In this paper, we derive a new 2D brittle fracture model for thin shells via dimension reduction, where the admissible displacements are only normal to the shell surface. The main steps include to endow the shell with a small thickness, to express the threedimensional energy in terms of the variational model of brittle fracture in linear elasticity, and to study the $\Gamma$-limit of the functional as the thickness tends to zero.

The numerical discretization is tackled by first approximating the fracture through a phase field, following an Ambrosio-Tortorelli like approach, and then resorting to an alternating minimization procedure, where the irreversibility of the crack propagation is rigorously imposed via an inequality constraint. The minimization is enriched with an anisotropic mesh adaptation driven by an a posteriori error estimator, which allows us to sharply track the whole crack path by optimizing the shape, the size, and the orientation of the mesh elements.

Finally, the overall algorithm is successfully assessed on two Riemannian settings and proves not to bias the crack propagation.

Keywords: Dimension reduction; brittle fracture on thin shells; phase-field approximation; free discontinuity problems; anisotropic mesh adaptation; finite elements.

## 1. Introduction

The problem of finding reasonable two-dimensional (2D) models of elasticity for plates and shells dates back to more than 100 years ago with contributions of J. Bernoulli, L. Euler, G. R. Kirchhoff, T. von Kármán and many others (see, e.g. the Kirchhoff-Love plate theory and the Föppl-von-Kármán equations ${ }^{(36151 \mid 54161)}$ ).

In recent works, a 2D model is usually obtained as a limit of a 3D one: the target surface (shell or plate) is endowed with a fictitious thickness $\rho>0$ and the limit as $\rho \rightarrow 0$ is studied. Considering the variational framework of elasticity, such a limit is computed in terms of $\Gamma$-convergence ${ }^{[28}$ In the context of linearized elasticity, a comprehensive work by Ciarlet about 2D models can be found in Ref. 23 for thin plates and in Ref. 24 for thin shells. In these monographs, the convergence of the solution to the 3 D model is considered, avoiding the notion of $\Gamma$-convergence. A justification of the above results in terms of $\Gamma$-convergence has been provided successively in Ref. 45. Related works in the case of nonlinear elasticity can be found, for instance, in Refs. 42, 43 and 44 ,

In this paper, we develop and analyze a new 2D model of brittle fractures on thin shells, moving from the variational theory of brittle fractures in linearly elastic materials. ${ }^{[11]}$ Accordingly, the total energy of a body $U \subset \mathbb{R}^{3}$ subject to a displacement $u: U \rightarrow \mathbb{R}^{3}$ is given by

$$
\begin{equation*}
\frac{1}{2} \int_{U} \hat{\boldsymbol{C}} \hat{\boldsymbol{\epsilon}}(u): \hat{\boldsymbol{\epsilon}}(u) \mathrm{d} x+\kappa \mathcal{H}^{2}\left(J_{u}\right) \tag{1.1}
\end{equation*}
$$

where $\hat{\boldsymbol{C}}$ is the stiffness tensor, $\hat{\boldsymbol{\epsilon}}(u)$ stands for the symmetric gradient of $u, J_{u}$ is the jump set of $u, \mathcal{H}^{2}$ denotes the 2D Hausdorff measure, and $\kappa>0$ is the toughness of the material. Because of compactness issues, the natural domain of definition of functional (1.1) is $\operatorname{SBD}(U)$ or $\operatorname{GSBD}(U)$, the space of (generalized) special functions of bounded deformation. We refer to Refs. 55, 22 and 29 for further details on these spaces. In this setting, we can find a dimension reduction result in Ref. 14 where the authors investigate thin films bonded to a stiff substrate. In case of nonlinear or anti-planar elasticity, where the bulk energy in (1.1) is expressed in terms of the full gradient $\nabla u$, the domain of the energy functional simplifies to $\operatorname{SBV}(U)$ or $\operatorname{GSBV}(U){ }^{6}$ Such an approach has been used to investigate dimension reduction problems in Refs. 12, 13 and 19. However, all the cited works are obtained for a planar setting, i.e. the target 2D surface is a subset of $\mathbb{R}^{2}$.

The main contribution of this paper is the derivation of a brittle fracture model for general surfaces. As in (1.1), we stick to linearized elasticity. Analogously to the anti-plane shear setting, which has been the first one tackled in the variational formulation of fractures, ${ }^{32}$ we only consider displacement fields normal to the surface. The advantage of this choice is that the displacement field can be described by a scalar function, since its direction is fixed, so that we can still adopt the space GSBV. We defer the general case to future work.

In more detail, in Sec. 2 we introduce the geometric setting by considering a 2D surface $\phi(\omega) \subset \mathbb{R}^{3}$, where $\omega \subset \mathbb{R}^{2}$ is open, bounded, with Lipschitz boundary, and
$\phi: \omega \rightarrow \mathbb{R}^{3}$ is an immersion. We endow this surface with a thickness $\rho>0$, so that our reference configuration becomes $\Phi\left(\Omega_{\rho}\right)$, with $\Omega_{\rho}:=\omega \times\left(-\frac{\rho}{2}, \frac{\rho}{2}\right)$ and $\Phi$ a suitable extension of $\phi$. We start with a strong formulation of brittle fracture, where a state of the system is described by a pair displacement-fracture ( $u, K$ ) for $K \subseteq \Phi\left(\Omega_{\rho}\right)$ closed and $u \in C^{1}\left(\Phi\left(\Omega_{\rho}\right) \backslash K ; \mathbb{R}^{3}\right)$. In this setting, we express the functional (1.1) in curvilinear coordinates on $\Omega_{\rho}$. After a second change of variables, we remove the dependence of the integration domain on the thickness, passing from $\Omega_{\rho}$ to $\Omega_{1}$. Then, we restrict the admissible displacements to those which are normal to the surface. As a standard approach in free-discontinuity problems, ${ }^{6}$ the functional is relaxed to $\operatorname{GSBV}\left(\Omega_{1}\right)$. Section 2.3 is devoted to the $\Gamma$-convergence analysis as the thickness tends to zero. The limit functional will be defined for $u \in \operatorname{GSBV}\left(\Omega_{1}\right)$ independent of $x_{3}$ by

$$
\begin{equation*}
\frac{1}{2} \int_{\Omega_{1}} b|u|^{2} \mathrm{~d} x+\frac{\mu}{2} \int_{\Omega_{1}} \nabla u^{\top} A \nabla u \mathrm{~d} x+\kappa \int_{J_{u}} \sqrt{\nu_{u}^{\top} A \nu_{u} \sqrt{a}} \mathrm{~d} \mathcal{H}^{2} \tag{1.2}
\end{equation*}
$$

where $A$ is a symmetric positive definite matrix related to the metric tensor of $\phi(\omega), b$ is a function of the stiffness $\hat{\boldsymbol{C}}$ and of the curvature of the surface, $\mu>0$ is the second Lamé coefficient, and $\nu_{u}$ is the approximate unit normal to $J_{u}$. In contrast to the Euclidean setting, the geometry of the surface and the magnitude of the displacement $|u|$ directly contribute to the energy of the elastic shell due to curvature effects. Moreover, all the quantities in (1.2) are independent of $x_{3}$, so that the integrals could be written on $\omega$.

Section $[2.4$ introduces the regularized reduced model based on a phase-field approximation of (1.2) in the sense of Ambrosio and Tortorelli, ${ }^{[78]}$

$$
\begin{aligned}
\mathcal{F}_{\varepsilon}(u, v):= & \frac{1}{2} \int_{\omega} b|u|^{2} \mathrm{~d} x+\frac{\mu}{2} \int_{\omega}\left(v^{2}+\eta_{\varepsilon}\right) \nabla u^{\top} A \nabla u \mathrm{~d} x \\
& +\kappa \int_{\omega}\left[\frac{1}{4 \varepsilon}(1-v)^{2} \sqrt{a}+\varepsilon \nabla v^{\top} A \nabla v\right] \mathrm{d} x
\end{aligned}
$$

for $u \in H^{1}(\omega), v \in H^{1}(\omega ;[0,1])$. Loosely speaking, $v$ is a regularization of the crack set such that where $v$ is close to one the material is sound, while where $v \ll 1$, a fracture is detected.

The minimization of the functional $\mathcal{F}_{\varepsilon}$ is used to simulate the fracture process driven by a time-dependent boundary condition $g$. Following Ref. 3, according to a quasi-static approximation, at each time $t_{i}$ a new state $\left(u\left(t_{i}\right), v\left(t_{i}\right)\right)$ of the thin shell is computed as the limit as $j \rightarrow \infty$ of the alternating minimization

$$
\begin{align*}
& u_{j}:=\arg \min \left\{\mathcal{F}_{\varepsilon}\left(u, v_{j-1}\right): u \in H^{1}(\omega), u=g\left(t_{i}\right) \text { on } \partial \omega\right\}  \tag{1.3}\\
& v_{j}:=\arg \min \left\{\mathcal{F}_{\varepsilon}\left(u_{j}, v\right)+\frac{\alpha}{2 \tau}\left\|v-v\left(t_{i-1}\right)\right\|_{L^{2}(\omega)}^{2}: v \in H^{1}(\omega), v \leq v\left(t_{i-1}\right)\right\} \tag{1.4}
\end{align*}
$$

where $\alpha>0$ is a fixed parameter and $\tau>0$ is the time increment. In particular, the new state $\left(u\left(t_{i}\right), v\left(t_{i}\right)\right)$ is a critical point of $\mathcal{F}_{\varepsilon}(u, v)+\frac{\alpha}{2 \tau}\left\|v-v\left(t_{i-1}\right)\right\|_{L^{2}(\omega)}^{2}$. We refer to Definitions 3.1 and 3.2 and Proposition 3.1 for further details.

We note that the inequality constraint in (1.4) takes care of the irreversibility condition, i.e. no healing of the crack is allowed $[47 / 52 / 53$ As in Ref. 33, the presence of an $L^{2}$-penalization in (1.4) ensures the convergence to a unilateral gradient flow in the time continuous limit. Instead, to approximate a quasi-static evolution of the crack as in Refs. 1, 2, 4, 17, 20, 52, 53 and 65, we choose $\alpha$ small enough.

Following Ref. 10, we couple the alternating minimization with an anisotropic mesh adaptation procedure. The rationale is that the phase field $v$ is close to one in large portions of the domain, while it exhibits very steep gradients to reach zero in a thin neighborhood of the crack. For this reason, the mesh needs to be very fine only across the crack. As an alternative, to ensure accuracy, one should resort to a very fine uniform grid. This might be prohibitive from a computational point of view, whereas an adaptive mesh significantly contains the computational effort of the algorithm. Moreover, compared to isotropic adapted meshes, ${ }^{20121}$ anisotropic grids further improve the efficiency of the numerical scheme, since the triangles can be stretched along the crack.

Since the alternating minimization (1.3)-(1.4) is discretized in a finite element setting ${ }^{10120}$ in Sec. 3.2 we derive an anisotropic a posteriori error estimator to measure the distance from an exact critical point. This estimator drives the generation of the new anisotropic adapted mesh relying on a metric based strategy proposed in Refs. 40, 55] and 56, as detailed in Sec. (4. Compared to the numerical approaches of Refs. 16, 17, 20, 10 and 11, the main novelty is that we now take care of the inequality constraint in (1.4) exactly. ${ }^{[52153]}$ This implies that the Euler-Lagrange conditions satisfied by a critical point $(u, v)$ of $\mathcal{F}_{\varepsilon}(u, v)+\frac{\alpha}{2 \tau}\left\|v-v\left(t_{i-1}\right)\right\|_{L^{2}(\omega)}^{2}$ are expressed by a variational inequality rather than an equality, in contrast to Ref. 10 where a penalization of the irreversibility condition is adopted and to Refs. 16 and 17 where $v$ is set to 0 where $v\left(t_{i-1}\right)$ is below a certain threshold.

Finally, in Sec. 5, we assess the proposed model and the anisotropic discretization on two non-Euclidean settings, i.e. a piece of a cylinder and a piece of a sphere. This verification allows us to establish the reliability of the new dimensionally reduced brittle fracture model and of the anisotropic mesh adaptation procedure, which does not bias the evolution of the crack path.

## 2. The Two-Dimensional Model

Before providing the technical details, we clarify some basic notation.
Given an open subset $U \subset \mathbb{R}^{n}$, we denote the space of functions of bounded variation by $\mathrm{BV}(U)$ and the space of special functions of bounded variation by $\operatorname{SBV}(U)$. The set of generalized special functions of bounded variation is indicated by $\operatorname{GSBV}(U)$. Furthermore, we define the following function spaces:

$$
\begin{aligned}
\operatorname{SBV}^{2}(U) & :=\left\{u \in \operatorname{SBV}(U): \nabla u \in L^{2}(U), \mathcal{H}^{n-1}\left(S_{u}\right)<\infty\right\}, \\
\operatorname{GSBV}^{2}(U) & :=\left\{u \in \operatorname{GSBV}(U): \nabla u \in L^{2}(U), \mathcal{H}^{n-1}\left(S_{u}\right)<\infty\right\},
\end{aligned}
$$

where $\nabla u$ denotes the approximate gradient of $u, S_{u}$ is the discontinuity set of $u$, and $\mathcal{H}^{n-1}$ stands for the ( $n-1$ )-dimensional Hausdorff measure. We refer to Refs. 6 and 33 for all the definitions and details on the theory of functions of bounded variation. We recall here that, for $u \in \operatorname{GSBV}(U)$, the set $S_{u}$ is $\mathcal{H}^{n-1}$-rectifiable. We will denote by $\nu_{u}$ the approximate unit normal to $S_{u}$, whereas, for a generic rectifiable set $K$, we denote by $\nu_{K}$ the associated approximate unit normal. We further note that $\operatorname{GSBV}^{2}(U)$, unlike $\operatorname{GSBV}(U)$, is a vector space (see Ref. 30).

Throughout the paper, we systematically use the Einstein summation convention, where Greek indices take values 1 and 2, and Latin indices run from 1 to 3 .

### 2.1. Geometric setting

Let $\omega \subset \mathbb{R}^{2}$ be an open and bounded set, and let $\phi \in C^{2}\left(\bar{\omega} ; \mathbb{R}^{3}\right)$ be an injective immersion, i.e. the tangent vectors $a_{\alpha}=\partial_{\alpha} \phi$ are linearly independent. Defining the vector $a_{3}:=\frac{a_{1} \times a_{2}}{\left\|a_{1} \times a_{2}\right\|}$, normal to the surface $\phi(\omega)$, we obtain the basis $\left\{a_{1}, a_{2}, a_{3}\right\}$ of $\mathbb{R}^{3}$. In Fig. $\mathbb{1}$, we find an illustration of this configuration. The contravariant basis $\left\{a^{i}\right\}$ is defined by $a^{i} \cdot a_{j}=\delta_{j}^{i}$, where $\delta_{j}^{i}$ denotes the Kronecker delta, $a_{3}=a^{3}$. The covariant components of the metric tensor are given by $a_{\alpha \beta}:=a_{\alpha} \cdot a_{\beta}$. We set $\left(a^{\alpha \beta}\right):=\left(a_{\alpha \beta}\right)^{-1}$ which is its contravariant component matrix. Note that $a^{\alpha \beta}=$ $a^{\alpha} \cdot a^{\beta}$. Moreover, we simply define $a:=\operatorname{det}\left(a_{i j}\right)$.

The covariant components $b_{\alpha \beta}$, the mixed components $b_{\alpha}^{\beta}$ of the curvature tensor, and the Christoffel symbols $\Gamma_{\alpha \beta}^{\sigma}$ are defined by

$$
\begin{equation*}
b_{\alpha \beta}:=a_{3} \partial_{\alpha} a_{\beta}, \quad b_{\beta}^{\alpha}:=a^{\alpha \sigma} b_{\sigma \beta}, \quad \Gamma_{\alpha \beta}^{\sigma}:=a^{\sigma} \partial_{\alpha} a_{\beta} \tag{2.1}
\end{equation*}
$$

respectively. Note that we omit the dependence on spatial variable when not explicitly needed.

Remark 2.1. By the assumptions on $\phi$, we obtain that there exist two positive constants $c$ and $C$, both independent of $x \in \omega$, such that

$$
\begin{equation*}
c|\zeta|^{2}<a_{\alpha \beta} \zeta^{\alpha} \zeta^{\beta}<C|\zeta|^{2} \quad \text { for all } \zeta \in \mathbb{R}^{2} \tag{2.2}
\end{equation*}
$$

We further make use of the continuity of $\phi$ on the compact set $\bar{\omega}$ to obtain upper and lower bounds for all the quantities in (2.1).

Fig. 1. Geometric setting of the surface.

In this work, we only deal with manifolds that are covered by one single chart $\phi$. To deal with more complex manifolds, e.g. compact manifolds, such as a sphere or a torus, we have to resort to more than one chart, each one satisfying (2.2), and then to glue them properly.

We now modify the surface $\phi(\omega)$ by adding a thickness, $\rho>0$, as illustrated in Fig. 2. Thus, we define $\Omega_{\rho}:=\omega \times\left(-\frac{\rho}{2}, \frac{\rho}{2}\right)$ and the map $\Phi: \Omega_{\rho} \rightarrow \mathbb{R}^{3}$ by

$$
\begin{equation*}
\Phi(x):=\phi\left(x_{1}, x_{2}\right)+x_{3} a_{3} \quad \text { for all } x=\left(x_{1}, x_{2}, x_{3}\right) \in \Omega_{\rho}, \tag{2.3}
\end{equation*}
$$

with $\phi(\omega)=\Phi(\omega \times\{0\})$, that is, $\phi(\omega)$ is the middle surface of $\Phi\left(\Omega_{\rho}\right)$. We recall that in view of Theorems 3.1-1 in Ref. 24 it is not restrictive to assume that $\Phi$ is a diffeomorphism.

Concerning the notation related to $\Phi\left(\Omega_{\rho}\right)$, symbols with or without a hat are associated with the original Cartesian $\left(\Phi\left(\Omega_{\rho}\right)\right)$ or curvilinear $\left(\Omega_{\rho}\right)$ coordinate system, respectively. In particular, it is understood that $x \in \Omega_{\rho}$ with $\hat{x}=\Phi(x)$ when related in the same statement. We define the covariant basis $g_{i}:=\partial_{i} \Phi$ and the corresponding metric tensor $g_{i j}:=g_{i} \cdot g_{j}$. By (2.3), we obtain

$$
g_{\alpha}=a_{\alpha}+x_{3} \partial_{\alpha} a_{3} \quad \text { and } \quad g_{3}=a_{3}=a^{3}=g^{3}
$$

The contravariant basis $\left\{g^{i}\right\}$ denotes the dual basis of the covariant basis, i.e. $g_{i} \cdot g^{j}=\delta_{i}^{j}$. It follows that the inverse of $\left(g_{i j}\right)$ is given by $g^{i j}:=g^{i} \cdot g^{j}$. Additionally, we define $g:=\operatorname{det}\left(g_{i j}\right)$. For the mapping $\Phi$, we also introduce the corresponding Christoffel symbols, denoted by $\Lambda_{i j}^{k}:=g^{k} \cdot \partial_{i} g_{j}$, such that the symmetry condition, $\Lambda_{i j}^{k}=\Lambda_{j i}^{k}$, holds.

