mostly produced through AM (Attanasio, 2022). These high-end, flagship projects can certainly make

the AM community proud, yet such successes don't move us towards a democratic, accessible AM utopia at all. They will remain luxury niches and as much as they are inspiring, they are of little interest for the purpose of this paper. Let us have a look at the accessible budget area instead.

Wherever a mass production effort can be implemented and makes economic sense, unless currently unforeseeable technological jumps occur in the AM methods, almost by definition mass production will be more efficient than AM. AM enthusiasts may react to this with counterarguments such as less transport costs and fewer CO2 emissions if locally 3D printed, less material waste due to topology optimisation and more efficiency due to customisation. These arguments can be perfectly valid within specific, well-defined niches. Such niches have a "sweet spot" which differs from the numbers of traditional mass production and are far less common than AM supporters -including myself- would like to admit. Furthermore, the idealised vision of a locally produced, efficient and tailored part tends to forget the time, effort and amount of iterations usually required to produce a successful 3D model (Killi, 2017).

Once a suitable niche is identified, namely, when there is need for customised parts in a middle-range production volume where the price of the part allows for the development process, then AM makes perfect sense as end-product. This has already happened in objects which are small, expensive, and benefit from customisation, such as hearing aids (Killi, 2013). Beyond these very narrow spaces AM still struggles to establish itself though.

The previous analysis regards mostly industrial production. What happens at the other end of the spectrum instead? Could the crafts not be interested in AM as well?

Machine-made crafts

> *"The greatest dilemma faced by the modern artisan-craftsman is the machine. Is it a friendly tool or an enemy replacing work of the human hand?"*
>
> Richard Sennett (Sennett, 2008)

In his extensive crafts' analysis, Sennett reflects on the introduction of machine production. The cold, mass-produced perfection, opposes handwork's irregular but warm soul. He quotes an Encyclopaedia article on glassblowing: *"imperfect, handmade glass has virtues: these are irregularity, distinctiveness, and what the writer refers to vaguely as character"* (Sennett, 2008).

Yet, as we have seen before, AM is certainly not a good example of mass-produced perfection. Firstly, AM's output does not come in mass volumes. Secondly, irregularities, layers, filaments and support-structure scars are quite a quintessential trademark of it. [3] Could AM be too irregular to be accepted as a valid industrial end-product and at the same time too precise to be discarded as a legit craft? Looking at both ends of current market's spectrum -crafts and industrial production- it would seem this is the case. Yet I would like to argue this should not necessarily be AM's future, appreciated only by techy makers and figurine collectors. The fact that we have insofar failed to accept and embrace AM's character does not mean that it doesn't have one.

At BIT's 2018 World Congress of Smart Materials, Dr. Brando Okolo reported that one of the early concerns regarding the 3D printed PEEK prothesis they were producing was to reduce the surface roughness. Their parts were manufactured with top-quality, extremely fine filaments, yet the results were nowhere near the smoothness of standard casted pieces. It was only after a surgeon asked them not to polish them because a rougher surface increases biological adhesion, that they realised this was a feature rather than a flaw (Philipp et al., 2018). This possible advantage has been previously mentioned (Reeves, 2013) and is now being integrated as one parameter to manage in order to optimise prothesis tolerance and adhesion (Shilov et al., 2022). Similar analysis have been carried out, for instance, aiming at make smart use of SLS' natural porosity to develop sound-absorbing objects (Zieliński et al., 2022).

Figures 1 and 2 show a simple earring design oriented in slightly different angles on an FDM printer. [4] The different orientations result in different surface patterns. If consciously used as an aesthetic element, the ugly duckling output of the cheapest desktop 3D printer may turn to have a character. Furthermore, in this case a "silky" a character that could not be produced either by hand or through mass production.

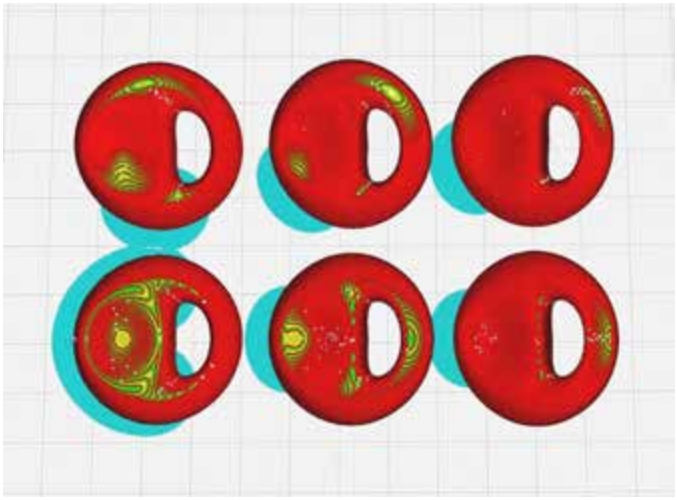

Figure 1. Simple earring with different orientations at the printing bed. Design and photo: Ricardo Simian, 2022

The ceramics department has been more open to embrace the new materiality which 3D printers can offer. Maybe because each clay 3D print ends up being truly unique no matter how reliable your materials and hardware are? Extruding ceramics almost looks like a living process, where minuscule bubbles and irregularities in the mix can lead to notoriously divergent results, if you manage to get to the end of the print at all. Plenty of artsy examples on this regard can be found on Pinterest and similar platforms. It seems like clay artists have less of an issue in accepting this machine as an extension of their hand instead of a replacement.

3 In his 2018 book Stephen Hoskins dedicates a full chapter to AM crafts and craftspeople, yet without mentioning a single time flaws, irregularities, imperfections nor shortcomings of the technology. On the contrary, the whole analysis focuses on case studies where AM methods are used to produce complex designs, suited only to CAD modelling and high-end design boutiques. Hoskins, S. (2018). *3D printing for artists, designers and makers* (2nd ed.). Bloomsbury.

4 FDM stands for "fused deposition modelling", the AM method where material is extruded through a nozzle. This technique encompasses a large range of applications, from small plastic desktop printers to large concrete-pouring machines and is one of the most widespread AM methods. Savini, A., & Savini, G. G. (2015, 18-19 Aug. 2015). A short history of 3D printing, a technological revolution just started. 2015 ICOHTEC/IEEE International History of High-Technologies and their Socio-Cultural Contexts Conference (HISTELCON)

Figure 2. FDM earring printed in different orientations.
Design, 3D print, and photos: Ricardo Simian, 2022

Figure 3 shows a 3D printed clay cup alongside the original 3D model. The modelled overhanging circular rings of the 3D model become irregular blobs and waves in reality, producing a semi-regular, not entirely predictable pattern. Through this production methods, can't we aim to enter the realm of the character-producing irregularities and distinctiveness which the Encyclopaedia praises on traditional glass blowing?

Jibbe van Schie's project "Woven translations" (Figure 4) interlaces ceramics and textile tradition through a self-assembled, multicolour clay 3D printer. *"My ceramic printer makes use of a process similar to the way tapestries are woven. Every colour is present at all times yet an image is created by bringing one of the colours to the surface"* (Van Schie, 2022).

Gartner's hype cycle explains that every emerging technology will experience an early peak of inflated expectations, a trough of disillusionment and a slope of enlightenment before reaching a plateau of productivity (Steinert & Leifer, 2010). AM has followed a very messy hype cycle and different actors will passionately argue that we find ourselves in entirely different points of the curve right now. I would argue that different niches have experienced almost independent curves, each field learning on its own time what must be learned to reach a plateau of productivity. Many fields, including AM crafts in general,

Figure 3. 3D printed clay cup with semi-regular patterns alongside the 3D model which was fed into the printed. Design, 3D print, and photos: Ricardo Simian, 2022

Figure 4. Woven translations designs by Jibbe van Schie.
Design, 3D print, and photos: Jibbe van Schie, 2022

have certainly not yet achieved that goal, otherwise the crafts market would look different today. Embracing the materiality which naturally comes out of 3D printers and developing aesthetic values may well be an important part of this long, raising slope of enlightenment.

The provided examples regard FDM-made objects, yet the analysis of the flaws and possible uses of them as advantages is not only limited to this technique. As previously mentioned, SLS provides rough and layered surfaces by nature, while SLA for most models require support structures which must be removed, leaving scars behind.[5]

It could be easy, and tempting, to reduce the mentioned shortcomings of AM to FDM only, or to wish that future developments will make them disappear altogether. SLS, SLA and all other AM methods have their unique finishing trademarks, which makes them inherently different from traditional mass-produced objects. It is true that AM's quality has increased since its origins, yet within any foreseeable development the basic elements of it -be it extruded textures, layers, or granular-sprayed surface roughness- are here to stay. Further research and analysis are required to discuss all of AM's existing techniques to the depth provided for FDM within this paper.

Additive manufacturing as an artistic tool

> *"I am not looking for the perfect print, actually, when the print is done I am not that interested in it anymore."*
>
> Sigrid Espelien (Espelien, 2022)

Norwegian clay artist Sigrid Espelien, currently PhD fellow at the Oslo National Academy of the Arts, goes beyond the use of AM as a method for artistic production to elevating the printing process into an artistic ceremony. *"Sometimes I think about it like watching a fire, because you don't know... when you are always printing new files you don't know how the printer will move and this collaboration with the machine -because you have to work together- becomes a very intimate process"* (Espelien, 2022).

In a techy field, where speed and efficiency are taken for granted as goals, Espelien's appreciation of the slowness of the 3D printing process is refreshing. Who could have thought that the romanticized vision of the artistic craftsman blowing glass, weaving on a loom or turning ceramics could be applied to the interaction with a 3D printer. *"It feels like a very sacred moment, or that I am actually finding a way to get closer to*

5 SLS stands for "selective laser sintering", a layer-by-layer, powder-based AM method. SLA is the abbreviation of "stereolithography", also a layer-by-layer process using photochemical reactions to solidify liquid resins. Ibid.

Figure 5. Photogrammetry from Bjørvika's Palèhaven shopwreck archeological excavation site, 3D printed in clay with the permission from the Norwegian Maritime Museum (detail). 3D print and photo: Sigrid Espelien, 2019

the landscape... because I can see it from the inside... I'm also thinking about how can I share this experience with people, the printing in itself, because is something that people feel distant from" (Espelien, 2022). Figure 5 shows a detail from one of Espelien's artistic readings of a landscape through AM.

This emotional appreciation and understanding of the printing process brings us back to the aesthetics question posed before. Once an object, and the production process behind it, are experienced as emotional, the discussion regarding its validity ends. The questions emerging from the artistic evaluation of an object or action may lead to a different, and endless, rabbit hole, but they shift the whole debate to a different dimension, away from the technical and ethical complaints aimed at AM as a production method listed before.

The archetypical debate on tradition vs innovation, man vs machine -of which 3D printers seemed to be doomed to become yet another iteration- entirely dissolves if AM becomes tradition. Clay turning was once a technological innovation, as opposed to the traditional approach for vase production by rolling a "clay rope" (Sennett, 2008). Clay 3D printing, and FDM 3D printing methods in general, brings us back to a filament/rope deposition method. Could this be treasured as a return to an ancient tradition? Maybe yes, but only if the crudeness of FDM's production methods is not only acknowledged but also emotionally embraced, as Espelien proposes.

Conclusions

Much attention has been given within the AM community to the technical improvements achieved, each of which moves us closer to the 3D print utopia, where high-quality mass production has become a daily, possibly even home-desktop reality. This is very understandable for an emerging technology struggling to define a niche for itself. Even more, it is the least we should expect from a set of technologies which have been introduced to the public as nothing less than the next industrial revolution.

Failure to deliver this dreamt utopia must not be necessarily understood as going back to the drawing board and restarting from scratch though. All the contrary.

In a recent conference at Stanford University Peter Thiel pessimistically stated "they promised us flying cars, and all we got was 140 characters". The backlash didn't wait, arguing that indeed we didn't get flying cars but we have now things like the internet and smartphones instead, and when offered the choice between those most people would choose our pocket-sized supercomputers before heavy hardware constantly speeding over our heads (Pooley & Tupy, 2022).

Similarly, 3D printers will likely never be the magical, multi-purpose, home sci-fi machines which would solve all our needs. Actually, if we think better of it, even if such machine could be produced the annoyance of having to shop products would only be replaced with the annoyance of having to shop printing cartridges and printing files. Plus dealing with the maintenance of the machine. Not a great step forward I would say. Independently from that, we didn't get such machines, but we got a new way of producing things, with an entirely new set of proprieties, pros and cons. We can either complain about them not being what we dreamt of, or we can start making wise use of them as they are.

One of the main focuses in the AM environment are developments in delivered quality, meaning machines are getting better in producing what customers would like to receive and we appreciate every improvement. This fact alone shows that there are evident issues and flaws in current AM. I propose shifting the attention from the ideal quality customers would like to see -which has been shaped after mass-production standards and aesthetics- to the qualities that AM spontaneously provides instead, developing new design paradigms from them.

One key element of making good use of the new available possibilities regards developing an idiomatic aesthetic which emerges from the technical possibilities of the technology, embracing its flaws as an intrinsic part of it. Once this process takes place flaws can become possibilities, features, or even character.

A further step on this line goes directly into artistic territory, when the production process itself acquires a value which goes beyond the industrial link between idea and finished object.

Further technological developments may arrive in the AM world, and they will be certainly welcome. In the meantime, there is space for further applications of the tools we have at hand today, something that is more likely to happen if we understand them precisely in that manner: tools in our hands.

Abstract

This paper explores the issue of the role of design and digital prototyping in the development of product-service systems in the smart cities, particularly concerning the spread of wireless connectivity technologies such as 5G and their use for innovative orientation and displacement purposes in urban contexts.

The first part of the paper reviews the technical and scientific literature to recount the main technological developments in smart cities with particular attention to the introduction of 5G to navigation systems. The second part analyzes a short collection of use cases to build smart systems for navigating, guiding, and orienting people in complex spaces. The collection and analysis of the cases help to identify the role of design (in the development of product-service systems for smart cities. The third part recounts Polaris, an interdisciplinary project involving design and computer science to develop an indoor navigation system designed for a smart university campus and smart cities. The project aims to realize tangible outputs that demonstrate the great potential offered by 5G, an intangible technology, which needs appropriate communication to future users. To do this, an advanced product/service has been designed, developed, and implemented capable of fitting into citizens' living spaces and environments, adapting, and supporting the end users who "inhabit" them. The conclusions present a critical discussion on the opportunities and limitations encountered when the design is faced with the conception and implementation of project outputs to foster the acceptance of technology.

