The overall reduced serial dependence in ASD observers under the 'standard' condition is linked to their over-specificity. In contrast, the distant effects in the 'dummy' condition, which were enhanced relative to the 'standard' condition and matched the levels seen in controls, appear to facilitate learning generalization. This extended memory trace, integrating information from multiple prior trials, may help create a generalized learning template across contexts, preventing overfitting to individual stimuli and promoting learning transfer. These findings provide insights into the mechanisms underlying perceptual learning and generalization in individuals with ASD and suggest potential strategies for improving learning transfer in this population.

Poster Session**411 - Diagnostic, Behavioral & Intellectual Assessment I**

May 1st, 2025, 5:30 PM - 6:30 PM - Hall 4A

411.127 Tele-ASD Diagnostic Assessment Tool for Adolescents/Adults (TADA)

H. H. Hartnett¹, G. Zilinskaite², R. Coleman³, J. I. Feldman⁴, R. J. Hundley⁵, C. Stone⁶, A. Swanson⁵, A. Vehorn⁶, T. G. Woynaroski⁴ and Z. Warren⁶, (1)Department of Pediatrics, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center / VKC TRIAD, Nashville, TN, (3)Department of Pediatrics, Vanderbilt University of Medical Center, Nashville, TN, (4)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN, (6)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN

Background: Timely and accurate identification of autistic individuals is a pressing public health challenge for all age groups. It is increasingly recognized that many autistic individuals are not identified as young children, and that accurate first-time diagnosis of autistic adults can promote autonomy, inclusion, and happiness across the lifespan. Unfortunately, when questions about autism emerge for undiagnosed adults, it is hard to find local pathways for evaluation. Telemedicine has been proven to address many barriers to diagnostic care access related to geography and provider availability. While considerable research has investigated the use of telemedicine to diagnose autism in young children, there are currently no psychometrically sound, validated tele-assessment tools that were designed for and with autistic adults.

Objectives: The overall goal of this project was to develop and evaluate a tele-assessment tool and procedure that supports diagnostic decision-making for adults presenting with concerns regarding autism. We proposed a computationally informed co-production process for development and evaluation of the tele-assessment tool. This process ultimately was designed to fuse advanced computational analyses with shareholder expertise by (1) mining a clinical database to identify behavioral targets indicative of autism and (2) translating these behaviors into telehealth assessment procedures in partnership with autistic adults and international experts in autistic adult assessment. Here, we present results of the computational analyses and identified feature sets.

Methods: We applied our previously established machine learning and feature engineering approach to a phenotypically rich clinical research data set (i.e. ADOS-2, Vineland, cognitive data, and other measures) of autistic adults and those with other diagnoses. Our computational approach began with a principal component analysis designed to identify the features most predictive of diagnostic status (autistic / other classification). We hypothesized that such features would be composed primarily of ADOS-2 codes, but with specific language/cognitive and adaptive behavior differences likely included.

Results: A sample of $n=214$ adolescents and adults (46% male; 72% autistic) ages 14 - 64 was randomly partitioned using a 70-30 split into a training set ($n=150$) and holdout set for validation ($n=64$). Of the models applied, a k-neighbors classifier ultimately yielded an accuracy of 90.7% or an unweighted average recall [UAR] of 90.5% with high sensitivity (91%) and specificity (90%). Across the theories of computational models, we attempted to identify the 10 most influential item sets from the best performing data and models (see Table 1). Of note, computational analysis identified slightly differing models among male and female participants with additional substantial overlaps and larger accuracy for females (see Table 2).

Conclusions: A relatively modest number of clinical features produced high levels of accuracy in differentiating autistic adults from adults with other concerns. Co-producing a tele-assessment tool for autistic adults via fusion of these computational results with clinical and lived expertise holds promise for creation of a novel tele-assessment tool. Results of ongoing work around tool construction and pilot data of accuracy in use will also be presented.

411.128 Understanding and Minimizing Reporting Discrepancy of Anxiety Symptoms in Children with Autism Spectrum Disorder
S. C. Boland¹ and **T. D. Barry²**, (1)Washington State University, Pullman, WA, (2)Psychology, Washington State University, Pullman, WA

Background: The caregiver- and self-reporting process is an essential component of clinical assessment and intervention for youth. Whereas research consistently supports differences in reporting (i.e., discrepancy) between autistic youth and their caregivers when rating internalizing symptoms, the nature of the discrepancy (e.g., which informant reports more or less symptoms, extent of agreement) remains mixed (e.g., Barbeau et al., 2020; Eussen et al., 2013). Furthermore, there is currently no known literature on how psychoeducation with facilitated discussion impacts the gaps in perception between caregivers and youth with ASD.

Objectives: The study aimed to assess: (1) factors that may contribute to informant reporting discrepancy between parent- and self-reports in internalizing symptoms among youth with ASD; (2) the efficacy of a psychoeducational intervention on reducing anxiety-related informant reporting discrepancy; and (3) potential moderators of intervention efficacy.

Methods: Participants were 79 caregivers and autistic youth (ages 10-17) who completed a series of questionnaires measuring youth internalizing symptoms. Parents also completed measures of self-reported distress and child ASD symptoms. If significant discrepancy between scores existed, families were randomly assigned to either an intervention or control condition. The intervention condition included an informational pamphlet on discrepancy and a Zoom-based joint outreach session to facilitate discussion about differences in scores and perceptions of the youth's anxiety. All youth completed a brief intelligence test, and all families repeated questionnaires 2-3 weeks post initial surveys. Families in the control group completed no tasks in between Time 1 and 2.

Results: Analyses tested correlations linking youth report and caregiver report of anxiety with verbal IQ (VIQ), ASD symptom severity, and caregiver distress. Polynomial regression equations were used to test the interaction hypotheses and the constraints imposed by directional and quadratic difference scores. Separate regression analyses were conducted to assess how VIQ, ASD symptom severity, and caregiver distress related to discrepancy on three measures of internalizing symptoms (SCARED Total, BASC Anxiety scale, and BASC Depression scale). Youth scores of anxiety (or depression) symptoms were regressed on caregiver scores of youth anxiety (or youth depression) symptoms and the predictor variable of VIQ, ASD symptom severity, or caregiver distress (for a total of nine polynomial regression models). All predictors were mean centered. Across the polynomial regression models, many of the interaction terms were significant demonstrating significant discrepancy between parent and youth reports on internalizing symptoms moderated by these variables. Additional analyses will examine demographic moderators and change in discrepancy from Time 1 to Time 2 based on intervention status.

Conclusions: There is evidence to suggest informant discrepancy affects longer-term child and family outcomes (e.g., Brookman-Frazee et al., 2008; Verhoeven et al. 2012). The current study aims to serve as a precursor to such research, adding a unique contribution to discrepancy research. This complex examination of reporter discrepancy using state-of-the-art techniques yields promising results for better understanding the nuance of youth symptom assessment. Full analyses of intervention efficacy will be completed prior to presentation.

411.129 Using Daily Phone Diaries to Examine the Everyday Activities of Autistic Adolescents

N. Bilinski¹, **C. Fassler¹**, **A. C. Modi^{1,2}** and **A. Duncan^{1,2}**, (1)Division of Behavioral Medicine and Clinical Psychology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)College of Medicine, University of Cincinnati, Cincinnati, OH

Background: While it is known that autistic teens without an intellectual disability (ID) may face challenges in areas including social skills, daily living skills (DLS), executive functioning, and emotion regulation, we know less about how these difficulties may impact their daily activities. Ecological momentary assessment and interviews have been used to examine daily activities, but these methods have limitations (e.g., rely on accurate memory recall, only collect data at specific intervals). The daily phone diary (DPD) is a comprehensive measure administered by an interviewer to construct a timeline of daily activities that a person engaged in over the last 24 hours. To our knowledge, no studies have utilized DPDs with autistic teens to examine the nature of their daily activities.

Objectives: To use DPDs to (1) examine the daily activities of autistic adolescents without ID, with a focus on the areas of DLS, social skills, and academics; and (2) examine teen's self-reported affect and companions during activities.

Methods: Teen in the study met inclusion criteria for a RCT that included (1) a diagnosis of autism; (2) $IQ \geq 70$; and (3) caregiver reported DLS challenges. Participants included 48 autistic teens (14 to 16 years, $M=15.3$, $SD=0.69$; 72.9% male; 83.3% White) without ID ($IQ M=100.9$, $SD=10.3$). All teen participants completed 3 consecutive DPDs (2 weekday, 1 weekend) at baseline. A trained interviewer called teens and had them walk through the last 24-hours and report any activities that lasted at least 5 minutes. Teens were asked to rate their emotional state on a 5-point scale from Very Positive to Very Negative. Interviewers coded the teen's activities into the categories of DLS (Personal, Domestic, Community), Social (Recreation at Home, Recreation Outside of the Home, Peer Interactions), and School (Homework/Studying, School Activities). Teens reported on any companions with them during activities. Descriptive statistics are being used to calculate the frequency of activities in each category/subcategory.

Results: Data collection is complete. We have cleaned DLS category data (see Figure 1). Results indicated that teens completed few Community DLS (total = 5), but completed a range of Domestic DLS (total = 106) and Personal DLS (total = 390). The DLS teens completed the most were Oral/Teeth Care (total = 97), Morning/Nighttime Hygiene Routine (total = 67), Hygiene Tasks (total = 63), Showering (total = 59), Cooking (total = 43), Medical Care (total = 26), and Cleaning Room (total = 20). Teens completed an average of 6.5 DLS per day, and of those 4.17 were completed independently. The entire data set will be cleaned and analyzed by December 2024.

Conclusions: Preliminary results reveal that autistic teens report completing a range of DLS during their everyday lives, but they are completing fewer DLS than would be expected based on their age and still requiring assistance from caregivers for about one-third of DLS. Further, few teens are engaging in Community DLS (e.g., purchasing items, going grocery shopping). The results have implications for interventions targeting essential skills that are needed to facilitate a successful transition after high school graduation.

411.130 Utility of the ASRS in Autism Diagnosis in a Pediatric Subspecialty Practice

S. F. Vess¹, J. M. Campbell², N. Vescovacci³ and H. Raper⁴, (1)Department of Pediatrics, Developmental Behavioral Section, Atrium Health Wake Forest Baptist Developmental Behavioral Pediatrics, Winston Salem, NC, (2)Psychology, Western Carolina University, Cullowhee, NC, (3)Wake Forest University School of Medicine, Winston-Salem, NC, (4)Atrium Health Wake Forest Baptist, Winston-Salem, NC

Background: Recent estimates show that the prevalence of Autism Spectrum Disorder (ASD) has increased to 1 in every 36 children across the United States since 2018. Timely intervention for children with ASD is critical in reducing long-term impacts associated with this condition, given that symptoms typically manifest during early childhood. Several ASD screening tools and parent reports, such as the Autism Spectrum Rating Scale (ASRS), are available to diagnosticians that are designed to enhance diagnostic accuracy, streamline the diagnostic process, and assess caregiver report of symptomatology. The authors of the ASRS report adequate reliability and validity, however, more research investigating the accuracy and utility of the ASRS as a diagnostic tool in pediatric subspecialty clinic practice is needed.

Objectives: N/A

Methods: The setting for this research is a pediatric subspecialty clinic affiliated with a children's hospital and a medical school in the SouthEastern United States. Between November 2023 and May 2024 every patient referred by their primary care provider for autism evaluation to the pediatric subspecialty practice was administered the ASRS as part of referral appointment intake process. Depending upon the age of the patient, either the ASRS parent report form A (ages 2- 5) or B (ages 6-18) was given to the primary caregiver by the psychometrist at one of two points in the process: following the intake appointment or during the testing appointment. A full autism evaluation utilizing a structured observation measure and diagnostic history interview as a minimum was then completed by either a psychologist or medical provider. A retrospective chart review was conducted on all new patient appointments during this time period. Inclusion criteria for this project was completion of both a parent ASRS and full autism evaluation resulting in a diagnostic decision. A total of 179 patients between the ages of 2 and 18 met inclusion criteria. Demographic data, ASRS total score, and Autism diagnostic decision data were analyzed to assess the efficacy of the ASRS within this patient sample.

Results: Receiver operating characteristic (ROC) curves for forms A and B yielded an area under the curve (AUC) of 0.596 and 0.463, respectively. Form A performed slightly better than chance while B performed worse than chance. Neither form met the threshold for a fair screening tool ($AUC \geq 0.70$), indicating a low diagnostic accuracy. Sensitivity was highest for ASRS forms A and B at the cut off value of 60 (compared to 65 and 70), however, the low specificity values at this cut off value indicate a high false positive rate.

Conclusions: Overall, the low sensitivity and specificity values indicate that the ASRS was a poor predictor of ASD diagnosis in this research sample. Data indicate that the ASRS had limited incremental value as part of the core diagnostic battery in our pediatric subspecialty clinic. Results led to the decision to revise clinic policy to discontinue mandatory use of the ASRS during our referral intake process and recommend less reliance on ASRS data as part of the diagnostic decision.

411.131 A Pilot Feasibility Study of Hybrid and Virtual Autism Assessments in Rural Appalachia: Addressing Barriers to Diagnosis

A. Scarpa¹, A. S. McLucas², D. C. Martino¹, V. V. Izaac³ and N. Shafique², (1)Department of Psychology, Virginia Tech, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA

Background: Access to formal autism diagnosis is critical for children to get early intervention. In rural Appalachian communities, obtaining a diagnosis is challenging due to a scarcity of specialists, resulting in families traveling long distances and facing years-long waitlists (Scarpa et al, 2020). This problem highlights the need for accessible alternatives to traditional in-person assessments to improve access to diagnoses and associated services. Prior studies suggest telehealth as a viable alternative (Dahiya et al., 2021), but no studies have assessed feasibility in rural Appalachia.

Objectives: This study aims to evaluate the pilot feasibility of using hybrid (in-person/virtual) and fully virtual diagnostic autism assessments for children from rural Appalachia.

Methods: Caregivers and their children were recruited from 15 counties in rural Appalachian Virginia. Families were eligible if their child was between 16 months through 17 years old, suspected of autism, scored above the clinical screening cutoff, and did not have a prior autism diagnosis. Data included the child's age, gender, and scores on parent-report screening instruments, including the Social Responsiveness Scale – 2nd Edition (SRS-2) and the Modified Checklist for Autism in Toddlers, Revised (M-CHAT-R). Children received a comprehensive diagnostic assessment using either a hybrid or fully virtual approach, including a developmental history, child observation, diagnostic interview, and intellectual, language, and adaptive functioning. Caregivers then completed the Acceptability of Intervention Measure, Intervention Appropriateness Measure, Feasibility of Intervention Measure, and an overall satisfaction survey to assess acceptability, appropriateness, feasibility, and satisfaction with the two assessment formats.

Results: Within 4 months, 119 families from 15 counties expressed interest in receiving autism assessments. Among them, 66% ($n=78$) of caregivers completed SRS-2 and M-CHAT-R screeners, with 94% ($n=73$) of those scoring in the moderate to severe range, indicating high likelihood of an autism spectrum disorder diagnosis. Of the 73 children (20 female, 35 male, 18 unreported) suspected of an autism spectrum diagnosis, ages ranged from 2 to 17 years old, with a mean of 7 years 11 months ($SD=4.32$). In the subsequent two months, five hybrid and six fully virtual comprehensive diagnostic assessments have been conducted, with post-assessment feasibility data completed by 7 caregivers (Mean completion = 1 family/week). Preliminary pilot data indicated that 100% of these 7 participants receiving virtual ($n=5$) or hybrid ($n=2$) assessments indicated either “Agree” or “Completely Agree” on every feasibility item assessed. At the rate of 1 family per week, we anticipate complete data on 20-25 more of the 73 eligible families by end of April 2025.

Conclusions: Autism diagnostic assessments remain limited in rural communities despite significant demand. The average age of children was 7 years 11 months, which is much later than the national average of 5 years (National Autism Data Center, 2024) for first identification of autism, suggesting many young children are not identified and thus limiting access to early interventions and services. Initial findings indicate that hybrid and virtual assessments are an acceptable and accessible method for reaching rural Appalachian populations, potentially bridging the gap in autism services in the U.S.

411.132 A Systematic Review of Adult-Reported Self-Regulation Measurement in Children Aged 0-8 Years

Y. Jiang¹, Y. Zhang², K. A. Brown Campbell¹, T. Zhong³, T. Zehner⁴, V. James⁵, B. Devlin⁶, E. A. Geer⁶ and S. Y. Shire¹, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)Faculty of Education, The University of Hong Kong, Hong Kong, Hong Kong, (3)Graduate College, Nanyang Technological University, Singapore, Singapore, Singapore, (4)Graduate School of Counseling, George Fox University, Portland, OR, (5)Department of Learning and Instruction, University at Buffalo, the State University of New York, Buffalo, NY, (6)Anita Zucker Center for Excellence in Early Childhood Studies at the University of Florida, Gainesville, FL

Background: Self-regulation is a multidimensional construct that includes three components: emotional, behavioral, and cognitive regulation (McClelland et al., 2010), which is a critical teaching target in early childhood. Yet, there is a lack of consensus on the definition of self-regulation, with diverse opinions on what facets, specific processes or skills/abilities, should be included (e.g., Jones et al., 2016; Karoly, 1993). To analyze, assess, and improve self-regulation skills in young children, and to evaluate the effectiveness of intervention programs, a clear definition and precisely targeted measures are critical.

Objectives: The purpose of this systematic review is to: (a) identify valid adult-reported measure of self-regulation in early childhood (i.e., 0-8 years), (b) characterize domains and facets of self-regulation assessed by these measures, and (c) analyze and extract the behavioral expressions of self-regulation across measures to inform research and practice supporting the development of young children's self-regulatory skills.

Methods: Published peer-reviewed articles were searched. After the removal of duplicates, five reviewers independently screened the titles and abstracts. Two reviewers independently assessed the full texts of the included studies and extracted informant based self-regulation measures from studies. Through analysis, a three-tiered classification system was established, starting with the most detailed processes (*facets*), which form the *domains* that, in turn, contribute to the broader *categories*. To support the third objective of this systematic review, a preliminary table of behavioral expression of the facets was generated. *Behavioral expression* refers to the observable behavioral performance that reflects these self-regulatory skills and processes. Inter-rater agreement was calculated for each section and ranged from 68.57% to 100%.

Results: In total, 20 measures were included in this review, which covered the cognitive, emotional, and behavioral aspects of self-regulation and could be used for children aged 3 months to 8 years. From the measures, 138 unique terms were extracted. Coders assigned a single facet code to different terms that describe the same concept, while assigning different facet codes to similar terms with different definitions, resulting in the creation of 62 final facet codes. After comparing the facet codes with self-regulation terms reported in reference articles, the reviewers identified 28 facets that represented the self-regulation skill (see Table 1), 8 facets that represented concepts broader than self-regulation, and 28 facets categorized as not representing self-regulation skills. The domains and categories of regulation for each facet were determined and are presented in Table 2, and 24 behavioral expressions of self-regulation skills were created and reported in Table 3.

Conclusions: This study is the first literature review to systematically investigate adult-reported measures of self-regulation in young children aged 0-8 years. Among those reviewed, measures were designed to capture caregiver and teacher reports of young children's self-regulation skills. Based on the results of the analysis, this review suggests that conceptual unification can enhance the understanding of self-regulation, and inform the development of a behavioral coding scheme to directly assess children's self-regulatory skills.

411.133 Acceptability and Feasibility of a Community-Delivered, Digital Tool for Neurodevelopmental Profiling

*D. Gajria¹, S. Bhavnani¹, E. H. Williams², N. M. Thompson^{2,3}, G. McCray⁴, M. Crespo-Llado⁵, D. Mukherjee⁶, T. Del Bianco^{7,8}, G. Lockwood Estrin⁹, L. Mason¹⁰, A. Ranjan¹, N. Midha¹, A. Singh¹, V. Harawa¹¹, C. Namathanga¹¹, R. Nkhata¹¹, A. Bennie¹¹, U. Kawelama¹¹, I. Mpakiza¹¹, A. Gautam¹², S. Gulati¹³, M. H. Johnson¹⁴, G. Lancaster⁴, M. Belmonte^{15,16}, E. Jones¹⁷, V. Patel^{18,19}, S. Chandran¹², E. Mbale²⁰, **G. Divan²¹**, M. Gladstone⁵ and B. Chakrabarti^{22,23,24}*, (1)Child Development Group, Sangath, New Delhi, India, (2)Centre for Autism, School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (3)Faculty of Health, Education and Society, University of Northampton, Northampton, United Kingdom, (4)School of Medicine, Keele University, Keele, United Kingdom, (5)Department of Women and Children's Health, Institute of Life Course and Medical Sciences, University of Liverpool, Liverpool, United Kingdom, (6)Indian Institute of Public Health, Public Health Foundation of India, Bengaluru, India, (7)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (8)School of Social Sciences and Professions, London Metropolitan University, London, United Kingdom, (9)School of Psychology, University of East London, London, United Kingdom, (10)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (11)University of Malawi, Blantyre, Malawi, (12)Indian Institute of Technology-Bombay, Mumbai, India, (13)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, Ansari Nagar, New Delhi, India, (14)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (15)The Com DEALL Trust, Bangalore, INDIA, (16)Department of Psychology, Nottingham Trent University, Nottingham, United Kingdom, (17)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (18)Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA, (19)Department of Global Health and Population, Harvard Medical School, Boston, MA, (20)Department of Pediatrics, Kamuzu University of Health and Sciences, Blantyre, Malawi, (21)Child Development Group, Sangath India, New Delhi, India, (22)Centre for Autism, School of Psychology and Clinical Language Sciences, University of Reading, Reading, UNITED KINGDOM, (23)India Autism Center, Kolkata, India, (24)Department of Psychology, Ashoka University, Sonapat, India

Background:

Timely identification of children at risk for developmental delays is hindered by lack of skilled professionals in low-and-middle-income countries, and reliance on lengthy assessment measures developed and normed in high-income countries. A portable, culturally adaptable assessment of neurodevelopment that can be administered by non-specialist workers (NSWs) can facilitate early intervention.

Objectives:

The STREAM project has developed and is currently validating a tablet-based, open-source, scalable tool, deliverable by NSWs in low-resource environments, to assess cognitive, social and fine motor development across diverse cultural settings. One key aim of this platform is to facilitate early detection of children with neurodevelopmental disorders, including autism.

Methods:

STREAM has adapted and combined three existing tools (1) Malawi Developmental Assessment Tool (MDAT), evaluating motor, social, and language abilities through observation and parent reports (Gladstone et al., 2010); (2) DEvelopmental assessment on an E-Platform (DEEP), assessing cognitive skills via gamified tasks (Bhavnani et al., 2019); and (3) Screening Tools for Autism Risk using Technology (START), evaluating social and sensory preferences (Dubey et al., 2024). The STREAM app has been designed to be culturally agnostic and administered offline by trained NSWs. It has been piloted with children in New Delhi, India and Blantyre, Malawi.