### 2.2. The reference model

In order to derive the 2 D model, we start from the brittle fracture energy from Francfort and Marigd ${ }^{411}$ in the original Cartesian coordinates, given by

$$
\begin{equation*}
E\left(\hat{u}, \hat{K}_{\rho}\right):=\frac{1}{2} \int_{\Phi\left(\Omega_{\rho}\right) \backslash \hat{K}_{\rho}} \hat{\boldsymbol{C}} \hat{\boldsymbol{\epsilon}}(\hat{u}): \hat{\boldsymbol{\epsilon}}(\hat{u}) \mathrm{d} \hat{x}+\kappa \mathcal{H}^{2}\left(\hat{K}_{\rho}\right), \tag{2.4}
\end{equation*}
$$

for $\left.\hat{u} \in C^{1}\left(\Phi\left(\Omega_{\rho}\right) \backslash \hat{K}_{\rho}\right) ; \mathbb{R}^{3}\right)$ describing the displacement field and for $\hat{K}_{\rho} \subset \Phi\left(\Omega_{\rho}\right)$ a closed and $\mathcal{H}^{2}$-rectifiable set describing the fracture. The constant $\kappa>0$ denotes

Fig. 2. Geometric setting of the thickened surface.
the toughness, which is a material-dependent constant. The stiffness tensor $\hat{\boldsymbol{C}}$ is given by

$$
\hat{\boldsymbol{C}}^{i j k l}=\lambda \delta^{i j} \delta^{k l}+\mu\left(\delta^{i k} \delta^{j l}+\delta^{i l} \delta^{j k}\right)
$$

with Lamé coefficients $\lambda \geq 0$ and $\mu>0$. The symbol: in (2.4) denotes the usual tensor product

$$
\hat{\boldsymbol{C}} \hat{\boldsymbol{\epsilon}}(\hat{u}): \hat{\boldsymbol{\epsilon}}(\hat{u})=\hat{\boldsymbol{C}}^{i j k l} \hat{\boldsymbol{\epsilon}}_{i j}(\hat{u}) \hat{\boldsymbol{\epsilon}}_{k l}(\hat{u})
$$

Furthermore, $\hat{\boldsymbol{\epsilon}}(\hat{u})$ denotes the strain given by the symmetric gradient

$$
\hat{\boldsymbol{\epsilon}}(\hat{u}):=\frac{1}{2}\left(\nabla \hat{u}+(\nabla \hat{u})^{\top}\right) \quad \hat{\boldsymbol{\epsilon}}_{i j}(\hat{u}):=\frac{1}{2}\left(\partial_{i} \hat{u}_{j}+\partial_{j} \hat{u}_{i}\right) .
$$

We remark that the following symmetries hold:

$$
\hat{\boldsymbol{C}}^{i j k l}=\hat{\boldsymbol{C}}^{j i k l}=\hat{\boldsymbol{C}}^{k l i j} \quad \text { and } \quad \hat{\boldsymbol{\epsilon}}_{i j}(\hat{u})=\hat{\boldsymbol{\epsilon}}_{j i}(\hat{u})
$$

Following the strategy of Ref. 24, we express (2.4) in terms of curvilinear coordinates. For this purpose, we express the vector field $\hat{u}$ in terms of the covariant basis, by defining $u_{i}: \Omega_{\rho} \rightarrow \mathbb{R}$ such that

$$
\begin{equation*}
\hat{u}(\hat{x})=u_{i}(x) g^{i}(x) \quad \text { or equivalently } u_{j}(x)=\hat{u}(\hat{x}) \cdot g_{j}(x) \tag{2.5}
\end{equation*}
$$

For $K_{\rho}:=\Phi^{-1}\left(\hat{K}_{\rho}\right), u \in C^{1}\left(\Omega_{\rho} \backslash K_{\rho} ; \mathbb{R}^{3}\right)$ and $\hat{u} \in C^{1}\left(\Phi\left(\Omega_{\rho} \backslash K_{\rho}\right) ; \mathbb{R}^{3}\right)$ related by (2.5), we get

$$
\begin{equation*}
E\left(\hat{u}, \hat{K}_{\rho}\right)=\frac{1}{2} \int_{\Omega_{\rho} \backslash K_{\rho}} \boldsymbol{C} \boldsymbol{\epsilon}(u): \boldsymbol{\epsilon}(u) \sqrt{g} \mathrm{~d} x+\kappa \int_{K_{\rho}} \sqrt{\left[\nu_{K_{\rho}}\right]_{i} g^{i j}\left[\nu_{K_{\rho}}\right]_{j}} \sqrt{g} \mathrm{~d} \mathcal{H}^{2} \tag{2.6}
\end{equation*}
$$

where $\left[\nu_{K_{\rho}}\right]_{k}$ is the $k$ th component of the unit normal to the surface $K_{\rho}, \boldsymbol{\epsilon}(u)$ stands for the strain in the curvilinear setting

$$
\boldsymbol{\epsilon}_{i j}(u):=\frac{1}{2}\left(\partial_{i} u_{j}+\partial_{j} u_{i}\right)-u_{k} \Lambda_{i j}^{k},
$$

and $\boldsymbol{C}$ is the elasticity tensor in the curvilinear framework

$$
C^{i j k l}:=\lambda g^{i j} g^{k l}+\mu\left(g^{i k} g^{j l}+g^{i l} g^{j k}\right)
$$

A simple scaling in the variable $x_{3}$ provides an integration domain independent of $\rho$, namely,

$$
\pi_{\rho}:\left\{\begin{array}{l}
\Omega \rightarrow \Omega_{\rho} \\
x \mapsto\left(x_{1}, x_{2}, \rho x_{3}\right)
\end{array} \quad \text { with } \Omega:=\Omega_{1}=\omega \times\left(-\frac{1}{2}, \frac{1}{2}\right)\right.
$$

For any closed set $K_{\rho} \subset \Omega_{\rho}$, we let $K:=\pi_{\rho}^{-1}\left(K_{\rho}\right)$. For any scalar, vector, or tensor field $q$, we add a subscript $\rho$ to denote the composition with $\pi_{\rho}$, i.e. $q_{\rho}:=q \circ \pi_{\rho}$.

In particular, for all $u \in C^{1}\left(\Omega_{\rho} \backslash K_{\rho} ; \mathbb{R}^{3}\right)$ we define $u_{\rho}:=u \circ \pi_{\rho}$ and, for $w \in$ $C^{1}\left(\Omega \backslash K ; \mathbb{R}^{3}\right)$,

$$
\begin{align*}
& \boldsymbol{\epsilon}_{\alpha \beta, \rho}(w):=\frac{1}{2}\left(\partial_{\alpha} w_{\beta}+\partial_{\beta} w_{\alpha}\right)-w_{k} \Lambda_{\alpha \beta, \rho}^{k} \\
& \boldsymbol{\epsilon}_{\alpha 3, \rho}(w):=\frac{1}{2}\left(\partial_{\alpha} w_{3}+\frac{1}{\rho} \partial_{3} w_{\alpha}\right)-w_{k} \Lambda_{\alpha 3, \rho}^{k} \\
& \boldsymbol{\epsilon}_{33, \rho}(w):=\frac{1}{\rho} \partial_{3} w_{3}-w_{k} \Lambda_{33, \rho}^{k} . \tag{2.7}
\end{align*}
$$

One can easily check that $\boldsymbol{\epsilon}_{\rho}\left(u_{\rho}\right)=\boldsymbol{\epsilon}(u) \circ \pi_{\rho}$, so that the energy functional (2.6) can be written as

$$
\begin{align*}
E(\hat{u}, \hat{K})= & \frac{\rho}{2} \int_{\Omega \backslash K} \boldsymbol{C}_{\rho} \boldsymbol{\epsilon}_{\rho}\left(u_{\rho}\right): \boldsymbol{\epsilon}_{\rho}\left(u_{\rho}\right) \sqrt{g_{\rho}} \mathrm{d} x \\
& +\kappa \rho \int_{K} \sqrt{\left[D^{\rho} \nu_{K}\right]_{i} g_{\rho}^{i j}\left[D^{\rho}{\nu_{K}}_{j}\right.} \sqrt{g_{\rho}} \mathrm{d} \mathcal{H}^{2}, \tag{2.8}
\end{align*}
$$

where $D^{\rho}:=\operatorname{diag}(1,1,1 / \rho)$.
Hereafter, we restrict the model to the case of displacements that are normal to the middle surface, i.e. of the form $u=\left(0,0, u_{3}\right)$, so that (2.5) is equivalent to $\hat{u}=u_{3} g^{3}=u_{3} a^{3}$. Hence, the whole problem can be expressed in terms of a scalar function $u$ and, with a slight abuse of notation, we set $\boldsymbol{\epsilon}(u):=\boldsymbol{\epsilon}(0,0, u)$ for all $u \in C^{1}\left(\Omega_{\rho} \backslash K_{\rho}\right)$.

Since $\Lambda_{i 3}^{3}=a^{3} \partial_{i} a_{3}=0$, by (2.7) we obtain, for all $u_{\rho} \in C^{1}(\Omega \backslash K)$,

$$
\begin{equation*}
\boldsymbol{\epsilon}_{\alpha \beta, \rho}\left(u_{\rho}\right)=-\Lambda_{\alpha \beta, \rho}^{3} u_{\rho}, \quad \boldsymbol{\epsilon}_{\alpha 3, \rho}\left(u_{\rho}\right)=\frac{1}{2} \partial_{\alpha} u_{\rho}, \quad \boldsymbol{\epsilon}_{33, \rho}\left(u_{\rho}\right)=\frac{1}{\rho} \partial_{3} u_{\rho} . \tag{2.9}
\end{equation*}
$$

Finally, we recall Theorems 3.2-1 and 3.3-1 in Ref. 24, which state some important convergence results of the geometric quantities in (2.8), for $\rho \rightarrow 0$.

Proposition 2.1. With the definitions above there holds the following:

$$
\begin{align*}
g_{\rho} & =a+O(\rho) \\
g_{\rho}^{\alpha \beta} & =a^{\alpha \beta}+O(\rho), \quad g_{\rho}^{\alpha 3}=0, \quad g_{\rho}^{33}=1,  \tag{2.10}\\
\Lambda_{\alpha \beta, \rho}^{3} & =b_{\alpha \beta}+O(\rho),
\end{align*}
$$

where we recall that $g:=\operatorname{det}\left(g_{i j}\right)$ and $a:=\operatorname{det}\left(a_{i j}\right)$. The convergence rates, as $\rho \rightarrow 0$, are uniform, i.e. they do not depend on $x \in \Omega$. Furthermore, there exist $c, C>0$ such that, for every $\rho>0$ sufficiently small,

$$
\begin{equation*}
c|\zeta|^{2} \leq g_{i j, \rho} \zeta^{i} \zeta^{j} \leq C|\zeta|^{2} \quad \text { and } \quad c|\zeta|^{2} \leq g_{\rho}^{i j} \zeta_{i} \zeta_{j} \leq C|\zeta|^{2} \quad \text { for all } \zeta \in \mathbb{R}^{3} . \tag{2.11}
\end{equation*}
$$

Proposition 2.2. The following relations hold:

$$
\begin{aligned}
& \boldsymbol{C}_{\rho}^{\alpha \beta \sigma \tau}=\lambda a^{\alpha \beta} a^{\sigma \tau}+\mu\left(a^{\alpha \sigma} a^{\beta \tau}+a^{\alpha \tau} a^{\beta \sigma}\right)+O(\rho), \quad \boldsymbol{C}_{\rho}^{\alpha \beta \sigma 3}=0, \\
& \boldsymbol{C}_{\rho}^{\alpha 3 \beta 3}=\mu a^{\alpha \beta}+O(\rho), \quad C_{\rho}^{\alpha \beta 33}=\lambda a^{\alpha \beta}+O(\rho), \quad C_{\rho}^{\alpha 333}=0 \quad C_{\rho}^{3333}=\lambda+2 \mu .
\end{aligned}
$$

The convergence rates as $\rho \rightarrow 0$ are uniform, i.e. they do not depend on $x \in \Omega$. Furthermore, there exist some constants $c, C>0$ such that, for $\rho>0$ sufficiently small,

$$
\begin{equation*}
c|\mathrm{M}|^{2} \leq C_{\rho}^{i j k l} \mathrm{M}_{i j} \mathrm{M}_{k l} \leq C|\mathrm{M}|^{2} \quad \text { for all } \mathrm{M} \in \mathbb{R}^{3 \times 3} \text { symmetric, } \tag{2.12}
\end{equation*}
$$

where $|\cdot|$ stands for the Frobenius norm.

As a consequence of Proposition 2.1) we can rewrite (2.8) as

$$
\begin{align*}
E(\hat{u}, \hat{K})= & \frac{\rho}{2} \int_{\Omega \backslash K} \boldsymbol{C}_{\rho} \boldsymbol{\epsilon}_{\rho}\left(u_{\rho}\right): \boldsymbol{\epsilon}_{\rho}\left(u_{\rho}\right) \sqrt{g_{\rho}} \mathrm{d} x \\
& +\kappa \rho \int_{K} \sqrt{\left[\nu_{K}\right]_{\alpha} g_{\rho}^{\alpha \beta}\left[\nu_{K}\right]_{\beta}+\frac{1}{\rho^{2}}\left[\nu_{K}\right]_{3}^{2}} \sqrt{g_{\rho}} \mathrm{d} \mathcal{H}^{2} . \tag{2.13}
\end{align*}
$$

### 2.3. Dimension reduction

With a view to the limit for $\rho \rightarrow 0$, we rescale the energy in (2.13) by $\rho^{-1}$ and observe that, as long as $\rho>0$, such a scaling does not change the "threedimensional" minimizer of the functional.

It is a standard, in the theory of free discontinuity problems, to relax the functional (2.13) from $C^{1}(\Omega \backslash K)$ to the space $\operatorname{GSBV}(\Omega)$ and to replace the set $K$ with the discontinuity set $S_{u}$. Hence, for all $u \in \operatorname{GSBV}(\Omega)$ and for all $\rho>0$, we define the functional

$$
G_{\rho}(u):=\frac{1}{2} \int_{\Omega} \boldsymbol{C}_{\rho} \boldsymbol{\epsilon}_{\rho}(u): \boldsymbol{\epsilon}_{\rho}(u) \sqrt{g_{\rho}} \mathrm{d} x+\kappa \int_{S_{u}} \sqrt{\left[\nu_{u}\right]_{\alpha} g_{\rho}^{\alpha \beta}\left[\nu_{u}\right]_{\beta}+\frac{1}{\rho^{2}}\left[\nu_{u}\right]_{3}^{2}} \sqrt{g_{\rho}} \mathrm{d} \mathcal{H}^{2} .
$$

The current goal is the computation of the $\Gamma$-limit of the sequence of functionals $G_{\rho}$ as $\rho \rightarrow 0$. For this purpose, we introduce the function space:

$$
\mathcal{U}:=\left\{u \in \operatorname{GSBV}^{2}(\Omega): \partial_{3} u=0,\left[\nu_{u}\right]_{3}=0\right\} .
$$

Remark 2.2. Conditions $\partial_{3} u=0$ and $\left[\nu_{u}\right]_{3}=0$ imply that $u \in \mathcal{U}$ is independent of $x_{3}$. This can be easily checked for $u \in \mathcal{U} \cap \operatorname{SBV}^{2}(\Omega)$, since the third component of the distributional derivative $\mathrm{D} u$ is zero, so that $u$ is constant with respect to $x_{3}$. By a truncation argument, this can be extended to every $u \in \mathcal{U}$. Therefore, we can identify $\mathcal{U}$ with $\operatorname{GSBV}^{2}(\omega)$.

As stated in Theorem 2.1 below, the $\Gamma$-limit of $G_{\rho}$ turns out to be

$$
\begin{aligned}
G_{0}(u):= & \frac{1}{2} \int_{\Omega} c^{\alpha \beta \sigma \tau} b_{\alpha \beta} b_{\sigma \tau}|u|^{2} \sqrt{a} \mathrm{~d} x \\
& +\frac{\mu}{2} \int_{\Omega} a^{\alpha \beta} \partial_{\alpha} u \partial_{\beta} u \sqrt{a} \mathrm{~d} x+\kappa \int_{S_{u}} \sqrt{\left[\nu_{u}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u}\right]_{\beta}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2}
\end{aligned}
$$

where

$$
c^{\alpha \beta \sigma \tau}:=\frac{2 \lambda \mu}{\lambda+2 \mu} a^{\alpha \beta} a^{\sigma \tau}+\mu\left(a^{\alpha \sigma} a^{\beta \tau}+a^{\alpha \tau} a^{\beta \sigma}\right)
$$

Remark 2.3. Analogously to (2.12), there exist two constants $c, C>0$, such that

$$
c|\mathrm{M}|^{2} \leq c^{\alpha \beta \sigma \tau} \mathrm{M}_{\alpha \beta} \mathrm{M}_{\sigma \tau} \leq C|\mathrm{M}|^{2} \quad \text { for all } \mathrm{M} \in \mathbb{R}^{2 \times 2} \text { symmetric. }
$$

This implies that, when $G_{0}(u)<\infty$, we have $b_{\alpha \beta} u \in L^{2}(\Omega)$.
We are now ready to state the result describing the 2 D model in terms of a $\Gamma$-convergence argument as the thickness $\rho$ of $\Omega_{\rho}$ tends to zero.

Theorem 2.1. Let $\mathcal{G}_{\rho}: L^{1}(\Omega) \rightarrow \mathbb{R}$ be defined by

$$
\mathcal{G}_{\rho}(u)= \begin{cases}G_{\rho}(u) & \text { for } u \in \operatorname{GSBV}^{2}(\Omega) \\ +\infty & \text { otherwise }\end{cases}
$$

and $\mathcal{G}_{0}: L^{1}(\Omega) \rightarrow \mathbb{R}$ by

$$
\mathcal{G}_{0}(u)= \begin{cases}G_{0}(u) & \text { for } u \in \mathcal{U} \\ +\infty & \text { otherwise }\end{cases}
$$

Then, $\mathcal{G}_{\rho} \Gamma$-converges to $\mathcal{G}_{0}$ with respect to the $L^{1}$-topology as $\rho \rightarrow 0$.
Proof. The proof follows directly from Propositions 2.3 and 2.4 below.
In order to prove Proposition 2.3, we further need the next auxiliary lemma.
Lemma 2.1. Let $\left\{\rho_{\ell}\right\}$, with $\rho_{\ell}>0$, be a null sequence. Let $u_{\ell}$ be such that $u_{\ell} \rightarrow u$ in $L^{1}(\Omega)$ as $\ell \rightarrow \infty$ and

$$
\begin{equation*}
\sup _{\ell \in \mathbb{N}} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)<\infty \tag{2.14}
\end{equation*}
$$

Then, $u \in \mathcal{U}$ and, up to a subsequence, $\boldsymbol{\epsilon}_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right) \rightharpoonup-b_{\alpha \beta} u$ and $\partial_{\alpha} u_{\ell} \rightharpoonup \partial_{\alpha} u$ weakly in $L^{2}(\Omega)$. Furthermore,

$$
\lim _{\ell \rightarrow \infty} \int_{S_{u_{\ell}}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right| \mathrm{d} \mathcal{H}^{2}=0
$$

Proof. Throughout the proof, $C>0$ denotes a generic constant, independent of $x \in \Omega$ and of $\rho_{\ell}$.

Since $\mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)$ is bounded, we have that $u_{\ell} \in \operatorname{GSBV}^{2}(\Omega)$. From (2.9), we have that, for sufficiently large $\ell$,

$$
\begin{align*}
\left|\nabla u_{\ell}\right|^{2} & =\sum_{\alpha}\left|2 \epsilon_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right)\right|^{2}+\left|\rho_{\ell} \epsilon_{33, \rho_{\ell}}\left(u_{\ell}\right)\right|^{2} \\
& \leq 4 \sum_{i, j}\left|\epsilon_{i j, \rho_{\ell}}\left(u_{\ell}\right)\right|^{2} \leq C C_{\rho_{\ell}}^{i j k l} \epsilon_{i j, \rho_{\ell}}\left(u_{\ell}\right) \epsilon_{k l, \rho_{\ell}}\left(u_{\ell}\right), \tag{2.15}
\end{align*}
$$

where the last inequality follows from (2.12). Furthermore, from Proposition 2.1, we infer that

$$
\begin{equation*}
C \leq\left[\nu_{u_{\ell}}\right]_{\alpha} g_{\rho_{\ell}}^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\rho_{\ell}^{2}}\left(\left[\nu_{u_{\ell}}\right]_{3}\right)^{2} \quad \text { and } \quad C \leq g_{\rho_{\ell}} . \tag{2.16}
\end{equation*}
$$

As a consequence, there holds

$$
C\left(\int_{\Omega}\left|\nabla u_{\ell}\right|^{2} \mathrm{~d} x+\mathcal{H}^{2}\left(S_{u_{\ell}}\right)\right) \leq \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right) \leq \sup _{\ell} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)<+\infty .
$$

Because of the $L^{1}$-convergence of $u_{\ell},\left\|u_{\ell}\right\|_{L^{1}(\Omega)}$ is uniformly bounded. Thus, by compactness properties of $\operatorname{GSBV}^{2}(\Omega)$ (see, e.g. Theorem 4.36 in Ref. 6), there holds $u \in \operatorname{GSBV}^{2}(\Omega)$ and $\nabla u_{\ell} \rightharpoonup \nabla u$ weakly in $L^{2}\left(\Omega ; \mathbb{R}^{n}\right)$.

Applying Theorem 5.8 from Ref. 66, we obtain

$$
\int_{\Omega}\left|\partial_{3} u\right|^{2} \mathrm{~d} x \leq \liminf _{\ell \rightarrow \infty} \int_{\Omega}\left|\partial_{3} u_{\ell}\right|^{2} \mathrm{~d} x
$$

Hence, using (2.9) and (2.15), we have

$$
\int_{\Omega}\left|\partial_{3} u\right|^{2} \mathrm{~d} x \leq \liminf _{\ell \rightarrow \infty} \rho_{\ell}^{2} \int_{\Omega}\left|\epsilon_{33, \rho_{\ell}}\left(u_{\ell}\right)\right|^{2} \mathrm{~d} x \leq C \liminf _{\ell \rightarrow \infty} \rho_{\ell}^{2} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)=0
$$

which yields $\partial_{3} u=0$. Now, we show that $\left[\nu_{u}\right]_{3}=0$. From Theorem 5.22 in Ref. [6, this lower semi-continuity property follows: For every $\tilde{\rho}>0$,

$$
\begin{align*}
\int_{S_{u}} & \sqrt{\left[\nu_{u}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u}\right]_{\beta}+\frac{1}{\tilde{\rho}^{2}}\left|\left[\nu_{u}\right]_{3}\right|^{2}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2} \\
& \leq \liminf _{\ell \rightarrow \infty} \int_{S_{u_{\ell}}} \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\tilde{\rho}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2} . \tag{2.17}
\end{align*}
$$

This yields that, for every $\tilde{\rho}>0$,

$$
\begin{equation*}
\frac{1}{\tilde{\rho}} \int_{S_{u}}\left|\left[\nu_{u}\right]_{3}\right| \sqrt{a} \mathrm{~d} \mathcal{H}^{2} \leq \liminf _{\ell \rightarrow \infty} \int_{S_{u_{\ell}}} \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\tilde{\rho}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2} \tag{2.18}
\end{equation*}
$$

From Proposition (2.1) (2.14), and (2.16), for sufficiently large $\ell$ we deduce

$$
\begin{align*}
\int_{S_{u_{\ell}}} & \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\tilde{\rho}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2} \\
& \leq \int_{S_{u_{\ell}}} \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} g_{\rho_{\ell}}^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\rho_{\ell}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{g_{\rho_{\ell}}} \mathrm{d} \mathcal{H}^{2}+C \sqrt{\rho_{\ell}}+C \rho_{\ell} \\
& \leq \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)+C \sqrt{\rho_{\ell}}+C \rho_{\ell} \tag{2.19}
\end{align*}
$$

By assumption (2.14), the right-hand side of (2.19) turns out to be uniformly bounded. Thus, combining (2.18) and (2.19), we derive

$$
\int_{S_{u}}\left|\left[\nu_{u}\right]_{3}\right| \sqrt{a} \mathrm{~d} \mathcal{H}^{2} \leq C \sqrt{\tilde{\rho}} \quad \text { for every } \tilde{\rho}>0
$$

The previous inequality implies that $\left[\nu_{u}\right]_{3}=0$ on $S_{u}$, so that $u \in \mathcal{U}$.
As in (2.15), we obtain that $\left\|\partial_{\alpha} u_{\ell}\right\|_{L^{2}(\Omega)}$ and $\left\|\epsilon_{\alpha \beta, \rho}\left(u_{\ell}\right)\right\|_{L^{2}(\Omega)}$ are uniformly bounded. Then, the weak convergence follows from (2.9) and (2.10).