Keywords

5G Technology; Smart Cities; Smart Direction; Internet of Things; Prototyping; Digital Fabrication

Introduction

Old-world cities are urban conglomerates, resulting from the stratification over time of cultures and inhabiting structures of various types and natures. Over time, the general needs have changed, evolved, and reconfigured, but only since the last century, at the end of the great world conflicts and thanks to the spread of large-scale self-aware medicalization, the implementation of security systems, and the creation of social, artistic, and cultural networks (Li et al., 2016), it's unimaginable that there should be large empty spaces to be designed and built from scratch to respond to the new modern demands. An estimated 70 percent of the global population would be urbanized by 2050 (Lierow, 2014); a percentage that rises to 80 percent when considering just the European scale, which faces a prediction that 97 percent of buildings will have to undergo extraordinary maintenance or heavy renovation within the next 30 years (Beson et al., 2020). A transformation of this magnitude can be supported by the Internet of Things (IoT), which allows us to modify and transform the way we interact with our surroundings. Through the appropriate use of IoT, indoor and private spaces in homes already have acquired *smart* characteristics due to a multitude of small, low-cost, connected computing devices that can detect, process and report environmental data to cloud/internet services. However, this enabling dimension offered by technology (meant in its more confined digital dimension) when scaled in the urban dimension, clashes with a reality oversaturated by buildings and infrastructure built according to logics no longer in line with the needs of the present and even less with the ones aimed at for a more sustainable future. Hence the need to create demonstrators of possible smart solutions for Smart Cities, which are places where traditional networks and services are made more efficient with the use of digital solutions for the benefit of its inhabitants and business (European Commission, 2023).

Smart Direction in a Smart Campus

University campuses can offer a functional response to this kind of need, as they appear to be of particular interest for simulating and testing the effectiveness of projects aimed at scaling in Smart Cities (Min-Allah & Alrashed, 2020). Indeed, university campuses imitate cities in many ways: they generally extend over a large urban area, are composed of many different types of buildings (administrative buildings, laboratories, classrooms, residences, bars/restaurants) and popu-

lated by different types of people/users (Longo et al., 2021). At the same time, they turn out to be more controllable and manageable places at the level of actors involved and from the point of view of readiness for technology adoption, even when not fully mature. For this reason, recent studies and test-level applications have already been carried out to transform these places into Smart Campuses, particularly with: smart parking systems (Mohandes et al., 2019; Nagowah et al, 2019), microgrids (Alrashed, 2020), smart libraries (Antevski et al., 2016; Chan & Chan, 2018), classroom monitoring and occupancy estimation systems (Longo et al., 2020; Tse et al., 2021), and other sustainable solutions (Villegas-Ch et al., 2019; Ceccarini et al., 2021). To infuse these places with intelligence, it isn't enough to equip them with advanced technology, but it is necessary to develop a meaningful design around its use. This is where the service dimension plays a crucial role, not least in making the technology usable (Brettle et al., 2020), because the more it evolves and becomes performant, the less comprehensible it is if not linked to concrete and tangible results that demonstrate its effectiveness. This is especially relevant when it comes to 5G technology (Pujol et al., 2020), on which the main innovations in Smart Cities are expected to be based; however, its markedly intangible dimension makes 5G difficult to understand for the general public, which often sees it as an invisible enemy to be opposed. This widespread idea is difficult to eradicate, despite its lack of support from any scientific evidence, which on the contrary fights to prove exactly the opposite with analyses and reports commissioned by the governments (Camera dei Deputati, 2020). In particular, in the Italian landscape, evidence-based arguments do not turn out to be effective, where a large segment of the population (and therefore of the potential 5G users) does not place trust in this type of narrative stage. Thus, the demonstration of possible applications of 5G, through *use cases* of related services and products, assumes a relevant role in promoting faster and more functional technological development, as well as in countering the latest social resistance to this technology.

In this framework comes the Polaris project, developed by Polifactory and AntLab at Politecnico di Milano, which aims to propose an indoor navigation system capable of guiding users within complex buildings and structures, orienting them in horizontal and vertical movements in search of spaces located in different areas or levels. Polaris is the result of collaborative and interdisciplinary work, in which researchers with expertise in Design and Electronic and Information Engineering worked in synergy to create an efficient and functioning solution both at the level of system architecture and from the perspective of user interaction. The phases of conception, development, prototyping and verification, presented in the following sections, offered relevant insights identified in the final conclusions.

Smart Direction case studies toward bounding project requirements

This part presents the qualitative analysis of case studies as a strategy for State-of-the-art mapping and is used to support the designing part of the final solution. The case study method enabled the identification of "the "what" is being observed and the "how" it is being detected and the reasons why, in order to understand the role of design in the development of product-service systems for Smart Cities (Cohen, 2015). For their identification, desk research was conducted in order to collect tested product solutions or prototypes for navigation in the city. All projects stuck at the concept stage were not considered because the parameter of technical feasibility was given priority. The result are six case studies of projects that share a digital or service dimension, and sometimes have proprietary hardware that is functional in optimizing the use of the entire system. A summary of the six selected projects can be seen in Figure 1.

Figure 1. Chart summarizing information about the six case studies investigated.

More in detail, the first case is Dynamic Street (01), a signaling pavement made of hexagonal modules, equipped with light actuators. The grid modules can take different configurations and also host a plug and play element, i.e., a vertical structure equipped with accessory functions. This is an innovative project that, starting with a static non-wearable element, allows the spatial rearrangement. However, the lack of smart elements for transmitting and receiving data, does not allow the individual user to set customized paths to reach a specific touchpoint. The second example deals with the implementation through augmented reality of the Google Maps app (02) for outdoor walking navigation. To take advantage of this functionality, the user needs a smartphone compatible with Google's ARKit and ARCore, through which the association of the real environment with the digital one previously scanned by a Google Car takes place. The project is very interesting, especially in terms of reaching a touchpoint, but at the same time it has limitations in use because it only works outdoors and requires constant use of the smartphone with the camera on, which results in high battery consumption. Indoor Map (03), the third case study, enables the creation of detailed interactive and customized maps of interiors of public-use buildings to help visitors locate and reach points of interest. The interesting aspect revolves around the proprietary software that makes it possible to build a new map by following a few simple instructions, without the need for intervention by specialized technicians. Unlike the previous one, this case study works only in indoor environments; moreover, it works only after the user sets an itinerary. Beeline (04) is a navigation device for cyclists and motorcyclists, which displays a kind of compass that points to the destination previously set via a paired smartphone. While this solution promotes immediate directional readability, it doesn't optimize the navigation route, which in any case cannot be changed except via smartphone. The patent filed (05) by Amazon of a wearable device for identifying items inside the multinational corporation's warehouses is the fifth case study. Through haptic feedback, this solution lets the workers know if they are pointing their

hand to the correct stall. The interesting aspect of this system is that it uses a series of sensors located in the warehouse to locate the picker, who can move without consulting a screen and thus have maximum prehensility. The latest example is Garmin Varia (06), which is a bicycle radar that can signal the rear approach of vehicles from 200 meters away. The product also has a function for group pedaling, in which it bypasses the presence of other cyclists in its slipstream. This last example is interesting because it combines spatial feedback with the promotion of road safety.

Case study observations

The presented navigation systems are structured through three different needs, sometimes in combination: reaching a point, exploring an area or avoiding something. Remarkably, in terms of connectivity, none of the selected cases employ 5G technology, which, however, could be implemented to increase system stability and reduce data transmission latency times. Therefore, 5G should be considered as a concrete possibility for the scalability of the analyzed projects, as well as a solid base on which to structure proposals for new solutions useful for indoor navigation. Thanks to the outcomes of this reconnaissance, it was possible to conceive, design, prototype and test an indoor navigation system based on the use of 5G technology with the goal of simultaneously guiding multiple users to a customized touchpoint (unlike the 01 case), without the constant use of their smartphones (02 & 03 cases) as well as other personal (04 & 06) or corporate (05) devices.

Polaris: the Smart Direction System

Using the insights gathered from this reconnaissance, the Polaris indoor navigation system was designed and fabricated at Politecnico di Milano throughout "Base 5G" project, and then installed and tested on its Leonardo Campus, in order to provide a tangible demonstration of an intangible technology (Capdevila & Zarlenga, 2015). Polaris makes it possible to guide users within complex structures by orienting them in horizontal and vertical movements to search for spaces located in different areas or levels. This is possible thanks to a system consisting of a series of devices placed in the environment, the anchor nodes, capable of locating users as they move through the location. Such devices communicate via 5G technology with a control center that implements machine learning algorithms to continuously track users and, based on the users' location, controls beacons that guide them to their final destination. These beacons of light, the effector nodes, are also connected to the control center via 5G technology. Researchers from the area of Design and the area of Electrical and Information Engineering collaborated among themselves in the creation of the entire system, realizing: the logic at the control center, the technological infrastructure of the array devices (anchor and effector nodes), the study of their design according to versatility in different installation environments, the production by additive manufacturing of the necessary components, and the subsequent assembly.

Polaris system operation

Polaris is made up by a series of IoT devices spread throughout the indoor space interconnected through 5G technology. After an initialization phase in which the user signs in to the smart direction service, the system locates and tracks the user's position in indoor spaces through anchor nodes and returns navigation information to him/her through light indicators placed in the environment (effector nodes); hence, the person can be guided to his/her final destination without having to continuously observe a map on the smartphone. The anchor nodes operate through Raspberry PI4 equipped with BLE and WiFi communication interfaces to enable location and tracking of the user on the move. They scan Bluetooth Low Energy beacons sent by the user application, send messages to the control center through the communication system regarding the current location of the user(s). The effector nodes are composed of Raspberry PI0 and LED arrays, displaying navigation directions for users on the move. They receive commands from the control center to activate/deactivate the LED interfaces, on which specific indications are generated and recognizable by each user. The nodes are connected via WiFi technology with 5G CPEs. The 5G CPEs leverage 5G connectivity to connect the field network (anchors and effectors) with the control center. The control center receives messages from the anchor nodes notifying the current location of the users to be tracked, calculates the location of the users, works out the best path for each user based on his or her final destination and other context information, then commands the turn on/off of the effectors.

The service design part of Polaris

The architecture of the Polaris communication system is realized through a modular product to be placed in spaces, and an application through which to access the overall service. Polaris activation requires initialization through a user interface, which consists of an application installed on the personal smartphone.

The app allows users to register for the smart directions service by indicating their required destination and if needed other contextual information. The Polaris app can be integrated with the one for accessing university services (Figure) by then importing information from the associated database (calendars, exams, student/faculty profile, academic platform, floor plan of classrooms and common spaces, etc.) to which it then adds the smart indoor navigation system. The app allows the user to select his or her destination through three search modes: a *default* search (the user knows his or her destination), an *automatic* search (the user has an event saved on his/her calendar scheduled at a certain location), and finally a *suggested* search (when the user is looking for a particular type of service along the way).

Figure 2. Some screenshots from Polaris' Smart Direction app.

The product design part of Polaris

As mentioned before, the hardware part of Polaris consists on a modular product to be installed within the spaces to be navigated. The final design of the installed object (Figure 3) was designed for maximum flexibility and adaptability to very different spaces as well. Indeed, instead of making different objects for the anchor and effector nodes, the choice was made to design a structure of interconnected tubulars via tetrapod-shaped hollow joints, at the ends of which to place and orient the number of anchors and effectors necessary for the system's operation. In this way, we designed a product capable of adapting to the different layouts of buildings, and of being able to be flexibly fixed according to the material and architectural constraints. Thus, the density and type of hardware nodes to be placed in the space can be optimized. All nodes are designed to allow maximum accessibility to internal electronic components for updating and maintenance. The use of interconnected tubular elements to make up the entire system occurred to facilitate the wiring of all elements and can be sized in length to suit specific space needs. The usage choice of a connection via tetrapod joints was guided by the need to be able to provide directions both in architectural interiors with orthogonal grids and with more organic layouts. Attachment of the structure can be to ceiling, wall, stand/ground, and in all cases by means of screws/dowels or clamps, depending on the characteristics of the support and whether or not irreversible action can be taken on it.

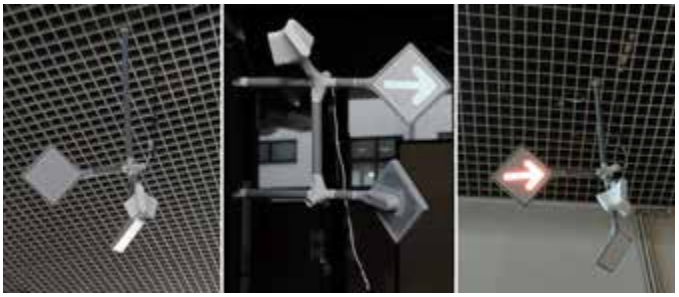

Figure 3. Polaris installed and tested at Building 11 of the Politecnico di Milano, Campus Leonardo, covering an indoor area of about 500 square meters on two floors.

All of these design choices were made with the clear goal in mind of making a working prototype through the technologies available in the university makerspace. Therefore, the product development phase was made by relying on the constraints of FDM and SLS 3D printing and laser cutting technologies. The design aspect, however, was developed to make the product also manufacturable by more traditional manufacturing technologies, such as injection molding, to facilitate the possible industrial scalability.

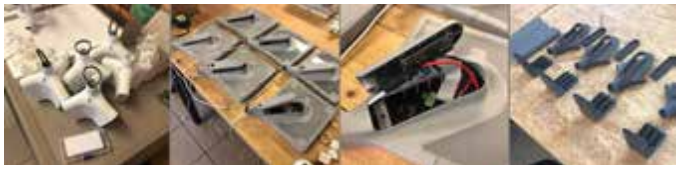

Figure 4. Polaris' prototyping phase.

The content of the pop-up indication on the LED matrix was also the subject of design, to ensure good readability of information, taking into account multi-user. The control center, recognizes the number of users searching for a different destination simultaneously and, thanks to machine learning, assigns a different color or symbol to each user upon login.

Conclusion

This project was positively evaluated by the grant committee as being able to comprehensively address and solve the challenges of both implementing a new technology in a working prototype and managing simultaneous multi-user navigation with a product/service that doesn't force users to use advanced information through a smartphone screen. During this experimentation, it was possible to see how, in the development of technologically advanced devices, a design-driven approach takes a central role due to the designer's ability to manage complexity and become an interpreter and translator of languages and processes. An advanced system architecture has taken a flexible and functional form to the needs of different indoor spaces and especially the users with whom it interacts. The developed service and app put usability at the center, as a technology must be immediately understandable and able to respond to user needs effectively through interactions that avoid slowing down people's lives in order to be accepted (Arthur, 2009). Hence, we can state that the outcomes of this challenge have shown how important is that the designers be recognized as a possible enabler of techno-innovation due to their distinctive interpretive ability and sensitivity.

Acknowledgments

We thank all the WP2 participants in "Base 5G" (Broadband InterfAces and services for Smart Environments enabled by 5G technologies) project, that make possible the realization of Polaris. All the authors also gratefully acknowledge the grant number E41B20000080007 of the POR FESR 2014-2020 / INNOVAZIONE E COMPETITIVITÀ call.

Fantastical Reality: designing virtual urban space through extended reality

Narmeen Marji, Mattia Thibault, Juho Hamari

Tampere University, Finland
Narmeen.Marji@tuni.fi, Mattia.Thibault@tuni.fi, Juho.Hamari@tuni.fi

Abstract

The rapid advancements in Extended Reality (XR) technologies and their integration into the urban design process bring the definition of 'space' and its production to the forefront, where a new type of designable space that accompanies, surrounds, and complements physical urban interventions emerges: the virtual space. XR technology has opened up new avenues for creating virtual content in urban contexts. However, despite the potential for XR to fundamentally alter how we create and experience urban environments, there is a lack of literature on how to use XR to create immersive and accurately placed virtual experiences that complement our physical urban realities.