Results:

Data on STREAM have been collected in India and Malawi, respectively, from 1851 and 1880 children aged 0-6 years (50% girls) from communities and 104 and 155 children (33% and 39% girls respectively) diagnosed with, or at risk of, neurodevelopmental disorders including autism spectrum disorder (ASD), intellectual disability and cerebral palsy. Families of community-based children at both sites approached to participate in the study were interested (97.3% in India, 99.4% in Malawi), though this rate was reduced for children with neurodevelopmental disorders in India (64.16%, versus 97.8% for Malawi). In India, 26% of community-based children and 24.3% of children with NDDs were stunted (height-for-age z-score less than 2 standard deviations from the mean). In Malawi, these figures were 32.4% for community-based children and 40.7% for children with NDDs. Amongst children from the community, in India 6 and in Malawi 4 of the 12 STREAM tasks evoked 100% completion rates and the remaining tasks ranged from 97% to 99.5%, demonstrating high acceptability and feasibility of STREAM administration. These were reduced amongst children with neurodevelopmental disorders, ranging from 18-99%, simple gaze and visuomotor tasks being most consistently completed.

Conclusions:

STREAM, as administered by NSWs, constitutes an acceptable and feasible assessment of children's neurocognitive development. By the end of 2025, this study will provide reference data for the early childhood period (0-6 years) on key domains of cognition, social and fine motor domains, including test-retest reliability and sensitivity to change. Data will be validated against a) chronological age, b) Griffiths Mental Development Scales as a gold-standard measure of child development, c) height-for-age and d) risk factors known to negatively impact development. Once validated, the STREAM app would have the potential to be a scalable neurodevelopmental assessment tool for preschool-aged children administered by NSWs in low-resource settings.

411.134 Accuracy of a Novel Community Identification of Developmental Disabilities (CIDD) Tool in Ethiopian and Kenyan Settings

T. H. Kifle¹, M. Belina Feyasa², V. Angwenyi³, M. Demissie⁴, M. Washington-Nortey⁵, E. Mwangome⁶, T. Eshetu⁶, N. Githinji⁷, S. Fadil⁸, T. Azemeraw⁹, C. Nasambu¹⁰, K. Goldsmith¹¹, T. Charman¹², A. Belay⁹, F. Girma¹³, C. R. Newton¹⁰, C. Hanlon¹⁴, A. Abubakar¹⁵ and R. A. Hoekstra¹⁶, (1)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, KCL, London, United Kingdom, (2)Centre for Innovative Drug Development and Therapeutic Trials for Africa, and Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (3)Institute for Human Development, Institute for Human Development Aga Khan University, Nairobi, Kenya, (4)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (5)Neurosciences group, KEMRI/Wellcome Trust Research Programme, Kilifi, Kilifi, Kenya, (6)Addis Ababa University, Addis Ababa, Addis Ababa, Ethiopia, (7)Neurosciences group KEMRI wellcome trust, Kilifi Kenya, Kilifi, Kilifi, Kenya, (8)Psychology, Kings College London, London, London, United Kingdom, (9)Center for Innovative Drug Development and Therapeutic Trials for Africa, Addis Ababa University, Addis Ababa, Addis Ababa, Ethiopia, (10)Neurosciences group, KEMRI/Wellcome Trust Research Programme, Kilifi, Kenya, (11)Biostatistics and health informatics, Institute of Psychiatry Psychology and neuroscience Kings College London, London, London, United Kingdom, (12)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (13)Department of Psychiatry, Department of Psychiatry Addis Ababa University College of Health Science, Addis Ababa, Addis Ababa, Ethiopia, (14)Centre for clinical brain science, University of Edinburgh, Edinburgh, Edinburgh, United Kingdom, (15)Department of Psychiatry, University of Oxford, Oxford, Kenya, (16)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM

Background: Children with autism and other developmental disabilities (DD) in Africa often remain unidentified and undiagnosed due to a lack of awareness and scarcity of qualified human resources. Community-based proactive case finding is a task-sharing approach whereby trusted community members undertake home visits to improve identification and help seeking. This method has been found effective in increasing identification and referral for mental health problems in low-income settings, but has not previously been used to identify children with DD. Following extensive community consultations our team developed the Community Identification of Developmental Disabilities (CIDD) tool comprising vignettes and context-appropriate images, and a training package for community support workers (CSWs) administering the tool. **Objectives:** To evaluate the accuracy of the CIDD tool in identifying children with DD.

Methods: The study was conducted in three sites: Addis Ababa in Ethiopia, informal settlements in Nairobi and rural Kilifi in Kenya. Community members with a good knowledge of the local community of children (including health workers, teachers and caregivers of children with DD) were trained as CSWs. They were advised to administer the CIDD to caregivers of children they considered at risk of delayed development and to encourage referrals. Families taking up the referral were assessed by primary health care professionals trained in assessment of DD following principles of the World Health Organization's mental health Gap Action Programme (mhGAP), followed by assessment by a clinical specialist for diagnostic verification. The positive predictive value (PPV) of the CIDD was determined against both assessments.

Results: Data from 994 CIDDs were available across all sites (mean child age 5.7 years; 61% boys, see Table 1). The majority of assessments returned a CIDD positive result (n = 971, 97%) indicating the caregiver (89% female, 58% educated at primary school level or below) recognised their child in the CIDD vignettes and shared the CSW's concerns about their child's development. Out of 971 CIDD positive cases, 908 families (94%) took up the referral for assessment by an mhGAP-trained health worker. Full diagnostic assessment data from a clinical specialist were available for 855 children. For 40% of children this was their first diagnostic assessment; in Kilifi, 64% of children had not accessed a diagnostic assessment prior to the CIDD. The PPV of the CIDD against the mhGAP assessor was 92%; the PPV of the CIDD against specialist clinical verification was 91%, indicating excellent positive predictive value. 839 children were seen by both the mhGAP trained assessor and the clinical specialist. The mhGAP assessor correctly classified the child's DD diagnostic status in 88% of cases compared to the gold standard specialist assessment (inter rater reliability = .86).

Conclusions: With focused training and using the CIDD tool, trusted and respected members of the community were able to accurately identify children at risk of DD, and to encourage help-seeking. Trained primary healthcare workers accurately diagnosed DD in most cases. In contexts with limited specialist provision, high stigma and low DD awareness, the CIDD is a promising method to improve identification of DD and encourage service engagement.

**411.135 Age-Related Differences in Clinical Profiles of Youth Seeking an ASD Assessment in a Specialized Child Psychiatric Clinic: An Exploratory Chart Review**

M. Plourde^{1,2}, V. Langlois³, A. Côté⁴ and V. Courchesne⁵, (1)Psychology, Université de Montréal, Montréal, QC, Canada, (2)CIUSSS du Nord-de-l'Île-de-Montréal, Montreal, QC, Canada, (3)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (4)Psychology, Université de Montréal, Montreal, QC, Canada, (5)University of Montreal, Montréal, QC, Canada

Background: Clinical profiles of children seeking an ASD evaluation, particularly in relation to age, remain underexplored in the literature [1]. Autism detection age shows significant heterogeneity [2]. Although early screening is preferable, various factors may influence the timing of diagnosis, such as lower educational levels or socioeconomic status, which may account for later consultations [3]. Regarding clinical profiles, preliminary findings suggest differences in psychiatric comorbidities depending on age of assessment, with neurodevelopmental comorbidities more frequently diagnosed in younger individuals and mental health comorbidities more frequently diagnosed in teenagers [4]. These results indicate that age may serve as an indicator of distinct clinical profiles, reflecting specific challenges associated with ASD assessment across different age groups. While studies have looked at characteristics of autistic individuals diagnosed at different ages, to our knowledge, none have compared children diagnosed with ASD to those who received an alternative diagnosis [1,5]. There is, however, substantial evidence suggesting that typical signs of autism may diminish with age, which could imply that early screening is more likely to lead to an ASD diagnosis [6,7].

Objectives: The main objective of this study is to document the clinical characteristics of individuals assessed at the Autism Spectrum Disorder Evaluation Clinic, of the Rivière-des-Prairies Hospital (Montreal). We aim to compare children who receive an ASD diagnosis to those who don't and to explore how age might affect this diagnostic assessment.

Methods: Clinical data from 411 youths (male-to-female ratio of 4 : 1) were extracted. The files of 76 patients (18.49%) were closed pending, primarily because they had been evaluated at another clinic before attending their consultations. The remaining children were divided into two groups: those under 6 years old and those aged 6 to 17 years and 11 months at time of assessment. These two groups were then separated in two subgroups based on whether they received an ASD diagnosis or not. Descriptive statistics were conducted to explore differences in clinical profile between the four subgroups. (<6, ASD (n=125), <6, no-ASD (n=50), 6-17, ASD (n=42), 6-17, no-ASD (n=107)).

Results: A significantly higher proportion of children under 6 years old received an ASD diagnosis (70.22%) compared to those aged 6 to 17 years and 11 months (28%, $p < .0001$). Age appears to be a determining factor concerning the duration of assessment (care episode), with individuals over six years old tending to have longer care episodes (<6: 151.82 days vs. 6-17: 242.56 days). In terms of requests made for consultations with professionals (multidisciplinary, occupational therapy, neuropsychology, speech therapy, psychology, etc.), no clear pattern was observed among the four subgroups. However, age appears to be a determining factor for requests in neuropsychology with older patients requiring neuropsychological assessment more often ($p < .0001$) (<6, ASD: 0.80%; <6, no-ASD: 8.00%; 6-17, ASD: 33.33%; 6-17, no-ASD: 25.23%).

Conclusions: These findings underscore the critical clinical differences between preschoolers and school-aged children seeking ASD evaluation, highlighting the specific challenges of assessment at an older age. These results underscore the importance of a better understanding of the developmental trajectories of autistic characteristics.

411.136 An Analysis of the Brief Observation of Symptoms of Autism (BOSA) and the Autism Diagnostic Observation Schedule-2 (ADOS-2) in Adolescents and Adults

J. E. Ederer¹, L. A. Lampinen², L. T. V. Vo³ and V. H. Bal¹, (1)Graduate School of Applied and Professional Psychology, Rutgers Graduate School of Applied and Professional Psychology, Piscataway, NJ, (2)Rutgers University, New Brunswick, NJ, (3)Graduate School of Applied and Professional Psychology, Rutgers University - New Brunswick, Piscataway, NJ

Background:

There is an increasing number of adolescents and adults being referred for first time autism diagnosis, and evidence suggests that this population has a different symptom profile than adults who were diagnosed with autism in childhood (Huang et al., 2020, Fombonne et al., 2020, Jadav & Bal, 2022). While the Autism Diagnostic Observation Schedule-2 (ADOS-2) is widely-used for autism evaluations, initial validation studies primarily included adults diagnosed in childhood. The ADOS-2 is also limited in its brief nature and focus on interaction with a clinician. The Brief Observation of Symptoms of Autism (BOSA), derived from the ADOS-2, was developed in response to in-person assessment restrictions during the COVID-19 pandemic. The BOSA focuses on interaction with a familiar other and has shown promise as an adapted tool for remote diagnostic testing (Dow et al., 2022). Post-COVID, the BOSA may be useful as a supplemental diagnostic measure for first-time diagnosis of adolescents or adults, or as a brief method to re-affirm community diagnostic status in research studies. As COVID-19 restrictions have relaxed, new opportunities have emerged to explore the clinical utility of the BOSA and directly compare information gained during this brief assessment to the ADOS-2.

Objectives:

To compare BOSA and the ADOS-2 scores and classifications in a sample of adolescents and adults.

Methods:

Participants were 31 adolescents and adults referred to an autism diagnostic research study ($M_{age}=20.48$ years ($SD=6.47$); 51.6% male, 32.3% female, 16.1% gender nonconforming; 83.8% had Best Estimate Clinical Diagnoses (BECD) of Autism). Participants had scores on the BOSA F2 and the ADOS-2 Module 3 (n=8) or Module 4 (n=23) collected at the same visit. Correlations were used to explore the associations between ADOS-2 Social Affect (SA) and Restricted Repetitive Behaviors (RRB) and BOSA Social Communication and Social Interaction (SC & SI) and RRB domain scores. McNemar's test was used to explore the association between ADOS-2 and BOSA classifications.

Results:

ADOS-2 SA scores were positively correlated with BOSA SC & SI scores ($r=.65$, $p<.001$); RRB domains were also correlated ($r=.30$, $p=.049$). Sensitivity was acceptable (ADOS: 85%, BOSA: 81%) but specificity was low (n=6; 40%) on both instruments. There were few differences in instrument classifications; 80% of participants had the same classification (n=20 above; n=2 below cut-offs; $p=1.0$). The majority of participants with a BECD of Autism (65%) were above cut-offs on both the ADOS-2 and BOSA.

Conclusions:

Preliminary findings indicate that sensitivity of the ADOS-2 Modules 3 and 4 and BOSA F2 was similar and that the instruments yield highly similar instrument classifications. The BOSA may be helpful to clinicians who wish to supplement their diagnostic assessments with another observation, and a more feasible option for researchers who wish to go beyond self-report questionnaires to "confirm" community diagnostic status. Additional participants are currently being recruited to increase sample size and allow item comparisons across BOSA and ADOS-2 to better understand (in)consistencies in classifications. The strengths and limitations of using each instrument to inform diagnostic evaluations in different contexts will be discussed.

411.137 Applying Advanced AI Techniques to Identify ASD Patients' Phenotypic Subgroups in Using Partially Complete Data
W. Baskett¹, D. Q. Beversdorf² and C. R. Shyu³, (1)Bioinformatics, University of Missouri, Columbia, MO, (2)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, MO, (3)Institute for Data Science and Informatics, University of Missouri - Columbia, Columbia, MO

Background: ASD is a highly heterogeneous spectrum of conditions. Despite common characteristics, its presentation may vary dramatically from individual to individual. This makes it difficult for clinicians to predict what other developmental, physiological, or psychological comorbidities individuals with ASD may be at increased risk for. The relationships between ASD phenotypes are highly complex and go beyond simple linear correlation. While non-linear clustering and dimensionality reduction techniques such as Uniform Manifold Approximation and Projection (UMAP) are widely used, their power to represent extremely complex relationships between large numbers of variables is limited.

Objectives: We aim to better understand the relationships between different ASD phenotypes by leveraging advanced neural networks based techniques to discover high-level similarities between patient phenotypes. By leveraging more powerful methods we hope to help clinicians better understand what types of ASD patients are at risk of specific adverse outcomes. We aim to allow clinicians to identify a patient's phenotypic subgroup based on whatever data they may have available, even if that data is incomplete.

Methods: We used data from 359,282 individuals in the SFARI SPARK phenotype dataset, 147,469 of whom were diagnosed with ASD. The dataset contained 994 unique variables for each patient, though the information available varied significantly between patients. A Random Order AutoRegressive (ROAR) autoencoder was trained to reduce the dimensionality of the data by hierarchically encoding high-level information about each patient's phenotype into as few dimensions as possible within an embedding vector. Earlier dimensions in the hierarchy attempt to represent more important high-level information. This makes it possible to generate interpretable plots of the data by simply plotting the first two dimensions as a scatterplot.

Results: Figure 1 shows differences in how patients with similar phenotypes are grouped together in ROAR vs UMAP. ROAR embeddings are more likely to place phenotypically similar patients closer together. Figure 2 shows how closely points within the embedding space correspond to phenotype as the completeness of the data decreases. We show that the RBS-R of neighboring points is correlated at $R^2 = 0.85$ when all data is present and retains a correlation of $R^2 = 0.32$ even when repetitive behavior information is omitted.

Conclusions: We leverage advanced machine learning techniques to better understand the differences and similarities between ASD phenotypes. We demonstrate that our technique is more effective at identifying high level similarities between patient phenotypes when compared to other non-linear techniques such as UMAP.

411.138 Assessing Self-Determination in Autistic Adults: Development and Validation of the Aaspire Choices and Decisions Scale and the Self-Determination Inventory-Aaspire

S. Y. Kim¹, S. K. Kapp^{2,3}, K. Gillespie-Lynch¹, R. Kripke-Ludwig³, J. Maslak³, E. Frowner³, A. Joyce³ and C. Nicolaidis^{3,5}, (1)Korea University, Seongbuk-gu, Seoul, Korea, Republic of (South), (2)School of Psychology, Sport and Health Sciences, University of Portsmouth, Portsmouth, Hampshire, United Kingdom, (3)Academic Autism Spectrum Partnership in Research and Education (AASPIRE), Portland, OR, (4)Department of Psychology, CUNY Graduate Center, Staten Island, NY, (5)School of Social Work, Portland State University, Portland, OR

Background: Self-determination, or acting as the causal agent in one's life, is positively associated with quality of life and academic, social, and employment outcomes for autistic people (Kim, 2019). Our recent community-based participatory research (CBPR)-nested Delphi process with academic researchers and leaders from the autistic community and the health and social service systems identified self-determination as a high-priority outcome. However, panelists and team members noted accessibility concerns with existing measures and felt they may not fully capture the construct, especially in regards to whether someone is able or allowed to make their own decisions.

Objectives: To use a CBPR approach to: 1. Minorly adapt the *Self-Determination Inventory (SDI)* to increase accessibility to autistic adults. 2. Create the *AASPIRE Choices and Decisions Scale (CDS)*, measuring the extent to which a participant feels they are *able* or *allowed* to make their own choices and decisions. and 3. Evaluate the measures' psychometric properties.

Methods: Our team of academic and community partners collaboratively created direct and caregiver report versions of both instruments. We then conducted cognitive interviews with 37 autistic adults and caregivers, iteratively adapting instruments until participants felt they were accessible and captured the desired constructs. We analyzed data from 839 autistic participants, including 587 direct-reports (DR), 188 direct-reports with support (DR-S), and 64 caregiver-reports (CR). We performed exploratory factor analysis (EFA) on half the data from the *AASPIRE CDS* (stratified by report type) to identify factor structures, followed by confirmatory factor analysis (CFA) on the other half to confirm model fit. We used CFA to compare one-factor and three-factor models for *SDI-AASPIRE* and confirm model fit. We examined measurement invariance across report types, support needs, presence of intellectual disability, speech levels, and communication fluency, gender, race, and sexuality. After achieving measurement invariance, we used Wald tests to examine group differences in latent means and assessed internal consistencies.

Results: For the *CDS*, EFA identified a two-factor structure assessing Major life decisions (6-items) and Daily choices (7-items), confirmed by CFA (RMSEA=0.075, CFI=0.951, TLI=0.931, SRMR=0.037). Factor correlations in the three-factor model of *SDI-AASPIRE* were high (0.92–1.00), but the *SDI-AASPIRE* showed strong model fit with a one-factor structure (RMSEA=0.054, CFI=0.952, TLI=0.938, and SRMR=0.037). Both instruments achieved configural, metric, and scalar invariance across all characteristics, except report type. When examining model fit for the *CDS* and *SDI* separately by report type, DR and DR-S showed acceptable fits, but CR did not meet pre-specified criteria. After eliminating CR, configural, metric, and scalar invariance were achieved for report type for both instruments (Table 1). Latent mean differences showed participants who required support to complete the survey, those with less communication fluency and speech or with intellectual disability, had lower latent means in *AASPIRE CDS* and *SDI-AASPIRE* (Table 2). Both instruments demonstrated excellent internal consistency (alpha and omega > 0.90).

Conclusions: The *AASPIRE CSD* and *SDI-AASPIRE* are valid, reliable tools for assessing self-determination in autistic adults. Further research with a larger sample of CR is needed to understand discrepancies among DR, DR-S, and CR.

411.139 Assessing Utility of the SCQ for Autism Screening in Adolescents

J. Samuels¹, N. Gheorghita² and R. K. Greene³, (1)McLean Hospital / Harvard Medical School, Boston, MA, (2)Oregon Health & Science University, Portland, OR, (3)Oregon Health & Science University, Portland, OR

Background: Identifying and diagnosing Autism Spectrum Disorder (ASD) in adolescence can be challenging, as core features of ASD may be more subtle. Autistic teens may present with compensatory or masking behaviors, have higher cognitive functioning, or have had their symptoms misattributed to co-occurring conditions such as anxiety or depression (Duvall et al., 2022; Maenner et al., 2023; Mandy et al., 2018; Posserud et al., 2021). In this population, screening tools such as the Social Communication Questionnaire (SCQ; Rutter et al., 2003) are critical in determining the need for referral for comprehensive diagnostic assessment. Though previous research has shown that predictive utility of the SCQ may vary based on factors such as age and sex/gender for younger children (Evans et al., 2019), there is a need to explore how these factors may influence the utility of the SCQ in adolescents.

Objectives: The present study aims to evaluate the utility of the SCQ in predicting ASD diagnosis in adolescents, particularly whether it is moderated by factors such as sex assigned at birth (SAB) and cognitive functioning (IQ).

Methods: ROC curve analyses were employed to determine how well the SCQ differentiated between ASD and non-ASD groups. Univariate ANOVA analyses examined the impact of sex, gender, and cognitive on SCQ scores.

Results: Adolescent participants (N = 125, 50.4% male) aged 12-18 completed a comprehensive neurodevelopmental evaluation at an academic medical center. SCQ – Lifetime data was available for all participants, and full-scale IQ scores from standardized cognitive assessments (e.g., WISC-V) were available from a subsample of the larger group (N = 53). See Table 1 for demographics and descriptives.

ROC curve analysis indicated that the SCQ demonstrated poor overall predictive utility (AUC = .597) for distinguishing between adolescents with and without an ASD diagnosis in the full sample. A t-test indicated a near-significant difference ($p = .059$), with higher SCQ scores for individuals with an ASD diagnosis ($M = 18.08$) compared to individuals without an ASD diagnosis ($M = 15.71$).

When examined separately by SAB, the SCQ performed marginally better for AFAB individuals (AUC = 0.620) compared to AMAB individuals (AUC = 0.558), with AUC values indicating acceptable to poor discrimination, respectively. Similarly, univariate ANOVA revealed no significant differences in SCQ scores based on SAB ($F(1, 120) = 0.329, p = .567$) and logistic regression analysis further revealed that neither gender ($p = .542$) nor IQ ($p = .396$) significantly moderated the relationship between SCQ total score and ASD diagnosis.

Conclusions: The SCQ demonstrated limited predictive utility in identifying ASD in adolescents, with analyses indicating poor to marginally acceptable discrimination. Though adolescents with ASD tended to score slightly higher on the SCQ compared to those without ASD, the overlap in scores raises concerns about the effectiveness of existing cut-off scores in distinguishing between groups. These results suggest that the SCQ may not fully capture the symptom presentation of ASD in adolescents. Further research is necessary to explore whether adjusting the SCQ cutoff or the questions themselves might improve screening for this population.

**411.140** Associations between Demographic Characteristics and ADOS-2 Comparison Scores in a Large, Diverse Sample of Children and Adolescents

L. Olson¹, S. Zheng², A. J. Kaat³ and S. Bishop¹, (1)Psychiatry and Behavioral Sciences, University of California, San Francisco, San Francisco, CA, (2)Psychiatry and Behavioral Sciences, The University of Texas at Austin, San Francisco, CA, (3)Department of Medical Social Sciences, Northwestern University, Chicago, IL

Background: Research indicates that the validity of commonly used autism diagnostic assessment instruments can vary as a function of child characteristics (e.g., biological sex, cognitive ability). However, much of the work in this area has been limited by small-to-moderate samples that do not fully reflect the increasingly heterogeneous ASD diagnostic referral landscape.

Objectives: Leveraging assessments of >9,000 children and adolescents representing diversity in geography, race, SES, cognitive ability, and co-occurring diagnoses, the present study investigates associations between child characteristics and autism symptoms, as measured by calibrated severity scores (CSS), for Modules Toddler(T)-3 of the ADOS-2.