We now prove the lim inf-inequality.

Proposition 2.3. Under the same hypotheses as in Theorem 2.1] there holds $\mathcal{G}_{0} \leq$ $\Gamma$-liminf ${ }_{\rho \rightarrow 0} \mathcal{G}_{\rho}$.

Proof. Let $\left\{\rho_{\ell}\right\}$, with $\rho_{\ell}>0$, be a null sequence, and let $u_{\ell}$ be a sequence converging in $L^{1}(\Omega)$ to $u \in L^{1}(\Omega)$. Without loss of generality, we can assume that $\liminf _{\ell \rightarrow \infty} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)=\lim _{\ell \rightarrow \infty} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)<\infty$. From Lemma 2.1 it follows that $u \in \mathcal{U}$.

After some algebraic manipulations, we have

$$
\begin{equation*}
\mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)=I_{\rho_{\ell}}^{(1)}\left(u_{\ell}\right)+I_{\rho_{\ell}}^{(2)}\left(u_{\ell}\right)+I_{\rho_{\ell}}^{(3)}\left(u_{\ell}\right)+I_{\rho_{\ell}}^{(4)}\left(u_{\ell}\right) \tag{2.20}
\end{equation*}
$$

with

$$
\begin{aligned}
I_{\rho_{\ell}}^{(1)}\left(u_{\ell}\right):= & \frac{1}{2} \int_{\Omega}\left(\frac{2 \lambda \mu}{\lambda+2 \mu} g_{\rho_{\ell}}^{\alpha \beta} g_{\rho_{\ell}}^{\sigma \tau}+\mu\left(g_{\rho_{\ell}}^{\alpha \sigma} g_{\rho_{\ell}}^{\beta \tau}+g_{\rho_{\ell}}^{\alpha \tau} g_{\rho_{\ell}}^{\beta \sigma}\right)\right) \\
& \times \epsilon_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right) \boldsymbol{\epsilon}_{\sigma \tau, \rho_{\ell}}\left(u_{\ell}\right) \sqrt{g_{\rho_{\ell}}} \mathrm{d} x \\
I_{\rho_{\ell}}^{(2)}\left(u_{\ell}\right):= & \frac{1}{2} \int_{\Omega}(\lambda+2 \mu)\left(\frac{\lambda}{\lambda+2 \mu} g_{\rho_{\ell}}^{\alpha \beta} \boldsymbol{\epsilon}_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right)+\boldsymbol{\epsilon}_{33, \rho_{\ell}}\left(u_{\ell}\right)\right)^{2} \sqrt{g_{\rho_{\ell}}} \mathrm{d} x \\
I_{\rho_{\ell}}^{(3)}\left(u_{\ell}\right):= & 2 \mu \int_{\Omega} g_{\rho_{\ell}}^{\alpha \beta} \epsilon_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right) \boldsymbol{\epsilon}_{\beta 3, \rho_{\ell}}\left(u_{\ell}\right) \sqrt{g_{\rho_{\ell}}} \mathrm{d} x \\
I_{\rho_{\ell}}^{(4)}\left(u_{\ell}\right):= & \kappa \int_{S_{u_{\ell}}} \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} g_{\rho_{\ell}}^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\rho_{\ell}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{g_{\rho_{\ell}}} \mathrm{d} \mathcal{H}^{2} .
\end{aligned}
$$

We now prove the liminf-inequality for $I_{\rho_{\ell}}^{(1)}, I_{\rho_{\ell}}^{(3)}$ and $I_{\rho_{\ell}}^{(4)}$, whereas the term $I_{\rho_{\ell}}^{(2)}$ need not be estimated, being non-negative.

From pointwise convergence (up to a subsequence) of $u_{\ell}$ almost everywhere and from Proposition 2.1 we derive the pointwise convergence of the integrand of $I_{\rho_{\ell}}^{(1)}\left(u_{\ell}\right)$. Hence, by Fatou lemma, we obtain

$$
\begin{equation*}
\frac{1}{2} \int_{\Omega} c^{\alpha \beta \sigma \tau} b_{\alpha \beta} b_{\sigma \tau}|u|^{2} \sqrt{a} \mathrm{~d} x \leq \liminf _{\ell \rightarrow \infty} I_{\rho_{\ell}}^{(1)}\left(u_{\ell}\right) \tag{2.21}
\end{equation*}
$$

In view of (2.2), the map $v \mapsto \int_{\omega} a^{\alpha \beta} v_{\alpha} v_{\beta} \sqrt{a} \mathrm{~d} x$ is a norm in $L^{2}(\Omega)$ and is therefore weakly lower semi-continuous in $L^{2}(\Omega)$. Hence, using the weak convergence $\epsilon_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right) \rightharpoonup \frac{1}{2} \partial_{\alpha} u$ in $L^{2}(\Omega)$ proved in Lemma 2.1, we obtain

$$
\frac{1}{4} \int_{\Omega} a^{\alpha \beta} \partial_{\alpha} u \partial_{\beta} u \sqrt{a} \mathrm{~d} x \leq \liminf _{\ell \rightarrow \infty} \int_{\Omega} a^{\alpha \beta} \boldsymbol{\epsilon}_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right) \boldsymbol{\epsilon}_{\beta 3, \rho_{\ell}}\left(u_{\ell}\right) \sqrt{a} \mathrm{~d} x .
$$

From (2.2) and from Proposition 2.1, for sufficiently large $\ell$ it holds

$$
\begin{aligned}
& \int_{\Omega} a^{\alpha \beta} \boldsymbol{\epsilon}_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right) \boldsymbol{\epsilon}_{\beta 3, \rho_{\ell}}\left(u_{\ell}\right) \sqrt{a} \mathrm{~d} x \\
& \quad \leq \int_{\Omega} g_{\rho_{\ell}}^{\alpha \beta} \boldsymbol{\epsilon}_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right) \boldsymbol{\epsilon}_{\beta 3, \rho_{\ell}}\left(u_{\ell}\right) \sqrt{g_{\rho_{\ell}}} \mathrm{d} x+C \sqrt{\rho_{\ell}} \sum_{\alpha}\left\|\boldsymbol{\epsilon}_{\alpha 3, \rho_{\ell}}\left(u_{\ell}\right)\right\|_{L^{2}(\Omega)}^{2},
\end{aligned}
$$

namely,

$$
\begin{equation*}
\frac{\mu}{2} \int_{\omega} a^{\alpha \beta} \partial_{\alpha} u \cdot \partial_{\beta} u \sqrt{a} \mathrm{~d} x \leq \liminf _{\ell \rightarrow \infty} I_{\rho_{\ell}}^{(3)}\left(u_{\ell}\right) \tag{2.22}
\end{equation*}
$$

Proceeding as in (2.17)-(2.19), for every $\tilde{\rho}>0$, we have that

$$
\begin{align*}
& \kappa \int_{S_{u}} \sqrt{\left[\nu_{u}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u}\right]_{\beta}} \sqrt{a} \mathrm{~d} \mathcal{H}^{1} \\
& \quad \leq \liminf _{\ell \rightarrow \infty} \kappa \int_{S_{u_{\ell}}} \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\tilde{\rho}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2} \\
& \quad \leq \liminf _{\ell \rightarrow \infty} \kappa \int_{S_{u_{\ell}}} \sqrt{\left[\nu_{u_{\ell}}\right]_{\alpha} g_{\rho_{\ell}}^{\alpha \beta}\left[\nu_{u_{\ell}}\right]_{\beta}+\frac{1}{\rho_{\ell}^{2}}\left|\left[\nu_{u_{\ell}}\right]_{3}\right|^{2}} \sqrt{g} \mathrm{~d} \mathcal{H}^{2}+C \sqrt{\rho_{\ell}} \\
& \quad=\liminf _{\ell \rightarrow \infty} I_{\rho_{\ell}}^{(4)}\left(u_{\ell}\right) . \tag{2.23}
\end{align*}
$$

Summing up (2.21)-(2.23) and using that $I_{\rho_{\ell}}^{(2)}$ is non-negative, we deduce that

$$
\mathcal{G}_{0}(u) \leq \liminf _{\ell \rightarrow \infty} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)
$$

which concludes the proof.
In the next proposition, we prove the lim sup-inequality.
Proposition 2.4. Under the same hypotheses as in Theorem 2.1, there holds $\Gamma$ - $\lim \sup _{\rho \rightarrow 0} \mathcal{G}_{\rho} \leq \mathcal{G}_{0}$.

Proof. Let $\left\{\rho_{\ell}\right\}$, with $\rho_{\ell}>0$, be a sequence such that $\rho_{\ell} \rightarrow 0$ as $\ell \rightarrow \infty$. We can assume that $\mathcal{G}_{0}(u)<+\infty$ and thus $u \in \mathcal{U}$, otherwise, from Proposition 2.3, we have that $\liminf _{\ell \rightarrow \infty} \mathcal{G}_{\rho_{\ell}}(u)=+\infty$ and there is nothing to prove. Moreover, setting $u^{P}:=(-P) \vee u \wedge P$ for $P>0$, we clearly have that $u^{P} \rightarrow u$ in $L^{1}(\Omega)$ and $\mathcal{G}_{0}\left(u^{P}\right) \rightarrow$ $\mathcal{G}_{0}(u)$ for $P \rightarrow+\infty$. Therefore, we may just consider $u \in \operatorname{SBV}^{2}(\Omega) \cap L^{\infty}(\Omega)$.

We pick the sequence $u_{\ell}$ in $\operatorname{SBV}^{2}(\Omega) \cap L^{\infty}(\Omega)$ defined for all $\ell \in \mathbb{N}$ by

$$
u_{\ell}(x)=u\left(x_{1}, x_{2}\right) \exp \left(\frac{\lambda}{\lambda+2 \mu} a^{\alpha \beta} b_{\alpha \beta} \rho_{\ell} x_{3}\right) \quad \text { for } x=\left(x_{1}, x_{2}, x_{3}\right) \in \Omega
$$

It turns out that $u_{\ell} \rightarrow u$ in $L^{1}(\Omega)$ as $\ell \rightarrow \infty$ and that $u_{\ell}$ is bounded in $L^{\infty}(\Omega)$. Starting from (2.20), we show that each term $I_{\rho_{\ell}}^{(k)}\left(u_{\ell}\right)$ (for $k=1,2,3,4$ ) converges as expected.

Since all the functions involved in the exponential are uniformly bounded, it holds $\left|u_{\ell}\right| \leq C|u|$ for some constant $C>0$. Moreover, we deduce from (2.10) in Proposition 2.1 that

$$
\begin{equation*}
\left|\boldsymbol{\epsilon}_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right)\right|=\left|\Lambda_{\alpha \beta, \rho_{\ell}}^{3} u_{\ell}\right| \leq C\left|b_{\alpha \beta} u\right|+C \rho_{\ell}|u| . \tag{2.24}
\end{equation*}
$$

Since $u, b_{\alpha \beta} \in L^{\infty}(\Omega)$, the right-hand side of (2.24) is bounded, and hence, in view of (2.9) and Proposition[2.1] $\epsilon_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right) \rightarrow-b_{\alpha \beta} u$ in $L^{2}(\Omega)$. From (2.12) (replacing $\lambda$ with $\frac{2 \lambda \mu}{\lambda+2 \mu}$ ), we infer that there exists a constant $C>0$ such that

$$
\left(\frac{2 \lambda \mu}{\lambda+2 \mu} g_{\rho_{\ell}}^{\alpha \beta} g_{\rho_{\ell}}^{\sigma \tau}+\mu\left(g_{\rho_{\ell}}^{\alpha \sigma} g_{\rho_{\ell}}^{\beta \tau}+g_{\rho_{\ell}}^{\alpha \tau} g_{\rho_{\ell}}^{\beta \sigma}\right)\right) \boldsymbol{\epsilon}_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right) \boldsymbol{\epsilon}_{\sigma \tau, \rho_{\ell}}\left(u_{\ell}\right) \leq C \sum_{\alpha, \beta}\left|\boldsymbol{\epsilon}_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right)\right|^{2} .
$$

Therefore, by the dominated convergence theorem, it follows that

$$
\begin{equation*}
\lim _{\ell \rightarrow \infty} I_{\rho_{\ell}}^{(1)}\left(u_{\ell}\right)=\frac{1}{2} \int_{\Omega} c^{\alpha \beta \sigma \tau} b_{\alpha \beta} b_{\sigma \tau}|u|^{2} \sqrt{a} \mathrm{~d} x \tag{2.25}
\end{equation*}
$$

Moving to the term $I_{\rho_{\ell}}^{(3)}$, we have that $\left|\boldsymbol{\epsilon}_{\alpha 3}\left(u_{\ell}\right)\right| \leq C\left|\partial_{\alpha} u\right| \in L^{2}(\Omega)$, so that, using (2.11), we deduce that

$$
\begin{equation*}
\lim _{\ell \rightarrow \infty} I_{\rho_{\ell}}^{(3)}\left(u_{\ell}\right)=\frac{\mu}{2} \int_{\Omega} a^{\alpha \beta} \partial_{\alpha} u \partial_{\beta} u \sqrt{a} \mathrm{~d} x . \tag{2.26}
\end{equation*}
$$

Since it holds that

$$
S_{u_{\ell}}=S_{u}, \quad\left[\nu_{u_{\ell}}\right]_{3}=0, \quad \text { and } \quad\left[\nu_{u_{\ell}}\right]_{\alpha}=\left[\nu_{u}\right]_{\alpha},
$$

and thanks to Proposition 2.1, we obtain

$$
\begin{align*}
\lim _{\ell \rightarrow \infty} I_{\rho_{\ell}}^{(4)} & =\lim _{\ell \rightarrow \infty} \kappa \int_{S_{u}} \sqrt{\left[\nu_{u}\right]_{\alpha} g_{\rho_{\ell}}\left[\nu_{u}\right]_{\beta}} \sqrt{g_{\rho_{\ell}}} \mathrm{d} \mathcal{H}^{2} \\
& =\kappa \int_{S_{u}} \sqrt{\left[\nu_{u}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u}\right]_{\beta}} \sqrt{a} \mathrm{~d} \mathcal{H}^{2} . \tag{2.27}
\end{align*}
$$

Finally, we show that $I_{\rho_{\ell}}^{(2)}\left(u_{\ell}\right) \rightarrow 0$. With this aim, we note that

$$
\epsilon_{33, \rho_{\ell}}\left(u_{\ell}\right)=\frac{\lambda}{\lambda+2 \mu} a^{\alpha \beta} b_{\alpha \beta} u_{\ell}
$$

and, therefore, by Proposition 2.1 we have

$$
\left|g_{\rho_{\ell}}^{\alpha \beta} \boldsymbol{\epsilon}_{\alpha \beta, \rho_{\ell}}\left(u_{\ell}\right)+a^{\alpha \beta} b_{\alpha \beta} u_{\ell}\right| \leq C \rho_{\ell}\left|u_{\ell}\right| .
$$

Exploiting the fact that $u_{\ell} \in L^{\infty}(\Omega)$ and the uniformly bound of $\sqrt{g_{\rho_{\ell}}}$, we deduce

$$
\left|I_{\rho_{\ell}}^{(2)}\left(u_{\ell}\right)\right| \leq C \rho_{\ell}^{2}\|u\|_{L^{\infty}(\Omega)}^{2},
$$

which implies that $I_{\rho_{\ell}}^{(2)}\left(u_{\ell}\right) \rightarrow 0$. Eventually, this inequality, together with (2.25)(2.27), implies that $\lim _{\ell \rightarrow \infty} \mathcal{G}_{\rho_{\ell}}\left(u_{\ell}\right)=\mathcal{G}_{0}(u)$, which concludes the proof.

We point out that the limit functional $\mathcal{G}_{0}\left(\right.$ or $\left.G_{0}\right)$ is actually 2D. Since the integrands do not depend on $x_{3}$, as explained in Remark 2.2 we can simply replace $\Omega$ with the 2D domain $\omega$. Hence, for $u \in \operatorname{GSBV}^{2}(\omega)$ we have

$$
\begin{aligned}
G_{0}(u)= & \frac{1}{2} \int_{\omega} c^{\alpha \beta \sigma \tau} b_{\alpha \beta} b_{\sigma \tau}|u|^{2} \sqrt{a} \mathrm{~d} x+\frac{\mu}{2} \int_{\omega} a^{\alpha \beta} \partial_{\alpha} u \partial_{\beta} u \sqrt{a} \mathrm{~d} x \\
& +\kappa \int_{S_{u}} \sqrt{\left[\nu_{u}\right]_{\alpha} a^{\alpha \beta}\left[\nu_{u}\right]_{\beta}} \sqrt{a} \mathrm{~d} \mathcal{H}^{1} .
\end{aligned}
$$

Introducing the notation

$$
b:=\boldsymbol{c}^{\alpha \beta \sigma \tau} b_{\alpha \beta} b_{\sigma \tau} \sqrt{a} \quad \text { and } \quad A:=\left(a^{\alpha \beta}\right) \sqrt{a},
$$

we can rewrite $G_{0}$ as

$$
G_{0}(u)=\frac{1}{2} \int_{\omega} b|u|^{2} \mathrm{~d} x+\frac{\mu}{2} \int_{\omega} \nabla u^{\top} A \nabla u \mathrm{~d} x+\kappa \int_{S_{u}} \sqrt{\nu_{u}^{\top} A \nu_{u} \sqrt{a}} \mathrm{~d} \mathcal{H}^{1} .
$$

Note that, due to (2.2), the symmetric matrix $A(x) \in \mathbb{R}^{2 \times 2}$ is positive definite, uniformly with respect to $x \in \omega$, i.e. there exist $0<\alpha \leq \beta<+\infty$ such that

$$
\alpha|\zeta|^{2} \leq A(x) \zeta \cdot \zeta \leq \beta|\zeta|^{2} \quad \text { for every } x \in \omega \quad \text { and every } \zeta \in \mathbb{R}^{2} .
$$

### 2.4. The regularized reduced model

The numerical minimization of the functional $G_{0}$ can be tackled via phase-field models (see, e.g. Refs. 10, 16, 17 and 20). The seminal idea can be ascribed to Refs. 7 and 8, where the authors introduce an additional smooth variable, the phase field, which describes the fracture set. The results of Refs. 7 and 8 have been generalized in many ways,${ }^{[15|18| 3135 / 49}$ including the case of vector displacements ${ }^{[22}$ In our setting, we need a slightly more general result compared with Ref. 35, as we have to take into account the spatial dependence of $A$ in the phase-field term. The $\Gamma$-convergence result is stated in Theorem 2.2 below, whose proof is provided in Appendix A.

Theorem 2.2. For $\varepsilon>0$, let $\eta_{\varepsilon}>0$ be such that $\eta_{\varepsilon} / \varepsilon \rightarrow 0$ as $\varepsilon \rightarrow 0$. Define the family of functionals $\left\{\mathcal{F}_{\varepsilon}\right\}_{\varepsilon>0}$, with $\mathcal{F}_{\varepsilon}: L^{1}(\omega) \times L^{1}(\omega) \rightarrow \mathbb{R}$ such that

$$
\begin{align*}
\mathcal{F}_{\varepsilon}(u, v):= & \frac{1}{2} \int_{\omega} b|u|^{2} \mathrm{~d} x+\frac{\mu}{2} \int_{\omega}\left(v^{2}+\eta_{\varepsilon}\right) \nabla u^{\top} A \nabla u \mathrm{~d} x \\
& +\kappa \int_{\omega}\left[\frac{1}{4 \varepsilon}(1-v)^{2} \sqrt{a}+\varepsilon \nabla v^{\top} A \nabla v\right] \mathrm{d} x \tag{2.28}
\end{align*}
$$

for all $u \in H^{1}(\omega), v \in H^{1}(\omega ;[0,1])$ and $\mathcal{F}_{\varepsilon}(u, v):=+\infty$ otherwise. Then $\mathcal{G}_{0}=$ $\Gamma$ - $\lim _{\varepsilon \rightarrow 0} \mathcal{F}_{\varepsilon}$ in the $L^{1}$-topology.

Proof. See Appendix A
We remark that, loosely speaking, for small $\varepsilon$, the phase field minimizing $\mathcal{F}_{\varepsilon}$ is close to zero where the gradient of the displacement $u$ is large, whereas it approaches 1 elsewhere. This implies that the material is sound where $v$ is close to 1 , whereas a fracture is detected where $v \ll 1$. In particular, the third integral in (2.28) converges to the length of the crack set.