This work aims to address this gap in the literature by exploring the potential of XR technology, specifically AR, for designing virtual urban space. The study follows a Research through Design approach (RtD), materializing findings through an experimental project in the form of a mixed-reality application that augments the city of Tampere, Finland. The developed application introduces virtual urban space as a space for cultural and artistic co-creation, offering the public a tool to reshape and envision their city through the lens of Augmented Reality (AR).

This work offers insight into the latest tools and software development kits (SDK) used to augment large-scale urban areas. It proposes a solution for accurately placing virtual content in urban environments, and presents considerations for designing virtual urban space, as well as current technology limitations and future research avenues.

Introduction

In today's world, ever-evolving technologies have seemingly swept the globe, blurring the line between what is real and what is not. This sensitive interplay between the physical and the imaginary has touched upon many aspects of our everyday life and has, in some cases, formed a new framework for understanding the world around us; creating novel ways to experience ordinary things.

Recent technologies have made it possible for different realities to exist and merge with the one we live in and interact with. The term Extended Reality (XR), an umbrella term that comprises Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR), but is not limited to these three, has come into existence and people are slowly escaping everyday life into this newly emerging form of reality that can be designed, adapted, and harnessed to improve the way we experience our surroundings (Liu et al., 2017).

XR technology has opened up new avenues for the creation of virtual content in urban contexts. However, despite the potential for XR technology to fundamentally alter how we create and experience urban environments, there is a lack of literature on how to use XR to create immersive and accurately placed virtual experiences that complement our physical urban realities.

This work aims to address this gap in the literature by exploring the potential of XR technology, specifically AR, for designing virtual urban space. The paper begins by reviewing the existing literature on XR technology and its use in urban design and envisioning future urban scenarios. It then presents a case study in Tampere, Finland that showcases the potential of using XR in designing virtual urban experiences while presenting the latest tools that facilitate this process. Finally, the paper discusses the opportunities XR technology offers and provides suggestions for further research in this area.

Background

The use of AR for Urban Design: Definitions and Justification

AR systems are those that allow real and virtual objects and information to coexist in the same space and provide real-time interaction. They allow the user to view the real world with overlaid virtual objects and enrich the user's experience and perception of reality with additional information. However, AR does not replace the real world as in the case of Virtual Reality (VR) (Redondo et al., 2017). According to Klopfer and Squire (2008), AR could be defined as "a situation in which a real-world context is dynamically overlaid with coherent location or context-sensitive virtual information" (p. 205). It is the synthesis of computer images in the real world (Zachary et al., 1997). And it can be identified by three basic features: 1) It combines real and virtual environments, 2) It is interactive in real-time, and 3) It provides accurate three-dimensional registration of real and virtual objects (Azuma,1997). Mobile

Augmented Reality (MAR) provides the aforementioned features without constraining the individual's location to a specially equipped area. It can be used anywhere, allowing the user to access AR experiences and add layers of information to any environment anytime through mobile devices (Höllerer and Feiner, 2004).

AR and VR share some similarities in terms of immersion, navigation, and interaction (Redondo et al., 2017). Unlike VR, which completely immerses the user in a virtual environment, AR allows users to experience the real world through a virtual overlay (Bower et al., 2014). It is important to highlight that the main goal of a VR system is using technology to replace rather than complement reality and create a new immersive environment, while the main goal of an AR system is to enhance reality by overlaying it with virtual content in a complimentary non-immersive way that enriches the user's perception of the real environment (Billinghurst et al., 2015).

In a discipline such as Urban Planning and Design, in which spatial and contextual information are core components of professional practice, Squire and Klopfer (2007) suggest that AR applications hold a particular promise and provide enormous potential for enhancing the design process due to their ability to connect academic content and practices with our physical, lived worlds. Potts et al. (2017) mention a shift and a direction toward the integration of AR in planning and designing public spaces in the physical world, and emphasize the possibility that urban planners will need to engage in both, the physical and the virtual placemaking process in the future.

Augmented Reality in Urban Design

The introduction of Augmented Reality applications into the architecture and urban design study and practice has provided a new channel of interaction with the built environment and produced a need for a new set of skills and a higher level of digital proficiency alongside traditional paper-based design and analysis skills to be developed in order to utilize these tools to their full potential (Indraprastha and Shinozaki, 2009).

Billinghurst et al. (2015) expand on the significance of augmented reality (AR) in the fields of architecture, urban planning, and urban design by pointing out that while 2D plans can show a building's layout in great detail, it would be challenging for the client to visualize the building through 2D drawings. Physical models, 3D renderings, and interactive flythroughs can therefore provide a solution to this problem, but they are scaled-down representations of the final space. These might not accurately portray the building's final image, including its final scale and placement within the urban context. The use of AR allows users to view full-sized 3D virtual models of future buildings placed in their intended contexts. (Calabrese and Baresi, 2017; Redondo et al., 2017). This allows AR to be utilized as a planning tool, placing different variations of the same building on-site and allowing for stakeholders' feedback, collaboration, and participation in the design process.

In addition to serving as a tool for visualizing future projects and urban development scenarios, Mesárošová et al. (2015) present an example of an application used in Urban Planning education called "Visionary Cities" created by AR Group Manusamo&Bzika. Through AR, the application provides the possibility to view and explore cities and concepts that were never built and remained as sketches, such as projects done by Archigram (A neo-futuristic avant-garde architectural group formed in the 1960s (Sadler, 2005)).

Envisioning Future Urban Scenarios Using XR

In today's world, there is a need for new urban visions that address pressing urban issues, concerns, and transformations such as overcrowding, social inequality, environmental degradation, climate change, urban gentrification, increased refugee influx, increased surveillance, technology and the smart city discourse in urban planning, etc. (Sevilla-Buitrago, 2013; Leorke, 2020). Augmented, virtual, and mixed reality can be powerful and effective tools that support the conceptualization, visualization, and communication of imagined urban futures.

A study by Shawash and Marji (2020) explores the potential of Mobile Augmented Reality (MAR) technologies as a tool for public engagement with ecologically sustainable urban regeneration projects. They present two urban development scenarios for envisioning a greener version of the city of Amman, Jordan by virtually reintroducing the city's enclosed and dried-up water stream and proposing sustainable water management solutions through an interactive table-top AR model of the site. The study envisions "what if" scenarios of the city's only water stream, and uses AR to present this vision to the public, engaging them in the dialogue of imagining a greener, more sustainable future for their city.

A study by Thibault et al. (2021) proposes a fictional city, one that utilizes augmented city technologies "to produce creative and playful spaces for citizen–urban interventions" and places the people in the center of the place-making process. The proposed model uses the city as a resource for activities and initiatives that allow the people to shape their environment and envision shareable alternate scenarios, strengthening their right to be represented and to use the city. Residents can explore, create, and modify the city's virtual augmentations, and develop a sense of ownership over its public spaces (Thibault et al., 2021). The authors suggest that the required technologies that allow us to interact in unprecedented ways with the urban environment seem to be available and what is needed is to combine them in the right way.

The Challenges of World-scale AR

Calabrese and Baresi (2017) explore placing urban design proposals and student projects in an outdoor urban context in the city of Milan. They attempt to enhance the accuracy of placing virtual design interventions by detecting specific 3D models and using beacons (small, wireless transmitters that use Bluetooth technology to send signals to other nearby devices). However, the proposed solution adds additional complexity to the average user and requires the detected 3D object to be always in view.

Rohil and Ashok (2022) explore the use of building information modeling (BIM) software along with AR visualization to present two types of urban planning scenarios: the creation of new structures and the recreation of existing designs. They offer a more recent overview of the workflow and possible tools that can be used to integrate AR into architecture and urban design. Nevertheless, the presented results showcase a proposed design floating in space rather than being placed in its designated location and in the correct orientation and scale, and little is discussed on the potential of utilizing visual positioning systems (VPS) for enhancing placement accuracy and designing compelling virtual experiences.

Although many studies attempted to explore and use AR in the context of urban design and to augment urban space,

very few address the accurate placement of virtual content in urban areas. Whether the AR layer presented proposed buildings, urban development proposals, image/video overlays, creative 3D models, etc., its placement in the real world has faced challenges due to GPS and localization inaccuracy (Blum et al., 2013; Calabrese and Baresi, 2017; Redondo et al., 2017; Rohil and Ashok, 2022). The introduction of AR elements in urban contexts, whether marker-based AR (detecting a certain image or QR code through a device's camera to place virtual content) or marker-less AR (using a device's camera to detect vertical and/or horizontal planes or 3D objects in the surrounding environment to place virtual elements) or even location-based AR (utilizing specific location coordinates to load virtual content in specific areas), the placed virtual content in a large outdoor setting would shift, jitter, disappear, get misplaced, and move with the user's movement as they attempt to explore it.

Moreover, manual placement of large-scale virtual elements using a device's input (e.g., touch screen), such as buildings, urban furniture covering an entire street, indoor virtual content, etc. is inefficient and poses additional challenges and limitations to the users, especially if they are new to the technology and are not aware of the designer's decisions regarding optimal placement.

Another important consideration when designing XR experiences is the user's point of view (POV), which holds substantial implications for the design, perception, and overall efficacy of the immersive environment.

Utilizing a first-person perspective, or world-scale AR, enables users to perceive and engage with the urban environment from a human-scaled perspective, resulting in a more immersive experience. In urban XR experiences, the first-person perspective facilitates a more profound understanding of spatial relationships, architectural scale, and the experiential qualities of the built environment. This can offer insightful information on how people will use the built environment and how it will affect their perception of the area. This POV, however, can be constrained in terms of the quantity of data that can be concurrently displayed on the screen, which can make it harder to assess the design as a whole.

Alternatively, users are able to observe the complete area from a bird's eye view when using the third person perspective, such as in Tabletop AR, which offers a more objective and thorough view of the urban environment. the third-person perspective positions the user as an external observer, detached from the immediate context, and often overlooking the virtual environment from an elevated or distanced vantage point. This POV provides users with an overarching view of the urban fabric, enabling a more comprehensive understanding of the spatial structure, urban patterns, and connectivity. However, it may be less realistic and not as effective when expressing how people interact with the built environment compared to the first person POV and may reduce the sense of immersion and personal agency within the XR environment.

It's critical to consider which POV to use depending on the nature of the project and the desired feedback. For instance, first person POV might be more effective for assessing the pedestrian experience of a brand-new public space, while third person POV could be used for assessing the effects of a major development on the local urban fabric. The POV can also affect the usability and accessibility of XR technology for various users, the level of depth and accuracy necessary in designing the experiences, and the techniques used for evaluation and feedback.

The case study discussed in the following sections presents an example of utilizing XR technologies in co-creating virtual urban space. It explains the used tools and solutions for creating accurately placed, immersive virtual content in the city.

Methodology

This study draws on a comprehensive review of literature in the fields of XR technology, urban design and planning, as well as Human-Computer Interaction (HCI) and follows a Research through Design approach (RtD); "an approach to conducting scholarly research that employs the methods, practices, and processes of design practice with the intention of generating new knowledge." (Zimmerman and Forlizzi, 2014, p. 167). This work materializes insights and knowledge through an experimental project in the form of a mixed-reality application that augments the city of Tampere, Finland. The developed application introduces virtual urban space as a space for cultural and artistic co-creation, offering the public a tool to reshape and envision their city through the lens of augmented and mixed reality. To investigate the use of XR technology in designing virtual urban space, the presented case study involved observing and documenting the design process, the performance of the mixed reality application prototype, as well as users' reactions to it.

The ideation and development of the application prototype were done in the following steps:

1) Literature search on the use of XR in urban contexts as well as current challenges and technology limitations.
2) Identification of the latest open-source and available tools for augmenting city-scale spaces.
3) Schematic analysis of Tampere city's layout and optimal locations for introducing virtual content.
4) Informal interviews with local Finnish artists regarding the need for exhibiting their art in public spaces as virtual content.
5) Collection and design of context-specific virtual content to be placed in selected locations in the city.
6) Development and testing of the mixed reality application prototype using MAR and AR glasses.

This work aims to offer insight into the latest technologies used to augment large-scale urban areas, considerations for designing virtual urban space, as well as current limitations and future research avenues.

Case Study: the Tampere xRT Project

Tampere, Finland's third-largest city, is regarded as a hub for business, technology, and culture. The city is renowned for its cutting-edge technological research and advancements as well as its vibrant cultural scene, which features a wide range of museums, theaters, and festivals.

This project offers individuals access to alternative and novel viewpoints of the city that can enhance their daily lives by leveraging Tampere's diverse cultural experiences and the potential of XR.

By allowing users to shape their own virtual urban surroundings, the Tampere xRT project examines the idea of placemaking through XR and presents the city as an open exhibition. It offers a sustainable and accessible platform where local and international artists, cultural venues, and the public can share their visions of the city, by showcasing their art in virtual urban

space. The project explores how the public realm of Tampere can be co-created with XR through the collaboration of artists and the public.

Problem and proposed solution

For providing immersive and accurate AR experiences in outdoor urban settings, the project aimed to tackle the AR placement-accuracy challenges and offer an experience that can run on mobile devices as well as AR glasses. Different locations around the city were selected, those included a neighborhood park (Figure 1), a pedestrian bridge in the city center, and a landmark in Tampere's city center to explore the effectiveness of the AR solution in a 1) green setting, 2) an active pedestrian route, and 3) a distinguishable building and plaza. The design of virtual content in urban space not only provides a playful and interactive experience but can also enrich the public's perception of the city. This offers opportunities for visualizing future urban developments, historical information, and even fictional and fantastical scenarios as a form of speculative design that can widen users' imagination and allow them to rethink their surroundings.

Figure 1. Left: user viewing virtual content in a park using AR glasses, Right: the user's view through the AR glasses showing virtual 3D model in the park

Developing Urban XR Experiences: Tools and Technicalities

The project utilizes Visual Positioning Systems (VPS) to identify the users' location and accurately place the virtual content in physical space. The process begins with mapping specific locations in the city by using photographs, creating a spatial map and point clouds of the location, and extracting feature points that can be then detected, ensuring accurate localization (finding the position and orientation) and placement of the virtual content. For this process, the "Immersal" software development kit (SDK) was used, and the created maps of the scanned locations were then inserted into "Unity", a game development engine, for designing and determining the location of the virtual content that will augment the physical space (Figure 2).

The Immersal SDK facilitates the process of creating location-aware spatial environments using any mobile device, offering fast visual positioning with low system overhead. It enables devices to precisely locate and orient the users' view in the physical world, allowing accurate placement of persistent virtual content in their surroundings.

In addition to using the Immersal SDK, Google's Geospatial API recently released in 2022 was also used to add 3D virtual elements in locations that were not priorly scanned using Immersal's tools. Google's Geospatial API allows developers to use Google's pre-scanned data and feature points used in Google Street View AR to accurately place virtual content in any place in the world. However, the capabilities offered by Immersal's mapping tools by scanning specific building facades offer element-specific augmentation. This means that virtual content can be placed on certain windows, walls, ornamentation, roofs, etc.