Methods: Data from eight academic medical centers were aggregated and harmonized across ADOS-2 Modules T-3 (see Table 1). Hierarchical linear models were run for each Module to examine relationships between nonverbal abilities, demographic variables and ADOS-2 CSS, with site modeled as a random effect. Diagnosis, sex, age, race, ethnicity, and caregiver educational level were included as explanatory variables for all Modules. For Modules T and 1, nonverbal mental age was included as an explanatory variable, and for Modules 2 and 3, nonverbal IQ standard score was included. ADOS-2 CSS was the outcome variable for all analyses.

Results: See Table 2 for results from regression models. For Modules 1-3 there were significant main effects of autism diagnosis on ADOS-2 CSS. For the toddler Module, the effect of diagnosis on CSS was dependent on age such that older age was associated with higher CSS in the autism group. For Modules T, 2, and 3, there were significant main effects of nonverbal cognitive ability on CSS: higher nonverbal ability was associated with lower CSS. For Modules 2 and 3, male sex was associated with higher CSS. For Module 3, age was negatively associated with CSS.

Additionally, Modules 2 and 3 showed effects of race such that Black/AA participants showed lower CSS (Module 2) and Asian participants showed higher CSS (Module 3), relative to white participants.

Conclusions: Although ADOS-2 CSS have been found to be less influenced by child-level characteristics than raw scores, these scores are still not immune to the effects of developmental or demographic variables. Consistent with previous analyses of autism symptom measures, we observed negative associations between nonverbal cognitive ability and CSS. Age showed less consistent relationships with CSS: for Modules T-2, age was not associated with CSS, whereas older age was associated with lower CSS for Module 3. This negative association between age and CSS on Module 3 likely reflects that verbally fluent individuals with autism show symptom reductions with age. It may also reflect ascertainment bias such that individuals referred for autism diagnostic assessment at later ages typically have milder autism symptom profiles. We also observed effects of race and sex for Modules 2 and 3: African American children showed lower CSS (Module 2) and Asian children showed higher CSS (Module 3). Males showed higher CSS on these Modules. Planned analyses will examine whether observed associations between cognitive and demographic factors and CSS are explained by measurement noninvariance at the ADOS-2 item level.

411.141 Autism, Intelligence, Language, and Adaptive Behavior, Disentangling a Complex Relationship

C. Failla¹, I. Scarcella², N. Vetrano³, S. Previti³, G. Tartarisco⁴, D. Vagni⁵, G. Pioggia⁴ and F. Marino⁴, (1)Institute for Biomedical Research and Innovation, National Research Council (CNR), Italy, Messina, Italy, (2)Institute for Biomedical Research and Innovation-IRIBCNr, MESSINA, ITALIA, Italy, (3)Institute for Biomedical Research and Innovation, National Research Council (CNR), Italy, Messina, Italy, Italy, (4)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy, Messina, Italy, (5)Institute for Biomedical Research and Innovation, National Research Council (CNR), Italy, Messina, Italy

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental disorder characterized by a range of intellectual and language abilities. Its heterogeneity is acknowledged in modern diagnostics, complicating research and necessitating precision medicine and a multidimensional approach for individualized treatment and accurate assessment. Intellectual and language functioning influence adaptive skills and symptomatology. Thus, assessing adaptive functioning in a multidimensional and multi-informant manner is crucial, highlighting the importance of comprehensive evaluations. This study explores the interplay between autistic traits, demographic variables, IQ, adaptive functioning, and the applicability of ICD-11 classifications.

Objectives: This study aims to examine the relationships between autistic traits. Demographic factors, IQ, adaptive functioning, and the applicability of ICD-11 classifications. It assesses how well these diagnostic criteria align with intellectual and language abilities in ASD

Methods: We analyzed data from the initial global evaluation of 60 diverse autistic children (aged 35 to 120 months; IQ range 16 to 118). Parent-reports using the Vineland Adaptive Behavior Scale (VABS-II) were compared with standardized assessments from the Psychoeducational Profile (PEP-3). Children's intellectual levels were assessed using Griffiths Scales of Child Development (Griffiths III) and the Autism Diagnostic Observation Schedule (ADOS-2) was used for autistic traits. They were further classified according to the ICD-11 diagnostic system, functional language, and intellectual functioning levels. Correlations among variables, group comparisons, and multivariate analyses were performed.

Results: The analysis indicates a linear effect of IQ on all adaptive scales and the impact of autistic traits on directly measured adaptive functioning. A factorial effect was observed due to changes concerning specific age, intellectual, and linguistic levels, which do not completely align with ICD-11 categorization. Additionally, a negative correlation between intelligence and measured autistic traits was found. Parental age, education level, and age at childbirth were also found to affect various adaptive scales.

Conclusions: The study questions the ICD-11's proposed distinctions in IQ and language functioning for ASD, advocating for more refined categorization and developmental considerations. It underscores the intricate relationship between autistic traits, IQ, and communication skills, casting doubt on the precision of diagnostic tools across the spectrum. Parental reports and direct assessments are essential for comprehensive evaluation, with parental education and age influencing children's behaviors and skills. The study calls for a nuanced approach to ASD assessment, integrating various metrics and sources of information for a detailed phenotyping necessary for personalized interventions and biological research.

411.142 Autism-Specific Training Is Associated with Primary Care Clinicians' (PCCs) Confidence in Diagnosing Autism

A. C. Austin¹, S. Dufek², G. Perez Liz³, B. Freedman⁴, A. T. Wieckowski⁵, C. Weitzman⁶, L. McClure¹, G. Vivanti⁷, D. T. Vader⁸, A. C. Stahmer⁹, Y. Algur⁹ and D. L. Robins³, (1)Drexel University, Philadelphia, PA, (2)Psychiatry and Behavioral Sciences, UC Davis Health, MIND Institute, Sacramento, CA, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)Nemours Children's Health, Wilmington, DE, (5)Harvard Medical School, Boston, MA, (6)A.J. Drexel Autism Institute, AJ Drexel Autism Institute, Philadelphia, PA, (7)Dornsife School of Public Health, Drexel University, Philadelphia, PA, (8)UC Davis MIND Institute, University of California at Davis MIND Institute, Sacramento, CA, (9)Epidemiology & Biostatistics, Drexel University, Philadelphia, PA

Background:

Traditional autism diagnostic evaluations have lengthy waitlists and delay access to autism-specific supports (Wieckowski et al., 2022). The American Academy of Pediatrics has recommended that general pediatricians can make an initial diagnosis of autism (Hyman et al., 2020). Research has shown high concordance between general pediatricians' and multidisciplinary teams' autism diagnoses when pediatricians have confidence in their diagnosis (Penner et al., 2023). Primary care clinicians (PCCs) – including physicians, nurse practitioners, and others – have the potential to decrease delays in accessing to autism-specific intervention services by promptly diagnosing autism in their patients (Hyman et al., 2020; Zwaigenbaum et al., 2015). However, there is limited knowledge on the factors impacting PCCs' confidence in diagnosing autism.

Objectives:

This study aimed to 1) characterize confidence in diagnosing autism, specialty training (e.g., fellowship), autism-specific training, and PCC characteristics in an exploratory sample of PCCs, and 2) examine which clinician characteristics are associated with PCCs' confidence in diagnosing autism.

Methods:

PCCs (N=135) completed the Primary Care Beliefs and Practices Questionnaire (PCBP; adapted from Sices et al., 2003). PCCs reported their demographics, responded to "I feel confident to make a diagnosis of autism in some of my patients" and "I have been trained to diagnose autism in some of my patients" on a Likert scale from 1-5, strongly disagree to strongly agree, and "Did you complete any specialty or fellowship training?" with yes/no. The sample was characterized using descriptive statistics for PCCs' age, role, years in practice, sex, race, ethnicity, specialty training, autism training, and confidence in diagnosing autism. Confidence in making an autism diagnosis was dichotomized for analysis (no = "strongly disagree", "disagree" and "neutral", yes = "agree" and "strongly agree"). Logistic regression using a single model was used to characterize which clinician characteristics (autism training, years in practice, age, gender, race) were associated with PCCs' confidence in diagnosing autism.

Results:

Participants were majority White (67.2%), non-Hispanic (86.7%), female (69.2%), pediatricians (89.3%), with a mean age of 44.68 (SD=12.05) years, and mean of 15.04 (SD=12.55) years in practice. Most participants did not receive fellowship/specialty training (89.2%), whereas 54% received training to diagnose autism in some patients. Being trained to diagnose autism in some patients was significantly associated with higher odds of being confident in diagnosing autism in some patients, OR = 3.64, 95% CI = 2.04 – 6.49, $p < .001$. Years in practice, age, gender, and race were not associated with PCC's confidence in diagnosing autism.

Conclusions:

PCCs such as pediatricians are more likely to accurately diagnose autism when they feel confident (Penner et al., 2023). Consistent with our hypotheses, having training in diagnosing autism was associated with PCC's confidence in diagnosing autism. This supports the importance of providing autism-specific training to PCCs early in their careers to enhance confidence and potentially increase earlier access to diagnostic evaluation and more rapid access to autism-specific interventions. Future research should explore the nuances of PCCs' confidence in both diagnosing and excluding autism, and examine how this confidence translates into clinical practice.

411.143 Barriers to Developmental Intervention for Urban Minority Families: A Replication in Atlanta

J. N. Constantino^a, T. Perez Crawford^b, A. Zawoyski^c and B. Livingston-Burns^d, (1)Children's Hospital of Atlanta, Atlanta, GA, (2)Children's Healthcare of Atlanta, Atlanta, GA, (3)Children's Healthcare of Atlanta, Atlanta, GA, (4)Emory University School of Medicine, Atlanta, GA

Background: Numerous studies highlight significant racial disparities in developmental outcomes of U.S. children affected by autism spectrum disorder (ASD). Recently, in 3 successive reports from the Autism and Developmental Disabilities Monitoring (ADDM) program of the US Centers for Disease Control and Prevention (CDC) (birth cohort years 2014, 2016, and 2018), we and our collaborators reported that although the prevalence of community-diagnosed ASD had equalized for Black and non-Hispanic White (NHW) children in the United States, there has persisted a pronounced racial disparity in the proportion of ASD-affected children with comorbid intellectual disability (ID), on the order of 50% for Black children with ASD vs 20% for White children with ASD. We subsequently documented in a large case series in St. Louis, Missouri that timely diagnosis for Black children, despite establishing service eligibility for developmental therapy, did not resolve major racial disparities in access to such intervention until supplemental services that supported access and participation of families was established. Data from the current sample replicate and extend findings to a group of children within the Metro Atlanta area.

Objectives: N/A

Methods: We provided diagnostic assessments to 66 children suspected of ASD or related conditions under age 3 years in Atlanta, Georgia. In our sample, 92% of the children identify as Black with an additional 5% identifying as Black in addition to other ethnicities. Referrals originated from the children's primary care providers, typically following a moderate- or high-risk MCHAT-R screening as part of their well child check. Ninety-two percent were governmentally insured under GA Medicaid or by a contracted care management organization (CMO). Sixty-five met diagnostic criteria for ASD (mean age of diagnosis 2 years, 5 months) and were judiciously case-managed to acquire community-based developmental therapy services.

Results: Ten children were enrolled in early intervention services, including Part C, through a local agency prior to their third birthdays. The remainder experienced significant challenges in accessing developmental therapies. Critical barriers included: (1) lengthy processes for intervention enrollment following diagnosis, many of which persisted past the time when the children aged out of Part C; (2) transportation barriers for center-based developmental intervention options; (3) non-eligibility for specific resource streams funding the developmental interventions.

Conclusions: This case series constitutes a replication of prior observations of severe barriers in access to developmental intervention for families of young Black children affected by autism. Scientific documentation of the disparity in access to intervention--and correlated disparity in cognitive and adaptive function--have not yet translated into systematic efforts to ensure that early-diagnosed children are receiving interventions that have shown promise in resolving this serious enduring disparity in outcome. By the time of the 2025 INSAR meeting, additional data on intervention access and cognitive outcomes of the early-diagnosed children will be presented and discussed with respect to implications for health policy.

411.144 Can Caregivers of Toddlers with Autism Characteristics Administer in-Home Assessments to Fidelity When Coached By Remote Assessors?

E. R. Britsch¹, C. Perryman², S. Heath³, A. S. Carter⁴, W. L. Stone⁵, S. Broder-Fingert⁶, S. R. Edmunds⁶, B. R. Ingersoll⁷, A. Wainer⁸ and R. C. Sheldrick⁹, (1)Psychology, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA, (3)University of Massachusetts Boston, Boston, MA, (4)Department of Psychology, University of Massachusetts Boston, Boston, MA, (5)UMASS Medical School, Boston, MA, (6)Psychology, University of South Carolina, Columbia, SC, (7)Psychology, Michigan State University, East Lansing, MI, (8)Department of Psychiatry and Behavioral Sciences, Rush University Medical Center, Chicago, IL, (9)Boston University School of Public Health, Boston, MA

Background: There has been a recent surge in the development and implementation of virtual assessment tools for toddlers with suspected autism (Berger et al., 2022). While most virtual assessments studied have been diagnostic tools, research suggests that observational assessments of skills such as motor imitation and social communication may be well suited to assess progress in early intervention (MacDonald et al., 2014). We developed a virtual adaptation of such an assessment tool for use in a clinical trial, with assessors with a range of training backgrounds (i.e., bachelor's to doctoral level) achieving high fidelity to the protocol (RISE CPP; Tagavi et al., 2024). While prior work suggests that caregivers find virtual autism assessment tools to be generally acceptable (Corona et al., 2021), little is known about the fidelity of caregivers in administering virtual assessments.

Objectives: This study aims to answer three questions: (1) Do caregivers (coached by remote assessors) administer a virtual assessment to fidelity across different types of tasks? (2) Is caregiver fidelity associated with their assessor-coach's fidelity? (3) Does caregiver fidelity vary across demographic characteristics or parenting stress and self-efficacy?

Methods: The RISE CPP (Tagavi et al., 2024) was administered to toddlers with social communication delays ($n=53$, 19 girls, 16-34 months) at three time-points in an ongoing multi-site clinical trial evaluating birth-to-three services for autism. Using telehealth, caregivers were coached on administering tasks to elicit toddler's social communication and imitation skills. Trained assessor-coaches ($n=18$) achieved fidelity ($>80\%$) on at least three supervised CPPs before coaching families independently. Twenty percent of each assessor-coach's CPPs were randomly selected, such that only one assessment per family is included in analyses. Research assistants coded caregiver fidelity on a 0-2 scale for each task, with higher values representing higher fidelity. Caregivers completed a demographic survey at enrollment and the Parenting Stress Index (Abidin, 1990) and the Parenting Efficacy Scale (Teti & Gelfand, 1991) at each assessment.

Results: Table 1 displays child and caregiver demographic characteristics. Non-parametric statistics (Kendall's tau; Friedman's and Kruskal-Wallis ANOVAs) were used due to significant skew. Assessor-coach fidelity (Mean = 96.05; Range = 83.1-100) and caregiver fidelity were high (Mean = 94.6; Range = 70.3-100), with a significant correlation between assessor-coach and caregiver fidelity ($\tau = 0.275$; $p < 0.01$). Caregivers demonstrated high fidelity across tasks with no differences on tasks eliciting imitation or communication ($\chi^2(1) = 1.96$; $p = 0.162$; see Figure 1). Caregiver fidelity was not associated with parenting stress, parenting self-efficacy, or child/caregiver age (τ s = -0.121 to 0.120; $ps > 0.25$), nor did it vary by child sex or child/caregiver race or ethnicity ($ps > 0.30$).

Conclusions: Caregivers from diverse backgrounds effectively administered a virtual assessment tool when coached by assessors with a range of training backgrounds, with high fidelity across both communication and imitation tasks. Neither concurrent parenting stress nor parenting self-efficacy were associated with caregiver fidelity. Findings show promise for further development and validation of flexible, virtual assessment options, with potential for increasing capacity for measuring intervention progress for toddlers with suspected autism.

**411.145** Can Expert Clinicians 'Hear' the Autism Diagnosis at a Vocal and Preverbal Stage? a First Impression Study

M. Weyland¹, P. Maes² and M. Kissine³, (1)ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium, (2)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (3)ACTE — Center of research in Linguistics — ULB Neuroscience, Université libre de Bruxelles, Brussels, Belgium

Background: Clinicians frequently report being able to rapidly detect autism just from hearing an autistic individual's vocal production, even before direct interaction. While prior research indicates that vocal characteristics can influence diagnostic judgments, it remains unclear how accurate such spontaneous diagnostic judgments may be and which characteristics of vocalization drive them.

Objectives: This study aimed to determine whether expert clinicians can accurately differentiate the vocalizations of young autistic children from those of non-autistic peers above chance levels, and to evaluate the effectiveness of canonical babbling stimuli compared to vocalic productions in facilitating this differentiation. We hypothesized that expert clinicians would: (1) differentiate above chance level the vocalizations of young autistic children from those of young non-autistic children, and (2) perform better with canonical babbling stimuli (containing at least one vowel and one consonant) than with vocalic productions (containing only vowels).

Methods: Sixty-one French-speaking expert clinicians in autism categorized a total of two hundred and twenty 1.5- to 2-second-long vocal samples from 9- and 18-month-old children from three distinct groups (infants at elevated likelihood for autism who received a diagnosis (ELA+) vs. those who did not (ELA-) vs. those at low likelihood for autism (LLA)) into "autistic" or "non-autistic" categories. Vocalizations were randomly presented and included early both preverbal productions, vocalic and canonical babbling production. Stimuli came from naturalistic 6-hour home recordings.

Results: Results showed that discriminability calculated with d-prime (d') for 9-month-old stimuli was .08, indicating near-chance detection. For 18-month-olds, d' increased to .23, reflecting moderate ability to differentiate autistic from non-autistic vocalizations. Accuracy was notably improved for 18-month-old stimuli (see Fig.1 Detection of autism diagnosis from vocalizations at 9 and 18 months; Hits, False alarms and Sensitivity). At 9 months, responses for canonical babbling stimuli in the ELA+ group were significantly lower than in the ELA- and LLA groups ($p < .0001$), with correct responses being above chance only for vocalic productions and not for canonical babbling in the ELA+ group. The opposite trend was observed for the ELA- and LLA groups. At 18 months, correct responses for ELA+ canonical babbling remained significantly lower than for ELA- and LLA groups ($p < .0001$), while vocalic productions were identified similarly across all groups (see Fig.2 Interaction between Production type and Diagnostic group at 18 months and chance level).

Conclusions: These findings suggest that detecting autistic traits from infant vocalizations is challenging, despite relative improvement over time. The fact that respondents were more accurate in identifying vocalic productions in autistic children (ELA+), but not in canonical babbling, with the opposite findings in non-autistic groups (ELA- and LLA), suggests that clinicians' relied on articulatory maturity rather than on autism-specific vocal patterns to make a decision. Overall, these results highlight the potential and limitations of using brief vocal samples for early ASD detection. However, further research on initial perceptions of maturity in early production appears promising for the early detection of language development delays.

411.146 Capturing Perspectives Regarding the Diagnostic Odyssey from Caregivers in SPARK Using the Events History Calendar Questionnaire

Z. Algaze¹, G. Caprara², L. Green Snyder³, J. A. Benson⁴, E. M. Butter⁵, P. Feliciano⁶, A. Gulsrud⁷, J. F. Harris⁸, R. P. Goin-Kochel⁹, A. S. Kolios¹⁰, R. Landa¹¹, L. Shulman¹², E. Wodka¹³, C. Klaiman¹³, J. Pandey² and S. Consortium³, (1)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Simons Foundation, New York, NY, (4)Marcus Autism Center, Emory University, Atlanta, GA, (5)Nationwide Children's Hospital/Ohio State University, Columbus, OH, (6)Department of Pediatrics, Boston Children's Hospital, Boston, MA, (7)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (8)Children's Specialized Hospital, Mountainside, NJ, (9)Baylor College of Medicine, Houston, TX, (10)Marcus Autism Center, Atlanta, GA, (11)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (12)546 Wilmerding Ave., Bronx, NY, (13)Emory University/Marcus Autism Center, Atlanta, GA

Background: Research has shown that obtaining an autism spectrum disorder (ASD) diagnosis often involves significant delays. Constantino et al. (2020) investigated the timing of diagnosis and the factors contributing to diagnosis delays in African American youth using the Events History Calendar Interview (EHCI). The EHCI enables caregivers to detail their diagnostic journey and identify diagnostic barriers. While ASD diagnosis rates have become more equitable across racial groups, significant ASD diagnosis delays and disparities in intellectual disability diagnosis rates persist. Our study examines data from a larger project adapting the EHCI into an electronic questionnaire to allow for broader dissemination, utilizing the reach of the SPARK study to collect caregivers' perspectives on a national level.

Objectives: This study examined caregivers' perspectives on their autism diagnostic journey, aiming to better understand areas of improvement for diagnostic and functional outcomes.

Methods: Participants included 985 children (ages 4 to 14; 76% Male; 66% White) and their caregivers (ages 22-81) from 4 racial groups (White, Black/African American, Asian, Multiracial) who participated in the SPARK study. Caregivers electronically completed the EHCI questionnaire. Building on Constantino et al. (2020), we used the adapted EHCI questionnaire to analyze responses across and within racial groups. Bivariate correlations were calculated within each racial group to assess relationships among age at parental first concerns, age at diagnosis, age at service initiation, family income at first concerns, and diagnostic stage, (time between diagnosis and EHCI completion).

Results: Diagnosis delay, defined as the time from initial concern to official diagnosis, was longest for White respondents (Mean=28.4, SD=25.3 months) and shortest for Black (Mean=18.1, SD=28.2 months) and Asian (Mean=18.1, SD=21.9 months) respondents. Diagnostic stage calculations (age in months at survey completion – age in months at diagnosis) showed similar gaps by race, with the shortest gap for Multiracial (Mean=58.7, SD=15.1 months) and the longest for Asian (Mean=59.2, SD=10.2 months) respondents. All racial groups reported significant professional wait times and evaluation unavailability as major barriers to receiving a diagnosis (59.5% and 41.7%, respectively). The number of professional visits was similar across groups, with 26.9% reporting 3-5 visits and 19.6% reporting at least 6 visits. Bivariate correlation results with noted significance can be found in Tables 1 and 2. Notably, there were moderate positive correlations across all races between age of first concern and age at diagnosis (White, $r=0.46$, $p<0.001$; Black, $r=0.27$, $p<0.001$; Asian, $r=0.51$, $p<0.001$; Multiracial, $r=0.34$, $p<0.001$). There were also weak negative correlations between age at service initiation and income at first concern in White and Multiracial families ($r=-0.12$, $p<0.001$; $r=-0.17$, $p<0.001$, respectively).

Conclusions: Our findings suggest that racial category may no longer be the sole contributing factor in diagnosis delays or service initiation. Across all races, participants noted significant diagnosis (age 4) delays from their initial developmental concerns (age 2). Attention to other parent-report factors that could be impacting delays should be explored, including: symptom severity, socio-economic status, and intellectual disability diagnosis. By the time of the meeting, these additional factors will be presented and discussed, particularly at the regional level.