With a view to the numerical approximation of the functional $\mathcal{F}_{\varepsilon}$, for small $\varepsilon>$ 0 , we restrict the function space to $H^{1}(\omega) \times H^{1}(\omega ;[0,1])$, and omit the subscript $\varepsilon$, as it will be fixed in the numerical test cases. Moreover, for all $u \in H^{1}(\omega), v \in$ $H^{1}(\omega ;[0,1])$, we introduce the stored elastic energy

$$
\begin{equation*}
\mathcal{E}(u, v):=\frac{1}{2} \int_{\omega} b|u|^{2} \mathrm{~d} x+\frac{\mu}{2} \int_{\omega}\left(v^{2}+\eta_{\varepsilon}\right) \nabla u^{\top} A \nabla u \mathrm{~d} x \tag{2.29}
\end{equation*}
$$

and the dissipation potential

$$
\begin{equation*}
\mathcal{D}(v):=\kappa \int_{\omega}\left[\frac{1}{4 \varepsilon}(1-v)^{2} \sqrt{a}+\varepsilon \nabla v^{\top} A \nabla v\right] \mathrm{d} x \tag{2.30}
\end{equation*}
$$

so that

$$
\begin{equation*}
\mathcal{F}(u, v)=\mathcal{E}(u, v)+\mathcal{D}(v) \tag{2.31}
\end{equation*}
$$

Note that $\mathcal{F}(u, v)$ is Frchet-differentiable in $H^{1}(\omega) \times\left[H^{1}(\omega) \cap L^{\infty}(\omega)\right]$ (see, e.g. Proposition 1.1 in Ref. (20), with

$$
\begin{aligned}
& \qquad \begin{array}{l}
\partial_{u} \mathcal{F}(u, v)[\varphi]=\int_{\omega} b u \varphi \mathrm{~d} x+\mu \int_{\omega}\left(v^{2}+\eta_{\varepsilon}\right) \nabla u^{\top} A \nabla \varphi \mathrm{~d} x, \\
\partial_{v} \mathcal{F}(u, v)[\psi]=\mu \int_{\omega} v \psi \nabla u^{\top} A \nabla u \mathrm{~d} x+\kappa \int_{\omega}\left[\frac{1}{2 \varepsilon}(v-1) \psi \sqrt{a}+2 \varepsilon \nabla v^{\top} A \nabla \psi\right] \mathrm{d} x, \\
\text { for all } u, \varphi \in H^{1}(\omega), v, \psi \in H^{1}(\omega) \cap L^{\infty}(\omega) \text {. }
\end{array} \text {. }
\end{aligned}
$$

## 3. The Discrete Setting: A Finite Element Approximation

Let $\omega \subset \mathbb{R}^{2}$ be a polygonal domain, and let $\left\{\mathcal{T}_{h}\right\}_{h>0}$ be a family of triangulations of $\omega$. For every $h>0$, we denote by $T$ a generic element of $\mathcal{T}_{h}$ and we set $h_{T}:=$ $\operatorname{diam}(T)$, where $h=\max _{T \in \mathcal{T}_{h}} h_{T}$. Furthermore, we denote by $\mathcal{V}_{h}$ the set of all the vertices of $\mathcal{T}_{h}$ and define $N_{h}:=\# \mathcal{V}_{h}$.

The discretization is cast in the space

$$
\mathcal{X}_{h}:=\left\{u \in H^{1}(\omega):\left.u\right|_{T} \in \mathbb{P}_{1}(T), \text { for every } T \in \mathcal{T}_{h}\right\}
$$

of piecewise continuous linear finite elements, whose Lagrangian basis is denoted by $\left\{\xi_{l}\right\}_{l=1}^{N_{h}}$. We assume that this basis satisfies the non-positivity condition

$$
\begin{equation*}
\int_{\omega} \nabla \xi_{l}^{\top} A \nabla \xi_{m} \mathrm{~d} x \leq 0 \quad \forall l, m \in\left\{1, \ldots, N_{h}\right\}, l \neq m \tag{3.1}
\end{equation*}
$$

For the particular choice $A=I$, with $I$ the identity matrix, this condition is satisfied when $\mathcal{T}_{h}$ is an acute-angle mesh, and it ensures a discrete maximum principle in $\mathcal{X}_{h},{ }^{25159}$ i.e. that the phase field takes values in $[0,1]$ along the evolution (cf. Proposition 6.14 in Ref. (3). In the present context, the matrix $A$ corresponds to a metric tensor of a Riemannian manifold multiplied by a positive function. Thus, by coordinate transformation, condition (3.1) is fulfilled if the triangulation is acute in the Riemannian space. Indeed, according to the notation of Sec. 2, the tangential gradient is

$$
\nabla_{\tau} \hat{u}:=\left.\left(\nabla \tilde{u}-\left\langle\nabla \tilde{u}, g^{3}\right\rangle g^{3}\right)\right|_{S} \quad \forall \hat{u} \in C^{1}(\phi(\omega))
$$

where $\tilde{u}$ is an extension of $\hat{u}$ to $\Phi\left(\Omega_{\rho}\right)$, which is characterized by a thickness $\rho$. Then, by coordinate transformation, (3.1) is equivalent to

$$
\int_{\phi(\omega)} \nabla_{\tau}\left(\xi_{l} \circ \phi^{-1}\right)^{\top} \nabla_{\tau}\left(\xi_{m} \circ \phi^{-1}\right) \mathrm{d} x \leq 0 \quad \forall l, m \in\left\{1, \ldots, N_{h}\right\}, l \neq m
$$

In general, the space $\mathcal{X}_{h}$ is endowed with the norm on $H^{1}(\omega)$. However, we also adopt the norm

$$
\|v\|_{\mathcal{X}_{h}}=\left(\int_{\omega}\left|\Pi_{h}\left(v^{2}\right)\right| \mathrm{d} x\right)^{\frac{1}{2}} \quad \text { for all } v \in \mathcal{X}_{h}
$$

where $\Pi_{h}$ denotes the Lagrangian interpolant associated with the space $\mathcal{X}_{h}$.
We introduce now the discrete counterpart of the elastic energy (2.29) and of the dissipation potential (2.30): for every $u, v \in \mathcal{X}_{h}, 0 \leq v \leq 1$, let

$$
\begin{aligned}
\mathcal{E}_{h}(u, v) & :=\frac{1}{2} \int_{\omega} b|u|^{2} \mathrm{~d} x+\frac{\mu}{2} \int_{\omega}\left(\Pi_{h}\left(v^{2}\right)+\eta_{\varepsilon}\right) \nabla u^{\top} A \nabla u \mathrm{~d} x, \\
\mathcal{D}_{h}(v) & :=\kappa \int_{\omega}\left[\frac{1}{4 \varepsilon} \Pi_{h}\left((1-v)^{2}\right) \sqrt{a}+\varepsilon \nabla v^{\top} A \nabla v\right] \mathrm{d} x
\end{aligned}
$$

which leads to the definition of the discrete phase-field energy (2.31) by

$$
\mathcal{F}_{h}(u, v):=\mathcal{E}_{h}(u, v)+\mathcal{D}_{h}(v) \quad \text { for } u, v \in \mathcal{X}_{h}, 0 \leq v \leq 1
$$

It holds that $\mathcal{F}_{h}(u, v)$ is Fréchet differentiable with

$$
\begin{aligned}
\partial_{u} \mathcal{F}_{h}(u, v)[\varphi]= & \int_{\omega} b u \varphi \mathrm{~d} x+\mu \int_{\omega}\left(\Pi_{h}\left(v^{2}\right)+\eta_{\varepsilon}\right) \nabla u^{\top} A \nabla \varphi \mathrm{~d} x \\
\partial_{v} \mathcal{F}_{h}(u, v)[\psi]= & \mu \int_{\omega} \Pi_{h}(v \psi) \nabla u^{\top} A \nabla u \mathrm{~d} x \\
& +\kappa \int_{\omega}\left[\frac{1}{2 \varepsilon} \Pi_{h}((v-1) \psi) \sqrt{a}+2 \varepsilon \nabla v^{\top} A \nabla \psi\right] \mathrm{d} x
\end{aligned}
$$

for all $u, v, \varphi, \psi \in \mathcal{X}_{h}$.
Remark 3.1. In general, the energy functional $\mathcal{F}$ is discretized via restriction to the finite element space, i.e. by setting $\mathcal{F}_{h}:=\left.\mathcal{F}\right|_{\mathcal{X}_{h} \times \mathcal{X}_{h}}$. Here, following Refs. 22 and 10, we define $\mathcal{F}_{h}$ using the operator $\Pi_{h}$. This ensures that also the discrete phase field takes values in $[0,1]$ (see Proposition 6.14 in Ref. 3).

### 3.1. An alternating minimization scheme

In order to approximate a quasi-static fracture evolution, we adopt here the scheme used in Refs. 10, 16, 17 and 20, which is based on an alternating minimization procedure. For a given time interval, $\left[0, T_{f}\right]$, with $T_{f}>0$, we consider the time step $\tau=\frac{T_{f}}{k}$, where $k \in \mathbb{N}$ is the number of time steps, and we denote the time levels by $t_{i}:=i \tau$ for $i \in\{0, \ldots, k\}$. Let $g$ be the time-dependent Dirichlet boundary condition for the displacement field, assumed to be an absolutely continuous function in $A C\left(\left[0, T_{f}\right] ; W^{1, p}(\omega)\right)$, with $p>2$. The adopted alternating minimization scheme works as follows: Let $u_{0}, v_{0} \in \mathcal{X}_{h}$ the assigned initial values. Then, for every
$i \in\{1, \ldots, k\}$ and every $j \in \mathbb{N}$, we inductively set $u_{i, 0}:=u_{i-1}, v_{i, 0}:=v_{i-1}$ and

$$
\begin{align*}
& u_{i, j}:=\arg \min \left\{\mathcal{E}_{h}\left(u, v_{i, j-1}\right): u \in \mathcal{X}_{h}, u=g\left(t_{i}\right) \text { on } \partial \omega\right\}  \tag{3.2}\\
& v_{i, j}:=\arg \min \left\{\mathcal{F}_{h}\left(u_{i, j}, v\right)+\frac{\alpha}{2 \tau}\left\|v-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2}: v \in \mathcal{X}_{h}, v \leq v_{i-1}\right\}, \tag{3.3}
\end{align*}
$$

where $\alpha>0$ is a tuning parameter. As shown in Proposition 3.1, there exists a subsequence $j_{m}$ such that $\left(u_{i, j_{m}}, v_{i, j_{m}}\right)$ admits a limit in $\mathcal{X}_{h} \times \mathcal{X}_{h}$ as $m \rightarrow \infty$. Thus, we set

$$
u_{i}:=\lim _{m \rightarrow \infty} u_{i, j_{m}} \quad \text { and } \quad v_{i}:=\lim _{m \rightarrow \infty} v_{i, j_{m}}
$$

The inequality constraint in (3.3) enforces the irreversibility of the fracture. In this way, the phase field is constrained to decrease in time to avoid any crack healing. Moreover, the constraint $v \geq 0$ is no longer required, since the adopted discretization automatically guarantees $v_{i, j} \geq 0$ (see also Remark (3.1).

Following Theorems 4.3, 5.13 and 5.17 in Ref. 3, we can show that, in the time continuous limit, the algorithm (3.2)-(3.3) detects a unilateral $L^{2}$-gradient flow for the functional $\mathcal{F}_{h}$. Moreover, we obtain full consistency when $h \rightarrow 0$, namely, a sequence of $L^{2}$-gradient flows of $\mathcal{F}_{h}$ converge to an $L^{2}$-gradient flow of $\mathcal{F}$.

As for the additional parameter $\alpha$, we assume that it is very small, so that a gradient flow of $\mathcal{F}_{h}$ is expected to be close to a quasi-static evolution along critical points ${ }^{[53157]}$ The choice $\alpha=0$, made in Ref. 2 in order to directly obtain a quasistatic evolution, does not ensure an energy balance when $h \rightarrow 0$.

Since $u \mapsto \mathcal{F}_{h}(u, v)$ is a convex map, the minimization (3.2) is equivalent to

$$
\begin{equation*}
\partial_{u} \mathcal{E}_{h}\left(u_{i, j}, v_{i, j-1}\right)[\varphi]=0 \quad \text { for every } \varphi \in \mathcal{X}_{h}, \quad \text { with } \varphi=0 \text { on } \partial \omega . \tag{3.4}
\end{equation*}
$$

The minimization (3.3), instead, is equivalent to the variational inequality (cf. Chap. 3 of Ref. 50)

$$
\begin{equation*}
\partial_{v} \mathcal{F}_{h}\left(u_{i, j}, v_{i, j}\right)\left[v_{i, j}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}\left(\left(v_{i, j}-v_{i-1}\right)\left(v_{i, j}-\psi\right)\right) \mathrm{d} x \leq 0 \tag{3.5}
\end{equation*}
$$

for all $\psi \in \mathcal{X}_{h}$, with $\psi \leq v_{i-1}$.
These remarks justify the following definition of a critical point of $\mathcal{F}_{h}$, subject to the inequality constraint in (3.3).

Definition 3.1. Let $u, v, \tilde{v} \in \mathcal{X}_{h}$ with $0 \leq \tilde{v} \leq 1$. We define $(u, v)$ as a discrete critical point with bound $\tilde{v}$ if the following two conditions hold:

$$
\begin{align*}
& \partial_{u} \mathcal{E}_{h}(u, v)[\varphi]=0 \quad \forall \varphi \in \mathcal{X}_{h}, \quad \text { with } \varphi=0 \quad \text { on } \partial \omega,  \tag{3.6}\\
& \partial_{v} \mathcal{F}_{h}(u, v)[v-\psi]+\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}((v-\tilde{v})(v-\psi)) \mathrm{d} x \leq 0 \quad \forall \psi \in \mathcal{X}_{h}, \quad \text { with } \psi \leq \tilde{v} . \tag{3.7}
\end{align*}
$$

Note that, relations (3.6)-(3.7) are equivalent to the single inequality

$$
\partial_{u} \mathcal{E}_{h}(u, v)[\varphi]+\partial_{v} \mathcal{F}_{h}(u, v)[v-\psi]+\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}((v-\tilde{v})(v-\psi)) \mathrm{d} x \leq 0
$$

for all $\varphi \in \mathcal{X}_{h}$ with $\varphi=0$ on $\partial \omega$ and for all $\psi \in \mathcal{X}_{h}$ with $\psi \leq \tilde{v}$.
We will also employ the continuous counterpart of Definition 3.1.

Definition 3.2. Let $u \in H^{1}(\omega)$ and $v, \tilde{v} \in H^{1}(\omega ;[0,1])$. We define $(u, v)$ as a critical point with bound $\tilde{v}$ if the following two conditions hold:

$$
\begin{aligned}
& \partial_{u} \mathcal{E}(u, v)[\varphi]=0 \quad \forall \varphi \in H^{1}(\omega), \quad \text { with } \varphi=0 \quad \text { on } \partial \omega \\
& \partial_{v} \mathcal{F}(u, v)[v-\psi]+\frac{\alpha}{\tau} \int_{\omega}(v-\tilde{v})(v-\psi) \mathrm{d} x \leq 0 \quad \forall \psi \in H^{1}(\omega ;[0,1]), \quad \text { with } \psi \leq \tilde{v} .
\end{aligned}
$$

Following the idea of Proposition 2 in Ref. 21, we show the convergence of the minimization scheme (3.2)-(3.3) to a discrete critical point. The result can easily be extended to a space-continuous scheme where $\mathcal{X}_{h}$ is replaced by $H^{1}(\omega)$ in (3.2) and (3.3).

Proposition 3.1. Let $i \in\{1, \ldots, k\}$ and $\left(u_{i, j}, v_{i, j}\right)$ be defined as in (3.2)-(3.3). Then, $\left(u_{i, j}, v_{i, j}\right)$ converges, up to a subsequence, as $j \rightarrow \infty$ to a discrete critical point $\left(u_{i}, v_{i}\right) \in \mathcal{X}_{h} \times \mathcal{X}_{h}$ with bound $v_{i-1}$.

Proof. We have that, for all $j \in \mathbb{N}$

$$
\begin{aligned}
\mathcal{F}_{h}\left(u_{i, j}, v_{i, j}\right)+\frac{\alpha}{2 \tau}\left\|v_{i, j}-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2} & \leq \mathcal{F}_{h}\left(u_{i, j-1}, v_{i, j-1}\right)+\frac{\alpha}{2 \tau}\left\|v_{i, j-1}-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2} \\
& \leq \mathcal{F}_{h}\left(u_{i, 0}, v_{i, 0}\right)+\frac{\alpha}{2 \tau}\left\|v_{i, 0}-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2}
\end{aligned}
$$

Since $A$ is uniformly positive definite, the sequence ( $u_{i, j}, v_{i, j}$ ) is bounded in $\mathcal{X}_{h} \times$ $\mathcal{X}_{h}$. Hence, we can extract a subsequence $j_{k}$ such that, for some $u_{i}, v_{i}, w \in \mathcal{X}_{h}$, we have

$$
\begin{equation*}
\nabla u_{i, j_{k}} \rightarrow \nabla u_{i}, \quad v_{i, j_{k}} \rightarrow v_{i}, \quad v_{i, j_{k}-1} \rightarrow w \quad \text { as } k \rightarrow \infty \tag{3.8}
\end{equation*}
$$

This also implies $u_{i, j_{k-1}} \rightarrow u_{i}$ and $v_{i, j_{k-1}} \rightarrow v_{i}$ as $k \rightarrow \infty$.
We now prove that $\left(u_{i}, v_{i}\right)$ is a discrete critical point. In view of (3.4) and (3.5), there holds for all $k \in \mathbb{N}$ and for all $\varphi, \psi \in \mathcal{X}_{h}$ with $\varphi=0$ on $\partial \omega$ and $\psi \leq v_{i-1}$

$$
\begin{aligned}
& 0=\partial_{u} \mathcal{E}_{h}\left(u_{i, j_{k}}, v_{i, j_{k}-1}\right)[\varphi], \\
& 0 \leq \partial_{v} \mathcal{F}_{h}\left(u_{i, j_{k}}, v_{i, j_{k}}\right)\left[\psi-v_{i, j_{k}}\right]+\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}\left(\left(v_{i, j_{k}}-v_{i-1}\right)\left(\psi-v_{i, j_{k}}\right)\right) \mathrm{d} x
\end{aligned}
$$

Passing to the limit for $k \rightarrow \infty$, it follows that

$$
\begin{align*}
& 0=\partial_{u} \mathcal{E}_{h}\left(u_{i}, w\right)[\varphi] \\
& 0 \leq \partial_{v} \mathcal{F}_{h}\left(u_{i}, v_{i}\right)\left[\psi-v_{i}\right]+\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}\left(\left(v_{i}-v_{i-1}\right)\left(\psi-v_{i}\right)\right) \mathrm{d} x \tag{3.9}
\end{align*}
$$

We recall that the last inequality implies that $v_{i}$ is a solution of (3.3) with displacement $u_{i}$.

It remains to show that $v_{i}=w$. By (3.2) -(3.3) and by the convergence result in (3.8), we have that

$$
\begin{aligned}
\mathcal{F}_{h}\left(u_{i}, w\right)+\frac{\alpha}{2 \tau}\left\|w-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2} & =\lim _{k \rightarrow \infty} \mathcal{F}_{h}\left(u_{i, j_{k}}, v_{i, j_{k}-1}\right)+\frac{\alpha}{2 \tau}\left\|v_{i, j_{k}-1}-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2} \\
& \leq \lim _{k \rightarrow \infty} \mathcal{F}_{h}\left(u_{i, j_{k-1}}, v_{i, j_{k-1}}\right)+\frac{\alpha}{2 \tau}\left\|v_{i, j_{k-1}}-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2} \\
& =\mathcal{F}_{h}\left(u_{i}, v_{i}\right)+\frac{\alpha}{2 \tau}\left\|v_{i}-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2} .
\end{aligned}
$$

By strict convexity, (3.3) has a unique solution. Hence, $v_{i}=w$. Inequalities (3.9) imply that $\left(u_{i}, v_{i}\right)$ is a discrete critical point with bound $v_{i-1}$.