Nevertheless, the localization of the devices faced some challenges after sunset, since the spatial maps were created from images captured during the daytime. This was resolved by mapping the environment at different times of the day to capture the context in different lighting conditions and ensure correct AR placement and environment detection in all settings.

The projects' results were shared with the public, as well as Tampere's municipality and multiple cultural venues including the Tampere theatre, Tampere Art Museum, and Tampere City Library, which all presented a positive attitude toward the introduction of XR in the city and the proposed platform.

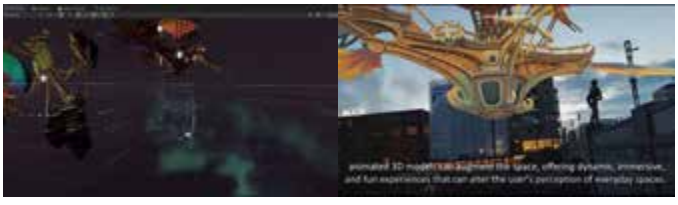

Figure 2. Left: Unity's work space showing the point clouds of the bridge and the placement of virtual content, Right: mobile screenshot of the bridge area through the AR app, showing the placed virtual content in its physical location.

Conclusion

XR technology is rapidly developing and the intersection between the real and the virtual is increasing at a quick pace. This study discussed the use of XR in urban contexts, the design of virtual urban space, and the tools available today to facilitate this process. Following an RtD approach, this work presented a case study that explores the latest software development kits for creating accurately placed AR content in large urban settings. Moreover, the study offered a possible solution for a challenge frequently faced while exploring the usability of AR in outdoor contexts.

XR offers great potential for the fields of architecture, urban planning, and design, and allows us to envision and experience future urban scenarios in real-time on-site and in full scale.

For architects, urban designers, planners, and other professionals involved in shaping the built environment, XR technology opens up new design options, promotes teamwork, streamlines decision-making, and boosts productivity as it can be connected with other technologies like Building Information Modeling (BIM), Geographic Information System (GIS), and Internet of Things (IoT). Additionally, by focusing on more immersive and interactive experiences rather than 2D drawings and models, XR has the potential to revolutionize the design discipline, resulting in new processes, tools, and techniques for design as well as new ways for practitioners and stakeholders to collaborate and communicate with one another.

However, the current state of XR technology, specifically MAR is limited by the utilized hardware and requires large processing power, which can result in low refresh rates, device overheating, and a lack of immersion for users with older devices. Moreover, further research is needed on designing good quality and context-specific virtual content for augmenting urban spaces without overpopulating them and creating visual noise for the users. Several social and regulatory challenges

are also presented when implementing XR technologies in the urban realm, those include but are not limited to accessibility, safety, privacy, impact on the built environment, as well as legal and regulatory issues, which could be explored in future research.

The Metapolis – cities between a ripple and a blur

Ian Nazareth

RMIT University, Australia

ian.nazareth@rmit.edu.au

Abstract

If the metaverse is the aggregated, embodied internet of experiences, applications, and products - a three-dimensional virtual world of decentralised interoperable networks, then, the Metapolis is the surrogate quasi-urban assemblage – a distributed scaffold and matrix of gateways and terminal experience architectures that coalesces in its wake. It contains the footprints, detritus, infrastructure and residue of our collective digital avatars and augmented experiences.

The Metapolis is without starting points or end points, an ambiguous and unstable category. The incumbent city and the Metapolis exist contemporaneously as contingent, unstable actions. The interaction between the post-industrial city, the metaverse and the Metapolis is not a logical Venn diagram but combustion. The city as particles and waves, that occur in superposition of each other, i.e., cities occupying the same coordinate infrastructures, organised by compatible data and metadata. Here, two seemingly distinct spatio-temporal phenomena converge upon the same reality, the conjuration and incursion of the 'built' environment into the internet.

The paper discuses s a conceptual framework and presents projects developed through a discrete combinatorial procedure - utilising data structures, spatialising APIs, point-clouds, and generative adversarial networks – an interface connecting the physical city, its digital twin and the open metaverse.

The Metapolis is manifested as a fluctuating spatio-temporal domain – a transient state between the incumbent city and the metaverse. Fundamentally, it is recognised as a 'realm' – operationally a physical territory and a formal category. It could be understood as a higher entity that provides a probability distribution and potential for the outcomes, mediating and inscribing the rules of play. It deploys a deep texture mapping – weaving together abstract and material signifiers. It appears as a seamless experience of consciousness – switching between, and burnishing over the folds amid real and symbolic, coupling the physical and virtual cities.

The Metapolis is an ordering of self-contained entities of functional significance. Complexity emerges from the consequential interactions of finitely bounded individual preferences. The city reacts more precisely to patterns and behaviours. Even objects are now subsets of the patters of utility. Emergent solution to emergent problems that, conserve historical layers. The Metapolis is the capacity to of urban infrastructures to abstract - a conceptual scheme to reconcile and map geography onto information, between the known and unknown. The metropolis and the Metapolis are a network of entangled infrastructures at a constituent level. They remain linked and share a common, unified state. Information and actions carry across the meta-physical breach. The Metapolis is an approximation and correlation to its physical counterpart.

Within this construct the paper also explores the potential for open-ended and user / operator / consumer generated architectures. As a spatial organised directory tree of information and unitary structure, the gravity of connections and intensity of uses delimit the temporal shape and form and restructure the potential of the city's network.

The research investigates the relationship between the embodied internet and its interaction with the incumbent city and the metaverse, and friction, challenges, and opportunities for machine intelligence in generative techno-social development.

Author keywords

Metaverse; AI; smart cities; digital twins; point-cloud; real-time analytics, urban narrative; cyber

Note: The style and language of the paper engages with the agency of critical, reflective, narrative, and descriptive text as well embracing socio-cultural and technological critique as a generative device for the qualitative design-research process.

Introduction

There's a world of goods and services, of extraction and making... and activities – Newtonian, Darwinian and perhaps Dickensian. Far beyond, there's an intangible sphere of hypothesis, conjecture and supposition – of accelerationism, dilation and escalation. Risk, liquidity, short sells, margin calls... volatility. Between, lies a proscenium where services are stages and goods are props. Sounds rather Machiavellian. Fungible commodities, tangible goods and intangible services synthesise a transactional event... i.e. the experience economy. The interaction between the two is not a logical Venn diagram but combustion. A breach that resists identity. This is the Metapolis.

Note, Clarification: The use of Metapolis, is the author - Ian Nazareth's own description of the term utilised in reference to the theoretical and design project, while Métapolis – references the use of the terminology by François Ascher

The economy emerges through intentional and arbitrary interactions and intersections of subjective factors, dispersed throughout a market and landscape of options. Usually, the city serves as the conduit and receptor for information encoding and extraction. Information is collected, categorised, and re-categorised at various scales and resolutions. The internet not only accomplishes this task but also feeds back into the city's physical substrate. This process produces an experiential reality that is both individual and collective. The challenges of abundance and scarcity reverberate back to the urban environment. There is no singular reality but an unavoidable technological singularity.

Data infrastructures, digital and physical artefacts - from low-poly forms to gradual high-resolution, high-fidelity architectures add a meta-layer, where forms become a representation of themselves, mirroring the technology that produces them. And vice-versa. The realm of the real and possible blur. The Metapolis occupies a conceptually flexible domain, to abstractly represent the city, in order to fully comprehend its potential. It is uncovering a future where variants can exist contemporaneously. It utilises spatio-temporal models of the existing as a comparative to manifold, heterogenous models for potential action and speculation. It creates a functional representation that stands in for the collection of objects and actions. It enables a city that senses far beyond normal limitations of the incumbent city.

The physical city in-turn provides a medium for strategic interactions with economic and other rational agents. The emergent choices are interdependent and produce outcomes corresponding to preferences - these outcomes are unintended or unknowable to the agents. (As discussed later, outcomes are contingent, and within certain parameters, possible only if they can be observed in the first place)

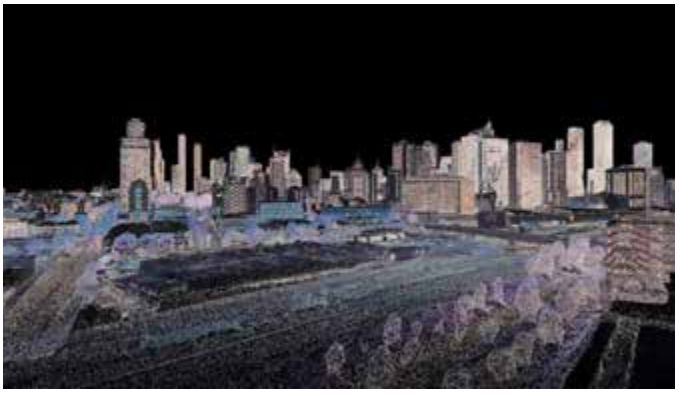

Figure 1. Visualising the temporal city through information modelling and data point clouds as a model of experiencing the mediated contemporary city. Image: Ian Nazareth and Lester Li. (Raw information extracted from the City of Melbourne LIDAR Point Cloud Data)

Deviation and slippage between the physical city and the virtual provide alternate modes of legibility. At present, it seems convenient that the two are not viewed or discussed in the same frame of reference. Its beneficial and indeed profitable to regard them as separate rather than coupled. The historic city *and* the benign metaverse. It is arguable naive, to assume the sensation to develop as separate categories, when in all likelihood, there is an embodied relationality, an eventual site of contestation rather than resolution. The relationship is likely exploitative.

Spaces in the Metapolis are hybrid and augmented world's spawned between a concept and experimental demonstration, between the real and unfathomable. It exhibits surrealism or the hyper-realist temperament subjected to a slow process of assimilation by a situationist impulse.

The Vector of Information

The balance of exchange is always weighed and measured, calculated, taking into account a relation without exchange, an abusive relation. The term abusive is a term of usage. Abuse doesn't prevent use. The abuse value, complete, irrevocable consummation, precedes use- and exchange-value. Quite simply, it is the arrow with only one direction. _ Michel Serres

With Web3, the incumbent city and the metaverse (internet) are now working on the same axis - to shape normative desire. 'Use value' and in ever increasing share – 'exchange value' are deployed as an immutable characteristic of late-capitalism. However, the dynamic is compounded by variables of 'sign value' (Jean Baudrillard's concept that takes into account the stature and status imparted, over the material, utility or functional value) - and Michel Serres' claim of 'abuse value' – goods and services of inadequate utility.

The divide between the physical and virtual realms - the fissure and the overrun - serves as a nexus of interaction and exchange, which is both necessary and perplexing. Traffic does not flow without friction or in a single direction; it may be asymmetrical. The urban environment, as well as the metaverse, could exhibit hyper-parasitism, where the host and the parasite are both parasitic entities. It is critical to acknowledge and comprehend the control, ownership, and directionality of information and material flow in both the digital and physical cities. There are finite physical resources directed to breed indeterminable exchange, sign, and abuse value. Once things are untethered from physical or material reality, the possibility of something emerging from nothing becomes viable. When the vector is reversed, inoperable and unserviceable elements become harmful and treacherous.

There is an unacknowledged friction between the city and the city. Between the physical, incumbent city and its digital twin, its internal representative model and the metaverse. Between physical artefacts and virtual avatars, between particles and pixels. Between clarity and allusion. Between matter and event. The opposite of network effects (any situation in which the value of a product, service, or platform depends on the number of buyers, sellers, or users who leverage it) is likely chaos theory and the butterfly effect (the idea that small things can have non-linear impacts on a complex system) Digital scarcity and exuberance meets real world serviceability and cultic hysteria.

What happens when trim of autonomous selfhood is peeled back? What if the physical city and the virtual metaverse compete for space, time, resources and your finite attention? What if they are adversarial by nature? What if the city is not synonymous with its digital self? What if the interde-

pendencies are burdening? What happens when the physical city loses its centrality?

Post Internet, Web3

Figure 2. User Interfaces and spatio-temporal architecture, of the post-internet and Web3, merge in The Crypto Miner's Share-house project. Image: Ian Nazareth and Jason Ho.

Post Internet Reality describes a period that corresponds to an extreme present where the internet in its every manifestation - its perception, influence, fragmentation, polarisation, disruption, accelerationism, and speculation - is the milieu. It is where and when the microgenres and subcultures of the internet influence the aesthetic, form, and relational hierarchies of the architecture of the city. The semantic web, blockchain, digital ownership etc., in their universality and omniscience, cannot be separated from political, cultural, and economic reality. It presents the multiplicative, ratcheting effect of combinatorial innovation. It is the emancipation and burdening of the infrastructures of the city. It is when the virtual is inapparent yet imperious.

Web3 is the ensuing restatement of the conceptual narrative of the internet. It is the internet as a topological entity, through processes of decentralisation and tokenisation, that anticipates the proliferation of transparency and ownership - an internet of value, and transactions at the speed of thought. It is the web that already fractionally exists, but also a medium that suggests an interoperability across platforms, systems, and protocols. New codes, technologies and platforms are each incompatible ecologies, with non-transferable assets, and it remain to be seen how these systems integrate. Nevertheless, they embody an ever-changing topography that might produce discrete ontologies, rather than a unification.

The paradigm of the Post Internet Reality implies that even seemingly radical technologies enter the common parlance. It represents a space that is physical, tangible space but also intangible paradoxical realm. The spaces are seemingly contained within the medium and format of their genesis, but escape the cliché of abstracted data, as they realise a philosophical, socio-cultural reality. Between non-space and a sensorial stimulation.

The following project elaborates on these ideas through the mode of design practice research.

The Metapolis and the Metablock

So, they used brick instead of stone, and tar instead of mortar. – Genesis 11:3

Early descriptions of the *'métapolis'* attempt to capture a multi-faceted city, generated by accelerated changes and hypermodernity in contemporary society, and consequent

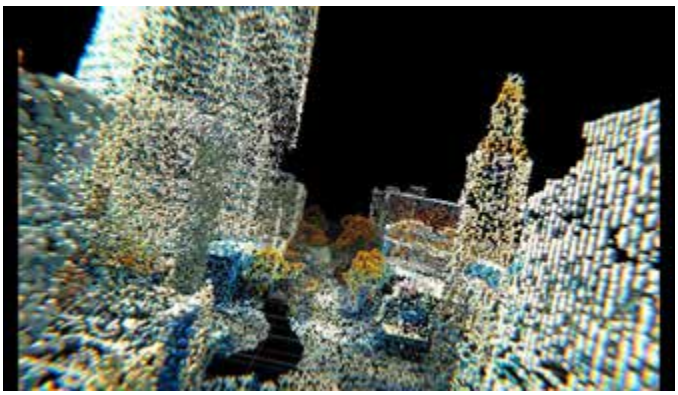

Figure 3. The Metapolis – visualized through modelling spatial architecture, meta-data and poin-cloud models where pixel refer to real-time usage statictics of programs within the built environment. Image: Ian Nazareth and Kevin Gao. (Raw data extracted from the City of Melbourne Open Data Portal, and City of Melbourne LIDAR Point Cloud Data)

transformation of the architecture of the city and urban arrangements. Urban sociologist François Ascher engaged the term *'métapolis'* to describe the phenomena of the urban experience that brings into view a discontinuous, heterogenous, networked model of the city. The spaces that make up a *métapolis* are highly mixed, though not necessarily contiguous. It extends beyond the conception of the metropolis. The Metapolis is extended and re-defined with the concept of the digital twins and the metaverse and utilised in reference to the theoretical and design project, while *Métapolis* is a reference to the use of the terminology by François Ascher.