411.147 Caregiver-Identified Strengths in Children Attending Their First Neurodevelopmental Assessment: Development of the Child Autism and Neurodevelopment Strengths Checklist

K. A. Boulton¹, L. Hankin², A. Hodge³, N. Ong⁴, N. Silove⁵ and A. J. Guastella⁶, (1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)University of Sydney, Camperdown, NSW, Australia, (3)Sydney Children's Hospital Network, Sydney, NSW, Australia, (4)The Children's Hospital at Westmead, Sydney, NSW, Australia, (5)Sydney Children's Hospital Network, Sydney, Australia, (6)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia

Background: There has been a growing focus on the importance of understanding strengths in children with neurodevelopmental conditions and how such knowledge can be used to support clinical practices. There has, however, been limited research exploring systematic reports of strengths from caregivers of children with neurodevelopmental conditions, most commonly autism, at the time of their first diagnostic assessment. As a result, there are no frameworks guiding how caregiver-identified strengths can be integrated into the assessment process to inform feedback sessions and personalise intervention and support strategies following a diagnosis.

Objectives: The aim of this study was to understand caregiver-identified strengths for children attending a child neurodevelopment assessment service, with the most frequent assessment being for autism. We then present a child autism and neurodevelopment strengths checklist based on these strengths, and discuss the utility of this checklist for clinical services.

Methods: Participants were caregivers of 686 children aged 1.17 – 17.58 years ($M=6.50$, $SD=3.56$, 70% male), attending a tertiary-level assessment service. Overall, 75% of children received a diagnosis of autism. Caregivers completed an intake survey prior to their child's diagnostic assessment. Free text responses to the question "What do you think are your child's strongest points (what does he or she do best)?" were used to assess strengths. Free text responses were analysed using qualitative content analysis to generate codes, categories and themes.

Results: Content analysis identified 61 unique strengths, which were categorised into six meta-themes: cognitive and intellectual (identified in 45% of children), social and interpersonal (identified in 41% of children), hobbies and passions (identified in 38% of children), character and personality (identified in 34% of children), physical (identified in 27% of children), and behavioural (identified in 20% of children). The most frequently reported specific strengths across children were 'kind caring, and compassionate', 'social and friendly', 'loving and affectionate', 'music, singing and dancing', and 'good memory recall'. We also discuss similarities and differences in strengths profiles between children who received a diagnosis of autism and those who did not. Following content analysis, identified themes and specific strengths were collated into a checklist (The Child Autism and Neurodevelopment Strengths Checklist) that can be completed by caregivers at the time of diagnostic assessment.

Conclusions: This is the first study to examine caregiver-identified strengths in children with neurodevelopmental concerns, principally autism, at the time of their first diagnostic assessment. The depth and breadth of strengths identified challenges multiple stereotypes about the characteristics of children with NDCs and provides a framework for how a strengths-based approach may be incorporated in diagnostic assessments and reports.

To support clinical services in implementing a strengths-based approach from a child's first diagnostic assessment, we present a checklist, The Child Autism and Neurodevelopment Strengths Checklist, which can be completed by caregivers and integrated by clinicians into assessment feedback and recommendations. We then discuss what is required to use this knowledge to inform strengths-based practices that can support clinical practice and inform on child health and development and family well-being.

411.148 Caregivers' Reports of Emotion Regulation in Autistic Toddlers with and without Language Delay

K. Rowland¹, A. R. Borowy² and S. R. Edmunds², (1)University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC

Background: Autistic toddlers show early differences in both their ability to regulate emotions and in language development (Kwok et al., 2015; Cibralic et al., 2019). Greater language ability relates to better emotion regulation in neurotypical and autistic populations (Cohen & Mendez, 2009; Cibralic et al., 2023). Meltdowns, one facet of emotion regulation, are a concern for caregivers of autistic toddlers (Maskey et al., 2012; Silva & Schalock 2011). Meltdowns are characterized by intense responses (e.g., aggression, self-injury) to various stressors (Mazefsky et al., 2013). Lower language and IQ are proposed markers for more intense meltdown behaviors in autistic individuals (Williams et al., 2018). Some research supports this suggestion, showing differences in the presentation of externalizing behaviors associated with meltdowns for children with lower cognitive ability; however, the direction of this relationship varied (Gohari et al., 2024; Mazurek et al., 2013). Other research reports no differences in the intensity and frequency of these behaviors for autistic children (Lorang et al., 2021; Maddox et al., 2018).

Objectives: To examine whether language ability is related to differences in the intensity and frequency of responses to stressors in a sample of 2- to 5-year-old autistic toddlers.

Methods: Twenty-eight caregivers completed a 15-minute Meltdown Qualitative Interview (MQI) regarding their toddler's meltdown behaviors. Behavior frequency scores were assigned based on caregivers' reports of injurious and aggressive behaviors (e.g., self-injury, hitting/kicking, etc.). Caregivers completed the BRIEF-P and EDI-YC, measures of toddlers' reaction intensity and frequency when dealing with stressors.

Developmental quotients for overall verbal ability were created using the average of preschoolers' expressive and receptive language age equivalents on the Mullen or DAS-II. Toddlers were dichotomized into a Language Delay (LD) or No Delay (ND) group based on the average amount of domain-specific developmental delay required to receive federally-funded early intervention ($SS \leq 70.43$; Edmunds et al., 2023).

Results: When examined as a continuous variable, language scores were not significantly correlated with BRIEF-P Emotional Control scores ($r=0.35$, $p=0.1$); however, language was significantly positively correlated with EDI-YC Reactivity ($r=0.45$, $p=0.02$) (Figure 1). When examined dichotomously, a two-sample t-test found no differences in BRIEF-P Emotional Control between the ND and LD groups, $t(19.89)=-1.27$; $p=0.22$; however, for EDI-YC Reactivity, the ND group ($M=61.95$, $SD=11.16$) scored significantly higher than the LD group ($M=53.52$, $SD=9.11$), $t(25.00)=-2.19$; $p=0.04$. In the preliminary examination of the qualitative data, no differences in the variety of aggressive behaviors were found between groups, and frequency of these behaviors were not correlated with language ability ($ps > .05$). Further qualitative analysis will occur prior to April 2025 to provide a more rigorous assessment of potential differences in meltdown topography and intensity based on language abilities.

Conclusions: Greater language predicted more intense reactivity in autistic toddlers, conflicting with previous literature on language and emotion regulation. For some autistic toddlers, verbal learning may be encouraged when experiencing more dysregulation. No differences in meltdown frequency and variety may indicate a more nuanced picture of emotion regulation, where autistic toddlers have varied regulatory abilities, but similar reactions upon encountering stressors.

411.149 Psychometric Evaluation of the Brief Autism Symptom Criteria Interview (BASCI)

S. Speeth¹, E. Crowley¹, N. Flores¹, T. W. Frazier² and M. Uljarevic³, (1)John Carroll University, Cleveland, OH, (2)Psychology, John Carroll University, Cleveland, OH, (3)Psychiatry & Behavioural Sciences, Stanford University, Palo Alto, CA

Background: Online diagnostic evaluations for Autism Spectrum Disorder (ASD) increased in prominence during the COVID-19 pandemic and have continued as a mechanism for improving diagnostic delays for children at increased likelihood of receiving a diagnosis. It is crucial to ensure that tools used in online evaluations have strong psychometric properties. The Brief Autism Symptom Criteria Interview (BASCI) was developed for use in a set of nationwide online diagnostic clinics as a parent interview to aide clinicians in the collection of autism symptom information.

Objectives: The primary aim was of the present study was to evaluate the reliability and construct validity of the BASCI across a large demographically- and geographically-diverse clinical sample of children between 15 months to 10 years old who completed an online diagnostic evaluation.

Methods: Data were obtained from 08/2022 to 10/2023 and included 2543 children ages 15 months to 10 years old participating in a set of nationwide online autism evaluation clinics. The measure is a 31-item dichotomously scored instrument and was completed by the attending pediatrician ($k=29$) during the initial visit. Additional measures collected included: The Modified Checklist for Autism in Toddlers-Revised (M-CHAT-R); the Autism Symptom Dimensions Questionnaire (ASDQ); the Tele-ASD Peds (TAP); and the Childhood Autism Rating Scale, 2nd Edition, based on patient observation (CARS-2 obs). Completion time, factor structure, scale and conditional reliability, convergent validity, and diagnostic efficiency of the BASCI was evaluated.

Results: Sample characteristics were consistent with a childhood autism evaluation clinic (Median Age=50 months, 68% male, 66% ASD diagnosed) and were highly diverse (21% Hispanic, 30% Black or African American, 52% public insurance) with children from 39 US States. BASCI completion time was variable but almost always less than 50 minutes (Median=29.8 minutes, 25%ile=24.8, 75%ile=35.6). A two-factor bifactor solution fit the data well (RMSEA=.036, CFI=.941, TLI=.931), with a general ASD factor and social communication/interaction and restricted/repetitive behavior specific factors (Figure 1). Scale reliability was very good for the total and social communication scales ($\alpha=.84$ and $.81$ respectively) and adequate for the restricted/repetitive behavior scale ($\alpha=.70$). Conditional reliability was adequate or better for the total score in the range of the latent trait important for diagnostic differentiation. Convergent validity with other autism symptom measures was moderate to high ($r=.37$ to $.46$; Figure 2), consistent with expectations for a same-construct, different information source correlations. In this clinically challenging (already screened) sample, diagnostic efficiency was fair to good (AUC=.690, 95% CI=.67-.71).

Conclusions: The present results indicate that the BASCI is a brief, easily completed measure with a readily interpretable factor structure, broadly consistent with DSM-5 criteria, as well as good scale and conditional reliability, particularly given the instrument's primary purpose as a diagnostic aide. Convergent validity evidence was good and diagnostic efficiency was adequate but below what would be desired to provide incremental validity to other observational instruments. Additional research is needed to evaluate construct validity and diagnostic efficiency. Future revisions of the instrument should consider using ordinal scaling to further enhance reliability and validity.

411.150 Clinician Impact on the Identification and Diagnosis of Female Autistic Youth: A Scoping Review

J. Beriont¹ and **J. Parish-Morris²**, (1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Autistic girls and women are more likely than autistic males to be identified late, misdiagnosed, or not recognized at all. Thus far, most investigations into this phenomenon have focused on characterizing sex-based differences in autism presentation, demonstrating that under-recognition of autistic females is a real problem, or, most recently, describing the landscape of processes and systemic factors that predict under-diagnosis or misdiagnosis in this subgroup. However, little is known about clinicians' specific roles and impacts within these systems. The goal of this scoping review is to lay the foundation for future medical education interventions that target clinician knowledge and competence, to improve their ability to identify autism in individuals assigned female at birth.

Objectives: To synthesize current knowledge about the impact of clinician-level factors on the recognition and diagnosis of female autistic youth.

Methods: The authors searched four electronic bibliographic databases (PubMed/MEDLINE, Embase, PsycINFO, and CINAHL) for relevant literature with the help of a research librarian. To be included, articles must: (1) directly or indirectly assess the role of the clinician (2) as it relates to the identification, referral, or diagnosis of autism (3) in female children or adolescents. After compiling the final corpus, we used a thematic analysis framework to produce our preliminary findings. To complete the review, we will continue to iteratively refine our analyses and solicit feedback from interested parties to inform our conclusions.

Results: Of 336 unique articles screened for inclusion, 61 papers published before our search (July 23, 2024) were deemed eligible and included in the review. The selection process is shown in a PRISMA flow diagram (Fig. 1). Our overarching results thus far suggest that inadequate knowledge about female-typical, socially motivated, and camouflaged presentations of autism prevents both specialists and non-specialists from effectively identifying, referring, and diagnosing female autistic youth. The impact of this knowledge gap is magnified by poor awareness that the issue exists; in other words, many clinicians are confidently making uninformed assessments because they "don't know what they don't know." In addition, multiple clinician-level cognitive biases can impede the path to diagnosis, including bias toward observation over patient/caregiver report, diagnostic overshadowing, expectancy bias, and implicit and/or explicit gender bias related to autism.

Conclusions: This scoping review highlights the critical impacts of clinician bias and unfamiliarity with non-classic presentations of autism on the identification and diagnosis of female autistic youth. Our results provide a foundation for the development of future professional education interventions and curricula aimed at increasing knowledge and awareness about autistic girls and women, which will better equip clinicians to make early, accurate diagnoses and improve long-term outcomes.

411.151 Clinician Needs for Autism Diagnostic Training in Malaysia: Insights from a Focus Group Study

N. Kamal Nor¹, **K. Ilias²**, **S. Kamaralzaman³**, **A. Z. Che Daud⁴**, **W. W. Yang⁵** and **S. A. Zubir⁶**, (1)Paediatrics, Universiti Kebangsaan Malaysia Specialist Children's Hospital, Petaling Jaya, Selangor, Malaysia, (2)Department of Psychology, Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia, (3)Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia, (4)Faculty of Health Sciences, Universiti Teknologi Mara, Puncak Alam, Selangor, Malaysia, (5)Faculty of Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur, Federal Territories, Malaysia, (6)Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Federal Territories, Malaysia

Background:

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition that requires precise diagnostic evaluation and early intervention. Clinicians in Malaysia play a crucial role in the assessment and diagnosis of ASD. However, there is a growing need to understand their training requirements, current practices, tools used, and strategies employed when encountering challenging cases. This study aims to explore the perspectives of specialists working across eight hospitals in Malaysia to identify the specific training needs and strategies employed in the context of ASD diagnosis.

Objectives:

To explore and describe the perspectives of specialists managing neurodevelopmental conditions in Malaysia on ASD diagnosis.
To identify specific training needs and strategies employed for diagnosis of ASD in children in Malaysia.

Methods:

A qualitative research design was employed, consisting of focus groups with a total of 20 specialists from psychology (n=4), psychiatry (n=9), and paediatrics (n=7). Participants reported having over 3 years of experience diagnosing children with ASD and related conditions. Participants were recruited from eight hospitals located in various regions of Malaysia. The focus group discussions centered on three key areas: (1) current clinical practices in ASD diagnosis, (2) the diagnostic tools utilized, and (3) strategies employed when faced with challenging or complex cases.

Results:

Thematic analysis of discussion notes revealed several common themes among the participating clinicians. First, while the use of standardized diagnostic tools is widespread, there is a desire for continuous updates and access to culturally adapted instruments for ASD diagnosis. Clinicians emphasized the importance of adapting international guidelines to the Malaysian context. Additionally, challenges in interprofessional collaboration and communication were highlighted, suggesting the need for improved interdisciplinary training. Clinicians expressed the need for advanced training programs that offer both theoretical knowledge and practical skills to enhance diagnostic accuracy and sensitivity. Furthermore, they emphasized the importance of training on cultural sensitivity and understanding the diverse population of individuals with ASD in Malaysia.

In handling challenging cases, clinicians reported using a collaborative problem-solving approach and seeking guidance from peers and interdisciplinary teams. Regular case discussions were highlighted as a valuable strategy for improving diagnostic accuracy and developing effective intervention plans.

Conclusions:

The results of this focus group study underscore the importance of addressing the specific needs of clinicians involved in the diagnosis of ASD in Malaysia. Findings suggest the necessity for specialized training programs that incorporate culturally adapted diagnostic tools, enhance interdisciplinary collaboration, and promote ongoing professional development. These insights can inform the development of targeted training initiatives to better equip clinicians in Malaysia for accurate and timely ASD diagnosis, ultimately improving outcomes for individuals with autism in the country.

411.152 Clinicians' Perspectives on the Differential Diagnosis of Autism, Attachment Difficulties and Complex Post Traumatic Stress Disorder: A Qualitative Framework Analysis

A. Quinton¹, D. Spain², R. Sarr³, F. Happé⁴ and F. Rumball⁵, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (5)Adult ASD Assessment Service and Transforming Care Team, Oxleas NHS foundation trust, Kent, United Kingdom

Background: Autism, attachment difficulties and Complex PTSD (CPTSD), can present with overlapping characteristics or presentations in children. This can create challenges in differential diagnosis, particularly when conditions may co-occur. Understanding clinicians' perspectives on how they approach these complexities is essential for improving diagnostic practices.

Objectives: To explore how clinicians with expertise in autism assess and differentiate between autism, attachment and CPTSD in children, focusing on their experiences, challenges, and perspectives in the diagnostic process.

Methods: An online survey was conducted with 37 clinicians, predominantly from the UK, including clinical psychologists, psychiatrists, and speech and language therapists. Participants shared their insights on assessment practices through open-ended questions, and their responses were analysed by applying a framework analysis to the data (Gale et al., 2013). Through mapping and interpretation of the framework matrix, we were able to highlight any contrasting opinions amongst different professions.

Results: Five key themes emerged and were further divided into subthemes. The themes included: (1) Experienced Clinicians – Clinicians with more experience demonstrated greater confidence in differentiating between autism and trauma-related conditions, often relying on clinical intuition rather than assessment tools; (2) Multidisciplinary Teams – The majority of clinicians emphasised the importance of working in multidisciplinary teams to ensure holistic assessments in more complex cases; (3) Developmental History – Taking a comprehensive developmental history was identified as crucial for differential diagnosis. Challenges included reliability of informant recall or a lack of history due to the child's circumstances; (4) Assessment Tools – While tools like the ADOS were commonly used, clinicians stressed the importance of not relying solely on tools, suggesting that clinical judgment is key; (5) Systemic Challenges – Clinicians noted systemic barriers, such as resource limitations, that impact the quality of assessments.

Conclusions: Further research is needed to refine diagnostic tools, particularly for differential diagnosis of attachment difficulties and autism. Training that integrates the current silos of autism, attachment and trauma-related expertise, as well as shadowing opportunities for less experienced clinicians, is desired by clinicians. Collaborative efforts between disciplines and better integration of trauma and developmental services are essential for improving diagnostic accuracy and providing appropriate support for children with more complex presentations.

411.153 Coder Agreement of Autistic-like Behaviors in Children with Autism during Remote Academic Assessment

G. Castillo-Martinez¹, A. Eisenhut², E. Grimes³, I. Lozano⁴, C. Blaes⁵, M. Keller-Margulis⁴ and S. S. Mire⁵, (1)Baylor University, Waco, TX, (2)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (3)School of Education, Baylor University, Waco, TX, (4)Psychological, Health, and Learning Sciences, University of Houston, Houston, TX, (5)Psychological, Health, and Learning Sciences, Baylor University, Houston, TX

Background: Accurately measuring foundational academic skills in evaluations for children with autism is crucial for fostering their academic success (Harry et al., 2022). Remote learning and assessments surged following the COVID-19 pandemic (Reicher, 2020), emphasizing the need to examine how behavioral characteristics specific to autism may affect the administration, results, and utility of remote approaches to academic evaluation (Mire et al., 2022). Traditionally, assessments of autism-related behaviors occur in-person, but relatively less is known about effective strategies and best practices for accurately capturing these behaviors in virtual settings. This presents unique challenges for educators and clinicians tasked with assessing academic skills of autistic children, as remote environments introduce new variables that may influence behavior and academic skill demonstration. Consequently, there is a need for behavioral observations during remote assessment sessions that are both valid and reliable for special populations, like children with autism.

Objectives: This study has three primary objectives. First, we categorize common behavioral observations of children with autism during remote academic assessment, creating a clearer framework for identifying and classifying these behaviors in a remote environment. Second, we identify which autistic-like behaviors contribute to variability in coder agreement when assessments are conducted in a remote setting. By understanding behaviors prone to disagreement among coders, challenges unique to virtual assessments with autistic students may be elucidated. Lastly, we explore potential contributors to discrepancies between coders, such as differences in interpreting certain behaviors or difficulties in observing subtle cues in the virtual environment.

Methods: Our sample included 10 elementary-aged students (8 boys, 2 girls) with a clinical diagnosis of autism spectrum disorder, or an autism educational classification recruited through a partnership with a public school district in a large metropolitan area in Texas. Our research team recorded and remotely administered math, reading, and writing curriculum-based measurement probes for between 1 and 5 sessions. Two research assistants coded each video to identify behaviors characteristic of autism during the assessment sessions. Following behavioral observations, we examined factors that could have influenced inter-observer agreement scores for each behavioral category. We used algorithm items from the Autism Diagnostic Observation Schedule-2 (Lord et al., 2012) Module 3 to categorize behaviors into (a) social affect (SA) and (b) restricted and repetitive behaviors (RRB).

Results: Current findings suggest factors including (a) coders' experience with autistic students, (b) coders' formal training in autism diagnostic evaluation, (c) variability in children's symptom presentation, and (d) nuances of administering assessments via the remote modality, affected coder agreement. Ongoing analyses are underway to assess the relationship between SA and RRB behaviors and interobserver agreement, providing insight into behaviors more challenging to observe and accurately identify through a remote modality may affect academic skill assessment.

Conclusions: Understanding factors that may influence the reliability and validity of remote academic assessment for children with autism will provide critical insights into improving the accuracy and consistency of assessment approaches. Ultimately, this line of work has the potential to improve academic outcomes for autistic learners.

411.154 Comparing Cognitive and Adaptive Functioning between Children Identified By a School-Based Universal Screening Program and a Clinically-Ascertained Sample

S. James¹, C. J. Smith¹ and N. L. Matthews², (1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)Southwest Autism Research and Resource Center, Phoenix, AZ

Background: Many autistic individuals go undetected until school-age or later and do not receive a diagnosis until adulthood (Huang et al., 2020). Identification of autism spectrum disorder (ASD) before symptoms become clinically significant can lead to improved functional outcomes and quality of life (Sandbank et al., 2023). Our team recently implemented a school-based universal screening program designed to identify school-aged children with social challenges (James & Smith, 2022). Understanding potential differences in cognitive and adaptive functioning (AF) between children identified and subsequently diagnosed with ASD through the program and children who received a diagnostic evaluation outside of a screening model may shed light on the utility of school-based universal screening and inform intervention strategies.

Objectives: To compare cognitive and adaptive functioning of autistic students identified by universal screening to an age- and sex-matched sample of clinically referred children who received an ASD diagnosis outside of a screening model.

Methods: Secondary data analysis was conducted using (1) data collected from participants who were evaluated as a result of school-based universal screening and (2) archived records collected from a clinically ascertained sample of children diagnosed with ASD at our research center. Analyses focused on a sample of children and adolescents ($n = 86$, mean age 9.56 years) matched on age at evaluation and biological sex assigned at birth. Independent samples T-tests were conducted to compare scores on the Kaufman Brief Intelligence Test, Second Edition (Kaufman & Kaufman, 2006) and Vineland Adaptive Behavior Scales, Second/Third Edition (Sparrow et al., 2005, 2016).

Results: Composite IQ ($t(84)=2.67, p<.01$) and Adaptive Behavior Composite (ABC) ($t(84)=3.16, p<.01$) scores were significantly higher for students who were evaluated as part of the universal screening program compared to children in the clinically ascertained sample. The largest difference in AF domain scores was in Socialization ($t(84)=4.06, p<.001$), followed by Communication ($t(84)=2.88, p<.01$), then Daily Living Skills ($t(2.17)=5.86, p<.05$). (See Table 1.)

Conclusions: Children in both groups had composite IQs in the average range; however, adaptive behavior composites were significantly lower than IQ scores, suggesting functional impairment. Children identified through the universal screening program had significantly higher AF scores compared to clinically referred children. This may suggest that universal screening detected students before functional impairment was identified by parents or teachers and resulted in an earlier diagnosis than would have been the case if children were not identified through screening.

Identifying autism before functional impairment is observed may prompt caregivers to seek a diagnostic evaluation and enable access to evidence-based interventions and support that could facilitate improved functioning and quality of life.