### 3.2. An anisotropic a posteriori error analysis

Goal of this section is to quantify the error associated with a computed discrete critical point through the minimization (3.2)-(3.3). In particular, we exploit the benefits led by the employment of an anisotropically adapted mesh. We adopt the setting in Ref. 39] to recover the anisotropic information, and we consider a reference triangle $\hat{T}$, so that, for $T \in \mathcal{T}_{h}$, there exists an affine map $\mathcal{R}_{T}: \hat{T} \rightarrow T$, with $\mathcal{R}_{T}(\hat{x})=M_{T} \hat{x}+\theta_{T}$ for all $\hat{x} \in \hat{T}$, where $M_{T} \in \mathbb{R}^{2 \times 2}$ is invertible and $\theta_{T} \in \mathbb{R}^{2}$ is the shift vector. We choose $\hat{T}$ as the equilateral triangle inscribed in the unit circle with one vertex at $(0,1)$. Hence, if $T \in \mathcal{T}_{h}$ has vertices $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right),\left(x_{3}, y_{3}\right)$, we have

$$
M_{T}=\frac{1}{3}\left(\begin{array}{ll}
\sqrt{3}\left(x_{2}-x_{1}\right) & 2 x_{3}-x_{1}-x_{2} \\
\sqrt{3}\left(y_{2}-y_{1}\right) & 2 y_{3}-y_{1}-y_{2}
\end{array}\right) \quad \text { and } \quad \theta_{T}=\frac{1}{3}\binom{x_{1}+x_{2}+x_{3}}{y_{1}+y_{2}+y_{3}}
$$

We consider the singular value decomposition $M_{T}=U_{T} \Sigma_{T} V_{T}^{\top}$, of the matrix $M_{T}$, with $U_{T}=\left[\mathbf{r}_{T, 1}, \mathbf{r}_{T, 2}\right], V_{T} \in \mathbb{R}^{2 \times 2}$ orthogonal and $\Sigma_{T} \in \mathbb{R}^{2 \times 2}$ diagonal with entries $\sigma_{T, 1} \geq \sigma_{T, 2}>0$. Hence, for every vector $z \in \mathbb{R}^{n}$ the following inequality holds

$$
\begin{equation*}
\sigma_{T, 2}|z| \leq\left|M_{T} z\right| \leq \sigma_{T, 1}|z| \tag{3.10}
\end{equation*}
$$

Geometrically, the left singular vectors $\mathbf{r}_{T, i}$ identify the directions of the semiaxes of the ellipse circumscribed to $T$, while the singular values $\sigma_{T, i}$ measure the corresponding lengths, with $i=1,2$. The deformation of $T$ is quantified by the aspect ratio $s_{T}:=\sigma_{T, 1} / \sigma_{T, 2} \geq 1$, where $s_{T}=1$ for equilateral triangles. The matrices $U_{T}$ and $V_{T}$ apply rotations, whereas the matrix $\Sigma_{T}$ deforms the element (see Fig. (3).

We denote by $\left.\hat{u}\right|_{\hat{T}}:=u \circ \mathcal{R}_{T}$ the pull-back on the reference triangle of a generic function $u: T \rightarrow \mathbb{R}$, and we set $\hat{e}:=\mathcal{R}_{T}^{-1}(e)$ for all $e \in E_{h} \cap T$, where $E_{h}$ represents

Fig. 3. Geometric sketch of the affine map $\mathcal{R}_{T}$, together with the main anisotropic quantities.
the skeleton of $\mathcal{T}_{h}$. We recall here the anisotropic interpolation error estimates derived in Refs. 39 and 40 for the quasi-interpolant operator $Q_{h}{ }^{[26 / 58] 60}$

Lemma 3.1. Assume that $\#\left(\Delta_{T}\right) \leq \mathcal{N}$ and $\operatorname{diam}\left(\mathcal{R}_{T}^{-1}\left(\Delta_{T}\right)\right) \leq C_{\Delta}$ for every $T \in \mathcal{T}_{h}$, with $\#(\cdot)$ and $\operatorname{diam}(\cdot)$ the cardinality and the diameter of a given set, and $\Delta_{T}=\left\{\cup_{K \in \mathcal{T}_{h}} K: K \cap T \neq \emptyset\right\}$ the patch of elements associated with $T$. Then, for every $T \in \mathcal{T}_{h}$, every $e \in E_{h}$ with $e \in \partial T$, and every $u \in H^{1}\left(\Delta_{T}\right)$, there hold

$$
\begin{aligned}
& \left|u-Q_{h} u\right|_{H^{s}(T)} \leq C_{s} \frac{1}{\sigma_{2, T}^{s}}\left\|M_{T}^{\top} \nabla u\right\|_{L^{2}\left(\Delta_{T}\right)}, \quad s=0,1 \\
& \left\|u-Q_{h} u\right\|_{L^{2}(e)} \leq C_{2}\left(\frac{h_{e}}{\sigma_{T, 1} \sigma_{T, 2}}\right)^{1 / 2}\left\|M_{T}^{\top} \nabla u\right\|_{L^{2}\left(\Delta_{T}\right)},
\end{aligned}
$$

where $C_{i}=C_{i}\left(\hat{T}, \mathcal{N}, C_{\Delta}\right)$ for $i=0,1,2$.
We also provide the anisotropic error estimate associated with the Lagrangian interpolant $\Pi_{h}$ (for the proof, see Proposition 3.3 in Ref. 10), together with the equivalence result between the standard $H^{1}\left(\Delta_{T}\right)$-seminorm and the corresponding anisotropic counterpart:

Lemma 3.2. Let $v, \psi \in \mathcal{X}_{h}$ and $T \in \mathcal{T}_{h}$. Then, we have

$$
\left\|v \psi-\Pi_{h}(v \psi)\right\|_{L^{2}(T)} \leq \hat{C} h_{T}^{2}|v|_{W^{1, \infty}(T)}\|\nabla \psi\|_{L^{2}(T)}
$$

where $\hat{C}=\hat{C}(\hat{T})$.
From (3.10), we directly infer the following Lemma:
Lemma 3.3. Let $z \in H^{1}(\omega)$ and $T \in \mathcal{T}_{h}$. Then, we have

$$
\sigma_{T, 2} \leq \frac{\left\|M_{T}^{\top} \nabla z\right\|_{L^{2}\left(\Delta_{T}\right)}}{\|\nabla z\|_{L^{2}\left(\Delta_{T}\right)}} \leq \sigma_{T, 1}
$$

Finally, we introduce the notation for the jump of the conormal derivative of a function $w \in \mathcal{X}_{h}$ :

$$
\llbracket A \nabla w \rrbracket:= \begin{cases}\left|\left(\left.\nabla w\right|_{T}-\left.\nabla w\right|_{T^{\prime}}\right)^{\top} A \nu_{T}\right| & \text { on } e \in E_{h} \quad \text { if } \exists T, T^{\prime} \in \mathcal{T}_{h}: T \cap T^{\prime}=e \\ 2|\nabla w|_{T}^{\top} A \nu_{T} \mid & \text { on } e \in E_{h} \text { if } \exists T \in \mathcal{T}_{h}: e \subset \partial \omega \cap \partial T,\end{cases}
$$

with $\nu_{T}$ the unit outward normal vector to $T$. Moreover, we define the edge length function $h_{\partial T}: \partial T \rightarrow \mathbb{R}$ by $h_{\partial T}=h_{e}$ for $e \in E_{h} \cap \partial T$.

Theorem 3.1. Let $\left(u_{h}, v_{h}\right) \in \mathcal{X}_{h} \times \mathcal{X}_{h}$ be a discrete critical point with bound $\tilde{v}_{h} \in \mathcal{X}_{h}$. For every $T \in \mathcal{T}_{h}$, we define the quantities

$$
\begin{aligned}
\gamma_{T}\left(u_{h}, v_{h}\right):= & \left\|p\left(u_{h}, v_{h}\right)\right\|_{L^{2}(T)}+\frac{\mu}{\sigma_{T, 2}}\left\|\left(v_{h}^{2}-\Pi_{h}\left(v_{h}^{2}\right)\right) A \nabla u_{h}\right\|_{L^{2}(T)} \\
& +\frac{\mu}{2 \sqrt{\sigma_{T, 1} \sigma_{T, 2}}}\left\|\sqrt{h_{\partial T}}\left(v_{h}^{2}+\eta_{\varepsilon}\right) \llbracket A \nabla u_{h} \rrbracket\right\|_{L^{2}(\partial T)} \\
p\left(u_{h}, v_{h}\right):= & b u_{h}-2 \mu v_{h} \nabla u_{h}^{\top} A \nabla v_{h}-\mu\left(v_{h}^{2}+\eta_{\varepsilon}\right) \nabla u_{h} \cdot \operatorname{div}(A), \\
\rho_{T}\left(u_{h}, v_{h}\right):= & \left\|q\left(u_{h}, v_{h}\right)\right\|_{L^{2}(T)}+\frac{\kappa \varepsilon}{\sqrt{\sigma_{T, 1} \sigma_{T, 2}}} \| \sqrt{h_{\partial T} \llbracket A \nabla v_{h} \rrbracket \|_{L^{2}(\partial T)}} \\
& +\frac{h_{T}^{2}}{\sigma_{T, 2}}\left\|\mu \nabla u_{h}^{\top} A \nabla u_{h}+\frac{\kappa}{2 \varepsilon} \sqrt{a}\right\|_{L^{2}(T)}\left|v_{h}\right|_{W^{1, \infty}(T)} \\
& +\frac{\alpha h_{T}^{2}}{\tau \sigma_{T, 2}}\left\|\nabla\left(v_{h}-\tilde{v}_{h}\right)\right\|_{L^{2}(T)}, \\
q\left(u_{h}, v_{h}\right):= & \mu v_{h} \nabla u_{h}^{\top} A \nabla u_{h}+\frac{\kappa}{2 \varepsilon}\left(v_{h}-1\right) \sqrt{a}-2 \kappa \varepsilon \nabla v_{h} \cdot \operatorname{div}(A)+\frac{\alpha}{\tau}\left(v_{h}-\tilde{v}_{h}\right) .
\end{aligned}
$$

Then, we have

$$
\begin{equation*}
\left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)[\varphi]\right| \leq C \sum_{T \in \mathcal{T}_{h}} \gamma_{T}\left(u_{h}, v_{h}\right)\left\|M_{T}^{\top} \nabla \varphi\right\|_{L^{2}\left(\Delta_{T}\right)} \quad \forall \varphi \in H_{0}^{1}(\omega), \tag{3.11}
\end{equation*}
$$

and

$$
\begin{align*}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi\right) \mathrm{d} x \\
& \leq C \sum_{T \in \mathcal{T}_{h}} \rho_{T}\left(u_{h}, v_{h}\right)\left\|M_{T}^{\top} \nabla\left(\psi-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)} \tag{3.12}
\end{align*}
$$

for all $\psi \in H^{1}(\Omega)$ with $\psi \leq \tilde{v}_{h}$.

Proof. The linearity of $\varphi \mapsto \partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)[\varphi]$ yields

$$
\begin{equation*}
\left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)[\varphi]\right| \leq\left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)\left[\varphi-\varphi_{h}\right]\right|+\left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)\left[\varphi_{h}\right]\right| \tag{3.13}
\end{equation*}
$$

We consider the first term on the right-hand side. Using the divergence theorem and the fact that every second derivative of $\left.u_{h}\right|_{T}$ is zero, we have

$$
\begin{aligned}
\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)\left[\varphi-\varphi_{h}\right]= & \sum_{T \in \mathcal{T}_{h}}\left\{\int_{T} b u_{h}\left(\varphi-\varphi_{h}\right) \mathrm{d} x-\mu \int_{T}\left(2 v_{h} \nabla u_{h}^{\top} A \nabla v_{h}\right.\right. \\
& \left.+\left(v_{h}^{2}+\eta_{\varepsilon}\right) \nabla u_{h}^{\top} \cdot \operatorname{div}(A)\right)\left(\varphi-\varphi_{h}\right) \mathrm{d} x \\
& \left.+\mu \int_{\partial T}\left(v_{h}^{2}+\eta_{\varepsilon}\right) \nabla u_{h}^{\top} A \nu_{T}\left(\varphi-\varphi_{h}\right) \mathrm{d} x\right\} \\
= & \sum_{T \in \mathcal{T}_{h}}\left\{\int_{T} p\left(u_{h}, v_{h}\right)\left(\varphi-\varphi_{h}\right) \mathrm{d} x\right. \\
& \left.+\frac{\mu}{2} \int_{\partial T}\left(v_{h}^{2}+\eta_{\varepsilon}\right) \llbracket A \nabla u \rrbracket\left(\varphi-\varphi_{h}\right) \mathrm{d} x\right\} .
\end{aligned}
$$

Hence, by the Cauchy-Schwarz inequality

$$
\begin{aligned}
\left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)\left[\varphi-\varphi_{h}\right]\right| \leq & \sum_{T \in \mathcal{T}_{h}}\left\{\left\|p\left(u_{h}, v_{h}\right)\right\|_{L^{2}(T)}\left\|\varphi-\varphi_{h}\right\|_{L^{2}(T)}\right. \\
& \left.+\frac{\mu}{2}\left\|\left(v_{h}^{2}+\eta_{\varepsilon}\right) \llbracket A \nabla u_{h} \rrbracket\right\|_{L^{2}(\partial T)}\left\|\varphi-\varphi_{h}\right\|_{L^{2}(\partial T)}\right\} .
\end{aligned}
$$

We now select $\varphi_{h}:=Q_{h} \varphi$. By Lemma 3.1. we can estimate

$$
\begin{align*}
\left|\partial_{u} \mathcal{E}_{h}\left(u_{h}, v_{h}\right)\left[\varphi-\varphi_{h}\right]\right| \leq & C_{3} \sum_{T \in \mathcal{T}_{h}}\left(\left\|p\left(u_{h}, v_{h}\right)\right\|_{L^{2}(T)}+\frac{\mu}{2 \sqrt{\sigma_{T, 1} \sigma_{T, 2}}}\right. \\
& \left.\times\left\|\sqrt{h_{\partial T}}\left(v_{h}^{2}+\eta_{\varepsilon}\right) \llbracket A \nabla u_{h} \rrbracket\right\|_{L^{2}(\partial T)}\right)\left\|M_{T}^{\top} \nabla \varphi\right\|_{L^{2}\left(\Delta_{T}\right)} \tag{3.14}
\end{align*}
$$

where $C_{3}:=\max \left\{C_{0}, C_{2}\right\}$.
We now deal with the second contribution on the right-hand side of (3.13). Using (3.6), Lemmas 3.1 and Lemma 3.3, and the fact that $Q_{h}$ preserves the boundary values, we obtain

$$
\begin{aligned}
\left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)\left[\varphi_{h}\right]\right|= & \left|\partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)\left[\varphi_{h}\right]-\partial_{u} \mathcal{E}_{h}\left(u_{h}, v_{h}\right)\left[\varphi_{h}\right]\right| \\
\leq & \sum_{T \in \mathcal{T}_{h}}\left\|\mu\left(v_{h}^{2}-\Pi_{h}\left(v_{h}^{2}\right)\right) A \nabla u_{h}\right\|_{L^{2}(T)}(\| \nabla \varphi \\
& \left.-\nabla \varphi_{h}\left\|_{L^{2}(T)}+\right\| \nabla \varphi \|_{L^{2}(T)}\right) \\
\leq & C_{4} \sum_{T \in \mathcal{T}_{h}} \frac{\mu}{\sigma_{T, 2}}\left\|\left(v_{h}^{2}-\Pi_{h}\left(v_{h}^{2}\right)\right) A \nabla u_{h}\right\|_{L^{2}(T)}\left\|M_{T}^{\top} \nabla \varphi\right\|_{L^{2}\left(\Delta_{T}\right)}
\end{aligned}
$$

with $C_{4}:=1+C_{1}$. This last estimate, combined with (3.14), provides estimate (3.11).

Let us now deal with (3.12). By (3.7), for every $\psi \in H^{1}(\omega)$ and every $\psi_{h} \in \mathcal{X}_{h}$ with $0 \leq \psi, \psi_{h} \leq \tilde{v}_{h}$ we have

$$
\begin{align*}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi\right) \mathrm{d} x \\
& \leq \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi\right) \mathrm{d} x \\
&-\partial_{v} \mathcal{F}_{h}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right]-\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}\left(\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right)\right) \mathrm{d} x \\
& \leq \underbrace{\partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[\psi_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(\psi_{h}-\psi\right) \mathrm{d} x}_{\text {(I) }} \\
&+\underbrace{\partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right]-\partial_{v} \mathcal{F}_{h}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right]}_{(\mathrm{II})} \\
&+\underbrace{\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right) \mathrm{d} x-\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}\left(\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right)\right) \mathrm{d} x}_{\text {(III) }} \tag{3.15}
\end{align*}
$$

where, in the second inequality, we have added and subtracted the terms $\partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[\psi_{h}\right]$ and $\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right) \psi_{h} \mathrm{~d} x$.

We consider the term (I). After integrating by parts on each element $T \in \mathcal{T}_{h}$, we obtain

$$
\begin{aligned}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[\psi_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(\psi_{h}-\psi\right) \mathrm{d} x \\
&= \sum_{T \in \mathcal{T}_{h}}\left\{\mu \int_{T} v_{h}\left(\psi_{h}-\psi\right) \nabla u_{h}^{\top} A \nabla u_{h} \mathrm{~d} x+\frac{\kappa}{2 \varepsilon} \int_{T}\left(v_{h}-1\right)\left(\psi_{h}-\psi\right) \sqrt{a} \mathrm{~d} x\right. \\
&-2 \kappa \varepsilon \int_{T} \nabla v_{h} \cdot \operatorname{div}(A)\left(\psi_{h}-\psi\right) \mathrm{d} x+\kappa \varepsilon \int_{\partial T} \llbracket A \nabla v_{h} \rrbracket\left(\psi_{h}-\psi\right) \mathrm{d} x \\
& \quad\left.+\frac{\alpha}{\tau} \int_{T}\left(v_{h}-\tilde{v}_{h}\right)\left(\psi_{h}-\psi\right) \mathrm{d} x\right\}
\end{aligned}
$$

which can be bounded by the Cauchy-Schwarz inequality as

$$
\begin{align*}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[\psi_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(\psi_{h}-\psi\right) \mathrm{d} x \\
& \quad \leq \sum_{T \in \mathcal{T}_{h}}\left\|q\left(u_{h}, v_{h}\right)\right\|_{L^{2}(T)}\left\|\psi_{h}-\psi\right\|_{L^{2}(T)} \\
& \quad+\kappa \varepsilon \sum_{T \in \mathcal{T}_{h}}\left\|\llbracket A \nabla v_{h} \rrbracket\right\|_{L^{2}(\partial T)}\left\|\psi_{h}-\psi\right\|_{L^{2}(\partial T)} \tag{3.16}
\end{align*}
$$

We then choose $\psi_{h}=Q_{h} \psi$ and note that $Q_{h}\left(\psi-v_{h}\right)=\psi_{h}-v_{h}$ and $\psi-\psi_{h}=\psi-$ $v_{h}-Q_{h}\left(\psi-v_{h}\right)$. This choice, together with Lemma 3.1, allows us to rewrite (3.16) as

$$
\begin{align*}
& \partial_{v} \mathcal{F}_{h}\left(u_{h}, v_{h}\right)\left[\psi_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(\psi_{h}-\psi\right) \mathrm{d} x \\
& \leq \\
& \quad C_{3} \sum_{T \in \mathcal{T}_{h}}\left(\left\|q\left(u_{h}, v_{h}\right)\right\|_{L^{2}(T)}+\frac{\kappa \varepsilon}{\sqrt{\sigma_{T, 1} \sigma_{T, 2}}}\left\|\sqrt{h_{\partial T}} \llbracket A \nabla v_{h} \rrbracket\right\|_{L^{2}(\partial T)}\right)  \tag{3.17}\\
& \quad \times\left\|M_{T}^{\top} \nabla\left(\psi-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)} .
\end{align*}
$$

Next, we estimate term (II). The equality

$$
\left(v_{h}-1\right)\left(v_{h}-\psi_{h}\right)-\Pi_{h}\left(\left(v_{h}-1\right)\left(v_{h}-\psi_{h}\right)\right)=v_{h}\left(v_{h}-\psi_{h}\right)-\Pi_{h}\left(v_{h}\left(v_{h}-\psi_{h}\right)\right)
$$

yields

$$
\begin{aligned}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right]-\partial_{v} \mathcal{F}_{h}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right] \\
&= \sum_{T \in \mathcal{T}_{h}}\left\{\mu \int_{T}\left(v_{h}\left(v_{h}-\psi_{h}\right)-\Pi_{h}\left(v_{h}\left(v_{h}-\psi_{h}\right)\right)\right) \nabla u_{h}^{\top} A \nabla u_{h} \mathrm{~d} x\right. \\
&\left.+\frac{\kappa}{2 \varepsilon} \int_{T}\left(v_{h}\left(v_{h}-\psi_{h}\right)-\Pi_{h}\left(v_{h}\left(v_{h}-\psi_{h}\right)\right)\right) \sqrt{a} \mathrm{~d} x\right\} .
\end{aligned}
$$

Thus, thanks to the Cauchy-Schwarz inequality, to Lemma 3.2 and to the choice of $\psi_{h}$, we obtain

$$
\begin{aligned}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right]-\partial_{v} \mathcal{F}_{h}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right] \\
& \quad \leq \sum_{T \in \mathcal{T}_{h}}\left\|\mu \nabla u_{h}^{\top} A \nabla u_{h}+\frac{\kappa}{2 \varepsilon} \sqrt{a}\right\|_{L^{2}(T)}\left\|v_{h}\left(v_{h}-\psi_{h}\right)-\Pi_{h}\left(v_{h}\left(v_{h}-\psi_{h}\right)\right)\right\|_{L^{2}(T)} \\
& \quad \leq \hat{C} \sum_{T \in \mathcal{T}_{h}} h_{T}^{2}\left\|\mu \nabla u_{h}^{\top} A \nabla u_{h}+\frac{\kappa}{2 \varepsilon} \sqrt{a}\right\|_{L^{2}(T)}\left|v_{h}\right|_{W^{1, \infty}(T)}\left\|\nabla\left(\psi_{h}-v_{h}\right)\right\|_{L^{2}(T)}
\end{aligned}
$$

Now, since $\psi_{h}-v_{h}=\left[Q_{h}\left(\psi-v_{h}\right)-\left(\psi-v_{h}\right)\right]+\psi-v_{h}$, by exploiting Lemma 3.1 for $s=1$ and Lemma 3.3, we conclude that

$$
\begin{align*}
& \partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right]-\partial_{v} \mathcal{F}_{h}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi_{h}\right] \\
& \leq \\
& \leq \hat{C} C_{4} \sum_{T \in \mathcal{T}_{h}} h_{T}^{2}\left\|\mu \nabla u_{h}^{\top} A \nabla u_{h}+\frac{\kappa}{2 \varepsilon} \sqrt{a}\right\|_{L^{2}(T)}\left|v_{h}\right|_{W^{1, \infty}(T)} \\
& \quad \times\left(\frac{1}{\sigma_{2, T}}\left\|M_{T}^{\top} \nabla\left(\psi-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)}+\left\|\nabla\left(\psi-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)}\right) \\
& \leq  \tag{3.18}\\
& \quad C_{5} \sum_{T \in \mathcal{T}_{h}} \frac{h_{T}^{2}}{\sigma_{T, 2}}\left\|\mu \nabla u_{h}^{\top} A \nabla u_{h}+\frac{\kappa}{2 \varepsilon} \sqrt{a}\right\|_{L^{2}(T)}\left|v_{h}\right|_{W^{1, \infty}(T)} \\
& \quad \times\left\|M_{T}^{\top} \nabla\left(\psi-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)},
\end{align*}
$$

with $C_{5}=2 \hat{C} C_{4}$. We proceed in a similar way on term (III) in (3.15), so that we obtain

$$
\begin{align*}
& \frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right) \mathrm{d} x-\frac{\alpha}{\tau} \int_{\omega} \Pi_{h}\left(\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right)\right) \mathrm{d} x \\
& \quad \leq \sum_{T \in \mathcal{T}_{h}} \frac{\alpha}{\tau}|T|^{\frac{1}{2}}\left\|\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right)-\Pi_{h}\left(\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi_{h}\right)\right)\right\|_{L^{2}(T)} \\
& \quad \leq \hat{C} \sum_{T \in \mathcal{T}_{h}} \frac{\alpha h_{T}^{2}}{\tau}|T|^{\frac{1}{2}}\left|v_{h}-\tilde{v}_{h}\right|_{W^{1, \infty}(T)}\left\|\nabla\left(\psi_{h}-v_{h}\right)\right\|_{L^{2}(T)} \\
& \quad \leq C_{5} \sum_{T \in \mathcal{T}_{h}} \frac{\alpha h_{T}^{2}}{\tau \sigma_{T, 2}}\left\|\nabla\left(v_{h}-\tilde{v}_{h}\right)\right\|_{L^{2}(T)}\left\|M_{T}^{\top} \nabla\left(\psi-v_{h}\right)\right\|_{L^{2}(T)} \tag{3.19}
\end{align*}
$$

where, in the last inequality, we have also exploited the property that $v_{h}-\tilde{v}_{h}$ is piecewise affine. Combining estimates (3.17)-(3.19), we deduce result (3.12).