The metaverse is not an escapism but an immersive interactive computer-generated reality where actions are performed. David Chalmers argues that virtual objects are real objects - that virtual reality is causal and real. It exists independently of us as individual or collectives and it's not an illusion. By extension, implying that interacting data structures are concrete, with evidence of cause and effect.

The conception of Metapolis subscribes to a scenario where entities have both spatial and temporal properties, substantive constraints and hence counterfactuals. To further interrogate and speculate about the concepualisation of the Metapolis, a block within the metaverse is utilised as an analogue to the city block in the physical incumbent city. As part of this project, data from the City of Melbourne (Australia)

Figure 4. The Metablock – speculative digital city block in the metaverse, where growth and behavior are products of a real-time patterns of occupation with its the analogous city block in the City of Melbourne. Image: Ian Nazareth and Kevin Gao. (Raw data extracted from the City of Melbourne Open Data Portal)

and the Digital Twin Victoria are utilised to build operative data models.

The city-block in meta coordinate space presents a quandary. Not only for a system to navigate a frontier of manifold potential, but a querying of the ontology of the urban block itself. While the architecture of the traditional city block in a city grid is a dogmatic hypothesis for action, of abstract appropriation and exploitative economic expression, it is firmly bound within extractive material logics and structural etiquette. Discrete econometric conditions, carefully contrived scarcity and decentralised property ensure that hyperbolic free market conditions prevail within meta-space as well. *But released from other bounded topologies and relational network impulsions, what forms the instructive conditions of spatio-temporal continuity in the meta block? What orthodoxies and archetypes will be revisited or generated?*

The dilemma for its spatial architecture begins with a challenge to orthodoxies of representations of formal characters that are in their new medium - immersive, experiential, spatial morphologies themselves. Unlike discrete representation, these are more immediate. The representation is the occupation. Space and time have a discursive relationship - as movement or mobility is perceptual and ambiguous, but also interactive.

Design is probabilistic or at the very least stochastic - generative conditions and communicative infrastructures that engender a likelihood of interaction, programmatic and social adjacency. Operationally and arguably, this is a qualitative, spatial agenda plotted on a probability matrix. Likelihood of encounters are increased by constraints of economics, scale, geometry, and materialism. Concentration is a human proclivity, recurrently mobilised through design. If the city is about the maximum things out can do in a day this poses further queries or variables - *Is the aggregate of (all) possibility conserved across meta and physical dimensions? And if possibilities are self-organised and limitless, what then defines a phenomenology? Or semiology? Are they closed loops or self-organised open-ended threads?*

The experience of the Metapolis is delivered across decentralised datascape through kinematic portals. These are frames that contain spatial references, the systems of motions and relative timescale. A realm where the city's geometrical description, is subjected to force and movement through its expanse.

Spaces and programs within the block are products of self-conditioned contingency - associative, proportionate qualities and relational responses to and within its locality. Contiguity and the capacity for concentrations, combinations, dilations and alterations are a response to adjacent stimuli. The Metablock is an ecology of immediacy and an architecture of spasmodic bursts, abrasion and contact where a series of local (near-field) changes organise within a spatialised data cloud of loosely organised simultaneous geo-local behaviours. Between clustering and void-ing, an emergent geometry of continuous transformations, foments.

Connected into the city's digital twin platform, real-time city infrastructure, and open metaverse the Metablock's growth, availability and structure is linked to real-time models of usage and occupation - some of these behaviours are amplified. The city and the Metablock are a network of entangled infrastructures at a constituent level. It offers a dynamic re-distributed of the infrastructures of the city - instinctive, instructive and reactive. It processes the circumstance, use and occupancy of the city, the overlaps, and breaks.

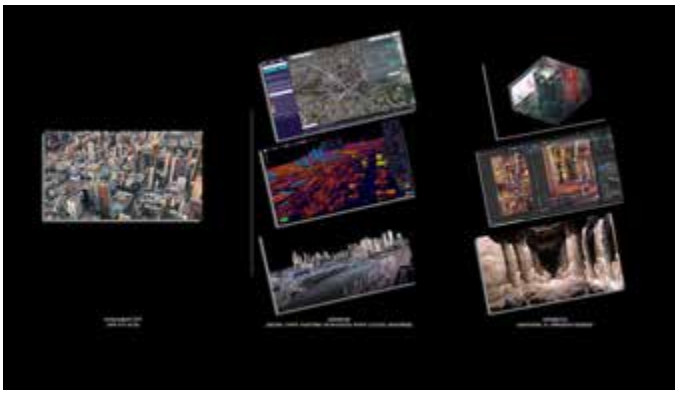

Figure 6. The Metapolis conceptual platform – (i) the incumbent city (the city as is), (ii) the Metapolis – that connects smart city platform technology, digital twins, real-time analytics, APIs and (iii) the Metablock that builds on the data models of the Metapolis to reconstitute a city block in the open metaverse, spatialized through AI diffusion model and search terms. Image: Ian Nazareth. (The diagram also includes images from HEAVY.AI, NVIDIA Omniverse and City of Melbourne LIDAR Point Cloud Data)

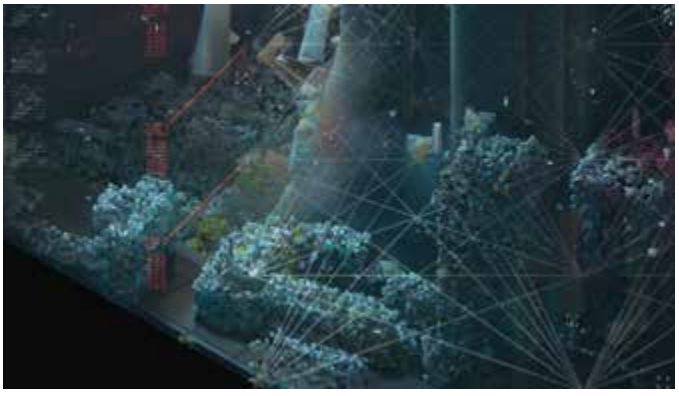

Figure 5. The Metablock – data architecture and spatial architecture are referenced, while a user interface overlays analytical models, data, usage statics, density and other parameters that offer an augmented reading of the city block in the physical city and metaverse. Image: Ian Nazareth and Kevin Gao.

This is conceptually and operatively a platform to connect or tether the physical city, its digital twin and the metaverse, - experimenting with data clouds, real-time information, application programming interfaces (APIs) and real-time analytic platforms HEAVY.AI built on Nvidia Omniverse for collaboration and simulation. The project can further connect to other analytical platforms at a city or neighbourhood level – and consider their value to AI diffusion models. Looking across this emerges as a scaffold connecting the incumbent the service and the metaverse.

The Metablock is a spatially organised directory tree of information, a unitary structure - gravity of connections and intensity of uses delimit the temporal shape and form and restructure the potential of the network. Fissures in data structure clear margins for emergent categories. The metropolis and

the Metapolis are a network of entangled infrastructures at a constituent level. They remain linked and share a common, unified state. Information and actions carry across the meta-physical breach. The Metapolis is an approximation and correlation to its physical counterpart.

The incumbent city and the Metapolis exist contemporaneously as a contingent, unstable action. The city as particles and waves, that occur in superposition of each other, i.e., cities occupying the same coordinate infrastructures, organised by compatible data and metadata. Here, two seemingly distinct spatio-temporal phenomena converge upon the same reality. The Metapolis is perhaps isomorphic. It is a what the city could be, not merely what the city is. Its physical reality delineated by bits and a virtual reality circumscribed by matter and stuff.

Black box, Search terms, Prompts

The architecture of architecture in the metaverse recenters one's gaze. The possibility tends toward the implausible recreation of all conceivable expressions.

Could a spatial system iterate infinitely? Conversely, what if everything that can be imagined has already been designed? Does the infinite deny certain opportunities? What lies beyond the reach of iterability?

Like Jorge Luis Borges' 'La biblioteca de Babel' (Library of Babel) where a library (of infinite chambers is a repository for every permutation of the alphabet) metaphorically describes the universe, the Metapolis confronts the paradox of the infinite, to understand, control and visualise its boundlessness. There's an inherent futility contained in the irrationality – that limitless possibility exponentially reduces the probability of any meaningful experiences. Yet this scarcely detracts from the pursuit.

The architecture of the block is experimentally open-ended, and user/operator/consumer generated. It is therefore confined by the parameters of present mechanical and procedural reproductions. Despite any claims for highly differentiated and enunciated outputs, the process combines generalities, averaging out idiosyncratic products. In the context of language, where expressions cascades as genres, sub-genres and micro-genres, machine learning image generators are form of search engine. Debatably, an utterly original, authentic conception might be beyond comprehension.

The conception of a user generation city proposes a city recreated through the mind's eye, through text, prompts and suggestions. Expression and intention condensed through a flattened visual apparatus sewn together with the benevolence of generative adversarial networks and machine intelligence. This deploys language and perhaps 'design' as an automated combinatorial process. Like machines, human to are visual sampling machines, and a lexicon of words are lateral to a vocabulary of pictures.

Letters, words, phrases, styles, references are all equivalent and unitised – i.e., Search Terms – the fundamental indivisible component of spatial, visual comprehension. The terms are a stenography for a sequence of code and machine instructions, alphabets prearranged into pixels. Outcomes in the city depend on rank-ordering of search terms – the benign act of searching and observing from a distance changes reality. Consequences are contingent on whether they have been observed. Infinitely divisible spatial labyrinths are suspended in the gravity of the meta cities paring to the city's digital twin – the real. It seeks some description of an indivisible quantity within the infinite.

The two concepts utilised to further explore the spatiality of 'rooms' within the Metablock are described below. As discussed earlier, these spaces are linked to the data structure of the city block. This presents the possibility to link the volume and availability of meta spaces as a contingent function related to the behaviour of the city block in real-time.

Allegorical Space

In Book VII of 'The Republic', Plato presents a parable that would come to be known as 'The Allegory of the Cave' – Plato describes a group of prisoners, whose lives are confined to a cave without any connection to the world. A fire (or candle) behind them illuminates movements. Their experiences, consequently, are only determined through the shadows cast before them, scenes that preoccupy their fascination and experience of reality – they classify these illusions and phantoms as actual entities.

In the story one prisoner ventures outside the cave, to discover a world that is illuminated by the sun. He sees 'true' forms not just shadows of form, and details, and reflections, and colour and shadows too. Enlightened, he returns to the cave to help his companions mired in confusion and error – but his vision can now scarcely adjust to the darkness in the cave, while the group, firmly believe his travels to the outside have made him irrational and untrustworthy.

Figure 7. Allegorical Space – a conceptual image of spaces within the Metablock for meeting, gathering, hosting events etc., generated through the use of open-source AI diffusion models and search prompts, then re-modelled into interactive immersive three-dimensional environments through modelling, simulation and rendering, also utilising physics of gaming engines. Image: Ian Nazareth and Kevin Gao.

Of the numerous interpretations, this allegory submits that the things that are seen are flawed reflections of ideal forms, it highlights the problem of representation and a querying of the nature of reality. Plato's Cave is also a techno-philosophy - the fire as a technology that casts shadows to inform perception and make claims about reality. The metaverse and virtual reality experiences are conclusively a form of technol-

ogy that irradiates a perception on reality – between known and unknowable between real and simulated. *What insights might be gained from moving out of the real, into the meta, (and back into a cavern of the real)?*

The Allegory of Plato's Cave is a departure point for the ideas contained within the design process – of how spaces are conceptualised within the project as well as the expansive notion of outside world i.e., beyond the known. The language and hierarchies of the space seek utility in the imageability of illumination and shadows, the form making process, representation in a resonant interior. Here the potential to conceptualise, formalise and accentuate a space though the design of its sciography manifests in the material and textural effects. Each space deals with its own conception of reality, and a totalising, highly differentiated boundary condition.

Backrooms

The Backrooms are not an actual place. One might informally refer to it as a 'non-place'. It exists outside the boundary of programmable floor, beyond all accounts of area and coordinates of architecture. An unfathomable poche. The Backrooms are an infinite abandoned, unfurnished labyrinth or a rupture in the fabric of reality.

Figure 8. Backrooms – a conceptual image of spill out, circulation and ancillary spaces within the Metablock for meeting, collectivity etc., generated through the use of open-source AI diffusion models and search prompts, then re-modelled into interactive immersive three-dimensional environments through modelling, simulation and rendering, also utilising physics of gaming engines. Image: Ian Nazareth and Kevin Gao.

In the paradigm of video games, Backrooms are a space you might encounter if you pass through solid walls – i.e., 'no-clipping', a scenario where you navigate through a game environment with collisions disabled, to glimpse the other side – levels, sub-levels, easter eggs. In the contemporary city this is recognized as 'Junkspace' as described by Rem Koolhaas – 'not Modernity itself, but a residue and coagulation of products while modernization is in progress.'

The Backrooms emerged as an internet meme, but conceptually represent a physical and virtual dimension – real so long as you are in it, a space of prolonged neglect, a buffer, a ballast. It is a space between spaces, a spatial and informational breach. Free-roaming in open-world information landscape, where repetition is sought an instant remedy for infinite.

Conclusion

Presented through the artifice of an architectural project, the Metapolis associates fundamental urban processes, strategic, comprehensive, and statutory urban planning, zoning etc. with elementary digital subdivisions like blockchain, data analytics, machine learning, operating between physical and simulated fields. The research and speculations seek to gather agency in the 'territory' across the more established planning instruments and generative, emergent paradigms manifested by decentralisation and distribution. It empowers an exploration between the city and its digital counterpart – a space to contend with, simulate and augment the metropolis. The platform can serve as an analytical device and a space for collectivity, events etc.

The Metapolis is a dialogue among its temporary inhabitants and users. Logistically and operationally, it is the infinite recreation of interminable rearrangements. Like the city, in its quest for popularity and totality it is in a perpetual state of incompletion. The imagery and experience presented through the project is architectural, industrial, technological and landscape. The Metapolis is a conjuration of biological, mechanical, electronic, linguistic social ideas, and incursion of the built environment into the internet.

The Metapolis captures an emergent, fluctuating domain of architectural exploration catalysed by an internet of things (IoT), distributed platform technology, real-time analytics, Web3, the metaverse and AI. These technologies can be viewed as discrete but are here explored as interleaved variables that could collectively engender an augmented and immersive urban and architectural experience. The terminology and language respond to a landscape of socio-cultural, technological, and gaming syntax, borrowed, and deployed to extract a spatial grammar and advance contemporary architectural practice.