Table 1. Participant Assessment Scores

Variable	Universal Screening Group <i>m</i> (<i>SD</i>) (<i>n</i> = 43)	Clinically Ascertained Group <i>m</i> (<i>SD</i>) (<i>n</i> = 43)
KBIT		
Verbal SS	106.26 (17.23)	94.02 (18.96)
Nonverbal SS	107.07 (19.10)	102.26 (19.38)
Overall IQ Composite	108.09 (18.73)	97.65 (17.55)
VABS		
Communication SS	86.93 (13.45)	77.49 (16.78)
Daily Living Skills SS	90.23 (14.42)	83.00 (16.43)
Socialization SS	81.6 (11.56)	70.21 (14.31)
Adaptive Behavior Composite SS	84.33 (11.49)	75.88 (13.20)

411.155 Comparison of Different Eye Tracking Measures for Identification of Autism in Children

H. Krasnolob¹ and **I. Dinstein²**, (1)*Cognitive and Brain Sciences Department, Ben-Gurion University, Beer-Sheva*, (2)*Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel*

Background: Eye-tracking has emerged as a powerful tool in autism research, enabling the identification of social attention and gaze behavior differences between autistic and typically developing children. Previous studies have suggested that such gaze differences reduce the exposure of children to social information, potentially altering their development. Previous studies have mostly used region of interest (ROI) analyses to quantify the total amount of time participants gaze at specific regions. Other studies have used time-series analyses to examine temporal and spatial differences in gaze patterns. Here we compare these approaches in a large dataset of recordings from young children.

Objectives: Compare the accuracy of classification between autism and control children when analyzing the same eye-tracking data using ROI versus time-series analyses.

Methods: We analyzed 486 eye-tracking recordings, 363 from autistic children (mean age: 4.81 ± 1.63 yo) and 123 from controls (mean age: 3.21 ± 1.35 yo) collected at the Azrieli National Centre for Autism and Neurodevelopment Research (ANCAN) in Israel using an EyeLink 1000+ eye tracking system. Children viewed a 90 sec video with a naturalistic social interaction. ROIs of faces, objects, body parts, and background were manually annotated in each frame of the video. Time-series of X and Y gaze position per frame were combined into a single time-course of radial position from top left corner of the screen. Five gaze measures were evaluated: (1) Euclidean distance between the gaze time-course of each child and the mean gaze time-course of the control group (2) the average pair-wise correlation of gaze time-courses between each child and each of the control children (3) the percentage of time gazing at faces (4) the percentage of time gazing at objects (5) the ratio of faces to objects. We performed a receiver operating curve (ROC) analysis for each of the measures to determine their ability to separate autism and control children and report the area under the curve (AUC) of each.

Results: The Euclidean distance measure exhibited the strongest classification (AUC= 0.73) followed by the ratio between faces and objects (AUC=0.69), the pair-wise correlation measure (AUC= 0.67) and individual face and objects ROI measures (AUC= 0.66 and 0.64 respectively).

Conclusions: These results demonstrate that time-series analyses have an advantage over ROI analyses in identifying gaze differences between autistic and control children. They suggest that the temporal structure of visual attention differs in autism beyond overall social preferences and point to additional

411.156 Concordance between Direct Observation (TELE-ASD-PEDS) and Caregiver Report (TASI) during Telehealth Visits
S. F. Vejnoska¹, C. Orendain Soto², J. Sherman¹, A. C. Stahmer³, S. R. Rieth⁴ and S. Dufek⁵, (1)UC Davis MIND Institute, Sacramento, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)UC Davis MIND Institute, University of California at Davis MIND Institute, Sacramento, CA, (4)Child and Family Development, San Diego State University, San Diego, CA, (5)Psychiatry and Behavioral Sciences, UC Davis Health, MIND Institute, Sacramento, CA

Background:

Telehealth approaches to autism assessment burgeoned during COVID-19 (Zwaigenbaum et al., 2021). The TELE-ASD-PEDS (TAP; Corona et al., 2021) is an observation-based caregiver-mediated tele-assessment of autism-related behaviors in toddlers. It has high rates of diagnostic agreement with in-person assessment (Corona et al., 2024). The Toddler Autism Symptom Inventory (TASI; Coulter et al., 2021) is a semi-structured caregiver interview that assesses autism-related behaviors in children under three. To our knowledge, limited research has compared the concordance of these two autism-related behavior measures to determine whether different information is obtained from caregiver report versus a brief observation. Understanding the concordance of these measures administered via telehealth can provide preliminary information about their individual contribution during the diagnostic process.

Objectives:

Compare concordance between the TAP and the TASI for 1) overall autism likelihood and 2) individual DSM-5 domain criterion items (social communication items A1-A3 and restricted, repetitive behavior (RRB) items B1-B4) to better understand the overlap of information gathered by both measures through telehealth.

Methods:

Data come from 95 children participating in a study in community early intervention settings across California. At enrollment, children were under 30 months ($M = 24.73$, $SD = 5.58$) and receiving services for social communication delays. Children were primarily male (67.37%) and Hispanic/Latino (55.79%). They were assessed using the TAP, with examiners rating seven key behaviors on a 1-3 Likert scale. A total score of 12 or higher indicates an increased likelihood of autism. Caregivers were interviewed using the TASI which provides an evaluation of the overall likelihood of autism and the presence or absence of each DSM-5 criterion.

TAP ratings were transposed to the DSM-5 criteria with a score of 3 on a behavior indicating the child met criteria for social communication items (A1, A2) or RRB items (B1, B4). Following the guidance of Kwiecien and colleagues (2011), Cohen's kappa was used to assess the concordance between the TAP and the TASI.

Results:

Comparisons demonstrated weak agreement between the TAP and TASI for the overall autism likelihood ($k = 0.44$), with agreement on 78.95% of cases ($N = 14$ autism unlikely, $N = 61$ autism likely). On DSM-5 criteria, we found minimal agreement for B1 ($k = 0.23$), and no agreement for A1 ($k = 0.16$), A2 ($k = 0.16$), and B4 ($k = 0.03$) criteria. Table 1 provides a breakdown of the agreement between the two measures. For DSM-5 criteria, we observed a pattern whereby information from caregivers on the TASI was more likely to result in the child meeting the individual criterion than from the brief TAP observation.

Conclusions:

These results demonstrate the importance of incorporating multiple sources of information in autism evaluation. Current gold standard measures of autism evaluation are strengthened by incorporating caregiver input and behavioral observations (Kim and Lord, 2012). These findings provide evidence that this is also the case for telehealth assessment. More research is needed to examine the individual strengths of each measure and their contributions to more accurate, best estimate autism diagnoses, especially during telehealth visits.

411.157 Creation of a Reliable Short-Form IQ Score Using the Stanford-Binet 5th Edition in Individuals with Autism and Other Developmental Disabilities

J. Esprit¹, M. Wendel¹, E. M. Butter^{1,2}, E. A. Youngstrom^{1,2} and K. G. Stephenson^{1,2}, (1)Nationwide Children's Hospital, Columbus, OH, (2)The Ohio State University, Columbus, OH

Background: The Stanford Binet Intelligence Scales 5th Edition (SB5) is an intelligence test measuring cognitive ability across five domains including Fluid Reasoning (FR), Quantitative Reasoning (QR), Knowledge (KN), Visuospatial Processing (VS), and Working Memory (WM). Each of the five domains contains two subtests, verbal and nonverbal, for a total of ten subtests. The full SB5 can take between 60-90 minutes to complete. Due to clinical barriers (e.g., interfering behaviors, illness, unforeseen circumstances), it is not always possible to administer a full assessment. This might be especially true for autistic and neurodiverse children. Although the SB5 includes an Abbreviated Battery IQ (ABIQ) as a short-form option, it is only based on two subtests and is less valid in cases of high subtest scatter and has low long-term stability. However, alternative short-forms other than the ABIQ do not exist. Having a more robust short-form of the SB5 would provide additional flexibility for clinicians and researchers who are not able to complete the full 10-subtest SB5.

Objectives: We investigated various 5-subtest short-forms of the SB5 in order to find one that is more reliable and stable than the 2-subtest ABIQ, has more coverage than either the Verbal IQ (VIQ) or Nonverbal IQ (NVIQ), but does not take as long to administer as the 10-subtest FSIQ.

Methods: The sample consisted of SB5 administrations from N=5,466 individuals ($M_{age}=8$ years, $SD_{age}=3.6$ years, 24% female, 75% White, 13% Black, 7% Multiple Race, 5% Other Race) referred for developmental testing at a pediatric hospital in the Midwestern region of the USA between 2010-2023. Using data from 80% of the full sample, 20 different 5-subtest combinations (with one subtest per factor) were separately regressed onto FSIQ. The best-fitting 5-subtest combination was defined by the lowest Akaike information criterion (AIC) from the individual regressions.

We used this regression formula to create a regression-based short-form IQ score (SFIQ) and validated it on the remaining 20% of the sample. We compared the correlation of the SFIQ with FSIQ to those of the VIQ and NVIQ. The long-term stability of the SFIQ was tested on a subsample with repeated SB5 administrations ($n=654$; $M_{interval}=1.7$ years, $SD_{interval}=2.1$ years) using the intraclass correlation (ICC) from linear mixed-effects models.

Results: The best-performing short form consisted of verbal subtests from the FR and KN domains and nonverbal subtests from the VS, QR, and WM domains ($R^2=.94$). The correlation between SFIQ and FSIQ was very high ($r=.97$), significantly higher ($p<.001$) than those of the VIQ ($r=.95$) and NVIQ ($r=.95$), and not impacted by subtest scatter. The long-term stability of SFIQ ($ICC=.80$) was like those of VIQ ($ICC=.82$) and NVIQ ($ICC=.81$).

Conclusions: We found a robust 5-subtest short-form of the SB5 that showed a strong relationship to FSIQ and acceptable long-term stability. This short-form provides a reliable alternative to the existing ABIQ and takes half the time of the FSIQ. Using this short-form version allows providers to obtain a reliable estimate FSIQ when completing a full SB5 is not feasible, such as when clinical barriers arise during test administration.

411.158 Data-Driven Approach to Reducing Autism Waitlists: A Novel Multi-Disciplinary Clinic for Assessing Frank Presentations of Autism Spectrum Disorder (ASD)

A. B. Schwartz, S. M. Larsen, O. H. Caron, H. R. Brown, S. M. Kanne and C. J. Black, Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY

Background: The prevalence of ASD has increased in recent years, resulting in significantly longer waitlists at clinics internationally. These lengthy waitlists are problematic, leading to later diagnosis, which affects access to critical intervention services that are strongly associated with positive outcomes (Zwaigenbaum et al., 2015). Various research studies have examined potential solutions to reduce diagnostic waitlists. However, few studies have used a data-driven approach to reduce waitlists by seeing children for an expedited assessment. The Autism Behavioral Assessment & Consultation (ABC) Clinic is a pilot clinic within a larger hospital-based ASD center, tasked with reducing waitlists using an algorithm designed to screen for children with frank presentations of ASD. The ABC clinic provides a multi-disciplinary evaluation for those who meet the established criteria, creating a more efficient and thorough diagnostic process.

Objectives: The current study aimed to detail the structure and design of the ABC clinic and explore the demographics of patients who have screened into the clinic.

Methods: The ABC clinic, adapted from the Thompson Center at the University of Missouri, began in January 2024. Twenty-nine patients have screened into the clinic, with 11 patients completing evaluations to date. Patients evaluated through the ABC clinic must meet the following criteria: under 6-years-old, minimally verbal, and a positive score on an ASD screening measure (e.g., Modified Checklist for Autism in Toddlers, Revised (M-CHAT-R) or Social Communication Questionnaire (SCQ)). Caregivers must endorse either OCD or sensory concerns, or both, and must not endorse aggressive behaviors, depressive symptoms, or unusual or excessive fears. The evaluation includes the standard clinic intake (for all patients) followed by a single-day in-person assessment (unique to ABC). The in-person 4-hour evaluation includes a developmental assessment, the Autism Diagnostic Observation Schedule (ADOS-2), a pediatrician visit, and a feedback appointment.

Results: The results found that the mean score on the autism screening measure was clinically elevated (M-CHAT-R: $M=11.25$, $SD=2.87$, $n=8$; SCQ: $M=23.96$, $SD=4.31$, $n=21$). The sample included 24 male and 5 female patients, 10 of whom were White, 8 Black or African American, and 8 Asian. 9 patients identified as Hispanic. About 27.59% of the patients' families had an income under the poverty line. The mean wait between intake and evaluation was 100 days, a significantly shorter wait than our regular diagnostic clinic. Of the 29 patients who met criteria, 2 received alternative evaluations, 16 are awaiting appointments, and 11 have completed their evaluation. 100% of the patients evaluated have received an ASD diagnosis.

Conclusions: The preliminary data suggests that the ABC clinic is an effective approach towards fast-tracking diagnosis of ASD in frank presentations. This helps families gain access to necessary interventions. The clinic's streamlined structure reduces barriers in the diagnostic process, which may be beneficial for those facing challenges coordinating transportation, taking time off work, or finding childcare. With a higher prevalence of medical comorbidities in ASD, the inclusion of a pediatric appointment allows for patients to receive medical care and appropriate recommendations. The present study supports using a data-driven approach to reduce waitlists at centers internationally.

411.159 Item Level Effects of the ADOS-2 (Toddler Module) on Expert Clinician Certainty

R. Young¹, C. Klaiman², H. Walum³, A. S. Kolios⁴, J. A. Benson¹, A. Klin¹ and W. Jones¹, (1)Marcus Autism Center, Atlanta, GA, (2)Emory University/Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA, (4)Marcus Autism Center, Emory University, Atlanta, GA

Background: The diagnosis of autism spectrum disorder (ASD), particularly in young children, can be complex. There are standardized tools (e.g., ADOS-2) that are used as an aide, but ultimately clinicians determine a final diagnosis. Previous literature has found that 30-40% of expert clinician diagnoses of ASD in toddlers and preschool-aged children are made with some level of uncertainty (McDonnell et al., 2018; Klaiman et al., 2022). In both studies, the greatest predictor of clinician uncertainty for both autistic and non-autistic toddlers was mid-level autism symptomatology.

Objectives: To understand factors that influence clinicians' final diagnosis, we aim to identify specific behaviors driving clinician certainty by analyzing item level associations between ADOS-2, Toddler module items, and certainty ratings.

Methods: Secondary analyses were performed using 16-30-month-old children from Klaiman et al.'s (2022) sample who received the ADOS-2 Toddler module (n=437). Item scores of 0-3 (or 0-4 for Item A1) were included for the purpose of this analysis; scores of 7-9 were excluded as they are not indicative of autism symptomatology. Per the ADOS-2 scoring rules, participants were assigned to a scoring algorithm based on age and/or language level, as indicated by their Item A1 score. Clinician certainty was rated on a 1 (0-20% certain) to 5 (81-100% certain) scale. Chi-square analyses between score and certainty rating were completed for each item. The Holm & Bonferroni method was used to account for multiple comparisons.

Results: Eight items (see *Table 1*) were significantly associated with clinician certainty. Among these items, we identified two primary categories: overall quality of social interaction and eye contact. Irrespective of final diagnosis, receiving a "1" on items in these categories decreased the chance that the clinician was 81-100% certain to < 50%. Notably, two items (B16A, C2) do not factor into either scoring algorithm. Multiple items significantly associated with certainty are only used in one of the scoring algorithms. For this reason, we repeated analyses, separating toddlers by which algorithm they received. Considering the 261 toddlers (ASD = 163) who were scored on Algorithm 1, six items impacted certainty (see *Table 2*), two of which (B16A, B18) are non-algorithm. Of the 176 toddlers (ASD = 63) who were scored through Algorithm 2, four items impacted certainty (see *Table 2*), all of which load onto the algorithm.

Conclusions: Beyond mid-level symptomatology, specific behaviors (e.g., quality of social interaction and eye contact) identified during the ADOS-2 impacted level of clinician certainty in a sample of 437 16-30-month-olds. Importantly, non-algorithm items are amongst those that affect certainty. These results highlight the complex diagnostic presentation of young children undergoing diagnostic evaluation. Results demonstrate the need for continued developmental monitoring and the use of biomarkers to help navigate the ambiguity of the heterogeneity of autism, particularly at this young age. More work is needed to determine if behaviors impacting certainty vary across demographic factors such as sex, race, and SES.

411.160 Developing a Quantitative Assessment Tool for Characterizing Social Domains in Autism

M. Uljarevic¹, L. Chetcuti², E. Spackman³, R. K. Schuck⁴, J. M. Phillips¹, T. W. Frazier⁵ and A. Y. Hardan¹, (1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, Australia, (3)Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (4)Department of Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (5)Psychology, John Carroll University, Cleveland, OH

Background:

Social difficulties are a cardinal feature of autism that frequently occur in other neurodevelopmental (NDD) and neuropsychiatric (NPD) conditions. Irrespective of the primary diagnosis, these difficulties can persist over time and contribute to poor outcomes for individuals and their families. However, despite their impact, the neurobiological mechanisms underpinning social difficulties are not adequately characterized by current diagnostic systems, which has stifled the development of effective supports. The Research Domain Criteria (RDoC) framework operationalizes a set of basic, biologically-driven processes that underpin social functioning, and, if disrupted, can impede one's ability to navigate the complexities of the social world. Quantifying these processes is critical for facilitating a better characterization of the social profiles seen in autism and other conditions and can eventually inform the personalization of supports. However, reliable, comprehensive and fit-for-purpose social functioning measures are sorely lacking.

Objectives:

Following methods outlined by the NIH Patient-Reported Outcome Measurement Information System (PROMIS) initiative to develop and stringently validate a new, dedicated measure of key RDoC social processes—Stanford Social Dimensions Scale (SSDS-2).

Methods:

A comprehensive item bank was developed to capture each of the RDoC constructs and sub-constructs. The preliminary item bank was reviewed by 50 research and clinical experts in social processing and six focus groups of parents of children who have autism, other neurodevelopmental conditions, or are neurotypical. Refined item bank was distributed online to parents of children with autism through the Simons Foundation Powering Autism Research for Knowledge (n= 984; M_{age}=11.23 years, SD_{age}= 3.56; 76% male) and parents of neurotypical (n= 1195; M_{age}=10.17 years, SD_{age}= 3.19; 54% male) and children with diverse NDD and NPD (n= 1281; M_{age}=10.65 years, SD_{age}= 3.27; 63% male). In addition to the SSDS-2 item bank, parents completed a battery of questionnaires to appraise convergent and divergent validity of the SSDS-2.

Results:

Confirmatory application of exploratory structural equation modeling (ESEM) was used to test the a priori factor structures of the SSDS-2, including 3-factor structure with broad attachment and affiliation (AA), social communication (SC) and understanding mental states (UMS) factors and with more fine-grained 6-factor solution encompassing AA, reception of facial and non-facial communication, production of facial and non-facial communication, and UMS factors. Both models showed strong fit indices with a 6-factor solution showing superior fit (comparative fit index and Tucker–Lewis index > .95, root mean square error of approximation and standardized root mean square residual < .06) and items loading onto the hypothesized factors. Crucially, the derived factor structure was invariant across age, sex, cognitive functioning and diagnostic status. Across all groups, all factors had good to excellent internal consistency (alpha ≥ .89), model reliability (omega ≥ .88), two-week test-retest reliability (ICC ≥ .86) and strong convergent and divergent validity.

Conclusions:

Our findings provide initial validation of a new scale designed to comprehensively capture individual differences in key social functioning processes. Future steps involve using the SSDS-2 in longitudinal studies and identifying informative subgroups with distinct profiles of strengths and areas of support across specific, well-defined social processes.

411.161 Developing an Objective Autism Index Using Arabic Remote Eye Tracking Paradigm for the Early Screening and Diagnosis of Autism Spectrum Disorder

F. Alshaban^{1,2}, **T. W. Frazier**³ and **M. Aldosari**⁴, (1)Neurological Disorder Research Center, Qatar Biomedical Research Institute, Doha, Doha, Qatar, (2)College of Health and Life Science/Hamad Bin Khalifa University, Education City, Doha, Qatar, (3)Psychology, John Carroll University, Cleveland, OH, (4)Center of Pediatric Neurology, Cleveland Clinic Foundation, Cleveland, OH

Background: Deficits in eye gaze are a hallmark feature of autism spectrum disorder (ASD) and are included in the gold standard diagnostic instruments. More than a decade of research into abnormalities of eye gaze has confirmed social attention deficit as a key feature of ASD. Across studies, diverse stimulus paradigms have elicited social attention abnormalities, ranging from decreased fixation to others' eyes and social scenes as early as 6 months of age, to gaze abnormalities during dyadic or joint attention bids in preschoolers and older children, to aberrant gaze toward dynamic social stimuli in order high-functioning individuals. Gaze patterns particularly those based on dynamic temporal analysis, may be a promising objective risk marker of ASD as well as a quantitative measure of autism symptoms spanning the full continuum of behavior. Developing an Arabic version of the tracking stimuli paradigm that mimics the English ones by previous studies to be used for Arabic-speaking individuals is challenging but promising.

Objectives: The primary aim of the present study was to create an objective, eye-based autism risk index using an Arabic version of the stimuli paradigm.

Methods: Children were recruited for comprehensive multidisciplinary evaluation of ASD and subsequently grouped by clinical consensus diagnosis (ASD n=150, non-ASD 120). Remote eye tracking using Arabic version stimuli. Dwell times were recorded for each priori-defined region of interest (ROI) and averaged across ROIs to create an autism risk index.

Results: Similar to the previous findings, the autism risk index had high diagnostic accuracy with the area under the curve (AUC)= .89 and .84, 95% CIs= .80-.97 and .70-.95, was strongly associated with Autism Diagnostic Observation Schedule-Second Edition severity score.

Conclusions: The autism risk index is a useful quantitative and objective measure of risk for autism in at-risk settings. Using the Arabic remote eye tracking paradigm proved to be as effective as the English version used in the previous research projects. Future research in larger samples is needed to cross-validate these findings. If a validated scale for clinical use, this measure could inform clinical judgment regarding ASD diagnosis and track symptom improvements.

411.162 Development and Initial Validation of Oera Baby: A Tool for Identifying Autism Spectrum Disorder Symptoms in Children Aged 18-48 Months from Low- and Middle-Income Countries

M. R. Dias¹, **N. Becker**², **L. Bagaiolo**³, **L. Mizael**¹, **W. Lojo**⁴, **C. Romano**⁵ and **C. S. de Paula**², (1)Human Developmental Sciences Graduate Program, Mackenzie Presbyterian University, sao paulo, SP, Brazil, (2)Human Developmental Sciences Graduate Program, Universidade Presbiteriana Mackenzie, São Paulo, SP, Brazil, (3)Grupo Gradual, SÃO PAULO, Brazil, (4)School of Psychology, Mackenzie Presbyterian University, sao paulo, SP, Brazil, (5)Grupo Gradual, São Paulo, Brazil

Background:

Although early detection of ASD accompanied by appropriate treatment is considered a key factor for a positive prognosis, there is a lack of valid instruments to detect ASD based on objective measures for children under 48 months in LMIC.

One brief and low-cost tool for assessing behavioral markers of ASD available in Brazil is the Observational Evaluation for Autism-OERA. It includes 8 specific, and 5 global observational items designed for use by trained multidisciplinary professionals. OERA was previously validated to differentiate ASD children from typical development children aged 3 to 10 years, demonstrating high sensitivity (92.75%) and specificity (90.91%).