With a view to the mesh adaptation procedure, we combine (3.11) and (3.12) in a single estimate, i.e.

$$
\begin{align*}
& \partial_{u} \mathcal{E}\left(u_{h}, v_{h}\right)[\varphi]+\partial_{v} \mathcal{F}\left(u_{h}, v_{h}\right)\left[v_{h}-\psi\right]+\frac{\alpha}{\tau} \int_{\omega}\left(v_{h}-\tilde{v}_{h}\right)\left(v_{h}-\psi\right) \mathrm{d} x \\
& \quad \leq C \sum_{T \in \mathcal{T}_{h}}\left[\gamma_{T}\left(u_{h}, v_{h}\right)\left\|M_{T}^{\top} \nabla \varphi\right\|_{L^{2}\left(\Delta_{T}\right)}+\rho_{T}\left(u_{h}, v_{h}\right)\left\|M_{T}^{\top} \nabla\left(\psi-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)}\right] \tag{3.20}
\end{align*}
$$

for all $\varphi \in H^{1}(\omega)$ with $\varphi=0$ on $\partial \omega$, and for all $\psi \in H^{1}(\omega)$ with $\psi \leq \tilde{v}_{h}$.
It is evident that result (3.20) is not yet useful in practice since it depends on the generic functions $\varphi$ and $\psi$. As detailed in the next section, to make computable the right-hand side of (3.20), we follow the approach in Ref. 10, first picking $\varphi=u-u_{h}$ and $\psi=v$, i.e. setting

$$
\begin{align*}
\Xi\left(u_{h}, v_{h}\right):= & \sum_{T \in \mathcal{T}_{h}} \Xi_{T}\left(u_{h}, v_{h}\right),  \tag{3.21}\\
\Xi_{T}\left(u_{h}, v_{h}\right):= & \gamma_{T}\left(u_{h}, v_{h}\right)\left\|M_{T}^{\top} \nabla\left(u-u_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)} \\
& +\rho_{T}\left(u_{h}, v_{h}\right)\left\|M_{T}^{\top} \nabla\left(v-v_{h}\right)\right\|_{L^{2}\left(\Delta_{T}\right)} \tag{3.22}
\end{align*}
$$

for any $T \in \mathcal{T}_{h}$, and then resorting to a gradient recovery procedure to replace the derivatives of $u$ and $v$.

## 4. From the Estimator to the Mesh

To commute $\Xi\left(u_{h}, v_{h}\right)$ into an actual a posteriori error estimator able to drive a mesh adaptation procedure, we follow the metric-based approach in Refs. 10, 56, 40 and 37. This consists of an iterative procedure, so that, at each iteration $j$, with
$j \geq 0$, (i) we compute the error estimator in the current mesh, $\mathcal{T}_{h}^{(j)}$; (ii) we derive the metric tensor field, $\mathcal{M}^{(j+1)}$; (iii) we build the new adapted mesh, $\mathcal{T}_{h}^{(j+1)}$. We now detail these three steps.
(i) For every $T \in \mathcal{T}_{h}^{(j)}$ and every $w \in H^{1}(\omega)$, using the singular value decomposition, $M_{T}=U_{T} \Sigma_{T} V_{T}^{\top}$, we can rewrite the norm $\left\|M_{T}^{\top} \nabla w\right\|_{L^{2}\left(\Delta_{T}\right)}^{2}$ in $\Xi_{T}\left(u_{h}, v_{h}\right)$ as

$$
\begin{aligned}
\left\|M_{T}^{\top} \nabla w\right\|_{L^{2}\left(\Delta_{T}\right)}^{2} & =\left\|\Sigma_{T} U_{T}^{\top} \nabla w\right\|_{L^{2}\left(\Delta_{T}\right)}^{2}=\sum_{i=1}^{2} \int_{\Delta_{T}} \sigma_{T, i}^{2}\left|\mathbf{r}_{T, i} \cdot \nabla w\right|^{2} \mathrm{~d} x \\
& =\sum_{i=1}^{2} \sigma_{T, i}^{2} \mathbf{r}_{T, i}^{\top} \mathcal{G}_{T}(w) \mathbf{r}_{T, i}
\end{aligned}
$$

where $\mathcal{G}_{T}: H^{1}\left(\Delta_{T}\right) \rightarrow L^{2}\left(\Delta_{T} ; \mathbb{R}^{2 \times 2}\right)$ is the symmetric semipositive definite matrix

$$
\mathcal{G}_{T}(w):=\left(\begin{array}{cc}
\int_{\Delta_{T}}\left|\partial_{1} w\right|^{2} \mathrm{~d} x & \int_{\Delta_{T}} \partial_{1} w \partial_{2} w \mathrm{~d} x \\
\int_{\Delta_{T}} \partial_{1} w \partial_{2} w \mathrm{~d} x & \int_{\Delta_{T}}\left|\partial_{2} w\right|^{2} \mathrm{~d} x
\end{array}\right)
$$

From (3.22), we obtain

$$
\begin{aligned}
\Xi_{T}\left(u_{h}, v_{h}\right)= & \gamma_{T}\left(u_{h}, v_{h}\right)\left(\sum_{i=1}^{2} \sigma_{T, i}^{2} \mathbf{r}_{T, i}^{\top} \mathcal{G}_{T}\left(u-u_{h}\right) \mathbf{r}_{T, i}\right)^{\frac{1}{2}} \\
& +\rho_{T}\left(u_{h}, v_{h}\right)\left(\sum_{i=1}^{2} \sigma_{T, i}^{2} \mathbf{r}_{T, i}^{\top} \mathcal{G}_{T}\left(v-v_{h}\right) \mathbf{r}_{T, i}\right)^{\frac{1}{2}}
\end{aligned}
$$

Now, the first-order partial derivatives of $u$ and $v$ in $\mathcal{G}_{T}$ are replaced via the wellknown Zienkiewicz-Zhu recovery procedure, ${ }^{\boxed{63164}}$ so that we obtain the local a posteriori error estimator

$$
\begin{align*}
\Xi_{T}^{R}\left(u_{h}, v_{h}\right)= & \gamma_{T}\left(u_{h}, v_{h}\right)\left(\sum_{i=1}^{2} \sigma_{T, i}^{2} \mathbf{r}_{T, i}^{\top} \mathcal{G}_{T}^{R}\left(u_{h}\right) \mathbf{r}_{T, i}\right)^{\frac{1}{2}} \\
& +\rho_{T}\left(u_{h}, v_{h}\right)\left(\sum_{i=1}^{2} \sigma_{T, i}^{2} \mathbf{r}_{T, i}^{\top} \mathcal{G}_{T}^{R}\left(v_{h}\right) \mathbf{r}_{T, i}\right)^{\frac{1}{2}} \tag{4.1}
\end{align*}
$$

where $\left[\mathcal{G}_{T}^{R}\left(w_{h}\right)\right]_{i j}=\int_{\Delta_{T}}\left(\partial_{i} w_{h}-R^{i}\left(w_{h}\right)\right)\left(\partial_{j} w_{h}-R^{j}\left(w_{h}\right)\right) \mathrm{d} x$, with $i, j=1,2, w_{h} \in$ $\mathcal{X}_{h}$ and where $\left[R^{1}\left(w_{h}\right), R^{2}\left(w_{h}\right)\right]^{\top}$ denotes the recovered gradient of $w_{h}$.
(ii) Two criteria drive the derivation of the metric, i.e. the minimization of the number of the mesh elements for a given accuracy TOL on the global error estimator,

$$
\Xi^{R}\left(u_{h}, v_{h}\right):=\sum_{T \in \mathcal{T}_{h}} \Xi_{T}^{R}\left(u_{h}, v_{h}\right)
$$

and the error equidistribution,

$$
\Xi_{T}^{R}\left(u_{h}, v_{h}\right) \leq \frac{\mathrm{TOL}}{\# \mathcal{T}_{h}^{(j)}}
$$

For this purpose, we first scale (4.1) with respect to the area $|T|=|\hat{T}| \sigma_{T, 1} \sigma_{T, 2}$ of the element $T \in \mathcal{T}_{h}^{(j)}$, such that

$$
\Xi_{T}^{R}\left(u_{h}, v_{h}\right)=\alpha_{T} \Upsilon_{T}\left(s_{T}, \mathbf{r}_{T, 1}\right)
$$

where

$$
\begin{aligned}
\alpha_{T} & :=|\hat{T}|\left(\sigma_{T, 1} \sigma_{T, 2}\right)^{\frac{3}{2}} \\
\Upsilon_{T}\left(s_{T}, \mathbf{r}_{T, 1}\right) & :=\left(s_{T} \mathbf{r}_{T, 1}^{\top} \Gamma_{T}\left(u_{h}, v_{h}\right) \mathbf{r}_{T, 1}+\frac{1}{s_{T}} \mathbf{r}_{T, 2}^{\top} \Gamma_{T}\left(u_{h}, v_{h}\right) \mathbf{r}_{T, 2}\right)^{\frac{1}{2}} \\
\Gamma_{T}\left(u_{h}, v_{h}\right) & :=\bar{\gamma}_{T}^{2}\left(u_{h}, v_{h}\right) \overline{\mathcal{G}}_{T}^{R}\left(u_{h}\right)+\bar{\rho}_{T}^{2}\left(u_{h}, v_{h}\right) \overline{\mathcal{G}}_{T}^{R}\left(v_{h}\right), \\
\bar{\gamma}_{T}\left(u_{h}, v_{h}\right) & :=\frac{\gamma_{T}\left(u_{h}, v_{h}\right)}{\left(|\hat{T}| \sigma_{T, 1} \sigma_{T, 2}\right)^{\frac{1}{2}}} \quad \text { and } \quad \bar{\rho}_{T}\left(u_{h}, v_{h}\right):=\frac{\rho_{T}\left(u_{h}, v_{h}\right)}{\left(|\hat{T}| \sigma_{T, 1} \sigma_{T, 2}\right)^{\frac{1}{2}}}, \\
\overline{\mathcal{G}}_{T}\left(w_{h}\right) & :=\frac{\mathcal{G}_{T}\left(w_{h}\right)}{|\hat{T}| \sigma_{T, 1} \sigma_{T, 2}} \quad \text { with } w_{h}=u_{h}, v_{h} .
\end{aligned}
$$

Note that the quantity $\Upsilon_{T}\left(s_{T}, \mathbf{r}_{T, 1}\right)$ implicitly depends also on $\mathbf{r}_{T, 2}$ via the orthonormality condition $\mathbf{r}_{T, 1}^{\top} \mathbf{r}_{T, 2}=0$.

Thus, to minimize the cardinality of the mesh (or, likewise, to maximize the triangle area) while enforcing the local accuracy $\operatorname{TOL} / \# \mathcal{T}_{h}^{(j)}$, we are led to solve the local constrained minimization problem

$$
\min _{s_{T} \geq 1, \mathbf{r}_{T, 1} \in \mathbb{S}^{1}} \Upsilon_{T}\left(s_{T}, \mathbf{r}_{T, 1}\right)
$$

$\mathbb{S}^{1}$ being the unit sphere. Following Ref. 38, we can analytically compute the unique solution to this problem, given by

$$
s_{T}^{*}=\sqrt{\frac{\vartheta_{T, 1}}{\vartheta_{T, 2}}}, \quad \mathbf{r}_{T, 1}^{*}=\mathbf{v}_{T, 2}
$$

with $\left\{\mathbf{v}_{T, i}, \vartheta_{T, i}\right\}$ the eigenpair of $\Gamma_{T}\left(u_{h}, v_{h}\right)$ for $i=1,2$, with $\vartheta_{T, 1}>\vartheta_{T, 2}$ and $\mathbf{v}_{T, i}^{\top} \mathbf{v}_{T, j}=\delta_{i j}$. Finally, the equidistribution criterion allows us to compute the optimal lengths

$$
\begin{equation*}
\sigma_{T, 1}^{*}=\left(\frac{\mathrm{TOL}}{\sqrt{2}|\hat{T}| \# \mathcal{T}_{h}^{(j)}} \sqrt{\frac{\vartheta_{T, 1}}{\vartheta_{T, 2}^{2}}}\right)^{\frac{1}{3}} \quad \text { and } \quad \sigma_{T, 2}^{*}=\left(\frac{\mathrm{TOL}}{\sqrt{2}|\hat{T}| \# \mathcal{T}_{h}^{(j)}} \sqrt{\frac{\vartheta_{T, 2}}{\vartheta_{T, 1}^{2}}}\right)^{\frac{1}{3}} \tag{4.2}
\end{equation*}
$$

The metric field $\mathcal{M}^{(j+1)}$ is approximated by a piecewise tensor, provided by

$$
\begin{equation*}
\mathcal{M}^{(j+1)} \|_{T}=\frac{1}{\left(\sigma_{T, 1}^{*}\right)^{2}} \mathbf{r}_{T, 1}^{*} \mathbf{r}_{T, 1}^{*, \top}+\frac{1}{\left(\sigma_{T, 2}^{*}\right)^{2}} \mathbf{r}_{T, 2}^{*} \mathbf{r}_{T, 2}^{*, T} \tag{4.3}
\end{equation*}
$$

for each $T \in \mathcal{T}_{h}^{(j)}$ (see Ref. 46). We remark that the mismatch between the index ( $j$ ) for the mesh and $(j+1)$ for the metric is due to the predictive feature of the adaptive algorithm, which exploits the information on the current mesh to extrapolate the "optimal" mesh for the next iteration.
(iii) This step is committed to a metric-based mesh generator. In particular, we choose the FreeFEM environment ${ }^{48}$ The metric $\mathcal{M}^{(j+1)}$ becomes the input to the built-in function adaptmesh, which provides the anisotropic adapted mesh $\mathcal{T}_{h}^{(j+1)}$.

## 5. Numerical Examples

Next step is to properly combine the minimization in (3.2)-(3.3) together with the adaptation procedure detailed in the previous section. With this aim, we resort to an approach that is a variant to Algorithms 2 and 3 in Ref. 10, itemized in Algorithm 1 below.

```
Algorithm 1 Alternating Minimization + Anisotropic Mesh Adaptation for Shells
    Input: TOL, \(\mathrm{TOL}_{m}, \mathrm{TOL}_{v}, \operatorname{MaxIt}, \alpha, \tau, u_{0}, v_{0}, \mathcal{T}_{h}^{(0)}\)
    for \(i=0\) to \(k\) do
    \(j \leftarrow 0 ; u_{i, 0} \leftarrow u_{0} ; v_{i, 0} \leftarrow v_{0}\)
        repeat
            \(m \leftarrow 0\)
            repeat
                    \(j \leftarrow j+1 ; m \leftarrow m+1\)
                    \(u_{i, j} \leftarrow \arg \min \left\{\mathcal{E}_{h}\left(u, v_{i, j-1}\right): u \in \mathcal{X}_{h}^{(m)}, u=g\left(t_{i}\right)\right.\) on \(\left.\partial \omega\right\}\)
                    \(v_{i, j} \leftarrow \arg \min \left\{\mathcal{F}_{h}\left(u_{i, j}, v\right)+\frac{\alpha}{2 \tau}\left\|v-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2}: v \in \mathcal{X}_{h}^{(m)}, v \leq v_{i-1}\right\}\)
            until \(m=\) MaxIt or \(\left\|v_{i, j}-v_{i, j-1}\right\|_{\infty}<\operatorname{TOL}_{v}\)
            compute \(\mathcal{M}^{(m+1)}\) based on (4.3)
            generate \(\mathcal{T}_{h}^{(m+1)}\) associated with \(\mathcal{M}^{(m+1)}\)
            \(v_{i, j} \leftarrow \Pi_{h}^{(m+1)}\left(v_{i, j}\right) ; v_{i-1} \leftarrow \Pi_{h}^{(m+1)}\left(v_{i-1}\right)\)
            until \(\frac{\left|\# \mathcal{T}_{h}^{(m+1)}-\# \mathcal{T}_{h}^{(m)}\right|}{\# \mathcal{T}_{h}^{(m)}}<\operatorname{TOL}_{m}\) and \(\left\|v_{i, j}-v_{i, j-1}\right\|_{\infty}<\operatorname{TOL}_{v}\)
            \(u_{i} \leftarrow \arg \min \left\{\mathcal{E}_{h}\left(u, v_{i, j}\right): u \in \mathcal{X}_{h}^{(m+1)}, u=g\left(t_{i}\right)\right.\) on \(\left.\partial \omega\right\}\)
            \(v_{i} \leftarrow \arg \min \left\{\mathcal{F}_{h}\left(u_{i}, v\right)+\frac{\alpha}{2 \tau}\left\|v-v_{i-1}\right\|_{\mathcal{X}_{h}}^{2}: v \in \mathcal{X}_{h}^{(m+1)}, v \leq v_{i-1}\right\}\)
            \(\mathcal{T}_{h}^{(0)}=\mathcal{T}_{h}^{(m+1)}\)
    end for
```

The procedure consists of three main loops: the outermost cycle steps over the quasi-static time advancing, the intermediate one manages the update of the mesh, while the innermost loop controls the optimization of the physical variables $u$ and $v$. This last phase is supervised by a maximum number MaxIt of iterations, together with a control on the increment of the phase field, to within the tolerance $\mathrm{TOL}_{v}$. In order to recover the possible lack of accuracy on $v$, the same check on the increment is also required in the intermediate loop, in combination with a stagnation of the mesh cardinality, up to a tolerance $\mathrm{TOL}_{m}$.

The minimization performed in lines 9 and 16 are carried out by an interior point method using the package IPOPT, ${ }^{[62}$ included in FreeFEM. [88 IPOPT is a common large-scale nonlinear optimization tool based on the interior point algorithm ${ }^{62}$ Both equality and inequality constraints can be tackled via suitable slack variables. The bound on the phase field can be directly enforced as a box constraint. Among the input parameters of IPOPT, the user has to also provide the gradient of the functional and of the constraint with respect to the phase field.

The metric computation in line 11 is driven by $u_{h}=u_{i, j}$ and $v_{h}=v_{i, j}$. The operator $\Pi_{h}^{(m+1)}$ is the Lagrangian interpolant associated with the mesh $\mathcal{T}_{h}^{m}$ evaluated at the vertices of the mesh $\mathcal{T}_{h}^{(m+1)}$, which is employed to project the phase field on the newly adapted mesh before the next iteration.

Table 1 gathers the values adopted in the numerical assessment for both the input parameters to Algorithm 1 and for the physical quantities involved in functional (2.28). For a sensitivity analysis with respect to some of these parameters in the anti-plane case we refer to Ref. 9. In the tests below, following Refs. 17, 20 and 10, we consider notched specimens characterized by a thin slit to model the initial crack. The time-dependent boundary condition in (3.2) is assumed to be linear. For technical reasons related to the definition of space $\operatorname{GSBV}(\omega)$, we extend the physical domain beyond the Dirichlet boundary. Such an extension turns out to be advisable also for the phase field in order to avoid an underestimate of the fracture energy when the damage approaches the Dirichlet boundary.