As we continue to allocate our time between physical, simulated, and virtual realms, we are edging closer to a scenario where a significant portion of our lived experience will be simulated rather than non-simulated. Although this is a groundbreaking and dynamic frontier, the research establishes a feasible framework and platform for unifying distinct entities and datasets, as well as a theoretical basis for navigating the transition and translation.

Towards data activation and engagement within a smart city

David van Staden

Cape Peninsula University of Technology, South Africa
vanstadend@cput.ac.za

Abstract

As part of a doctoral study this paper provides a data use reference model for Smart Cities, based on the various interaction points in a city. The SCIEP conceptual model is a way to understand the variances and interdependencies between data users aiding in a city's transformation with new service delivery that is citizen centric. It advocates a move from technologically focused Smart City planning to a more complementary approach to different and changing urban contexts and communities. The SCIEP conceptual model model presented in this paper imagines Smart City implementation as being citizen- centric in its approach, involving participation by all city stakeholders in the establishment of co-created and data driven ecosystem known as the Smart City. It does this by considering Smart City implementation as the establishment of urban intelligence through widespread ICT deployment and exchange combined with co- production and collaborative practices towards the uncovering and establishment of "data-driven innovation" and value (i.e creating new products and services) within a digitally driven ecosystem. The data model presented adds to current academic debate by gaining a better understanding of the role that data, its producers and consumers play in supporting various stakeholder engagement and governance practices when developing Smart City services. It offers a model foregrounding collaborative engagement practices to ensure that smart initiatives and their deployment are well aligned and appropriate in relation to various participatory networks and community engagement practices to establish a more inclusive, active citizenry. It also offers a way to interpret Smart City implementation by considering the context in which it operates in order to unlock its value and potential for providing new services to citizens, to improve their quality of life and enhance social and economic transformation.

Introduction

This paper puts forward the SCIEP conceptual model. The SCIEP model offers a multi-dimensional approach, imagining Smart City implementation as an overarching strategy that takes into account the contextual interstices, people, domains and associated resources needed to mobilise public and stakeholder value. The Smart City concept emerged as a viable model towards improving urban management and public life through the application of ICT and the optimisation and integration of smart technologies (Madakam and Ramachandran, 2015:34). As an instrument, the Smart City aims at improving cities by mobilising all city stakeholders in the creation of sustainable and equitable cities rooted in the use of technologies to establish a co-created, intelligent and connected city (Chamoso, Gonzalez-Briones, Rodriguez and Corchado, 2018:2). In essence, the Smart City concept is an attempt to render cities more efficacious for their citizenry, utilising its ability to optimise and integrate all city functionalities and infrastructure, such as resource optimisation and the advancement of public services.However, as each city is unique, the unlocking of its Smart City potential requires an exploration of its context and variables towards understanding and improving its operational efficiencies and functionalities, such as improving urban systems and accelerating digital transformation for a broader citizenry (Caird and Hallett, 2019:189). This research looked at Smart City implementation as an engagement practice. It offers a model and reports on the components that advance data driven Smart City implementation and engagement and how these components may be developed as a broader Smart City vision.

Methods: Constructing the SCIEP conceptual model

As part of a doctoral study exploring Smart City implementation as an engagement practice for the city of Cape Town, South Africa, this research started with a systematic literature review (SLR) and content analysis. The review was based on the assumption that Smart City implementation can play a significant role in addressing current urbanisation issues; however, the associated mechanism for unlocking its potential is unclear. The objective of the first-phase content and document analysis was to identify the central Smart City discourse and associated constructs and approaches in literature. Results from this content analysis process revealed 63 key elements which pertain to the Smart City discourse and enable a broadly defined overview of the components that lead towards Smart City implementation and engagement. These constructs were further refined regarding their purpose, process and objectives related to the conceptualisation of data through a process of constant comparison, analysis and labelling of raw data as a way of inferring meaning. The accumulation of such inferred meaning provided "potential indicators of a phenomenon" and, through constant compar-

ison and analysis, identified the unit of analysis that informs the theory (Pandit, 1996:1).This systematic approach and analytical process of constant comparison of the data served to identify abstract representations of a phenomenon. It involved the clustering of concepts into categories as they pertain to a phenomenon. The outcomes of this process of constant comparison disclosed 17 constructs, explicitly related to understanding Smart City implementation as a co-created ecosystem. Moreover, the outcomes uncovered the components that lead to Smart City implementation, engagement and the advancement of a local, more inclusive environment. The 17 constructs were further developed and interpreted using an inductive approach of constant comparison in order to understand and develop a Smart City vision that is geared towards engagement. Seven main concepts, specific to Smart City implementation as an engagement process, emerged from this process: 1) data, 2) co-production, 3) citizen participation, 4) knowledge management, 5) Smart City initiatives, 6) Smart City maturity, and 7) Smart City domains. These were further developed into the Smart City Implementation as an Engagement Practice model (SCIEP).

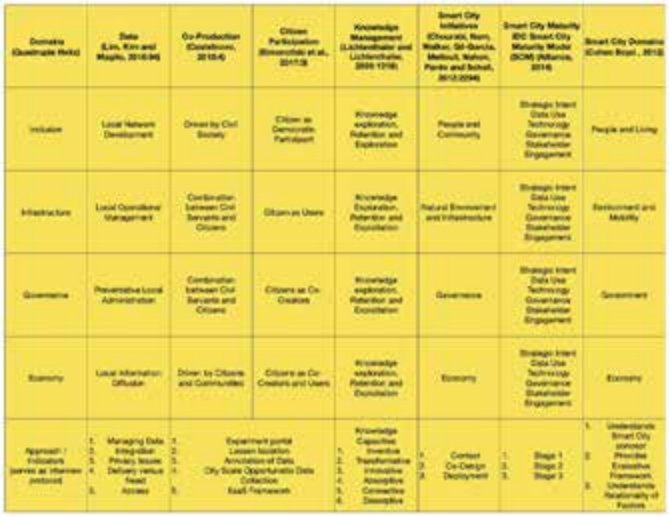

Figure 1. SCIEP conceptual model (Author's construct, 2020)

SCIEP Axis and its Meaning

The SCIEP conceptual model imagines Smart City implementation as being citizen-centric in its approach, involving participation by all city stakeholders in the establishment of co created and data-driven ecosystem known as the Smart City. It does this by considering Smart City implementation as the establishment of urban intelligence through widespread ICT deployment and exchange, combined with co-production and collaborative practices towards the uncovering and establishment of "data-driven innovation" and value (i.e creating new products and services) within a digitally driven ecosystem (Abella et.al., 2017:51). As such, the SCIEP model provides a set of variables by which to activate or establish Smart City implementation which enables social and economic evolution, taking into account the contextual nuances of a city and its wider developmental objectives, such as bridging the digital divide (Boyle and Staines, 2019:26). As such, the SCIEP model also advocates Smart City implementation that facilitates the creation of a more inclusive citizenry and in which citizens are perceived as prosumers (both producers and consumers of content) within the digital urban environment, therefore calling for a bottom-up approach and more participatory governance models to solve urban challenges and understand required city and stakeholder needs (Gutierrez et al., 2016:4). The SCIEP model and its axis, which I discuss below, offer a multi-dimensional approach by which to imagine Smart City implementation as either an overarching strategy from which to work or as a stage-based implemented model towards initiating and driving Smart City initiatives or measure projects, taking into account the needed considerations as they pertain to the contextual interstices, people, domains and associated resources towards mobilising public and stakeholder value.

The vertical axis of the SCIEP conceptual model

The vertical axis of the SCIEP conceptual model serves as a stage-based model for Smart City implementation. It can be thought of as a means of initiating scalable and practical citizen centric solutions, that form part of a city's innovation strategy and ecosystem. For example, in the domain of citizen participation, implementation could have as its focus seeking to permit engagement of collaborative digital practices and environments with citizens and the city, by leveraging citizens as city partners of an urban innovation platform (Madakam and Ramaswamy, 2015:3). As captured in the domain, this could be achieved either through perceiving citizens as (1) democratic participants, (2) citizens as users, or (3) citizens as creators of services. This is important as successful Smart Cities and their service delivery require new ways of public and participant engagement within an urban setting, that allow for more inclusionary platforms to serve as catalysts towards empowering citizens and to transform city management services (Burt, 2001:298; Paskaleva et al., 2015:131). Similarly, as captured in the "data" component, the model highlights the potential usage of data as they relate to (1) developing a local community and how citizen generated data can be reused to help users, (2) local operational management and how data from service providers can be used to improve government and company processes through improved data interoperability, (3) preventive local administration and how data from various companies, users or service providers are captured and leveraged in order to better understand the urban context and problem areas, as well as increase operational efficiencies, and (4) local information diffusion and how data from service providers and customers are leveraged for their usefulness to wider citizenry or stakeholders (Lim et al., 2018:93). These components can also work in tandem in the sense that the overall focus could be on data-use and the development of local network whilst being responsive to how it relates to aspects, such as knowledge management and how knowledge is leveraged for innovation or transformation.

The horizontal axis of the SCIEP model

The horizontal axis of the SCIEP model, therefore, highlights all key Smart City components as they relate to understanding Smart City implementation as a citizen-centric practice that operates within and contends with complex urban environments bearing diverse heterogenous contexts and urban challenges. Its components (horizontal axis), therefore, serve as essential recommendations in perceiving or modelling Smart City implementation as a co-created ecosystem

through an ongoing urban debate that utilises these components of data, co-production, citizen participation, knowledge management, Smart City initiatives, Smart City maturity and Smart City domains, in order to ensure that smart initiatives and their deployment are well aligned and appropriate in relation to various inclusive participatory networks and community engagement practices (Rodriguez-Bolivar, 2015). Furthermore, these key components and their activation as a framework for deployment ensure a better understanding and interpretation of what Smart City implementation should be in order to unlock its value with regard to providing new services to citizens, improving their quality of life and enhancing social and economic transformation and the advancement of a local more inclusive environment, while also focusing on adaptive, scalable and practical citizen-centric solutions as part of a city's innovation strategy and ecosystem (Gutierrez, Amaxilatis, Mylonas and Munoz, 2018:668). For example, the "Data" dimension calls for a data-driven Smart City approach where the activation of data is used as a tooling sport of Smart City initiatives. This dimension calls for consideration of issues, such as (1) associated challenges and required needs in dealing with a vast increase in generated data across distributed networks and data sources, (2) the structuring of data from several sources, such as sensors or city traffic cameras, etc., (3) the need for real-time data processing across city infrastructure and management, and user level, and (4) ensuring data reliability and value as gathered from several data sources (Santana et al., 2017:6). Furthermore, the "Data" domain considers the application of data analytics that support the application of IoT in matters, such as smart transportation, smart healthcare, the smart grid, etc. It also calls for a data-driven co-created city drawing on an array of distributed IoT technologies, data sources and data sets in order to resolve inner-city problems linked to better public services and an improvement in citizens' quality of life. This includes the leveraging of open data and the needed considerations with regard to making sure that (1) data are machine readable and facilitate use and reuse, (2) data are easily accessible on a publicly available online platform, (3) published data follow proper regulatory standards and formats in order to ensure interoperability between various data sets, (4) published data sets have an audit trail indicating the original, intended use which facilitates the interpretation of data sets and their use and reuse, (5) the need for a legal regulatory open data government framework that governs published data according to stakeholder concerns,(6) the need to define operational processes as a collective in order to regulate published data, as well as ensure data use, reuse and interoperability across data sets, (7) the need to generate and facilitate data interaction points between users in order to foster data supply and demand, as well as ensure data relevance and quality, (8) the need for a designated group of experts who manage a city's open data processes, and (9) the need to create and increase data demand in order to promote such issues as government transparency, efficiency improvement, and social and economic development (Nugroho et al., 2015:303).The components of co-production and citizen participation relate to garnering citizens participation in relation to planning and deployment of smart initiatives. As a set of recommendations, it centres around the need to establish collaborative citizen engagement and alternative forms of urban governance that allow citizenry and other stakeholders to collaboratively be part of the design and planning of urban spaces. This set of components supports a number of modalities of participation, as well as understanding the levels of participation within a Smart City, especially with regard to the context of the city and its people (Cardullo and Kitchin, 2019:5). Furthermore, citizen participation is seen as the means by which to enable public engagement, where digital communication tools are leveraged for their capacity to facilitate social conduct. As such, these tools often serve a mediating role towards activating aspects, such as co-production driven by citizens and communities, or citizen participation where citizens are co-creators and users of services (Niederer and Priester, 2016:137). Co-production and citizen participation, therefore, supports the application of digital tools to function as shared social objects towards identifying networks and their organisational conditions, as well as the "socio-material conditions" of communities or neighbourhoods (Niederer and Priester, 2016:137). Additionally, co-production and citizen participation reinforces sustainable forms of participation, and public and citizen engagement, centred around addressing public interests. Participation towards sustainability, therefore, includes the reconciliation of contextual nuances of place and space across the urban domains of economics, social factors and environment. It also supports participation, such as collaborative design, participatory decision-making, public discourse, participatory design challenges, policy integration and public resonance (Joss, 2014:49). The component "knowledge management" highlights the need to unlock latent urban value by supporting enhanced stakeholder interaction between industry, government, society and university. It, therefore, includes considerations around matters, such as open innovation and facilitating collaborative engagement amongst all participating city stakeholders towards a focused innovative action or goal (Paskaleva, et al., 2015:121). It includes a number of ways by which to leverage such engagement including inventive, absorptive and transformative capacities, etc. (Lichtenthaler and Lichtenthaler, 2009:1321). The "Smart City initiatives" component highlights key Smart City paradigms. These Smart City paradigms include (1) community and people, (2) natural environment and infrastructure, (3) governance, and (4) economy. It is within these paradigms, and with the establishment of these urban ecosystems in which social interaction occurs in diverse contexts, across different urban settings and with multiple associated social, infrastructural and technological characteristics, that smart services may be brought about through a blending of co-created social innovation practices based on actor or user needs (Aurigi and Odendaal, 2021:2). The "Smart City maturity" measures as part of the domain ways to determine a city's developmental stages in relation to its Smart City trajectory, as well as to ensure best practice and evaluation of Smart City projects. These measurements are (1) strategic intent, (2) data use, (3) technology, and (4) governance and stakeholder engagement. These variables can also be thought of as stage-based or sequential in nature, building on the preceding indictor or measurement in order to move towards full Smart City implementation. The component Smart City Domains highlights the key focus areas and factors towards establishing a Smart City that aims at resolving inner-city problems linked to public service availability, environmental sustainability, congestion, population density, inequality and liveabili-

ty, infrastructure and management, and smart services. These domains relate to (1) technological implementation, hardware and software frameworks; (2) the use of technological solutions to improve people and communities, emphasising creativity, heterogeneity and education; and (3) institutional governance and policy assistance (Lee et al., 2014:82; Anttiroiko et al., 2014:325). The bottom row titled "Indicators" provides a set of variables or guidelines by which to test or measure the extent or successful implementation of initiatives according to their corresponding SCIEP components. For example, under the "Data" component five variables are highlighted by which to test data-driven Smart City deployment. These variables are used to measure aspects, such as how data are managed in relation to local network development, and to what degree they are accessed, integrated and delivered.