Objectives:

The present study aimed to: (1) review and adapt the OERA tool for younger children, aged 18 to 48 months; (2) evaluate the content of the revised test using expert judges; and (3) assess the applicability of the new version of OERA, referred to as OERA-Baby, by experts.

Methods:

The study was conducted in four stages: (1) adaptation and construction of the initial version of OERA-Baby; (2) evaluation of the adaptation through expert judges' analysis; (3) a pilot study to assess the instrument's applicability; and (4) development of the final version of OERA-Baby based on the findings from the pilot study.

Results:

In Stage 1, the main adaptations made to the original OERA for suitability with children aged 18-48 months included modifications to the application format, opportunities, materials, and the number of tests. This involved the inclusion of two specific tests and one global test aimed at observing behavioral rigidity.

In Stage 2, two expert judges evaluated the 19 OERA-Baby, finding them to be clearly defined and effective in distinguishing between children with ASD and those with typical development. The judges recommended adding a pre-application questionnaire and replacing certain terms in the manual for clarity.

In Stage 3, a pilot study involving 13 children aged 18-48 months—comprising both those with ASD and those with typical development—demonstrated that seven tests were suitable, while two tests required adjustments.

Finally, in Stage 4, the final version of OERA-Baby was developed, incorporating 9 specific tests and 10 adjusted global tests. This version received positive evaluations from 11 specialist professionals, who deemed the application appropriate for clinical use.

Conclusions:

The development and adaptation of OERA-Baby represent significant advancements in the early detection of ASD in children younger than four years-old in developing countries. The systematic approach undertaken throughout the four stages of this study ensured that the final version of OERA Baby is both valid and reliable, effectively distinguishing between children with ASD and those with typical development. The incorporation of expert feedback and the pilot study further validated the instrument's applicability in clinical contexts. As a brief, low-cost tool, OERA-Baby has the potential to enhance early screening efforts in resource-limited settings, thereby improving early intervention strategies, particularly in such environments.

Future research should focus on further validating OERA-Baby across diverse populations, particularly Spanish speakers, and exploring its effectiveness in clinical practice to optimize outcomes for young children with ASD.

411.163 Development and Validation of Robotic Detection Technology for Assessing Autism

W. C. So¹, M. T. So² and Y. Y. Lee², (1)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, NA, Hong Kong (China), (2)The Chinese University of Hong Kong, Hong Kong, China

Background: Autism is a heterogeneous and complex neurological disorder. While significant training is required for clinicians to become proficient in diagnosing autism, given the heterogeneity of autism, only 60% to 70% of autism diagnoses made by licensed and experienced clinicians are made with certainty (Klaiman et al., 2024; Klin et al., 2000; McDonnell et al., 2019). There is also limited availability of experienced clinicians (Durkin et al., 2015), often resulting in long waiting times. An objective and standardized assessment for assessing autism is needed. There is a pioneering development of data-driven information and communication technology (ICT) solutions on improving objectivity and quantifying the diagnostic process, assessment, and evaluation of learning outcomes (reviews in (Bondioli et al., 2024). Yet, a few studies have explored the supporting role of robots in screening autism. Besides, they adopted either the Wizard-of-Oz (WoZ) paradigm or the semi-autonomous strategy (e.g., Arent et al. 2022) and largely focused on the detection of one autism feature (e.g., So et al., 2024).

Objectives: This study aimed to develop and validate robotic detection technology for assessing autism. It programmed an autonomous social robot to detect more than one autism feature (lack of eye gaze and repetitive motor movements) when engaging with children. We hypothesized that such technology would identify the presence or absence of autism, with the sensitivity and specificity reaching 0.8 or above and the Area under the Curve reaching 0.7 or above.

Methods: The robot HUMANE, installed with computer vision and linked with face and motion recognition technology, autonomously detected atypical eye gaze and repetitive motor movements, two of the features of autism, while narrating stories. It autonomously prompted the child if they did not establish eye gaze with the robot or produced motor movements for five seconds continuously. 119 three-to-six-year-old children ($M=4.53$, $SD=1.89$; 38 females) with or without autism participated. They all received the ADOS-2, the standard diagnostic tool for autism.

Results: HUMANE's detection performance – the number of robot prompts and the cumulative duration of inattentiveness/improper posture – was then validated against the calibrated severity score of ADOS-2 (see Table1). Sensitivity and specificity and DORs of indexes at the composite level performed better than those at the individual level. Similar results were found in the ROC curve analyses. The total number of robot prompts and the total inattentiveness and improper posture duration were competent in differentiating between the autistic and non-autistic groups with large AUCs of 0.86 ($SE=.03$; $p<.001$; 95%CI: .80-.93) and .84 ($SE=.04$, $p<.001$; 95%CI: .76-.91). The AUCs of individual indexes were lower, yet still higher than 0.7.

Conclusions: Our hypothesis was supported. The composite indexes generated in the detection of atypical eye gaze and improper posture systems could identify the presence or absence of autism in nearly 120 children, with sensitivity and specificity of at least .80 and AUCs of at least .84. As a result, this study has developed and validated robotic technology for assessing autism focusing on the autonomous detection of two features, atypical eye gaze and repetitive motor movements.

411.164 Development and Validation of the Currim Autism Digital Evaluation Tool (CADET) for Screening in Children with Limited Language Skills in Urban Karachi

F. Karim^{1,2,3}, **S. Saleem**⁴, **S. I. Azam**⁵ and **A. Rahman**⁶, (1)Department of Community Health Sciences, Aga Khan University, Karachi, SK, Canada, (2)Department of Neuroscience, Carleton University, Ottawa, ON, Canada, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Department of Community Health Sciences, Aga Khan University, Karachi, Sindh, Pakistan, (5)Department of Community and Health Sciences, Aga Khan University, Karachi, Pakistan, (6)Institute of Population Health, University of Liverpool, Liverpool, United Kingdom

Background:

Early detection of Autism in children is critical to creating an autism-friendly environment leading to a better prognosis. In a low middle-income country like Pakistan, there is a dearth of trained professionals and a lack of infrastructure to screen Autism in children. This study aimed to develop and validate a technology-mediated culturally relevant screening tool, shifting the task of a detailed, gold-standard assessment by a trained professional to a layman by giving an equally robust screening of Autism in children in low-resource settings, enhancing chances of early diagnosis of Autism and hence improving prognosis.

Objectives:

- To develop a digital parent-report tool for the screening of autism in children with limited language skills aged 31 months and older
- To validate this digital tool for the same demographic.

Methods:

The study was conducted in two phases.

Phase 1: The 'Currim Autism Digital Evaluation Tool (CADET)' was developed in six steps, based on existing validated tools and expert consultation. Six animated video vignette items relevant to autism diagnosis were selected and each item was illustrated using two animations of autistic and typical behavior created in collaboration with the Technology Innovation Support Center at Aga Khan University. It was designed as a parent-report tool and included audio aid to support those who cannot read. CADET was pretested with five mothers, modified based on feedback, and prepared for validation.

Phase 2: The validation study consisted of content validity, construct validity, and criterion validity. Content validity had been established in phase one; experts selected the items and gave their consensus on the content of the six items. Construct validity and criterion validity were assessed by applying CADET to screen and to compare three groups of children who have been earlier diagnosed as autistic, atypically developing, and typically developing by the only standard tool economically accessible in Pakistan, the Childhood Autism Rating Scale. A total of 84 children, 28 in each group, were randomly selected from the records of the Out Patient Department of Children's Hospital, Aga Khan University Hospital. The participants were parents of children between 31 months and 10 years. Construct validity and criterion validity of CADET were assessed by internal consistency and ROC analysis using Stata 14 and Medcalc 19.6.

Results:

The construct validity was assessed by Cronbach's α with an estimated value of 0.93. CADET showed sensitivity of 96.4% (95% CI (81.6% - 99.9%) and specificity of 100% (95% CI (87.6% - 100.0%)) between typically developing and autistic children. It showed sensitivity of 96.4 (81.6 - 99.9) and specificity of 92.8 (76.5 - 99.1) between autistic and non-autistic atypically developing children and it showed sensitivity of 89.2 (71.7 - 97.7) and specificity of 100.0 (87.6 - 100.0) when non-autistic atypically developing children were compared with typically developing children. The mean score difference between autistic and typically developing children was 5.35 ($p < 0.001$) and between autistic and atypically developing children, 3.8 ($p < 0.001$).

Conclusions:

The tool's initial testing shows it works at par with the gold standard and can be easily used by a layperson.

**411.165** Development of a Brief Form of the Screening Tool for Autism in Two-Year-Olds: Accuracy in Detecting Autism Spectrum Disorder in Toddlers

Y. R. Hung and **C. C. Wu**, Department of Psychology, Kaohsiung Medical University, Kaohsiung, Taiwan

Background: Early intervention is crucial for improving long-term outcomes in toddlers with autism spectrum disorder (ASD). However, despite the presence of symptoms in early childhood, ASD is often not diagnosed until after the age of three. While several screening tools exist globally, there is a lack of efficient methods for early ASD detection in many countries, including Taiwan. This is particularly challenging due to clinicians' heavy workloads and limited time for comprehensive assessments. The Screening Tool for Autism in Two-Year-Olds (STAT) has shown effectiveness in identifying ASD, but its full version may be too time-consuming for clinical use.

Objectives: This study aimed to develop and evaluate a brief form of the STAT (STAT-BF) to efficiently screen toddlers under 36 months of age for ASD in Taiwan, with the goal of enhancing early detection and enabling timely interventions.

Methods: This two-phase study aimed to develop (Study 1) and validate (Study 2) the STAT-BF. Study 1 involved two samples ($N = 80$), each consisting of 20 toddlers with ASD and 20 with developmental delays (DD), all under 36 months of age. Independent-sample t-tests confirmed no significant differences in key demographic variables between groups. All participants were administered the full STAT. Chi-square tests with Bonferroni correction ($ps < .004$) identified STAT items that consistently differentiated ASD from DD across both samples. These items were used to create the STAT-BF. Receiver operating characteristic (ROC) analysis was then employed to determine the optimal cutoff score for the selected items. Based on the results of Study 1, Study 2 aimed to validate the STAT-BF using a larger sample of 251 children (81 ASD, 55 mild-ASD, 115 DD). All participants underwent assessments using the Mullen Scales of Early Learning, STAT, and Autism Diagnostic Observation Schedule. The sensitivity, specificity, and agreement with clinical diagnoses of the STAT-BF were evaluated in this sample.

Results: In Study 1, five of the 12 STAT items (Turn-taking, Bubbles, Snack, Balloon, and Bag of Toys) significantly differentiated between ASD and DD in both samples and were selected to form the STAT-BF. ROC analysis on the combined sample ($N = 80$) revealed that the STAT-BF had an optimal cutoff score of 3, with high sensitivity (.93) and specificity (.90). In Study 2, using the same cutoff score, the STAT-BF demonstrated high sensitivity (91.4% for ASD and 90.9% for mild-ASD) and specificity (80.9% for DD), showing strong agreement with clinical diagnoses. The STAT-BF exhibited excellent accuracy in distinguishing toddlers with ASD and mild-ASD from those with DD.

Conclusions: The STAT-BF showed excellent accuracy in identifying toddlers at risk for ASD before 36 months of age. It offered a more time-efficient alternative to the full STAT while maintaining good psychometric properties. This brief screening tool could facilitate early detection and intervention for ASD in clinical settings in Taiwan. Future research should focus on longitudinal studies to further validate the STAT-BF's predictive validity and explore its applicability in diverse clinical settings.

411.166 Developmental and Behavioral Skill Profiles Among Autistic and Nonautistic Students within General Education Classrooms

N. J. Sparapani¹, J. B. McCauley², J. C. Bullen³, C. J. Alexander⁴, N. Gillis⁵, S. L. Birkeneder², A. Dimachkie Nunnally⁶, S. N. Cantos⁷, N. S. Tseng⁸ and P. Mundy⁹. (1)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (2)School of Education, University of California, Davis, Davis, CA, (3)UC Davis, Davis, CA, United Kingdom, (4)School of Education, School Psychology, University of California, Riverside, Riverside, CA, (5)University of California, Davis, Davis, CA, (6)UC Davis MIND Institute, M.I.N.D. Institute, UC Davis, Sacramento, CA, (7)School of Education, University of California, Davis, Sacramento, CA, (8)Teacher Education, University of California, Davis, CA, (9)Peter Mundy, Davis, CA

Background: Education systems have critical gaps effectively identifying and serving autistic students in general education classrooms (Young et al., 2020). This may, in part, be due to problems identifying students who do not exhibit 'enough' academic or behavioral need in the early years (Reynolds et al., 2009). Sociocultural factors such as race and ethnicity, sex, and socioeconomic status also contribute to under-identification or misidentification (Golson et al., 2021, Sturm et al., 2021). Recognizing patterns of students' developmental and behavioral characteristics may, alternatively, outline the important information teachers need to effectively support the autistic students in their classrooms. **Objectives:** The current study investigated the heterogeneity in developmental and behavioral skills within a neurodiverse sample of students in general education classrooms. **Methods:** Participating students ($n = 223$) and teachers ($n = 27$) were recruited for a 4-year exploration project (R324A210288) examining teacher-student interactions within TK–5th grade general education classrooms. Teachers completed a battery of questionnaires outlining their students' developmental and behavioral skills, trained members of the research team administered diagnostic and academic measures, and families completed two autism diagnostic screening tools, the C-JARS (Mundy et al., 2017) and SRS-2 (Constantino, 2014). **Results:** We report preliminary findings on a neurodiverse subsample of 150 students ($M_{age} = 6.79$; $SD = 1.55$; 83 autistic). The sample of participants were racially, ethnically, and linguistically diverse; 46% were female. Latent profile analysis was conducted using Mplus with 11 variables derived from teacher-ratings of students' skills, including executive functioning (BRIEF-2; Gioia et al., 2015), sensory processing (SP2; Parham et al., 2021), adaptive behavior (Vineland-3; Sparrow et al., 2017), and the presence of problematic behavior (CBCL-TRF; Achenbach et al., 2007). Models were estimated using full maximum likelihood so that participants with partially complete data could be included. An increasing number of classes were tested, and each model was compared using the Bayesian Information Criterion (BIC). Individuals were assigned to their most likely class using posterior probabilities. We then characterized the profiles by demographic, diagnostic, and academic information. A 5 profile solution best described the students' constellation of developmental and behavioral skills within the classroom ($AIC = 11917.44$, $BIC = 12128.19$, Entropy = .98), showing excellent overall model fit, the best fit in comparison with models of 3 and 4 profiles, and strong overall membership probability. The profiles are illustrated in Figure 1; demographic and academic skills by profile are presented in Table 1. The profiles differed on the presence of autism eligibility, with profile 1 and 5 being associated with reduced odds ($p = 0.001$; 0.35), and profiles 2 and 3 ($p = 0.01$; 0.001) associated with increased odds of being autism eligible. **Conclusions:** Autistic students were observed in each profile, however, there were relatively more autistic students in profiles 2, 3 and 4, which were characterized by differences in executive functioning, sensory processing, socialization and communication patterns, and the presence of behavior problems. Next, we will examine the influence of sociocultural factors on profile membership and investigate how profile membership predicts autism classification and academic achievement.

411.167 Differential Impact of Developmental Milestones, Demographic Factors, and Behavioral Features on Autism Screening in Boys and Girls

A. Kniola¹, N. N. Ludwig^{1,2}, V. Singh³, C. C. Bradley⁴, L. Carpenter⁴, E. F. Dillon⁵, S. M. Kanne⁶, S. H. Kim⁷, J. Parish-Morris^{8,9}, L. Green Snyder¹⁰ and E. Wodka^{2,3}, (1)Center for Neuropsychological and Psychological Assessment, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (4)Medical University of South Carolina, Charleston, SC, (5)Department of Life Sciences, Carroll University, Waukesha, WI, (6)Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY, (7)School of Psychology, Korea University, Seoul, Seoul, Korea, Republic of (South), (8)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (9)Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (10)Simons Foundation, New York, NY

Background: Previous research has shown that girls with a parent reported autism diagnosis may be less likely to meet the cut off score on the Social Communication Questionnaire (SCQ) and that an autism diagnosis may be given earlier to children who displayed delayed toileting milestones (Dillon et al., 2021; Petrou et al., 2018). Research also suggests that the accuracy of the SCQ may be impacted by income, parental education, and parental race for both boys and girls (Moody et al., 2017; Rosenberg et al., 2019). These findings were further supported by a recent study that found girls who had delayed milestones, parents with higher education, and scored within the clinical range on Thought Problems and Attention Problems were more likely to meet the cut off score (Kniola et al., 2024).

Objectives: The purpose of the current study was to expand on the findings of Kniola et al., (2024) and examine how milestone development, demographics, and emotional/behavioral functioning influence whether boys and girls (ages 4 to 18) with a previous diagnosis of autism are captured by a commonly used Autism screening tool (Social Communication Questionnaire: SCQ). We hypothesized that autistic individuals with fewer developmental delays, whose parents have lower education or are Black or Multiracial would be more likely to receive lower SCQ scores below the cutoff. Further, those with more symptoms of Withdrawal/Depression, Social Problems, Thought Problems, and Attention Problems on the (Child Behavioral Checklist: CBCL) would be more likely meet the SCQ cutoff.

Methods: A subset of participants enrolled in a large national cohort (SPARK) were included (40,174 autistic individuals, male = 31,460, female = 8,741). A cutoff score on the SCQ of 11 was used to form groups: Meet (M: 91.1% for males, 87.1% for females) and Not Meeting (NM: 8.9% for males, 12.9% for females).

Results: Autistic females were less likely than males to meet the cutoff. Autistic individuals who had delayed toileting and motor milestones and whose parent's attained higher education were more likely to meet the cutoff. Individuals who scored within the clinical range on the CBCL Thought Problems and Attention Problems syndrome scales were more likely to meet the cutoff. Race and reported symptoms on the Withdrawn/Depressed and Social Problems syndrome scales did not relate to meeting the cutoff for females. However, autistic males whose parents reported clinical symptoms on the Withdrawn/Depressed and Social Problems syndrome scales were more likely to meet the cutoff. Lastly, males who were white were less likely to meet the cutoff.

Conclusions: Results highlight the differences in presentation between males and females. The results also suggest that boys who present with typical symptoms may also be missed during the screening process based on race. Future research should examine additional factors that put children at a disadvantage for being accurately identified, which could impact access to early intervention services and future skill development.

411.168 Differential Item and Test Functioning of the Autism Diagnostic Interview-Revised across Race and Ethnicity in Preschool Age Children

B. Barger¹, E. Moody², **N. Reyes³**, S. Rosenberg⁴, C. Robinson Rosenberg⁵, R. Pretzel⁶, R. Grzadzinski⁷, C. Nadler⁸ and C. DiGuseppi⁹, (1)Georgia State University, Atlanta, GA, (2)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (3)University of Colorado, Anschutz Medical Campus, Aurora, CO, (4)University of Colorado Anschutz Medical Campus, Aurora, CO, (5)University of Colorado / JFK Partners, Aurora, CO, (6)University of North Carolina - Chapel Hill, Chapel Hill, NC, (7)Carolina Institute for Developmental Disabilities, Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (8)Children's Mercy Kansas City, Kansas City, MO, (9)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO

Background:

The Autism Diagnostic Interview-Revised (ADI-R) is a standardized parent interview widely used to assess the presence of autism spectrum disorder (ASD) traits. To date, no large-scale comparative psychometric analyses of the ADI-R across racial and ethnic groups have been conducted.

Objectives:

To investigate differential item functioning (DIF) and differential test functioning (DTF) of non-Hispanic White (NHW) vs. non-Hispanic Black (NHB) and Hispanic children on the ADI-R. Data come from the Study to Explore Early Development, a large case-control study of children with ASD 30–68.9 months old.

Methods:

Children completed an evaluation to determine study group status and developmental functioning. A two-step procedure was implemented to detect DIF and DTF: 1) likelihood-ratio χ^2 tests conducted sequentially to identify differential probabilities between NHB-NHW and Hispanic-NHW item endorsements for each ADI-R domain with all other items set as “anchors” and 2) items with $p_{B-H} < .05$ indicating DIF were then allowed to vary with all non-significant items set as anchors. Racial-ethnic differences were interpreted using Cohen’s d criteria: negligible, $d < .2$; small, $d \geq .2$ and $< .5$; moderate, $d \geq .5$ and $< .8$; and large, $d \geq .8$.

Results:

2,670 participants had ADI-R data of whom 1691 were NHW, 810 NHB, and 394 Hispanic.

NHW vs. NHB: No items on the *Communication* domain displayed DIF. Three items on the *Social* domain displayed DIF: 53 (shares; $d = 0.28$; small), 55 (offers comfort; $d = 0.25$; small), and 31 (uses others body to communicate; $d = 1.61$; large DIF) *large*. Three items on the *Restricted and Repetitive Behaviors (RRB)* domain displayed DIF: 69 (repetitive behaviors/interests; $d = 0.48$; small), 70 (compulsions/rituals; $d = 0.41$; small), and 71 (unusual sensory interests; $d = 0.72$; moderate). DTF was negligible for the *Communication* ($d = 0.03$) and *Social* ($d = -0.04$) domains and small for the *RRB* ($d = 0.28$) domain.

NHW vs. Hispanic: No items on the *Communication* domain displayed DIF. Two items on the *Social* domain displayed DIF: 31 (uses others body to communicate; large DIF) and 55 (offers comfort; small DIF). One item on the *RRB* domain displayed DIF: 70 (compulsions/rituals; small DIF). DTF was negligible for all scales ($d = 0.01, d = 0.01$, and $d = 0.09$, respectively).

Conclusions:

Compared to NHW children. Both NHB and Hispanic children showed large item-level differences on using others’ body to communicate. It is unclear why this item performed so differently across groups and warrants consideration. Regardless, DTF was mostly negligible and suggest that the ADI-R performs similarly across racial-ethnic groups. Findings can be used by clinicians to consider the equity of the ADI-R when diagnosing children with ASD and determining their treatment needs.

411.169 Differential Item and Test Functioning of the Autism Diagnostic Observation Schedule – Second Edition (ADOS-2) across Race and Ethnicity in Preschool Age Children

B. Barger^a, E. Moody^a, N. Reyes^a, S. Rosenberg^a, C. Robinson Rosenberg^a, R. Pretzel^b, R. Grzadzinski^c, C. Nadler^a and C. DiGuseppi^b, (1)Georgia State University, Atlanta, GA, (2)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (3)University of Colorado, Anschutz Medical Campus, Aurora, CO, (4)University of Colorado Anschutz Medical Campus, Aurora, CO, (5)University of Colorado / JFK Partners, Aurora, CO, (6)University of North Carolina - Chapel Hill, Chapel Hill, NC, (7)Carolina Institute for Developmental Disabilities, Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (8)Children's Mercy Kansas City, Kansas City, MO, (9)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: The Autism Diagnostic Observation Schedule–Second edition (ADOS-2) is a standardized child observation used to assess the presence of autism spectrum disorder (ASD) traits. To date, few large-scale comparative psychometric analyses of the ADOS-2 across racial and ethnic groups have been conducted.

Objectives:

To investigate differential item functioning (DIF) and differential test functioning (DTF) of non-Hispanic White (NHW) vs. non-Hispanic Black (NHB) and Hispanic children on ADOS-2 modules 1/2. Module 1 was designed for children with no/some words. Module 2 was designed for children with phrase speech. Data come from the Study to Explore Early Development, a large case-control study of children with ASD 30–68.9 months old.