### 5.1. A piece of a cylinder

We consider a piece of cylindrical surface with radius $R=1$ and length $L$. As the map $\phi$, we choose cylindrical coordinates

$$
(x, y) \mapsto\left(\begin{array}{c}
R \cos x  \tag{5.1}\\
R \sin x \\
y
\end{array}\right) \quad \text { for all }(x, y) \in \omega=\left(-\frac{\pi}{2}, \frac{\pi}{2}\right) \times(0, L)
$$

Table 1. Input parameters to Algorithm 1 and physical quantities for functional 2.28 .

| TOL | TOL $_{m}$ | TOL $_{v}$ | MaxIt | $\tau$ | $\varepsilon$ | $\eta$ | $\kappa$ | $\lambda$ | $\mu$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | ---: |
| $10^{-3}$ | $10^{-2}$ | $2 \cdot 10^{-3}$ | 8 | $10^{-2}$ | $5 \cdot 10^{-3}$ | $10^{-5}$ | 1 | 0 | 1 |

With this at hand, we have

$$
\left(a^{\alpha \beta}\right)=\left(\begin{array}{cc}
\frac{1}{R^{2}} & 0 \\
0 & 1
\end{array}\right), \quad\left(b_{\alpha \beta}\right)=\left(\begin{array}{cc}
-R & 0 \\
0 & 0
\end{array}\right) \quad \text { and } \quad \sqrt{a}=R
$$

For the crack initialization, we define the notch $\Gamma:=\left[-10^{-3}, 10^{-3}\right] \times[0,0.3]$, so that the computation takes place in $\omega \backslash \Gamma$. We also set

$$
g(t):= \begin{cases}t & \text { on }\left[10^{-3}, \pi / 2\right] \times\{0\}  \tag{5.2}\\ -t & \text { on }\left[-\pi / 2,-10^{-3}\right] \times\{0\} \\ 0 & \text { elsewhere }\end{cases}
$$

The extended domain adopted in such a case is $\omega \cup\left(-\frac{\pi}{2}, \frac{\pi}{2}\right) \times(-0.1,0]$.
In Fig. 4, we show the phase field computed for $L=1$ as well as a zoom in on the mesh close to the crack, where it exhibits a strong directional behavior.

Note that the term $\int_{\omega} \boldsymbol{c}^{\alpha \beta \sigma \tau} b_{\alpha \beta} b_{\sigma \tau}|u|^{2} \sqrt{a} \mathrm{~d} x$ in the functional (2.28) adds some energy even though the displacement is constant, due to a curvature effect. Furthermore, the boundary condition creates some tension along the boundary itself. Thus, if the length $L$ is sufficiently large, a crack is generated along the boundary before the original crack fully develops. This phenomenon is confirmed in Fig. 5 where we set $L=2$. The initial crack propagates until $t=2.83$. Then, at $t=2.84$ the surface suddenly breaks along the Dirichlet boundary. To contain this effect, we pick the Lamé coefficient $\lambda$ equals to zero in Table 1 .

We now weaken the surface by introducing holes. In particular, we consider the two configurations in Fig. 6] characterized by a single hole with radius 0.15 centered at $(0.3,0.75)$ and by three holes with radius 0.08 and centers $(-0.2,0.88)$, $(-0.2,0.68),(-0.2,0.48)$. In both cases, the crack bends entering the holes. This confirms that the crack path is not biased by the anisotropic mesh adaptation, consistently with what observed in Ref. 10.

In Fig. 7 we provide more quantitative information about the physics of the problem and the mesh adaptation procedure for all the considered configurations. In

Fig. 4. Piece of a cylinder: phase field at two consecutive times and detail of the mesh around the crack for $L=1$.

Fig. 5. Piece of a cylinder: phase field at three times for $L=2$.

Fig. 6. Piece of a cylinder: phase field at time $t=2.97$ and $t=1.46$ for the single-hole (left) and three-hole (right) configuration for $L=1$.

Fig. 7. Piece of a cylinder: crack length (left) and number of triangles (right) as functions of time for the configurations in Fig. (4) (a), in Fig. 6 left, (b), and in Fig. 6 right, (c).
particular, in the left panel, we plot the time evolution of the quantity $\kappa^{-1} \mathcal{D}_{h}\left(v_{h}\right)$, which $\Gamma$-converges to the length of the crack (see Sec. 2.4 and Appendix A), while, in the right panel, we show the trend of the cardinality of the mesh. Both the crack length and the number of triangles exhibit a similar trend since the most relevant phenomena occur around the crack path.

$t=1.46$

Fig. 8. Piece of a cylinder: specimen deformation for the three-hole configuration at different times.

Finally, we consider the effect, i.e. the deformation, induced by the crack propagation on the specimen for the three-hole configuration. With this aim, we apply to the undeformed surface the computed displacement $u_{h}$ along the normal direction $a^{3}$. However, for visualization purposes, we remove the points of the surface where the phase field is below a certain threshold, here set to $10^{-2}$, to model the physical crack. Figure 8 gathers 12 snapshots tracking the whole evolution of the crack, from the undamaged initial configuration to the complete breaking of the specimen.

### 5.2. A piece of a sphere

As a second test case, we consider a portion of a sphere with radius $R=1$. We adopt the parametrization

$$
(x, y) \mapsto R\left(\begin{array}{c}
\cos x \cos y \\
\sin x \cos y \\
\sin y
\end{array}\right) \quad \text { for }(x, y) \in \omega:=(-\bar{x}, \bar{x}) \times(-\bar{y}, \bar{y}),
$$

for some $0<\bar{x}<\pi, 0<\bar{y}<\frac{\pi}{2}$. With this setting, we have

$$
\left(a^{\alpha \beta}\right)=\frac{1}{R^{2}}\left(\begin{array}{cc}
\frac{1}{\cos ^{2} y} & 0 \\
0 & 1
\end{array}\right), \quad\left(b_{\alpha \beta}\right)=-R\left(\begin{array}{cc}
\cos ^{2} y & 0 \\
0 & 1
\end{array}\right) \quad \text { and } \quad \sqrt{a}=R^{2} \cos y
$$

We set $\bar{x}=\frac{\pi}{2}$ and we make two different choices for $\bar{y}$. Concerning the initial notch, we choose $\Gamma:=\left[-10^{-3}, 10^{-3}\right] \times[-\bar{y}, 0.3-\bar{y}]$ and we select $g$ as in (5.2) for the Dirichlet boundary condition.

Figure 9 shows on the left the final phase field at $t=2.38$ and for $\bar{y}=\frac{\pi}{6}$. Analogously as in the previous section, we modify the plain configuration by digging a hole with center at $(-0.25,0.5)$ and radius 0.15 . The associated function $v_{h}$, for $\bar{y}=\frac{\pi}{7}$, is displayed on the right of Fig. 9 for $t=2.64$. The choice for $\bar{y}$ avoids

Fig. 9. Piece of a sphere: phase field for the plain (left) and for the single-hole (right) configuration.
the generation of a secondary crack along the Dirichlet boundary, consistently with what remarked for the piece of cylinder test case.

## Appendix A. Proof of Theorem 2.2

In order to prove Theorem 2.2, we need the following two lemmas.

Lemma A.1. Let $I \subset \mathbb{R}, f, g \in C^{1}(\bar{I})$ with $f, g>0$ in $\bar{I}$. Assume that $\left(u_{\varepsilon}, v_{\varepsilon}\right) \rightarrow$ $(u, v)$ in $L^{1}(I)$ as $\varepsilon \rightarrow 0$ and that

$$
\begin{equation*}
\liminf _{\varepsilon \rightarrow 0} \frac{\mu}{2} \int_{I} v_{\varepsilon}^{2}\left|u_{\varepsilon}^{\prime}\right|^{2} \mathrm{~d} x+\kappa \int_{I}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2} f+\varepsilon\left|v_{\varepsilon}^{\prime}\right|^{2} g\right] \mathrm{d} x<+\infty \tag{A.1}
\end{equation*}
$$

Then, there holds $v=1$ a.e. and

$$
\begin{equation*}
\int_{S_{u}} \sqrt{f g} \mathrm{~d} \mathcal{H}^{0} \leq \liminf _{\varepsilon \rightarrow 0} \int_{I}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2} f+\varepsilon\left|v_{\varepsilon}^{\prime}\right|^{2} g\right] \mathrm{d} x \tag{A.2}
\end{equation*}
$$

Proof. Up to a subsequence, we assume that the lim inf in (A.1) is actually a limit. All the involved limits in the proof are considered as $\varepsilon \rightarrow 0$.

We have $v=1$ a.e. in $I$, since otherwise $\frac{1}{4 \varepsilon} \int_{I}\left(1-v_{\varepsilon}\right)^{2} f \mathrm{~d} x \rightarrow+\infty$. In order to prove (A.2], we fix $y_{0} \in S_{u}$ and $\delta>0$ such that $B_{\delta}\left(y_{0}\right) \subset I$. Arguing as in Refs. 35 and 18, we find a sequence $\left(y_{\varepsilon}\right)_{\varepsilon>0}$ in $B_{\frac{\delta}{2}}\left(y_{0}\right)$ such that $v_{\varepsilon}\left(y_{\varepsilon}\right) \rightarrow 0$. Since $v_{\varepsilon} \rightarrow 1$ a.e. in $I$, there exist $y^{+}, y^{-} \in B_{\delta}\left(y_{0}\right)$ such that $y^{-}<y_{0}<y^{+}$and $v_{\varepsilon}\left(y^{ \pm}\right) \rightarrow 1$.

It is easy to compute that

$$
1=\lim _{\varepsilon \rightarrow 0}\left(\int_{y_{\varepsilon}}^{y^{+}}\left(1-v_{\varepsilon}\right) v_{\varepsilon}^{\prime} \mathrm{d} x+\int_{y_{\varepsilon}}^{y^{-}}\left(1-v_{\varepsilon}\right) v_{\varepsilon}^{\prime} \mathrm{d} x\right) \leq \liminf _{\varepsilon \rightarrow 0} \int_{B_{\delta}\left(y_{0}\right)}\left(1-v_{\varepsilon}\right)\left|v_{\varepsilon}^{\prime}\right| \mathrm{d} x
$$

Therefore, by Young's inequality we obtain

$$
\begin{aligned}
\inf _{B_{\delta}\left(y_{0}\right)} \sqrt{f g} & \leq \liminf _{\varepsilon \rightarrow 0} \int_{B_{\delta}\left(y_{0}\right)}\left(1-v_{\varepsilon}\right)\left|v_{\varepsilon}^{\prime}\right| \sqrt{f g} \mathrm{~d} x \\
& \leq \liminf _{\varepsilon \rightarrow 0} \int_{B_{\delta}\left(y_{0}\right)}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2} f+\varepsilon\left|v_{\varepsilon}^{\prime}\right|^{2} g\right] \mathrm{d} x
\end{aligned}
$$

For each element in any discrete set $\left\{y_{1}, \ldots, y_{N}\right\} \subset S_{u}$ (with $N \leq \# S_{u}$ ) we can repeat the above argument for all $\delta>0$ such that $B_{\delta}\left(y_{k}\right) \cap B_{\delta}\left(y_{\ell}\right)=\emptyset$ for $k \neq \ell$, in order to obtain

$$
\begin{equation*}
N \inf _{I} \sqrt{f g} \leq \sum_{i=1}^{N} \inf _{B_{\delta}\left(y_{i}\right)} \sqrt{f g} \leq \liminf _{\varepsilon \rightarrow 0} \int_{I}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2} f+\varepsilon\left|v_{\varepsilon}^{\prime}\right|^{2} g\right] \mathrm{d} x \tag{A.3}
\end{equation*}
$$

Because of (A.1), the right-hand side of (A.3) is uniformly bounded. Therefore, $\# S_{u}$ must be finite and we can conclude (A.2) by taking the limit as $\delta \rightarrow 0$.

The limsup-inequality is first shown for a certain class of functions which are dense in the set $\operatorname{GSBV}^{2}(\omega) \cap L^{1}(\omega)$. ${ }^{[7]}$

Lemma A.2. Let $u \in \operatorname{SBV}^{2}(\omega)$ be such that
(1) $\overline{S_{u}}$ is the intersection of $\omega$ with a finite number of pairwise disjoint $(n-1)$ simplexes;
(2) $\mathcal{H}^{n-1}\left(\overline{S_{u}} \backslash S_{u}\right)=0$;
(3) $u \in W^{k, \infty}\left(\omega \backslash \overline{S_{u}}\right)$ for all $k \in \mathbb{N}$.

Then, there exists a sequence $\left(u_{\varepsilon}, v_{\varepsilon}\right)$ converging to $(u, 1)$ in $L^{1}(\omega)$ as $\varepsilon \rightarrow 0$ such that

$$
\begin{equation*}
\limsup _{\varepsilon \rightarrow 0} \mathcal{F}_{\varepsilon}\left(u_{\varepsilon}, v_{\varepsilon}\right) \leq \mathcal{F}(u, v) \tag{A.4}
\end{equation*}
$$

Proof. Throughout the proof, $C>0$ denotes an arbitrary constant independent of $\varepsilon>0$, which may vary from line to line, and the limits are considered as $\varepsilon \rightarrow 0$.

For the construction of a recovery sequence of $u$, we choose a smooth cut off function $\phi: \mathbb{R} \rightarrow \mathbb{R}$ with $\phi=1$ on $B_{\frac{1}{2}}(0)$ and $\phi=0$ on $\mathbb{R} \backslash B_{1}(0)$. For all $x \in \omega$, define $\tau(x)=\operatorname{dist}\left(x, S_{u}\right)$ and $\phi_{\varepsilon}(x)=\phi\left(\frac{\tau(x)}{\delta_{\varepsilon}}\right)$ for all $\varepsilon>0$, where $\delta_{\varepsilon}:=\sqrt{\varepsilon \eta_{\varepsilon}}$. In this way, we have $\frac{\delta_{\varepsilon}}{\varepsilon} \rightarrow 0$ and $\frac{\eta_{\varepsilon}}{\delta_{\varepsilon}} \rightarrow 0$. Let us consider the functions $u_{\varepsilon}=\left(1-\phi_{\varepsilon}\right) u$ on $\omega$. Then, we have $u_{\varepsilon} \in H^{1}(\omega), u_{\varepsilon}=u$ on $\omega \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)$ and $u_{\varepsilon} \rightarrow u$ in $L^{1}(\omega)$.

In order to construct the recovery sequence corresponding to $v=1$, a.e., we define $\sigma:[0, \infty) \rightarrow[0,1]$ by $\sigma(t)=1-\exp \left(-\frac{t}{2}\right)$, which solves the initial value problem

$$
\sigma^{\prime}=\frac{1}{2}(1-\sigma), \quad \sigma(0)=0 .
$$

We note that $\sigma$ is a strictly increasing, Lipschitz continuous function and $\sigma(t) \rightarrow 1$ as $t \rightarrow \infty$. For simplicity of notation, we set

$$
\varphi(\zeta, x):=\left(\frac{\zeta^{\top} A \zeta}{\sqrt{a}}\right)^{\frac{1}{2}} \quad \text { and } \quad \tilde{\tau}(x)=\frac{\tau}{\varphi(\nabla \tau, x)} \quad \text { for all } \zeta \in \mathbb{R}^{n}, x \in \omega
$$

We note that by the properties of $A$ and by Sec. 3.2.34 in Ref. 34 we can define $0<d:=\inf _{x \in \omega} \varphi(\nabla \tau, x)$ and $\infty>D:=\sup _{x \in \omega} \varphi(\nabla \tau, x)$. Furthermore, we set $\tilde{\delta}_{\varepsilon}:=\frac{\delta_{\varepsilon}}{\varepsilon d}$ for all $\varepsilon>0$ and

$$
\rho_{\varepsilon}:=D \varepsilon\left(\tilde{\delta}_{\varepsilon}-2 \ln \left(\frac{\varepsilon}{1+\varepsilon}\right)\right)
$$

so that $\rho_{\varepsilon} \rightarrow 0$ as $\varepsilon \rightarrow 0$. Now we define, for every $t>0$ and for every $x \in \omega$, $\sigma_{\varepsilon}(t):=\left\{\begin{array}{ll}0 & \text { for } t \in\left[0, \tilde{\delta}_{\varepsilon}\right) \\ \min \left\{1,(1+\varepsilon) \sigma\left(t-\tilde{\delta}_{\varepsilon}\right)\right\} & \text { otherwise }\end{array} \quad\right.$ and $\quad v_{\varepsilon}(x):=\sigma_{\varepsilon}\left(\frac{\tilde{\tau}(x)}{\varepsilon}\right)$.

Now, the sequence $\left(u_{\varepsilon}, v_{\varepsilon}\right)$ will be used as the recovery sequence for $(u, 1)$. It is easy to check that, for sufficiently small $\varepsilon>0$, there holds $v_{\varepsilon}=1$ on $\omega \backslash B_{\rho_{\varepsilon}}\left(S_{u}\right)$
and $v_{\varepsilon}=0$ on $B_{\delta_{\varepsilon}}\left(S_{u}\right)$. Moreover, $\nabla v_{\varepsilon}=0$ in $B_{\delta_{\varepsilon}}\left(S_{u}\right)$ and in $\omega \backslash B_{\rho_{\varepsilon}}\left(S_{u}\right)$, so that

$$
\begin{align*}
\mathcal{F}_{\varepsilon}\left(u_{\varepsilon}, v_{\varepsilon}\right)= & \left.\int_{\omega}| | u_{\varepsilon}\right|^{2} \mathrm{~d} x+\int_{\omega \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)} v_{\varepsilon}^{2} \nabla u_{\varepsilon}^{\top} A \nabla u_{\varepsilon} \mathrm{d} x \\
& +\eta_{\varepsilon} \int_{\omega} \nabla u_{\varepsilon}^{\top} A \nabla u_{\varepsilon} \mathrm{d} x+\frac{1}{4 \varepsilon} \int_{B_{\delta_{\varepsilon}\left(S_{u}\right)}} \sqrt{a} \mathrm{~d} x \\
& +\int_{B_{\rho_{\varepsilon}}\left(S_{u}\right) \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2}+\varepsilon \varphi^{2}\left(\nabla v_{\varepsilon}, x\right)\right] \sqrt{a} \mathrm{~d} x \tag{A.5}
\end{align*}
$$

Let us now estimate the integrals on the right-hand side of (A.5), separately. Since $u_{\varepsilon} \rightarrow u$ in $L^{1}(\omega)$, we have

$$
\begin{equation*}
\int_{\omega} b\left|u_{\varepsilon}\right|^{2} \mathrm{~d} x \rightarrow \int_{\omega} b|u|^{2} \mathrm{~d} x \quad \text { as } \varepsilon \rightarrow 0 \tag{A.6}
\end{equation*}
$$

As shown in Refs. 8, 35 and 31, we observe that

$$
\begin{align*}
\int_{\omega \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)} v_{\varepsilon}^{2} \nabla u_{\varepsilon}^{\top} A \nabla u_{\varepsilon} \mathrm{d} x \leq \int_{\omega} \nabla u^{\top} A \nabla u \mathrm{~d} x  \tag{A.7}\\
\eta_{\varepsilon} \int_{\omega} \nabla u_{\varepsilon}^{\top} A \nabla u_{\varepsilon} \mathrm{d} x \rightarrow 0 \quad \text { as } \varepsilon \rightarrow 0  \tag{A.8}\\
\frac{1}{4 \varepsilon} \int_{B_{\delta_{\varepsilon}\left(S_{u}\right)}} \sqrt{a} \mathrm{~d} x \rightarrow 0 \quad \text { as } \varepsilon \rightarrow 0 \tag{A.9}
\end{align*}
$$

Concerning the last term in (A.5), we introduce the notation

$$
\mathcal{K}_{\varepsilon}\left(v_{\varepsilon}\right):=\int_{B_{\rho_{\varepsilon}\left(S_{u}\right) \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)}}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2}+\varepsilon \varphi^{2}\left(\nabla v_{\varepsilon}, x\right)\right] \sqrt{a} \mathrm{~d} x .
$$

Precisely, we need to show that

$$
\begin{equation*}
\limsup _{\varepsilon \rightarrow 0} \mathcal{K}_{\varepsilon}\left(v_{\varepsilon}\right) \leq \int_{S_{u}} \sqrt{\nabla v^{\top} A \nabla v \sqrt{a}} \mathrm{~d} \mathcal{H}^{n-1} \tag{A.10}
\end{equation*}
$$

This inequality, together with (A.6)-(A.9), allows us to conclude the assertion (A.4) by taking the limsup in (A.5).

By the assumption on $\overline{S_{u}}$, it holds $\overline{S_{u}}=\bigcup_{i=1}^{N} \overline{S_{u}^{i}}$ for some $N \in \mathbb{N}$ and for some pairwise disjoint ( $n-1$ )-simplexes $\overline{S_{u}^{1}}, \ldots, \overline{S_{u}^{N}}$, so that, for sufficiently small $\varepsilon>0$, we can rewrite $\mathcal{K}_{\varepsilon}\left(v_{\varepsilon}\right)$ as

$$
\mathcal{K}_{\varepsilon}\left(v_{\varepsilon}\right)=\sum_{i=1}^{N} \int_{B_{\rho_{\varepsilon}}\left(S_{u}^{i}\right) \backslash B_{\delta_{\varepsilon}}\left(S_{u}^{i}\right)}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2}+\varepsilon \varphi^{2}(\nabla \tau, x)\right] \sqrt{a} \mathrm{~d} x .
$$

Hence, without loss of generality, we may assume that $\overline{S_{u}}$ itself is an $(n-1)$-simplex. We consider the $(n-1)$-dimensional hyperplane $\nu_{u}^{\perp}$ which contains $S_{u}$.