Significance and contribution of SCIEP conceptual Model

The SCIEP conceptual model is a framework by which to imagine or characterise what a Smart City and its initiatives can be when focused as an engagement practice involving all participating city stakeholders and users. It contributes to understanding Smart City implementation as a data-driven approach. Additionally, the establishment of urban intelligence, through widespread ICT deployment and exchange, serves as agency, combined with co-production and collaborative practices, towards the uncovering and establishment of "data-driven innovation" and value (i.e. creating new products and services) within a digitally driven ecosystem known as the Smart City (Abella et.al., 2017:51). The SCIEP conceptual model also takes into account the complexity and heterogeneous nature of modern urbanisation and the challenges many cities face in establishing relevant Smart City solutions. The model also offers the mechanisms and processes to be included in the creation of services, specifically in understanding how data - and access to data - within the Smart City concept add societal value through the synergy created by the exchange of data paired with citizen participation, a co-creation process and knowledge management approaches (Abella et.al., 2017:51). The SCIEP model adds to current academic debate by gaining a better understanding of the role that data, and producers and consumers of data, play in supporting various stakeholder engagements and governance practices when developing Smart City services. It offers a model which foregrounds collaborative engagement practices to ensure that smart initiatives and their deployment are well aligned and appropriate in relation to various participatory networks and community engagement practices to establish a more inclusive and active citizenry (Anttiroiko, 2015:26). It also offers a way to interpret Smart City implementation by considering the context in which it operates in order to unlock its value and potential for providing new services to citizens, to improve their quality of life and enhance social and economic transformation.

Abstract

Collaboration is one of the 21st century skills, and in our new digital and hybrid reality, the importance of designing technologies that support collaborative interaction in various ways has increased due to e.g., the recent Covid-19 pandemic and the need to decrease travel to keep down environmental impact and avoid unnecessary contributions to the climate emergency. Accordingly, designers of digital tools need to be educated regarding supporting collaborative interaction, online, on-site and hybrid. However, there is a lack of concrete teaching materials for how to design collaborative technologies. In this paper, we present an emerging pedagogical framework targeting technology design educations in higher education in teaching to develop students' knowledge and skills for how to design technology that mediates collaborative interaction. The pedagogical framework will be made available for everyone as an online open educational resource.

The framework is developed through a pedagogical design pattern method using a three-phased model for conducting educational design research and developing educational materials. The results are based on Laurillard's pedagogical pattern template (Laurillard, 2012), and further extended with the SOLO taxonomy for defining learning objectives (Biggs, 2003). Using one specific approach throughout simplifies consistency and coherence among the various parts. The pedagogical framework consists of 10 pedagogical patterns, which entail concrete teaching activities with accompanying learning goals. The teaching activities are divided into concepts, methods and practices:

Concepts explain the underlying conceptual and theoretical foundations that students need in order to take human collaborative interaction into account, both in their methods and in their design process, as well as in taking responsibility for their end product or service. An example of a teaching activity is a lecture on 'Collaborative interaction in Activity theory'.

Methods address methods for students to engage with groups, elicit requirements for design, and to practically design and evaluate collaborative technologies. An example of a teaching activity is a lecture and exercise on 'Requirements elicitation for collaborative technologies'.

Practices consists of case studies that illustrate best practices and case studies in designing collaborative technologies. An example is a lecture with an accompanying exercise on 'Designing for Collaborative co-located multi-display environments'. Together, these teaching resources, which are all freely available online, make up a framework that supports developing students' knowledge and skills for how to design technology that mediates collaborative interaction.

We believe that this work has two contributions. First of all, to propose what an emerging pedagogical framework for learning about designing collaborative technologies can be and open it up for critique and further development. Secondly, we also believe that a discussion on teaching practices is important in that it can contribute to developing the research field, as students display through their learning process, aspects that would perhaps have been hidden if we studied experienced designers, or only reflected on our own research practice.

Introduction

Collaboration is a very complex skill which involves coordination, cooperation and at its most advanced level, reflective communication (Bardram, 1998), and is considered as one of the 21st century skills (OECD, 2018). In a time where remote collaboration has become increasingly more important due to e.g., environmental emergency and pandemics (e.g., Tudor, 2022), the need for designing and developing technologies that efficiently support and mediate collaborative interaction has become a high priority.

Historically, most user interface research has focused on single-user systems, although this has been challenged by multi-user or group interfaces (Ellis et al., 1991), which are sensitive to such factors as group dynamics and organizational structure. Collaborative technologies come with design challenges, such as that technology designed for use by different groups must be flexible and accommodate a variety of team behaviors and tasks (Ellis et al., 1991). E.g., two different teams performing the same task use collaborative technology in very different ways (Rein and Ellis 1989), and the same team doing two separate tasks uses the technology differently for each task.

However, teaching as an activity has been somewhat neglected within fields such as Computer Supported Collaborative Work (CSCW, Brown et al., 2007). This in some contrast to HCI, in which teaching has played a more prominent role, and where textbooks summarize what is to be learnt (i.e. Preece et al., 2019) and there is a lively discussion in the community (e.g. Churchill et al., 2013; Eriksson et al., 2022a; Frauenberger and Purgathofer, 2019), including in various sub-fields (e.g. Child-Computer interaction (Van Mechelen et al., 2020), animal-computer interaction (Zamansky et al., 2017). Teaching technology design for collaborative interaction involves imparting a distinctive attitude – in particular a sensitivity to co-ordination. In this paper we aim to initiate a pedagogical framework for teaching design of technologies for collaborative interaction in higher education. We do so by transforming concepts, methods, and practices from research into concrete teaching activities with accompanying learning goals.

Using the materials presented here for teaching a course on designing collaborative technologies will not make the students become experts, but hopefully they will gain a much deeper understanding of how to engage with understanding a group and a setting, before coming to think about design. This might perhaps be the most important student outcome and a core lesson – the connected nature of the technical and the social. We are aiming for students to 'come to see' collaboratively, and through that develop students' knowledge and skills for how to design technology that mediates collaborative interaction.

Background

In the light of the COVID19-pandemic, it is easy to think of collaborative technologies as primarily communication technologies such as applications to support video meetings (e.g., Grønbæk et al., 2021). However, in this work, we refer to a broader notion, including everything from social drones (e.g., Obaid et al., 2022), digital games (e.g., Eriksson et al., 2022b), to the collaborative society (e.g., Jemielniak and Przegalinska, 2020), just to mention a few.

There are several definitions of what collaboration and collaborative interaction mediated by technologies is (e.g., Bardram, 1998; Correia et al., 2017; Roschelle and Teasley, 1995; Sedano et al., 2013; Shah, 2010). However, terms related to collaboration, such as cooperation, coordination, teamwork, social interaction, etc. are often used as synonyms or interchangeably, and there is no systematization of the terms used (Baykal et al., 2020b; Sedano et al., 2013). For instance, social interaction is a vital but insufficient condition for collaboration because some social interactions do not involve shared goals, accommodation of different perspectives or organized attempts to achieve the goals (OECD, 2018).

However, recently, we have seen a tendency to adopt the levels of collaboration as defined in Activity Theory (AT), in order to define collaboration in an operational way (Bardram, 1998; Baykal et al., 2020a; Eriksson et al., 2021). AT provides a method of understanding and analyzing a phenomenon, finding patterns, and making inferences across interactions (Kaptelinin and Nardi, 2009). With AT as a theoretical foundation, Engeström et al. (1997) defined three levels of collaborative interaction, and building on this definition, Bardram (1998) introduced a framework for collaborative interactions between users and mediating technology. This framework consists of three different levels of collaboration, from the simplest to the most complex form: Coordination, Cooperation and Reflective Communication. Acknowledging that there are many other models for defining collaboration, we will in this work lean towards the three levels of collaboration as deriving from Activity theory (Bardram, 1998; Engeström, 1987).

What do we mean by collaborative technologies?

The goal of collaborative technologies, or collaboration systems or groupware, is to assist groups in communicating, in collaborating, and in coordinating their activities, and can be defined as: computer-based systems that support groups of people engaged in a common task (or goal) and that provide an interface to a shared environment (Ellis et al., 1991). In the classic CSCW matrix (Johansen, 1988), four main areas of collaborative technologies are presented:

Face to face interactions: Collocated social interaction focuses on scenarios of 'same time, same place', that is, a synchronous interaction between individuals in close proximity, e.g., single display groupware. In synchronous interactions, such as spoken conversations, people interact in real time (Ellis et al., 1991). In technology development, this area has attracted less interest than technologies for remote connectedness, and hence remains less explored and characterized (Olsson et al., 2019).

Remote interactions: Focus on same time, different place and a typical technology is video conferencing. This is an area that has received increased attention lately, not least due to the COVID-19 pandemic (Tudor, 2022).

Continuous task: Focus on different time, same place, and typical examples are team rooms and large public displays. Interactions are asynchronous, meaning those in which people interact over an extended period of time (Ellis et al., 1991).

Communication and coordination: Focus on different times, different places, where typical examples are email and group calendars.

However, there is one area missing in the matrix, namely that of technologies to support *hybrid interaction*. Neumayr (2021) presents a systematic literature review of the contexts and tools of hybrid collaboration and meetings in HCI and CSCW, with the goal to unpack how hybridity matters when it confers an asymmetry on the coordinated activity. In this review, hybrid collaboration refers to *"collaborative practices that involve simultaneous co-located and remote collaboration with phases of both synchronous and asynchronous work that spans multiple groupware applications and devices"* (Neumayr et al., 2018) and hybrid meetings refer to video- or audio-based communication sessions among co-located and remote participants (Roussel and Gueddana, 2007). Hybrid collaboration switches back and forth between

all four quadrants of the time-space matrix. There are constant transitions between co-located and remote as well as synchronous and asynchronous collaboration. Further, users typically do not rely on a single groupware application or hardware device but simultaneously use different tools and devices during collaboration. Also, the team size is greater than just two collaborators and multiple coupling styles can coexist simultaneously within a single team, effectively dividing the whole team in multiple temporary subgroups of various sizes and an individual coupling style (Neumayr et al., 2018).

Although many systems can be categorized according to their primary emphasis and intent (Ellis et al., 1991), it is important to note that there is no rigid dividing line between systems that are considered collaborative and those that are not, or belonging to one category of the matrix or not. Due to the varying degrees of support for common tasks and shared environments, it is more appropriate to think of a collaborative technology spectrum rather than well-defined boxes (Ellis et al., 1991). In the work presented in this paper, we apply this thinking of collaborative technologies as a spectrum with constant transitions in time, space, and level of collaboration.

Methodology

A three-phased model for conducting educational design research and developing educational materials (McKenney and Reeves, 2018) was used as an underlying and guiding research and development framework. Educational design research is aimed at providing concrete solutions to educational practitioners in relation to practical and complex educational problems such as how teachers can teach collaborative interaction in technology design. Solutions can take the form of educational products and materials that both support teachers in their educational practice and seek to discover new knowledge that can inform future research, development, and practice within that domain.

Phase 1) Exploration and analysis

Exploring the existing domain of teaching design of collaborative technologies by firstly making an inventory of existing teaching practices and research production at our own universities. Secondly, by conducting a literature review on (teaching) design of collaborative technologies and through this developing the research grounding. This included e.g., searching SCOPUS for (TITLE-ABS-KEY (cscw) AND TITLE-ABS-KEY (teach*)), in which we found 135 results, but only one (Brown et al., 2007) actually addressing teaching collaborative technologies. In this phase we also invited two experts and interviewed them on their teaching practices in regard to designing collaborative technologies. We further snowballed on further research resources to include.

Phase 2) Design and construction

Based on phase one, two/three core competencies were identified, and a number of overarching learning objectives were extrapolated and described. Then the SOLO taxonomy (Biggs, 1982) was applied to the competencies and learning objectives to describe how we as teachers can develop students' competencies from a beginner to an advanced level. This led to the construction of an overarching model for how teachers can plan, carry out and evaluate teaching and learning on designing collaborative technologies. Based the results from the first phase, and on the core competencies and learning objectives, we developed a number of concrete learning activities consisting of lectures and exercises.

Phase 3) Evaluation and reflection

Alongside the design of the stand-alone teaching activities, an iterative peer-review of all activities was carried out using the pedagogical pattern evaluation method called shepherding (Harrison, 1999). This method ensured multiple cycles of evaluation, reflection, and revision of the activities throughout the project. Additionally, the teaching activities were put into practice and evaluated through 30 pilots involving around 40 teachers and 523 students coming from various disciplines, programs, institutions, and educational contexts in five universities in four different countries. After each pilot, the teacher was asked to fill out a questionnaire. The students involved in the pilots have been enrolled in bachelor (n=14 pilots), master (n=5 pilots) and mixed PhD \& master programs (n=11 pilots). The programs range from communication design (Faculty of architecture and design) to interaction design (Department of computer science), digital design (Faculty of Arts), Design, Technology and Society Program (Institute of Social Sciences), Design, Technology and Society Program (Institute of Media and Visual Arts), and experience economy (Faculty of Arts).

Pedagogical design pattern approach

The main outcome of the project – the collection of teaching activities – was developed using a modification of the pedagogical design pattern method (Goodyear, 2005; Köppe et al., 2017; Laurillard, 2012; Nørgård et al., 2019). The method is aimed at capturing "best practices" from research and practice, which are then developed into concrete activities for teaching and learning within a specific domain.

The pedagogical pattern method has been applied in order to elicit existing best practice from teachers and from related work found through snowballing. The method has been modified in that we have iteratively developed our own pattern template highly inspired by the pattern template suggested by Laurillard (2012) with the main difference that the students' learning objectives are formulated based on the SOLO taxonomy for defining intended learning outcomes and objectives (Biggs, 1982), for consistency and shared language. The template is complemented with teaching materials, such as suggested literature, worksheets, assignments, and presentation slides. Additionally, all visuals and figures in the developed teaching material are either private images with consent to be published from the owner or generated using artificial intelligence (DALL-E).

The pattern template consists of the following items (Italicized items are modifications from the original template prosed by Laurillard (2012):

- *Title* (Title of the pattern).
- Origin (the original source and later contributors).
- Summary (brief description of what is being taught and how).
- Topics (keywords that will help other teachers decide the relevance).
- Learning outcome (what the learner will know or be able to do by the end *defined using SOLO taxonomy*).