Methods:

Children completed an evaluation to determine study group status and developmental functioning. A two-step procedure was used to detect DIF/DTF: 1) likelihood-ratio χ^2 tests were conducted sequentially to identify differential probabilities between NHW-NHB and NHW-Hispanic item endorsements with all other items set as “anchors” and 2) items with $p < .05$ indicating DIF were then allowed to vary with all non-significant items set as anchors. Racial-ethnic differences were interpreted using Cohen’s d criteria: negligible, $d < .2$; small, $d \geq .2$ and $< .5$; moderate, $d \geq .5$ and $< .8$; and large, $d \geq .8$.

Results:

1,784 participants had ADOS-2 data of whom 883 were NHW, 607 NHB, and 294 Hispanic.

NHWvs.NHB

Module 1: One item on the *Social-Affect* domain displayed DIF: B-10 (joint attention; $d = 0.41$; small). No items on the *RRB* domain displayed DIF. DTF was negligible for both scales ($d = 0.02$ and $d < 0.01$, respectively).

Module 2: One item on the *Social-Affect* scale domain DIF: A-6 (pointing; $d = 0.63$; moderate). No items on the *RRB* domain displayed DIF. DTF was negligible for both scales ($d = 0.05$ and $d = 0.03$, respectively).

NHWvs.Hispanic

Module 1: Three items on the *Social-Affect* domain displayed DIF: A-2 (frequency of vocalizations ; $d = 0.36$; small), B-4 (integration of gaze ; $d = 0.26$; small), and B-10 (joint attention; $d = 0.37$; small). Two items on the *RRB* domain displayed DIF: D-1 (unusual sensory interests; $d = 0.38$; small) and D-2 (complex mannerisms; $d = 0.31$; small). DTF was negligible for both scales ($d = 0.05$ and $d = 0.07$, respectively).

Module 2: One item on the *Social-Affect* domain displayed DIF: A-6 (pointing; $d = 0.58$; moderate). No items on the *RRB* domain displayed DIF. DTF was negligible for both scales ($d = 0.08$ and $d = 0.07$, respectively).

Conclusions:

Compared to NHW children, both NHB and Hispanic children showed small differences on Module 1 initiation of joint attention, and moderate differences on Module 2 pointing. These differences warrant consideration. Regardless, DTF was negligible and suggest that overall, the ADOS-2 performs similarly across racial-ethnic groups. Findings can be used by clinicians to consider the equity of the ADOS-2 when diagnosing children with ASD and determining their treatment needs.

411.170 Differential Item and Test Functioning of the Social Responsiveness Scale – Second Edition (SRS-2) across Race and Ethnicity in Preschool Age Children

E. Moody¹, B. Barger², C. Nadler³ and N. Reyes⁴, (1)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (2)Georgia State University, Atlanta, GA, (3)Children's Mercy Kansas City, Kansas City, MO, (4)University of Colorado, Anschutz Medical Campus, Aurora, CO

Background: The Social Responsiveness Scale – Second edition (SRS-2) is a standardized parent-report questionnaire used to screen for autism spectrum disorder (ASD) traits. To date, no large-scale comparative psychometric analyses of the SRS-2 across racial and ethnic groups have been conducted.

Objectives: To investigate differential item functioning (DIF) and differential test functioning (DTF) of non-Hispanic White (NHW) vs. non-Hispanic Black (NHB) and Hispanic children on the SRS-2. Data come from the Study to Explore Early Development, a large case-control study of ASD in children 30–68.9 months old.

Methods: Children completed an evaluation to determine study group status and developmental functioning. A two-step procedure was implemented to detect DIF and DTF: 1) likelihood-ratio χ^2 tests were conducted sequentially to identify differential probabilities between NHW-NHB and NHW-Hispanic item endorsements for each scale with all other items set as “anchors” and 2) items with $p < .05$ indicating DIF were then allowed to vary with all non-significant items set as anchors. Racial-ethnic differences were interpreted using Cohen’s d criteria: negligible, $d < .2$; small, $d = .2$ and $< .5$; moderate, $d = .5$ and $< .8$; and large, $d \geq .8$.

Results:

5,868 participants had SRS-2 data of whom 3,682 were NHW, 1,385 NHB, and 801 Hispanic. See Table 1 for additional demographic and descriptive information.

Racial-ethnic differences are presented for items that showed moderate to large DIF.

NHW vs. NHB: Three of 65 items (4.6%) on the *Total* scale displayed DIF: one large (separates easily from caregivers) and two moderate (focuses attention and overly suspicious of others). Four items on the *Social-Awareness* domain displayed moderate DIF (aware of others, focuses attention, mis-matched facial expressions, and reacts to people as objects). One item on the *Social-Cognition* domain displayed moderate DIF (overly suspicious of others). One item on the *Social-Communication* domain displayed moderate DIF (overly serious facial expressions). One item on the *Social-Motivation* domain displayed large DIF (separates easily from caregivers). None of the items on *Autistic-Mannerisms* domain displayed moderate or large DIF. Overall, DTF was negligible or small for the total scale and each of the five domains.

NHW vs. Hispanic: Two of 65 items (3.1%) on the *Total* scale displayed large DIF (overly suspicious of others and separates easily from caregivers). One item on the *Social-Awareness* domain displayed moderate DIF (doesn’t mind being out-of-step with others). One item on the *Social-Cognition* domain displayed large DIF (overly suspicious of others). No items on the *Social-Communication* domain displayed moderate or large DIF. One item on the *Social-Motivation* domain displayed large DIF (separates easily from caregivers). No items on *Autistic-Mannerisms* domain displayed moderate or large DIF. Overall, DTF was negligible for the total scale and each of the five domains.

Conclusions: Compared to NHW children, both NHB and Hispanic children showed moderate to large item-level differences on being overly suspicious of others and separating easily from caregivers. These differences warrant consideration. Regardless, DTF was negligible and suggest that overall, the SRS-2 performs similarly across racial-ethnic groups. Findings can be used by clinicians to consider the equity of the SRS-2 when screening children for ASD.

411.171 Discrepancies between Clinician and Caregiver Ratings of Autism-Related Behaviors

A. S. Kolios¹, J. A. Benson², J. Pandey³, L. Green Snyder⁴, Z. Algaze⁵, E. M. Butter⁶, G. Caprara⁷, P. Feliciano⁷, A. Gulsrud⁸, J. F. Harris⁹, R. P. Goin-Kochel¹⁰, R. Landa¹¹, L. Shulman¹², E. Wodka¹¹, R. Young⁴, C. Klaiman¹³ and S. Consortium¹, (1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Emory University, Atlanta, GA, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Simons Foundation, New York, NY, (5)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (6)Nationwide Children's Hospital/Ohio State University, Columbus, OH, (7)Department of Pediatrics, Boston Children's Hospital, Boston, MA, (8)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (9)Children's Specialized Hospital, Mountainside, NJ, (10)Baylor College of Medicine, Houston, TX, (11)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (12)546 Wilmerding Ave., Bronx, NY, (13)Emory University/Marcus Autism Center, Atlanta, GA

Background: Parents' concerns regarding their child's development are a key component of clinical evaluations for autism spectrum disorder (ASD), informing clinicians of a child's symptoms across time and contexts. Since early diagnosis is a key predictor of better cognitive outcomes (Clark et al., 2018), it's imperative that we consider parent-clinician agreement in this window of time. However, several studies have highlighted informant discrepancies in ASD symptomatology ratings (e.g. Lerner et al., 2012; Jordan et al., 2019). In a recent paper, Azu et al. (2024) found that caregivers of 6-11-year-olds rated autism-related symptoms higher for males than females compared to clinicians, and that overall caregiver-clinician discrepancy was correlated with age of diagnosis and intervention hours.

Objectives: To further understand the role of parental reports in the early diagnosis of autism, we aim to assess clinician-caregiver discrepancy and external factors which may influence this discrepancy in a sample of children diagnosed between two and twelve years of age.

Methods: Analyses were conducted using data from 737 children in the SPARK cohort, all of whom were diagnosed with ASD. Participants were selected if they had completed an Autism Diagnostic Observation Schedule (ADOS-2), Social Communication Questionnaire (SCQ), and demographic surveys. Spearman's rank correlation coefficients were used to assess relationships between ADOS-2 and SCQ scores. Analyses were divided into two age groups: 2-5 years (24-72mos) and 6-11 years (72-144mos). A clinician-caregiver discrepancy variable was created by subtracting the z-scores of SCQ total scores from ADOS CSS z-scores. Wilcoxon rank-sum tests and Kruskal-Wallis tests compared discrepancies by gender and parent-reported cognitive level and support needs, while Spearman correlations examined associations between discrepancies and sex, age of diagnosis, age of first concern, and delay between first concern and diagnosis.

Results: Across age groups, ADOS-2 CSS scores and SCQ final scores had a significant, positive correlation. Clinician-caregiver discrepancy did not differ by gender or age of diagnosis in either group. Later-reported first concerns were associated with greater clinician-caregiver discrepancy in the 6-11 group, with clinicians rating symptom severity as greater than caregivers. Trending in the opposite direction, a greater delay between first concern and diagnosis was related to lower clinician ratings relative to caregiver ratings in both groups. Clinician-caregiver discrepancies were also associated with parent-estimated cognitive level and support needs, such that higher support needs and lower cognitive level groups received significantly lower clinician symptom ratings relative to caregiver ratings.

Conclusions: The caregiver-clinician dyad makes a critical team in the autism diagnostic journey. While the clinician completes well-validated assessments, parents fill in gaps of behaviors and symptomatology otherwise not seen within a clinic setting. Our findings suggest that in cases where parents note first concerns later, they may be underreporting symptoms. In cases that are confounded by possible co-occurring conditions, clinicians may be rating autism-specific symptom severity lower than scores generated by a standardized parent questionnaire. More work is needed to better understand parent-clinician discrepancies and how we can improve our clinician-administered and parent-report tools to ensure we are getting a holistic picture of the child.

411.172 Discrepancy between Frequency and Functional Impact of Autistic Features As Assessed By the Autism Impact Measure: Associations with Child and Family Characteristics

Y. J. Chen^{1,2}, E. Duku¹, C. Roncadin³, A. D'Angiulli⁴, V. Lee⁵, A. Kata¹, T. Bennett¹, A. Hanlon-Dearman⁶, J. Lai⁷, D. Singal⁷, L. Zwaigenbaum⁸ and S. Georgiades¹, (1)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (2)Department of Occupational Therapy and Graduate Institute of Behavioral Sciences, Chang Gung University, Taoyuan, Taiwan, (3)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (4)Department of Neuroscience, Carleton University, Ottawa, ON, Canada, (5)Department of Psychology, Carleton University, Ottawa, ON, Canada, (6)Department of Pediatrics & Child Health, University of Manitoba, Winnipeg, MB, Canada, (7)Autism Alliance of Canada, North York, ON, Canada, (8)University of Alberta, Edmonton, AB, Canada

Background: Autistic features have traditionally been assessed by behavioral frequency alone, which may not accurately reflect their impact on daily-life functioning (Kanne et al., 2014). The recently developed parent-reported questionnaire, the Autism Impact Measure (AIM), allows for evaluating both behavioral frequency and functional impact of autistic features. However, evidence on how well these two aspects align or differ in assessing needs related to autistic features remains limited. Identifying ‘protective’ factors linked to limited functional impact despite the frequency of autistic features can have important clinical implications.

Objectives: Using parent-reported data from the baseline of Pediatric Autism Research Cohort study—a Canadian prospective study involving children diagnosed with autism at ages 2 to 7 (N=279), this study aimed to: 1) estimate the discrepancies between behavioral frequency and functional impact across five AIM constructs (Repetitive Behavior, Atypical Behavior, Communication, Social Reciprocity, and Peer Interaction); 2) identify child and family characteristics associated with frequency-impact discrepancies for each AIM construct.

Methods: Twenty-nine AIM items that have demonstrated superior psychometric validity in previous research (Mazurek et al., 2020) were used for the current analyses. A latent difference model with partial scalar invariance across frequency and impact scales (see Figure 1 for model specification) was used to derive latent estimates of frequency-impact discrepancies ($\Delta\text{Imp-Freq}$) for each AIM construct separately. Child characteristics (age and sex assigned at birth) and family characteristics (primary caregiver’s education level, race/ethnicity, and household income) were included to examine their associations with frequency-impact discrepancies.

Results: On average, the latent difference estimates of frequency-impact discrepancies were significantly below 0 ($\Delta\text{Imp-Freq} = -.194$ to $-.585$, all $p < .001$), indicating that parents generally rated functional impact lower than behavioral frequency across AIM constructs. As shown in Figure 2, these $\Delta\text{Imp-Freq}$ estimates are highly variable (all variance parameters $p < .001$), with Social Reciprocity showing the greatest variability among all AIM constructs, whereas Communication showed a closer alignment between frequency and functional impact ratings. Older children tended to show more frequent atypical behaviors ($\beta = .190$, $p = .009$) but fewer social-communication difficulties ($\beta = -.181$ to $-.322$, all $p < .01$). Higher caregiver education and older child age were associated with greater $\Delta\text{Imp-Freq}$ estimates in repetitive/atypical behavior and communication difficulties ($\beta = .170$ to $.354$, all $p < .05$), while higher household income was associated with lower $\Delta\text{Imp-Freq}$ estimates in atypical behavior ($\beta = -.276$, $p = .003$). Neither child’s sex nor caregiver’s race/ethnicity was associated with frequency or frequency-impact discrepancy.

Conclusions: Our findings revealed substantial individual variability in the discrepancies between behavioral frequency and functional impact of autistic features during early childhood, particularly in social-reciprocity challenges, where the functional impact may be more contextually dependent than other autistic features. Older children showed greater functional impacts than expected based on frequency, likely due to increasing environmental demands. Higher household income may play an indirect role in buffering the functional impact of behavioral challenges, while higher-educated caregivers might have heightened expectations or be more attentive to how their child’s autistic features impact daily life. Our results highlight the importance of further research in developing family-centred, tailored strategies to foster autistic children’s resilience toward daily-life challenges associated with autistic features.

411.175 Early Identification of Autism in Toddlers with Early Medical Risk through Integrated Specialty Clinic

E. Pompan¹, M. Picoto¹, V. K. Ma², R. Stewart¹ and C. Silver³, (1)University of California Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND institute, Sacramento, CA, (3)MIND Institute and Department of Pediatrics, University of California, Davis, Sacramento, CA

Background: Toddlers with early medical risk due to pre-term delivery, low birth weight, or conditions requiring Neonatal Intensive Care Unit (NICU) stays are more likely to be identified with a neurodevelopmental condition as compared to healthy infants with term-birth (Davis et al., 2023). Approximately 7% of pre-term infants are later diagnosed with autism (Agrawal et al., 2018), compared to 2.7% in the general population (CDC, 2020). The average time from autism screening to evaluation in the United States is over two years (Chen et al., 2023), delaying access to early intervention. Identification of autism in toddlers with early medical risk can be further complicated by screening measure limitations and overshadowing by co-occurring developmental and medical conditions (Guy et al., 2015; McDonald & Jeste, 2022). Current care models for infants with medical risk include primary care pediatrics, subspecialty, and multi-disciplinary care, such as through High-Risk Infant Follow-up clinics (HRIF; Litt & Campbell, 2023). Emerging evidence suggests autism screening and evaluation in the context of HRIF using an integrated specialty care model results in earlier identification of autism (Raches et al., 2024).

Objectives: This study examines the effectiveness of autism screening and surveillance in an HRIF clinic and referral to integrated ‘fast-track’ autism evaluation clinic for reducing time to diagnosis in toddlers with early medical risk.

Methods: A retrospective chart review will be conducted of patients seen by a multi-disciplinary HRIF clinic and referred for autism evaluation following elevated screening or surveillance. Autism screening results, percentage of autism diagnoses, time from referral to evaluation, and age at diagnosis will be evaluated. Findings will be compared before and after the addition of a fast-track autism evaluation clinic within the developmental pediatrics department, and to national averages.

Results: Preliminary findings are reported. 50 patients were referred to fast-track autism evaluation clinic from an HRIF clinic. Of these patients, 27 were seen in fast-track clinic for autism evaluation (54%), 11 pending upcoming visit or scheduling (22%), 5 did not attend evaluation appointments (10%), 2 were diagnosed during regular HRIF visit (4%), 2 in other clinics (4%), and 3 declined referral (6%). Of the 31 patients evaluated for autism, 22 received an autism diagnosis (71%). Average time from referral to evaluation in fast-track clinic was 4.1 months and age at evaluation was 31.9 months-old, compared to national averages of 26.9 months wait and 48 months-old, respectively (Chen et al., 2023).

Conclusions: Conducting autism screening and surveillance in HRIF may reduce barriers to early identification, despite limitations of screening measures for these infants. An integrated specialty care model with referral to fast-track autism evaluation clinic yielded lower wait times and age at diagnosis than national averages. Some families declined or did not attend the autism evaluation appointments or received diagnoses in other clinics. Multiple pathways for autism screening and evaluation may be important for improving early identification and access to intervention for toddlers with early medical risk.

411.176 Emotion Dysregulation Predicts Impairments in Peer Interaction and Adaptive Functioning in Kindergartners with ASD

Y. Shin¹ and S. H. Kim², (1)School of Psychology, Korea University, Seoul, Seongbuk-gu, Korea, Republic of (South), (2)School of Psychology, Korea University, Seoul, Seoul, Korea, Republic of (South)

Background: Emotional Dysregulation (ED) refers to difficulties in using adaptive strategies to modulate emotional arousal and express it in socially appropriate ways (Gross et al., 2014). Early studies mainly focused on how ED affects comorbid mental health outcomes such as anxiety, depression and aggressive behavior in adolescents and adults with ASD. However, ED has been suggested to play a key role in prosocial skills and adaptive functioning in autistic children (Berkovits et al., 2017). Despite the emerging importance of ED as a factor influencing various early childhood developmental milestones, few studies have examined the relation between ED and peer engagement and everyday adaptive functioning in young children with ASD.

Objectives: This longitudinal study aims to understand whether categorical and continuous profile of ED at kindergarten-entry(T1) based on a widely used parent report, the Child Behavioral Checklist (CBCL), significantly predicts peer play skills and adaptive functioning in autistic children at kindergarten-entry(T1) and -exit(T2).

Methods: Participants included 74 children with ASD aged 52-79 months at T1 (Mage = 63.24 months, SDage = 5.08; 18 females) and 65-87 months at T2 (n=60, Mage = 72.48, SDage = 4.41). Caregivers completed the Child Behavior Checklist (CBCL) at T1, the Penn Interactive Peer Play Scale (PIPPS) and the Vineland Adaptive Behavior Scales-3 (VABS-3) at both T1 and T2. Furthermore, the severity of ED was measured based on the CBCL Depression Profile (CBCL-DP; Althoff et al., 2010) and CBCL Emotion Dysregulation Index (CBCL-EDI; Samson et al., 2014). The CBCL-DP is classified into three levels: typical (t-score below 180), moderate (t-score 181-209), and severe (t-score above 210). The CBCL-EDI ranges from 0 to 36 using a subset of items on the CBCL, with higher scores indicating more severe ED. Hierarchical linear regression was conducted after controlling for age, gender, and NVIQ to analyze whether ED assessed at T1 significantly predicts autistic kindergarten's concurrent(T1) and future(T2) peer interactions using the PIPPS T-scores (i.e., Play Disconnection, Play Disruption, Play Interaction) and Vineland Standard scores (i.e., Communication, Socialization, Daily Living Skills). In addition, one-way ANOVA was used to compare significant mean differences in the PIPPS and Vineland scores among the three CBCL-DP classifications.

Results: Hierarchical linear regression revealed that T1 CBCL-DP classifications and CBCL-EDI scores significantly predicted most domains of PIPPS and VABS-3 at T1 (all p 's<.001) except for the CBCL-EDI for Play Interaction (p =.084). For the longitudinal prediction, T1 CBCL-EDI scores significantly predicted all domains of PIPPS and Socialization of Vineland at T2 (all p 's<.001). T1 CBCL-DP classifications significantly predicted all Vineland domains and Play Interaction of PIPPS at T2 (all p 's<.01). There was a significant mean difference in Play Disruption both at T1 ($F(2, 70) = 16.26, p<.001$) and T2 ($F(2, 58) = 20.96, p<.001$) across three CBCL-DP categorical groups.

Conclusions: This research demonstrates a cascading effect of ED that continues to affect the quality of peer engagement and adaptive functioning in kindergarteners with ASD. Therefore, targeting ED even before school-entry can help maximize important functional outcomes, such as peer engagement and adaptive functioning during school transition.

411.177 Enhancing Autism Diagnostic Capacity in Bolivia Using an Echo Model

M. DuBay¹, P. Sarmiento², I. Lazarte³, H. Sans⁴ and S. Dorado⁵, (1)University of Virginia, Charlottesville, VA, (2)Serendipia, Cochabamba, Cochabamba, Bolivia (Plurinational State of), (3)Centro de Atención Múltiple María Yolanda CAMMY, Cochabamba, Cochabamba, Bolivia (Plurinational State of), (4)Cochabamba, Cochabamba, Bolivia (Plurinational State of), (5)Sombreritus, Tarija, Tarija, Bolivia (Plurinational State of)

Background:

One direct pathway to diagnosis involves recognition of early symptoms and referral for a developmental evaluation with a highly-trained medical professional. In low- and middle-income countries (LMICs), limits in public awareness of ASD symptoms, financial restraints, and professional capacity impede this pathway (Bhavnani et al., 2022; Jaen-Varas et al., 2014; Montenegro et al., 2022). In Bolivia, a LMIC in South America, there is no standardization for referrals, extreme geographic dispersion, few pre-professional programs, and a shortage of highly trained diagnosticians (Divan et al., 2021; Jaen-Varas et al., 2014). The pathway from recognition of symptoms to referral and diagnosis is tenuous in Bolivia for many families, resulting in extremely lengthy delays in identification and in connection to therapeutic supports.

Virtual professional development is a promising strategy to enhance diagnostic capacity across geographic distances. The ECHO framework (Extension for Community Healthcare Outcomes) provides training to professionals across geographic distances, improving care for various medical conditions, including ASD (Sanjeev et al., 2016; Sohn 2022; Mazurek 2017). Owing to its cost-effectiveness, virtual platform, and adaptability to diverse cultural contexts, ECHO has successfully increased ASD diagnostic capacity in multiple LMIC settings (Sungupta 2022; Giachetto 2019).

Objectives:

This project aimed to identify a means of enhancing the diagnostic pathway from recognition of symptoms to receipt of diagnosis in Bolivia using an ECHO professional development program.

Methods:

Diagnosticians (n=93 providers credentialed to give ASD diagnoses in Bolivia completed pre- and post-surveys on their ASD competence and confidence and attended 10 monthly ECHO sessions. Sixteen also completed post-interviews. Referring individuals were those who could provide referrals for diagnostic evaluations. Several hundred registered for one of two live webinars (n = 38 and 58 respectively), and four completed post-interviews. All participants were recruited via social media ads targeted to healthcare and educational professionals.

Each ECHO session included community building time, a didactic presentation on ASD evaluation, and a case presentation: one diagnostician described a patient's evaluation procedures and results, and received recommendations from group members. The ECHO hub team, four Bolivian ASD experts and the first author, facilitated the sessions and providing expert support. A final session with diagnosticians and referring individuals promoted local referring networks.