As illustrated in Fig. 10, we split the integration domain for $\mathcal{K}_{\varepsilon}$ in several parts, namely,

$$
S_{u}^{ \pm \perp}:=\left\{x \in \omega: x=y \pm t \nu_{u} \text { for some } y \in S_{u} \text { and } t>0\right\}, \quad S_{u}^{\perp}:=S_{u}^{-\perp} \cup S_{u}^{+\perp}
$$

Fig. 10. Splitting of the integration domain for $\mathcal{K}_{\varepsilon}$.
and we consider

$$
\begin{equation*}
\mathcal{K}_{\varepsilon}\left(v_{\varepsilon}\right)=\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+\perp}}\left(v_{\varepsilon}\right)+\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{-\perp}}\left(v_{\varepsilon}\right)+\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{u}^{\perp}}\left(v_{\varepsilon}\right), \tag{A.11}
\end{equation*}
$$

where, for $U \subset \omega$, we set

$$
\begin{equation*}
\left.\mathcal{K}_{\varepsilon}\right|_{U}\left(v_{\varepsilon}\right):=\int_{U \cap B_{\rho_{\varepsilon}}\left(S_{u}\right) \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)}\left[\frac{1}{4 \varepsilon}\left(1-v_{\varepsilon}\right)^{2}+\varepsilon \varphi^{2}\left(\nabla v_{\varepsilon}, x\right)\right] \sqrt{a} \mathrm{~d} x . \tag{A.12}
\end{equation*}
$$

First of all, note that, for all $x \in \omega \backslash \overline{S_{u}}$, we have

$$
\begin{equation*}
\nabla v_{\varepsilon}(x)=\frac{1}{\varepsilon} \sigma_{\varepsilon}^{\prime}\left(\frac{\tilde{\tau}(x)}{\varepsilon}\right)\left(\frac{\nabla \tau(x)}{\varphi(\nabla \tau(x), x)}-\frac{\tau(x) \nabla[x \mapsto \varphi(\nabla \tau(x), x)]}{\varphi^{2}(\nabla \tau(x), x)}\right) . \tag{A.13}
\end{equation*}
$$

In $S_{u}^{+\perp}$ we have that $\nabla \tau(x)=\nu_{u}$ is constant, and $x \mapsto \varphi\left(\nu_{u}, x\right)$ is Lipschitz continuous. Hence, (A.13) yields

$$
\varphi^{2}\left(\nabla v_{\varepsilon}, x\right) \leq \frac{1}{\varepsilon^{2}}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{\tilde{\tau}(x)}{\varepsilon}\right)\right|^{2}(1+C \tau(x))^{2}
$$

and from (A.12) we can estimate

$$
\begin{aligned}
\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+}}\left(v_{\varepsilon}\right) \leq & \left(1+C \rho_{\varepsilon}\right)^{2} \int_{S_{u}^{+\perp} \cap B_{\rho_{\varepsilon}}\left(S_{u}\right) \backslash B_{\delta_{\varepsilon}}\left(S_{u}\right)}\left[\frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{\tilde{\tau}(x)}{\varepsilon}\right)\right)^{2}\right. \\
& \left.+\frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{\tilde{\tau}(x)}{\varepsilon}\right)\right|^{2}\right] \sqrt{a} \mathrm{~d} x .
\end{aligned}
$$

Together with the Coarea formula (see, e.g. Theorem 2.93 in Ref. 6), we obtain

$$
\begin{align*}
\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+\perp}}\left(v_{\varepsilon}\right) \leq(1 & \left.+C \rho_{\varepsilon}\right)^{2} \int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}} \int_{S_{u}^{+\perp} \cap \partial B_{t}\left(S_{u}\right)}\left[\frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t}{\varepsilon \varphi\left(\nu_{u}, x\right)}\right)\right)^{2}\right. \\
& \left.+\frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t}{\varepsilon \varphi\left(\nu_{u}, x\right)}\right)\right|^{2}\right] \sqrt{a} \mathrm{~d} \mathcal{H}^{n-1} \mathrm{~d} t \tag{A.14}
\end{align*}
$$

We apply the coordinate transformation $x \mapsto x+t \nu_{u}$, which maps $S_{u}$ to $S_{u}^{+\perp} \cap$ $\partial B_{t}\left(S_{u}\right)$, to the inner integral of (A.14), obtaining

$$
\begin{align*}
\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+\perp}}\left(v_{\varepsilon}\right) \leq & \left(1+C \rho_{\varepsilon}\right)^{3} \int_{S_{u}} \int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}}\left[\frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t}{\varepsilon \varphi\left(\nu_{u}, x+t \nu_{u}\right)}\right)\right)^{2}\right. \\
& \left.+\frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t}{\varepsilon \varphi\left(\nu_{u}, x+t \nu_{u}\right)}\right)\right|^{2}\right] \sqrt{a} \mathrm{~d} t \mathrm{~d} \mathcal{H}^{n-1} \tag{A.15}
\end{align*}
$$

where we additionally used the fact that $\sqrt{a}$ is Lipschitz and bounded away from zero.

Note that, by construction,

$$
\sigma_{\varepsilon}^{\prime}(t)=\frac{1+\varepsilon}{2} \exp \left(\frac{\tilde{\delta}_{\varepsilon}-t}{2}\right) \quad \text { for } \tilde{\delta}_{\varepsilon}<t<\tilde{\delta}_{\varepsilon}-2 \ln \left(\frac{\varepsilon}{1+\varepsilon}\right)
$$

and $\sigma_{\varepsilon}^{\prime}=0$ otherwise. Thus, $\sigma_{\varepsilon}^{\prime}$ is decreasing in $\left(\tilde{\delta}_{\varepsilon}, \infty\right)$ with supremum $(1+\varepsilon) / 2$. Hence, with $\gamma_{\varepsilon}:=\tilde{\delta}_{\varepsilon} \varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)$ we can compute

$$
\begin{aligned}
\int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}} & \frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t}{\varepsilon \varphi\left(\nu_{u}, x+t \nu_{u}\right)}\right)\right|^{2} \mathrm{~d} t \\
& \leq \int_{\gamma_{\varepsilon}}^{\rho_{\varepsilon}} \frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t}{\varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)}\right)\right|^{2} \mathrm{~d} t+\int_{\delta_{\varepsilon}}^{\gamma_{\varepsilon}} \frac{(1+\varepsilon)^{2}}{4 \varepsilon} \mathrm{~d} t \\
& \leq \int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}} \frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t}{\varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)}\right)\right|^{2} \mathrm{~d} t+C \tilde{\delta}_{\varepsilon}
\end{aligned}
$$

for a.e. $x \in \omega$. Since $\sigma_{\varepsilon}$ is increasing and $x \mapsto \varphi\left(\nu_{u}, x\right)$ is Lipschitz continuous on $S_{u}$, we can estimate

$$
\begin{aligned}
\int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}} & \frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t}{\varepsilon \varphi\left(\nu_{u}, x+t \nu_{u}\right)}\right)\right)^{2} \mathrm{~d} t \\
& \leq \int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}} \frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t}{\varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)}\right)\right)^{2} \mathrm{~d} t
\end{aligned}
$$

Therefore, inserting the two previous estimates in A.15 we obtain

$$
\begin{aligned}
\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+}}\left(v_{\varepsilon}\right) \leq & \left(1+C \rho_{\varepsilon}\right)^{3} \int_{S_{u}} \int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}}\left[\frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t}{\varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)}\right)\right)^{2}\right. \\
& \left.+\frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t}{\varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)}\right)\right|^{2}\right] \sqrt{a} \mathrm{~d} t \mathrm{~d} \mathcal{H}^{n-1}+C \tilde{\delta}_{\varepsilon}
\end{aligned}
$$

We introduce another change of variables, namely, $t \mapsto t \varepsilon\left(\varphi\left(\nu_{u}, x\right)+C \rho_{\varepsilon}\right)$, so that

$$
\begin{align*}
\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+}}\left(v_{\varepsilon}\right) \leq & \left(1+C \rho_{\varepsilon}\right)^{4} \int_{\tilde{\delta}_{\varepsilon}}^{\tilde{\delta}_{\varepsilon}-2 \ln \left(\frac{\varepsilon}{1+\varepsilon}\right)}\left[\frac{1}{4}\left(1-\sigma_{\varepsilon}(t)\right)^{2}+\left|\sigma_{\varepsilon}^{\prime}(t)\right|^{2}\right] \mathrm{d} t \\
& \times \int_{S_{u}} \sqrt{\nu_{u}^{\top} A \nu_{u} \sqrt{a}} \mathrm{~d} \mathcal{H}^{n-1}+C \tilde{\delta}_{\varepsilon} . \tag{A.16}
\end{align*}
$$

Using the explicit form of $\sigma_{\varepsilon}$, we compute the first integral on the right-hand side of (A.16) as

$$
\begin{aligned}
& \int_{\tilde{\delta}_{\varepsilon}}^{\tilde{\delta}_{\varepsilon}-2 \ln \left(\frac{\varepsilon}{1+\varepsilon}\right)}\left[\frac{1}{4}\left(1-\sigma_{\varepsilon}(t)\right)^{2}+\left|\sigma_{\varepsilon}^{\prime}(t)\right|^{2}\right] \mathrm{d} t \\
& \quad=\int_{0}^{-2 \ln \left(\frac{\varepsilon}{1+\varepsilon}\right)}\left[\frac{1}{4}(1-(1+\varepsilon) \sigma(t))^{2}+\frac{1}{4}(1-\sigma(t))^{2}\right] \mathrm{d} t \\
& \quad \leq \frac{1}{2} \int_{0}^{\infty}(1-\sigma(t))^{2} \mathrm{~d} t=\int_{0}^{\infty}(1-\sigma(t)) \sigma^{\prime}(t) \mathrm{d} t=\int_{0}^{1}(1-t) \mathrm{d} t=\frac{1}{2}
\end{aligned}
$$

Hence, taking the limit in A.16) as $\varepsilon \rightarrow 0$, we deduce

$$
\left.\limsup _{\varepsilon \rightarrow 0} \mathcal{K}_{\varepsilon}\right|_{S_{u}^{+\perp}}\left(v_{\varepsilon}\right) \leq \frac{1}{2} \int_{S_{u}} \sqrt{\nu_{u}^{\top} A \nu_{u} \sqrt{a}} \mathrm{~d} \mathcal{H}^{n-1} .
$$

Repeating all the arguments above for $\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{-\perp}}\left(v_{\varepsilon}\right)$ with $\nabla \tau(x)=-\nu_{u}$ on $S_{u}^{-\perp}$, we infer

$$
\begin{equation*}
\limsup _{\varepsilon \rightarrow 0}\left(\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{-}}\left(v_{\varepsilon}\right)+\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+\perp}}\left(v_{\varepsilon}\right)\right) \leq \int_{S_{u}} \sqrt{\nu_{u}^{\top} A \nu_{u} \sqrt{a}} \mathrm{~d} \mathcal{H}^{n-1} \tag{A.17}
\end{equation*}
$$

Finally, we show that $\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{\bar{u}}^{\perp}} \rightarrow 0$ as $\varepsilon \rightarrow 0$. For $x \in B_{\rho_{\varepsilon}}\left(S_{u}\right) \backslash \overline{S_{u}}$, we claim that

$$
\begin{equation*}
|\nabla[x \mapsto \varphi(\tau(x), x)]| \leq \frac{C}{\tau(x)} \tag{A.18}
\end{equation*}
$$

Indeed, let $x, y \in B_{\rho_{\varepsilon}}\left(S_{u}\right) \backslash \overline{S_{u}}$. We set $\bar{\tau}:=\min \{\tau(x), \tau(y)\}, \bar{x}:=\pi_{B_{\bar{\tau}}\left(S_{u}\right)}(x)=$ $\pi_{S_{u}}(x)+\bar{\tau} \nabla \tau(x)$ and $\bar{y}:=\pi_{B_{\tau}\left(S_{u}\right)}(y)=\pi_{S_{u}}(y)+\bar{\tau} \nabla \tau(y)$, where $\pi_{E}$ denotes the projection onto $E \subset \mathbb{R}^{n}$. Since the projection on a convex set is Lipschitz continuous with Lipschitz constant equal to one, we have that $|\bar{x}-\bar{y}| \leq|x-y|$ and

$$
\begin{equation*}
|\nabla \tau(x)-\nabla \tau(y)|=\frac{1}{\bar{\tau}}\left|\bar{x}-\pi_{S_{u}}(x)-\left(\bar{y}-\pi_{S_{u}}(y)\right)\right| \leq \frac{2}{\bar{\tau}}|x-y| . \tag{A.19}
\end{equation*}
$$

Together with the positive definiteness of $A$, for $x, y \in B_{\rho_{\varepsilon}}\left(S_{u}\right) \backslash S_{u}$ and $\varepsilon$ sufficiently small we obtain

$$
\begin{aligned}
|\varphi(\nabla \tau(x), x)-\varphi(\nabla \tau(y), y)| & \leq C|\nabla \tau(x)-\nabla \tau(y)|+C|x-y| \\
& \leq \frac{C}{\min \{\tau(x), \tau(y)\}}|x-y|
\end{aligned}
$$

which yields (A.18).

From (A.13), we obtain

$$
\varphi^{2}\left(\nabla v_{\varepsilon}(x), x\right) \leq \frac{C}{\varepsilon^{2}}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{\tilde{\tau}(x)}{\varepsilon}\right)\right|^{2} \quad \text { for all } x \in \omega \backslash S_{u}^{\perp}
$$

We plug the above inequality into the expression of $\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{u}}\left(v_{\varepsilon}\right)$ and apply again the Coarea formula, so that

$$
\begin{align*}
\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{u}^{\perp}}\left(v_{\varepsilon}\right) \leq & C \int_{\delta_{\varepsilon}}^{\rho_{\varepsilon}} \int_{\partial B_{t}\left(S_{u}\right) \backslash S_{u}^{\perp}}\left[\frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t}{\varepsilon \varphi(\nabla \tau, x)}\right)\right)^{2}\right. \\
& \left.+\left.\left.\frac{1}{\varepsilon}\right|_{\sigma_{\varepsilon}^{\prime}}\left(\frac{t}{\varepsilon \varphi(\nabla \tau, x)}\right)\right|^{2}\right] \sqrt{a} \mathrm{~d} \mathcal{H}^{n-1} \mathrm{~d} t \tag{A.20}
\end{align*}
$$

Next, we use the coordinate transformation $x \mapsto x+\left(t-\delta_{\varepsilon}\right) \nabla \tau(x)$, which maps $\partial B_{\delta_{\varepsilon}}\left(S_{u}\right)$ onto $\partial B_{t}\left(S_{u}\right)$. Note that $\nabla \tau(x)=\nabla \tau(x+t \nabla \tau(x))$ and, from (A.19), we infer that $\left|\nabla^{2} \tau\right| \leq \frac{C}{\delta_{\varepsilon}}$ on $\partial B_{\delta_{\varepsilon}}\left(S_{u}\right) \backslash S_{u}^{\perp}$, so that the Coarea factor is bounded by $C \rho_{\varepsilon} / \delta_{\varepsilon}$. Hence, from (A.20) we deduce

$$
\begin{aligned}
\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{u}^{\perp}}\left(v_{\varepsilon}\right) \leq & \frac{C \rho_{\varepsilon}}{\delta_{\varepsilon}} \int_{\partial B_{\delta_{\varepsilon}}\left(S_{u}\right) \backslash S_{\frac{1}{u}}} \int_{0}^{\rho_{\varepsilon}-\delta_{\varepsilon}}\left[\frac{1}{4 \varepsilon}\left(1-\sigma_{\varepsilon}\left(\frac{t+\delta_{\varepsilon}}{\varepsilon \varphi(\nabla \tau, x+t \nabla \tau)}\right)\right)^{2}\right. \\
& \left.+\frac{1}{\varepsilon}\left|\sigma_{\varepsilon}^{\prime}\left(\frac{t+\delta_{\varepsilon}}{\varepsilon \varphi(\nabla \tau, x+t \nabla \tau)}\right)\right|^{2}\right] \sqrt{a} \mathrm{~d} t \mathrm{~d} \mathcal{H}^{n-1},
\end{aligned}
$$

where we again use the Lipschitz continuity and the uniform strictly positive boundedness of $a$, and additionally shift the integration domain with respect to $t$. Repeating the same arguments used for the estimate of $\left.\mathcal{K}_{\varepsilon}\right|_{S_{u}^{+\perp}}$, we obtain

$$
\begin{aligned}
\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{u}^{\perp}}\left(v_{\varepsilon}\right) & \leq \frac{C \rho_{\varepsilon}}{\delta_{\varepsilon}} \int_{\partial B_{\delta_{\varepsilon}}\left(S_{u}\right) \backslash S_{u}^{\perp}} \sqrt{\nabla \tau^{\top} A \nabla \tau \sqrt{a}} \mathrm{~d} \mathcal{H}^{n-1} \\
& \leq \frac{C \rho_{\varepsilon}}{\delta_{\varepsilon}} \mathcal{H}^{n-1}\left(\partial B_{\delta_{\varepsilon}}\left(S_{u}\right) \backslash S_{u}^{\perp}\right) .
\end{aligned}
$$

It is easy to check that $\partial B_{\delta_{\varepsilon}}\left(S_{u}\right) \backslash S_{u}^{\perp} \subset \partial B_{\delta_{\varepsilon}}\left(\partial S_{u}\right)$, where $\partial S_{u}$ denotes the relative boundary of $S_{u}$ in the hyperplane $\nu_{u}^{\perp}$. Hence,

$$
\begin{equation*}
\left.\mathcal{K}_{\varepsilon}\right|_{\omega \backslash S_{u}^{\perp}}\left(v_{\varepsilon}\right) \leq \frac{C \rho_{\varepsilon}}{\delta_{\varepsilon}} \mathcal{H}^{n-1}\left(\partial B_{\delta_{\varepsilon}}\left(\partial S_{u}\right)\right) \leq C \rho_{\varepsilon} \rightarrow 0 \quad \text { as } \varepsilon \rightarrow 0 . \tag{A.21}
\end{equation*}
$$

Summing up A.11, A.17), and A.21), we obtain the desired estimate A.10).

We now conclude the proof of Theorem 2.2.

Proof. We provide a proof which folds for a generic dimension $n$.

We first show the liminf-inequality. Let $\left(u_{\varepsilon}, v_{\varepsilon}\right)$ be a sequence converging to $(u, v)$ in $L^{1}(\omega)$. We assume, without loss of generality, that

$$
\liminf _{\varepsilon \rightarrow 0} \mathcal{F}_{\varepsilon}\left(u_{\varepsilon}, v_{\varepsilon}\right)=\lim _{\varepsilon \rightarrow 0} \mathcal{F}_{\varepsilon}\left(u_{\varepsilon}, v_{\varepsilon}\right)<+\infty
$$

Since the norm is lower semicontinuous, we clearly have

$$
\begin{equation*}
\int_{\omega} b|u|^{2} \mathrm{~d} x \leq \liminf _{\varepsilon \rightarrow 0} \int_{\omega} b\left|u_{\varepsilon}\right|^{2} \mathrm{~d} x \tag{A.22}
\end{equation*}
$$

Following the proof of Lemma 3.2 in Ref. 35], we obtain

$$
\begin{equation*}
\frac{\mu}{2} \int_{\omega} \nabla u^{\top} A \nabla u \mathrm{~d} x \leq \liminf _{\varepsilon \rightarrow 0} \frac{\mu}{2} \int_{\omega} v_{\varepsilon} \nabla u_{\varepsilon}^{\top} A \nabla u_{\varepsilon} \mathrm{d} x \tag{A.23}
\end{equation*}
$$

and by a slicing argument (see also Ref. (18), we obtain from Lemma A. 1

$$
\begin{equation*}
\kappa \int_{S_{u}} \sqrt{\nu_{u}^{\top} A \nu_{u} \sqrt{a}} \mathrm{~d} \mathcal{H}^{n-1} \leq \liminf _{\varepsilon \rightarrow 0} \kappa \int_{\omega}\left[\frac{1}{4 \varepsilon}(1-v)^{2} \sqrt{a}+\varepsilon \nabla v^{\top} A \nabla v\right] \mathrm{d} x . \tag{A.24}
\end{equation*}
$$

Combining the inequalities (A.22)-(A.24) we deduce the required lim inf-inequality. The $\Gamma$-lim sup-inequality immediately follows from Lemma A. 2 using the density result in Theorem 3.1 in Ref. 27 ,

## Acknowledgment

S.A. wishes to thank the Technical University of Munich, where he worked during the preparation of this paper, with partial support from the SFB project TRR109 Shearlet approximation of brittle fracture evolutions.
S.B. acknowledges the support of the DFG through the International Research Training Group IGDK 1754 Optimization and Numerical Analysis for Partial Differential Equations with Nonsmooth Structures'. Furthermore, S.B. appreciates the hospitality of MOX, Politecnico di Milano during several visits to S.M. and S.P.

Finally, S.M. and S.P. gratefully acknowledge the partial financial support by the INdAM-GNCS 2020 Projects.