TITLE	Requirements elicitation for collaborative technologies			
ORIGIN	TEDCO			
SUMMARY	Requirements elicitation is about exploring the problem space and defining what will be developed. Requirements range from functional to contextual such as e.g. social environment and user goals. Methods for gathering and analyzing data to elicit requirements will be presented and practiced.			
TOPICS	Methods for requirements elicitation, qualitative data analysis and evaluation			
LEARNING OUTCOME	• Students should be able to name methods for requirements elicitation and qualitative data analysis for collaborative technology. • Students should be able to formulate requirements for collaborative technology. • Students should be able to apply requirement elicitation in design of collaborative technology. • Students should be able to evaluate requirements in the design of collaborative technology.			
RATIONALE	Experiential learning; learning through practice.			
DURATION	3h			
LEARNERS	Design and engineering in higher education			
SETTING	Online, face-to-face, hybrid			
RESOURCES AND TOOLS	Slides in .ppt with lecture and assignment			
LEARNING CYCLES	Sequence of teaching–learning activities	Group Size	Time Mins	Code
	The teacher introduces students to relevant factors for eliciting requirements from qualitative data when designing collaborative technologies. Explains how they will be advised and evaluated	All	40	TCC1
	Students in groups practice analysis of qualitative data and/or requirements elicitation.	4	60	TPC1
	The teacher checks what the students are doing, and advises on aspects to consider.	4	3	TPC2
	The students share their practice outputs with peers, and gain access to peers' outputs as a model for their practice.	8	20	PMC1, 2
	The teacher chairs a class discussion, asking for reflections on experiences, and consolidating the lessons learned.	All	30	PCC1, 2, 3

Figure 1. Example of a completed pattern template - here for Requirements elicitation.

- Rationale (the learning approach or pedagogical design principle).
- Duration (total learning hours, not necessarily continuous).
- Learner characteristics (educational pre-requisites, experience, interests)
- Setting (face-to-face, blended, or online).
- *Resources and tools (the teaching materials e.g., lecture slides).*
- Group size (the range of minimum to any maximum).
- Learning cycles (Sequence of teaching–learning activities)

For the learning cycles, the following codes are used:

- Formative assessment FA
- Summative assessment SA
- Design elements for activities in the Conversational Framework Cycles Access to the teacher's concepts TCC1
- The means to articulate their concepts and reflections on practice TCC2
- Extrinsic feedback on questions or articulations of their concepts TCC3
- A practice environment that facilitates their actions TPC1
- Extrinsic feedback on their articulations of their actions TPC2
- A modeling environment that elicits their actions TMC1
- Intrinsic feedback on their actions from the model TMC2

Figure 2. The pedagogical framework for teaching design of technologies that mediate collaborative interaction. The framework is centred around the overarching learning objective, and consists of three parts: teaching activities, learning objectives, and concepts, methods and practices.

- Access to peers' concepts PCC1
- The means to articulate their concepts and reflections on practice PCC2
- Extrinsic feedback from peers on articulations of their concepts PCC3
- Sharing practice outputs with peers PMC1
- Access to peers' outputs as a model for their practice PMC2

For an example of a complete teaching pattern, see Figure 1.

Results

The overarching learning objective of the entire pedagogical framework is: *To develop student's knowledge and skills for how to design technology that mediates collaborative interaction*, see Figure 2. In order to strive for this learning objective, the teaching activities that the framework consists of are divided into concepts (Table 1), methods (Table 2), and practices (Table 3), each with its own learning objectives and pedagogical pattern. The teaching materials are available for download at https://www.tedco.se.

Considerations for applying the pedagogical patterns

The collection of teaching activities presented in the framework above is meant as an inspirational educational resource, where it is possible to pick and choose what is needed, and what fits into the existing curriculum. They are not designed for a specific curriculum or meant to be taught together as a course. However, there are many considerations to take when planning to teach about design of collaborative technologies including: Who are the intended students, and what curriculum are they following (computer science, engineering, social science)? Length of learning activity (workshop, full course)? Level of knowledge of the students in relation to designing collaborative technologies (beginner or more advanced)? The dimensions of knowledge, skills and attitude that need to be taught (awareness of aspects of collaborative technol-

Table 1. Overview of Concepts in teaching design of collaborative technologies.

Concepts in Design of Collaborative Technologies
The core concepts of collaborative technologies which are relevant for design research and practice, and what are the strategies to link these theory and concepts to design practice. Explains the underlying conceptual and theoretical foundations that students need in order to take collaborative interaction into count, both in their methods and in their design process, as well as in taking responsibility for their end product or service.
Learning Objectives
• Recognize and describe different aspects of collaborative interaction. • Analyze and critically reflect on how collaborative interaction is mediated by technology design
Pedagogical Patterns
• **Introduction to designing collaborative technologies.** Summary: The students are introduced to designing technologies that mediate collaborative interaction. This includes examples of technologies that mediate collaborative interaction, the elements that make up collaborative interaction, and various levels of collaborative interaction. • **Collaborative Interaction in Activity Theory.** Summary: The students are introduced with theoretical approaches and paradigms related to collaborative interaction mediated by technology. Students describe different aspects and levels of human collaboration mediated by technology. Topics for the final discussions is on how students would want to modify the systems to increase or enhance the current collaborative interaction.

Table 2. Overview of Methods in teaching design of collaborative technologies.

Methods in Design of Collaborative Technologies
The methods and approaches for understanding, investigating, and designing technologies for collaborative interaction. Addresses methods for students to engage with groups and their collaborative interaction mediated by technology design, and also to practically design and evaluate collaborative technologies.
Learning Objectives
• Identify and describe direct and indirect stakeholders of a collaborative technology design. • Elicit stakeholder requirements for collaborative technologies. • Integrate considerations for collaborative interaction into the design process. • Analyze, evaluate and critically reflect on the impact of a technology in collaborative interaction in context
Pedagogical Patterns
• **User research in designing collaborative technologies.** Summary: The students are introduced to relevant factors for performing field research when designing collaborative technology (distinctions from dyads to communities), three types of methods to achieve it (ethnography, artifact ecology, and network analysis). • **Requirements elicitation in designing collaborative technologies.** Summary: Requirements elicitation is about exploring the problem space and defining what collaborative technology will be developed. Requirements range from functional to contextual such as e.g., social, environment and user goals. Methods for gathering and analyzing data to elicit requirements for collaborative technologies will be presented. • **Evaluation of collaborative technologies.** Summary: The students learn how to evaluate the user experiences with the system. Students list the methods of evaluating user experience, and propose which method works best for their own system. Students also reflect on why studying user experiences is important, and in which phases of the design process this can play a meaningful role.

ogies, methods for practicing design of collaborative technologies)? When aiming for the overarching learning objective, the framework can be used in several different ways, see Figure 2. For instance, teachers can *explore the learning objectives* for each activity and select those that are the most relevant to their discipline, curriculum, or course. The learning objectives are described in broad terms, while the teaching

Table 3. Overview of Practices in teaching design of collaborative technologies.

Practices in Design of Collaborative Technologies
The practices and pedagogies highlighting how design problems related to collaborative interaction mediated by technology are more uncertain, more nuanced, or more complex than originally assumed. This complexity will be unfolded through a number of case studies. Consist of case studies that illustrate practices in designing collaborative technologies.
Learning Objectives
• Recognize, design, and analyze relevant factors for the design and collaborative aspects of multi-display environments. • Recognize, describe, and analyze relevant factors for the design of technologies for co-located interactions. • Recognize, describe, analyze and integrate hybrid collaboration aspects in the design of collaborative technologies. • Recognize and describe relevant taxonomy for extended reality and analyze aspects in synchronous extended reality remote collaboration systems. • Recognize and describe different aspects of collaborative society
Pedagogical Patterns
• **Designing for Collaborative co-located multi-display environments.** Summary: The students are introduced to the concept of multi-display environments (MDE), i.e., the coupling of several displays together to form a shared interactive environment. The concept is described through a framework and illustrative cases. • **Designing for Mobile and co-located collaborative interaction.** Summary: The students are introduced to designing for co-located collaborative interaction mediated by technology. A framework for designing co-located mobile interactions is presented that can be a useful tool for work in this area. • **Designing for collaborative interaction in hybrid settings.** Summary: The students are introduced to relevant factors for recognizing, analyzing and designing technology to support hybrid collaborative interaction, while reflecting on the consequences of the technologies. This includes understanding how hybridity matters to the tools and processes of collaboration and unpack how hybridity matters when it confers an asymmetry on the coordination that occurs within the interrelated concepts of collaboration. • **Designing for collaborative interaction in extended reality environments.** Summary: The students are introduced to the taxonomy for synchronous collaborative interaction in social augmented, mixed or virtual reality platforms. This includes understanding the main components for designing extended reality platforms that mediate collaboration. Opportunities and challenges of future virtual systems for collaboration are presented for future design considerations. • **Collaborative society.** Summary: Introduces to collaborative society, an emerging trend that changes the social, cultural, and economic fabric of human organization through technology-fostered cooperative behaviors and interactions. This includes different modes of cooperation, illustrated by examples such as sharing economy, peer production, social activism, internet of things, big data etc.

activities connected to each of the learning objectives execute them in concrete ways. Further, teachers can *combine concrete teaching activities* that move students from a simple (unistructural) to a complex (extended abstract) level of understanding of designing collaborative technologies in accordance with the SOLO taxonomy Biggs (2003). Teachers can also *combine concepts, methods and practices* that create a broad foundation for students to become designers of collaborative technologies. Whatever way is chosen, it is important for teachers to adapt and appropriate the teaching activities to fit their specific educational context (Hendry, 2020; Nilsson et al., 2020).

Experiences with using the teaching materials

The teaching materials were iteratively developed based on the peer-review process but were also evaluated based on a questionnaire by the teacher after pilots. Some of the teach-

ers gave concrete input to further development and design iterations of the teaching materials, such as a pilot using the Evaluation pattern, where the teacher states that 'the pattern on Evaluation should be split up into multiple parts'. Also, when the teaching material on stakeholder mapping was tested in a bachelor project course, the teacher comment that 'the workshop gave insights into the topic that could be taken into account in the further developments of the material, and that in general students tend to be well able to grasp 2x2 matrices in various contexts (not only placement of collaborative technologies, but also types of stakeholders could be classified in a 2x2 matrix)'. The teachers state that the added value of the piloted teaching material was: 1.) professional development within technology design for collaborative interaction, 2.) a qualitative update of the design curriculum of collaborative technologies, 3.) increased capacity to teach technology design for collaborative interaction in relevant and innovative ways.

Discussion

The pedagogical framework presented in this paper is the result of an inductive approach to the pedagogical pattern method, meaning that we started with our own and our colleagues research and teaching practices, and snowballed from there. This means that we are not trying to claim that this framework covers everything a student needs to know in order to develop knowledge and skills for how to design technology that mediates collaborative interaction. Rather, this is an initial approach to an emerging pedagogical framework. We are not claiming that an inductive approach is the best or only approach possible, a more deductive approach could have led to a different outcome. Also, the evaluation of the developed teaching material is so far restricted to iterative peer-review and questionnaire feedback from teachers after pilots. In future work, we would encourage further evaluation based on feedback from students, and not only rely on the teacher's conception based on the students observable learning.

Challenges and considerations

In this work, we have met a number of challenges and considerations that we need to pay attention to when designing teaching materials for the design of technologies that mediate collaborative interaction. The first issue is the lack of a common definition for collaboration. The term "collaboration" used interchangeably with similar but not synonymous words such as "social", "cooperative", "coordination" in the literature especially in technology design studies (Baykal et al., 2020b). Thus, in our teaching materials we adopted the following formulation for the term collaboration in order to identify the elements of collaborative interaction Collaboration is a technologically mediated social interaction between multiple people who share a common goal. Based on this formulation of the term, the core elements of the collaborative interaction include; Social (synchronous or asynchronous), Multiple people (human), Those people have a shared goal, Technology plays a mediating role between multiple people, Intention of designers and/vs. users' appropriation.

The second issue is also linked to the first one in that collaboration is a very complex phenomena which is not only difficult to define but also to analyze. To this extent, we found the levels of collaborative interaction defined in Activity Theory as the most comprehensive one. Derived from Activity Theory, Engeström defined three levels of collaborative interaction: 1. coordination, 2. cooperation, 3. reflective communication (Engeström, 1987; Engeström et al., 1997). This definition inspired some work particularly in CSCW (Kuutti and Arvonen, 1992) as well as in HCI in general by being used as a lens to analyze the collaborative interaction mediated by technology (Kaptelinin and Nardi, 2009; Kuutti et al., 1996; Bardram, 1998; Baykal et al., 2020a), albeit having its own limitations (Bødker et al., 1988). The future work may use the definition to analyze the collaborative activities in different scales (e.g., business models such as Uber, Airbnb which were built on shared economy as explained from a critical theoretical perspective in Collaborative Society by Jemielniak and Przegalinska), spaces (e.g. hybrid meetings, see Neumayr et al. 2021; Grønbæk et al. 2021), or realities and temporalities (e.g. envisioning and designing various interaction modalities and sensory inputs which require further investigation in social AR/VR/MR platforms (Schäfer et al., 2021).

The third issue is sort of an outcome of the former two in that the lack of a common definition and level of complexity of the phenomena for analysis yields a diverse but scattered knowledge of how to design for and evaluate the collaborative interaction (Baykal et al., 2020b), let alone the challenges in mediating a higher level of collaboration between the collaborating actors.

Intention and adoption in the design of collaborative technologies

In this framework, collaborative technologies are considered as a spectrum with constant transitions in time, space and level of collaboration. This is due to the fact that there is no rigid dividing line between systems that mediate collaborative interaction and those that do not. Many systems can be categorized according to their primary emphasis and intent (Ellis et al., 1991), but still most often have varying degrees of support for common tasks and shared environments and is also highly dependent on the specific adoption by the users in specific situations. So, this is why we in this work find it more appropriate to think of a collaborative technology spectrum rather than well-defined boxes, as in e.g., the CSCW matrix (Ellis et al., 1991). This, however, led to difficulties when designing the teaching materials, as the literature more often has a focus on the intention rather than actual use.

Another related challenge we experienced when developing the teaching material, especially when focused on practices, was that most literature has an emphasis on a specific technology or application, and not on the collaborative aspects as such. This led to many discussions on what is specific to designing technologies for mediating collaborative interaction, with the consequence of that much material has been excluded for being classified as too general. Examples of this are general theory on HCI for the pattern "Collaborative Interaction in Activity Theory", and even a whole pattern on "Prototyping collaborative technologies" was excluded.

Methods used

Applying the pedagogical pattern method worked well for the development of the teaching materials presented in this framework. Especially the use of the SOLO taxonomy as a shared language for defining learning objectives was experienced as very fruitful. The SOLO taxonomy became a shared language not only for the design team, but also in correspond-

ence with the teachers involved in the pilots, as they are used to SOLO in their practice. In regard to the pattern template inspired by Laurillard (2012), especially the learning cycles were highly useful in developing the teaching materials. The sequence of teaching-learning activities helped to provide at the same time a holistic and detailed take on the various materials, so that the lecture and exercises became better aligned.

Conclusion

In this paper, we have introduced an initial pedagogical framework for teaching design of technologies that mediate collaborative interaction. The framework is based on an inductive approach to the pedagogical pattern method in combination with the SOLO taxonomy. The framework is a first try to transfer concepts, methods and practices from research into concrete and inspirational teaching activities aimed for teaching in higher education. In the framework, collaborative technologies range across many different application areas, and without a well-framed definition. Still, the core elements include social interaction (synchronous or asynchronous), Multiple people (human), Shared goal, Technology as mediator between multiple people, Intention of designers, and User appropriation. In the framework, collaborative technologies are considered as a spectrum with constant transitions in time, space and level of collaboration. Hopefully this framework can inspire teachers in higher education to dive into the complex world of teaching in designing technologies for mediating collaborative interaction.