Results:

Surveys results indicated that diagnosticians' ASD competence ($p<.05$) and self-efficacy in ASD evaluations ($p<.05$) increased following the ECHO. Diagnosticians perceived a reduction in barriers ($p<.001$), and an increase in their professional networks ($p<.001$). Diagnosticians were also administering more ASD screening tools and diagnostic assessments ($p<.05$), and were referring for intervention supports more often ($p<.001$) following the ECHO. Interviews with diagnosticians and referring individuals will be analyzed qualitatively using a grounded theory approach. Preliminary results indicate an increase in valid accessible evaluation procedures, an increase in referrals, and a reduction in barriers related to professional capacities, but major remaining barriers is the systems of care and financial constraints.

Conclusions:

The ECHO methodology offers promise for increasing professional capacity for ASD care in LMIC. Potential for sustainability should be explored to maximize benefit.

411.178 Establishing Measurement Invariance of the Promis Depressive Symptoms Scale across Teen Self-Report and Parent Proxy Report

R. M. Benecke¹, L. Graham Holmes², J. S. Miller¹ and E. A. Kaplan-Kahn³, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Silberman School of Social Work, Hunter College, CUNY, New York, NY, (3)Center for Autism Research, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Autism research often assumes that parent proxy report and self-report can be treated as equivalent, even when measuring subjective constructs like depression. In order to treat such scores as equivalent, researchers must first establish that the scale measures the same construct in the same way across both groups, which can be done by assessing measurement invariance. The Patient-Reported Outcomes Measurement Information System (PROMIS) Depressive Symptoms scale has been soundly validated to measure depression in autistic adolescents, having previously demonstrated scalar invariance between the general population and autistic teens (Kaplan-Kahn et al., 2024); however, the question remains whether teen self and parent proxy report can be compared.

Objectives: Determine whether the PROMIS Depressive Symptoms scale demonstrates measurement invariance across autistic teen (14-17) self-report and parent proxy report.

Methods: We evaluated the pediatric self-report (Irwin et al., 2010) and parent proxy report (Irwin et al., 2012) short forms of the PROMIS Depressive Symptoms scale. Only items included in both versions of the scale were included in analyses. We conducted secondary CFAs on data from 139 parent-autistic teen dyads (Graham Holmes et al., 2020), using the lavaan package in R (Rosseel, 2012). After determining satisfactory fit for a unidimensional CFA model applied to separate and combined groups, we evaluated measurement invariance using multi-group confirmatory factor models. Levels of invariance assessed included configural (equality of structures), metric (equality of loadings), and scalar (equality of intercepts). Rather than relying on arbitrary cutoffs for determining “significant” non-invariance at each level, we utilized permutation testing with the semTools package in R, randomizing group assignment to obtain empirical distributions for fit indices (Jorgensen et al., 2018). Our analysis tested whether equivalent scores on the scales imply equal levels of the construct as reported by parents and teens. Additionally, we evaluated reliability using Cronbach’s alpha and used a t-test to check for group differences.

Results: Invariance was determined based on nonsignificant chi-squared and Comparative Fit Index (CFI) values under permutation testing (p -values $> .01$). The Depressive Symptoms model demonstrated configural, metric, and scalar invariance across groups (Table 1). Reliability was high across both groups and there was no significant difference in group t-score means (Table 2).

Conclusions: Because the PROMIS Depressive Symptoms scale demonstrates scalar invariance across parent proxy and teen self-report, researchers can confidently use this scale with both autistic teens and their parents, including meaningfully comparing scores between groups. Our study shows that autistic teens and their parents report depression at similar levels. Our finding allows researchers to ask the same questions of both autistic teens and their parents, allowing for triangulating responses and broadening the research population to include teens who may not be able to accurately self-report.

411.179 Evaluating the Agreement across Common Measures of Core Autism Symptoms

E. Waizbard^a, G. Or^a, E. Ferrer^a, B. Heath^a, S. J. Rogers^a, C. W. Nordahl^a, M. Solomon^a, D. G. Amaral^a and I. Dinstein^a, (1)Psychology, Ben-Gurion University of the Negev, Beer Sheva, Israel, Israel, (2)Ben Gurion University of the Negev, Beer Sheva, Israel, Israel, (3)UC Davis, Davis, CA, (4)Department of Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (5)Department of Psychiatry and Behavioral Sciences, University California Davis, Sacramento, CA, (6)Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel

Background: Different measures for autism symptoms are based on distinct sources of information and assessment procedures. The Autism Diagnostic Observation Schedule (ADOS) (Lord et al., 2012), measures symptoms in a specific, diagnostic situation where an individual interacts with an adult assessor. The Autism Diagnostic Interview-Revised (ADI-R) (Lord et al., 1994) measures symptoms through a structured parent interview administered by an assessor. The Social Responsiveness Scale (SRS) measures symptoms with a relatively short parent questionnaire. Many studies evaluating autism symptoms use one of these measures, often implicitly assuming that they measure the same construct. Recent reports, however, have shown modest correlations across their scores (Putnam et al., 2024; Ratto et al., 2018).

Objectives: To assess the agreement across autism symptom severity levels estimated by four measures listed below in the same children, while also separating severity scores for the social-communication and the restricted and repetitive behavior (RRB) domains. We also perform a factor analysis to determine whether a common factor for autism symptoms can be extracted across measures.

Methods: Seven-hundred and fifteen 2-to-5-year-old autistic children were evaluated from two cohorts: 1) the University of California, Davis MIND Institute Autism Phenome Project cohort, and 2) the Simons Simplex Collection cohort. Children were evaluated using four measures: ADOS-2 (clinician observation), ADI-R (clinician-administered parent interview), SRS (Constantino, 2002) (parent questionnaire) and Repetitive Behaviors Scale-Revised (RBS-R) (Bodfish et al., 2000), (parent questionnaire). First, we evaluated correlations between pairs of measures to quantify their agreement in estimating symptom severity per child. Second, we conducted a Factor Analysis to evaluate if a common factor for autism symptoms exists across measures. We performed both analyses separately for overall, RRB, and social-communication severity.

Results: The correlations analysis showed that symptom severity levels assessed by measures based on parental interviews and questionnaires (ADI, SRS, and RBS) exhibited medium-to-medium-high associations ($0.63 > r > 0.47$) when examining the respective overall, RRB, and social-communication severity scores across measures (Figure 1). In contrast, ADOS scores showed considerably weaker associations with the three other (parent-report based) measures, especially with parent questionnaires ($0.26 > r > 0.04$). The factor analysis demonstrated that models with one latent factor that includes all measures showed the best fit to the data, for overall, RRB, and social-communication severity. Factor loadings, however, differed across measures (Table 1). Loadings for the ADI, SRS and RBS-R ranged from medium-to-high while loadings for the ADOS remained low across models. This demonstrated that most of the variance in ADOS scores cannot be explained by a common factor for autism symptoms.

Conclusions: Common measures for autism symptoms can yield different severity levels for the same child. Such gaps could result from methodological differences, i.e., relying on parent report / questionnaires vs clinician observation. Alternatively, they may capture real-world differences in how autism symptoms present (and measure) in various contexts, i.e., an assessment situation vs the home environment. It is essential to understand differences in the evaluation of autism symptoms using various standardized measures and how this impacts research and clinical work.

411.180 Evaluation of the Convergent Validity and Clinical Utility of the Social Communication Questionnaire–Lifetime (SCQ-L) in an Early Assessment Sample

E. Hong, T. Womack and J. Jang, Thompson Autism and Neurodevelopmental Center at CHOC Children's Hospital, Orange, CA

Background: Early identification of autism spectrum disorder (ASD) is critical for effective treatment planning and timely intervention, which is linked to enhanced social, cognitive, and language development outcomes (Kasari et al., 2012.; Whitehouse et al., 2021). Despite these benefits, current assessment methods for identifying ASD can be time-consuming and require extensive training, which may delay access to early intervention. Thus, it is important to identify psychometrically robust tools for the early detection of ASD. The Social Communication Questionnaire–Lifetime (SCQ-L; Berument et al., 1999; Rutter et al., 2003) is a brief, caregiver questionnaire based on the Autism Diagnostic Interview–Revised (ADI-R; Le Couteur et al., 1989) and is one of the most widely-used tools to screen for ASD in clinical settings (Barnad-Brak et al., 2016). Although some studies have shown that the SCQ-L total score had positive correlations with gold-standard autism assessments, such as the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2; Chandler et al., 2007, Corsello et al., 2007), more research is needed to understand the relationship between caregiver-reported symptoms of ASD and clinician-rated symptoms of ASD. In particular, research is warranted to determine if the SCQ-L is a valid screening tool for toddlers and young children with neurodevelopmental concerns.

Objectives: The purpose of the present study is to evaluate the convergent validity between the SCQ-L, a caregiver-reported screening tool, and the ADOS-2, a clinician-administered assessment measure. More specifically, convergent validity between the SCQ-L total score and subscale scores (i.e., Reciprocal Social Interaction, Communication, Stereotyped Patterns of Behavior) and the ADOS-2 overall score and subscale scores (i.e., Social Affect, Restricted and Repetitive Behavior) will be examined to investigate the relationship between these two measures.

Methods: Partial correlation analyses, while controlling for demographic variables (e.g., age, gender), will be used to examine convergent validity between the SCQ-L and ADOS-2. Secondary analysis will investigate differences in SCQ-L total and subscale scores between diagnostic groups (i.e., ASD group and non-ASD group).

Results: The study sample included 470 children between the ages of 2 and 6 years ($M = 4.55$, $SD = 1.88$, range = 2.23-6.98) who were referred to an outpatient autism clinic at a pediatric hospital. Caregivers of all participants completed the SCQ-L as part of the intake process. Of this sample, some participants completed a comprehensive diagnostic evaluation to assess for ASD and were administered the ADOS-2. Diagnoses included, but were not limited to, ASD, global developmental delay, intellectual developmental disorder, language disorder, unspecified neurodevelopmental disorder, and/or attention-deficit/hyperactive disorder.

Conclusions: Data collection and analysis are currently underway to evaluate the convergent validity between the caregiver-reported SCQ-L and the clinician-rated ADOS-2 for assessing ASD symptoms. If weak convergent validity is found, this finding may have implications regarding differences between caregivers' perception of ASD symptoms and ASD symptom severity. If strong convergent validity is found, this finding may further support the use of SCQ-L as a time- and cost-effective screening tool for toddlers and young children with neurodevelopmental concerns. Study results and implications for clinical practice will be discussed further.

411.181 Examination of Novel Short Forms of WISC-V Among a Clinical Sample of Children with Neurodevelopmental Disabilities

M. Wendel¹, A. S. Levine², E. M. Butter³ and K. G. Stephenson¹, (1)Nationwide Children's Hospital, Columbus, OH, (2)Child Development Center, Nationwide Children's Hospital, Columbus, OH, (3)Nationwide Children's Hospital/Ohio State Univers, Columbus, OH

Background: Assessing intellectual ability is an essential feature of diagnosis and treatment, especially among children with neurodevelopmental disorders like Autism Spectrum Disorder (ASD) and Intellectual Developmental Disorder (IDD; Hristova et al., 2017; Ozonoff et al., 2017). Over one-third of children with ASD also have an intellectual disability (Charman et al., 2010; Maenner et al., 2023) while many children with ASD have above-average intelligence. Assessment of intellectual ability ultimately aids in understanding a child and identifying appropriate supports. The Wechsler Intelligence Scale for Children (WISC) is the most common measure of intellectual ability for children (Egeland et al., 2016; Rabin et al., 2016). The WISC requires over an hour to administer (Wechsler, 2014). Children with ASD and other neurodevelopmental disabilities often have behavior regulation difficulties, and testing can be complicated by task avoidance, inattention, hyperactivity, and general testing fatigue (Matson & Nebel-Schwalm, 2005). For this reason, rapid cognitive assessments are preferred among clinicians for the ASD population (Coolican et al., 2008). Brief assessment of intelligence, and specifically brief versions of the widely used WISC-V, can facilitate efficient assessment.

Few studies have examined the validity of WISC-V short forms. Lace et al. (2022) examined a total of ten 5-subtest and 4-subtest short forms among a sample of 268 children and adolescents referred for psychological assessment. Various four-subtest short forms were found to be valid. Specifically, 65 - 70% of regression-based estimates and 69–76% of prorated estimates were within 5 Standard Score points of FSIQ. Other research has demonstrated valid four-subtest WISC short forms, including Spanish WISC-IV short forms (Dasi et al., 2014), among children with Epilepsy (Hrabok et al., 2014), and gifted children (Aubry & Bourdin, 2018). Since there may be differences in the validity of IQ tests in autistic individuals (Stephenson et al., 2021), investigation of a short-form of the WISC-V in neurodevelopmental conditions is needed.

Objectives: Examine short forms of the WISC-V compared to the FSIQ.

Methods: The sample includes 727 children referred for developmental assessments between 2010 and 2023 within a large pediatric hospital (78% male; 77% White, 11% Black, 7% Multiracial, 2% Hispanic/Latino; Mage=10.8 years, SDage=2.8 years). Following Aubry and Bourdin (2018), 11 4-subtest short forms were calculated using linear regression. Composite reliability coefficient (Aubry & Bourdin, 2018; Tellegen & Briggs, 1967) and corrected correlation coefficients were calculated (Aubry & Bourdin, 2018; Girard & Christensen, 2008) based on reliability and inter-correlations published in the WISC-V manual (Wechsler, 2016).

Results: All 11 short forms had high reliability and were significantly correlated to the FSIQ. Reliability estimates ranged from $r_{cc} = .94-.96$. The highest-performing short form included Vocabulary, Matrix Reasoning, Figure Weights, and Digit Span subtests, and had a strong relationship to FSIQ ($r' = .93$, $p < .01$).

Conclusions: The results indicate that short forms of the WISC-V may have high utility among children referred for developmental assessments. Regardless of the four-subtest combination, short-form scores are similar to FSIQ scores. Future research is needed to determine external validity of short forms, including how they may compare to other cognitive tests and long-term outcomes.

411.182 Examining the Relationship between Symptom Severity and Adaptive Functioning in Children and Adolescents with Autism

C. K. Toolan, Department of Child Development, California State University, Dominguez Hills, Carson, CA

Background:

Research exploring the relationship between autism symptom severity and adaptive behavior has been mixed. Some studies indicate a weak relationship between constructs (e.g., Kanne et al., 2011); others (e.g., Perry et al., 2009) show a strong negative relationship. While clinical descriptions often emphasize symptom severity, understanding adaptive functioning may be equally important for characterizing individual differences, strengths, and support needs.

This understanding becomes even more crucial as children face different challenges across development. Age may also influence severity and adaptive skills, but few studies have included samples spanning across age ranges. Most focus on narrow age bands (e.g., 2-4 years old: Szatmari et al., 2015), thus limiting our developmental understanding of this relationship.

Objectives:

Examine the relation between autism symptom severity and adaptive skills in a large sample of children and adolescents, across a range of severity levels, language ability, and ages.

Methods:

This study uses secondary data from SFARI, a clearinghouse of autism research data. Data was combined from the Simons Simplex Collection, SPARK dataset, and Autism Inpatient Collection. Participants with assessments completed across primary measures were included ($n=1942$).

The following variables were analyzed:

- (1) Autism severity: Calibrated Severity Scores from the ADOS-2 (clinician-rated observational diagnostic assessment)
- (2) Language level: Based on ADOS-2 module administered (preverbal/single words, phrase speech, and verbally fluent)
- (3) Adaptive behavior: Total Adaptive Behavior Composites from the Vineland Adaptive Behavior Scales (parent-rated questionnaire)

Results:

Correlations indicated adaptive behavior and autism symptom severity were weakly related overall ($r=-.127$, $p<.001$) and across language levels (preverbal/single words: $r=-.141$, $p=.008$, $n=356$; phrase speech: $r=-.267$, $p<.001$, $n=461$; verbally fluent: $r=-.100$, $p<.001$, $n=1125$).

ANOVA indicated age was associated with lower adaptive behavior scores ($B=-1.78$, $p<.001$), while accounting for severity and language ($F=428.119$; $p<.001$).

Conclusions:

This study builds on previous work by not only increasing sample size, but also by including children and adolescents across ages and language abilities to more broadly represent the autism spectrum. Results confirm a weak relationship between autism symptom severity and adaptive behavior across language ability, suggesting they are related yet distinct factors. Findings also support previous work indicating a negative association between age and adaptive behavior, regardless of severity or language level.

These results suggest that interventions focusing solely on reducing autism symptoms may not necessarily translate to improved adaptive outcomes. This reflects a broader shift toward supporting independence and quality of life in autistic individuals and their families, rather than focusing on symptom reduction alone. While autism is often characterized by symptom severity and language ability, these findings emphasize the importance of considering the whole person and their participation in daily life, which may be better captured through measures of adaptive behavior and well-being.

411.183 Exploring Clinician-Caregiver Discrepancy in Diagnostic Assessment: Results from a Community Sample

R. Bradley¹, M. R. Kilmer¹, E. Shah¹, A. P. Houck² and L. B. Quetsch¹, (1)University of Arkansas, Fayetteville, AR, (2)The University of Arkansas, Fayetteville, AR, (3)Stony Brook University, Stony Brook, NY

Background: Best practices in autism assessment encourage clinicians to consider children's behavior across a variety of contexts. Thus, clinicians often rely on caregiver report to support diagnostic conclusions. However, it is possible that caregivers and clinicians may provide discrepant assessment data, with emerging research identifying demographic factors (e.g., socioeconomic status, child race, child sex), age at diagnosis, and amount of intervention received as key factors associated with informant discrepancies. Notably, most research examining informant discrepancies has drawn on samples of children with preexisting autism diagnoses. However, discrepant reports from informants can reflect meaningful information about symptom presentations across settings and clinical trajectories. As such, informant discrepancy may be implicated in diagnosis and treatment planning. Understanding factors associated with clinician-caregiver informant discrepancies in a diagnostic setting may support clinical decision-making.

Objectives: This study expands on existing research by investigating the relationship between clinician-caregiver discrepancies in ratings of autism characteristics and various child (age, sex, race, ethnicity, adaptive functioning) and family factors (caregiver stress, socioeconomic status).

Methods: Participants were 52 children (M age = 6 years) presenting to a grant-funded, community-based autism diagnostic program in a Southern state. Caregivers completed a demographic questionnaire, the Perceived Stress Scale, the Vineland Adaptive Behavior Scales, and the Social Responsiveness Scale (SRS-2) as a part of their child's intake. Children were assessed with the Childhood Autism Rating Scale (CARS-2) as a part of their evaluation.

Results: A clinician-caregiver informant discrepancy score was derived by calculating a standardized difference score from clinician CARS-2 ratings and caregiver SRS-2 ratings. Wilcoxon rank-sum tests were conducted to examine clinician-caregiver discrepancy scores by child sex and insurance status (i.e., private insurance or Medicaid) as a proxy of socioeconomic status. Bivariate correlations were used to assess the relation between discrepancy score and child age, race, ethnicity, adaptive functioning, and caregiver perceived stress. Clinician-caregiver discrepancy was not significantly associated with child sex ($W = 101$, $p = 0.99$), insurance status ($W = 226$, $p = 0.48$), age ($r(43) = .18$, $p = 0.40$), or race and ethnicity ($r(43) = 0.08$, $p = 0.62$; $W = 205$, $p = 0.29$). Child adaptive functioning ($r(42) = -0.29$, $p = .05$) and caregiver perceived stress ($r(30) = -0.47$, $p = .008$) were negatively associated with clinician-caregiver discrepancy.

Conclusions: Findings suggest that higher clinician ratings of autism characteristics, relative to caregiver ratings, were associated with lower child adaptive functioning. Higher caregiver relative to clinician ratings were linked to higher caregiver stress. Previous research has generally treated adaptive functioning and autism characteristics as distinct clinical constructs, but adaptive functioning difficulties may overshadow autism characteristics for some caregivers resulting in lower relative caregiver ratings. Caregiver stress may also shape caregiver perceptions of symptom severity among families presenting for a diagnostic assessment. Data collection is ongoing, and the current small, predominantly male ($n = 46$) sample limits generalizability. Further assessment of clinician-caregiver discrepancy is needed as data collection continues.

411.184 Exploring Phenotypic and Sociodemographic Influences on Cognitive-Adaptive Functioning Discrepancies in Neurodivergent Children

E. Wan¹, R. Schachar², J. Jones³, J. Crosbie⁴, E. Kelley⁵, J. P. Lerch⁶, E. Anagnostou⁷ and A. Kushki⁸, (1)Autism Research Center, Bloorview Research Institute, Toronto, ON, Canada, (2)Department of Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (3)Department of Psychiatry, Queen's University, Kingston, ON, Canada, (4)University of Toronto, Toronto, ON, Canada, (5)Department of Psychology, Queen's University, Kingston, ON, Canada, (6)Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, ON, United Kingdom, (7)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (8)Bloorview Research Institute, Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: Neurodevelopmental conditions, including autism, attention-deficit/hyperactivity disorder (ADHD), and obsessive-compulsive disorder (OCD), are associated with significant variation in cognitive and adaptive functioning. In the general population, adaptive functioning generally increases with cognitive abilities. However, this relation is more complex when observed across neurotypical and neurodivergent individuals, with a significant gap between cognitive and adaptive functioning. Specific concerns of adaptive functioning being significantly lower than cognitive abilities, mainly studied in the autism population with or without intellectual disabilities, can be observed in other neurodevelopmental conditions. Less is written about the correlates of this cognitive-adaptive functioning discrepancy in neurodivergent children. The present study addresses this research gap by characterizing the features that are most predictive of these discrepancies.

Objectives: This study aimed to characterize the phenotypic and sociodemographic predictors of cognitive-adaptive functioning discrepancy in a neurodiverse sample of children and adolescents.

Methods: The study used data from the Province of Ontario Neurodevelopmental Network (POND), comprising 902 participants (autism = 409, ADHD = 210, OCD = 36, neurotypical = 214, other = 33) aged 6-21 years. Cognitive functioning was measured with full-scale IQ (FSIQ) from the Wechsler family of tests, and adaptive functioning was measured with the Adaptive Behavior Assessment System-II (ABAS-II), specifically the General Adaptive Composite (GAC) score. The cognitive-adaptive functioning discrepancy was calculated as the difference between FSIQ and ABAS-II GAC scores. Phenotypic measures included social communication (Social Communication Questionnaire, or SCQ), ADHD symptoms (Strengths and Weaknesses of ADHD Symptoms and Normal Behavior Scale, or SWAN), OCD symptoms (Toronto Obsessive-Compulsive Scale, or TOCS), and mental health symptoms (Child Behavior Checklist, or CBCL). Sociodemographic data encompassed sex, age, race, household income, and caregiver education. Nine computational models were used to predict the cognitive-adaptive functioning discrepancy. SHapley Additive exPlanations (SHAP) analysis was used to interpret the contributions of individual features to the cognitive-adaptive functioning discrepancy predictions.

Results: The random forest model achieved the highest predictive accuracy ($R^2 = 0.876$, $p < 0.001$), outperforming other models with a mean absolute error of 4.14. SHAP analysis showed that FSIQ, SCQ, and inattentive traits were the most influential predictors of cognitive-adaptive functioning discrepancy. Higher FSIQ ($FSIQ \geq 100$) was associated with increased cognitive-adaptive functioning discrepancy across all groups, while social communication differences ($SCQ \geq 10$) and inattentive traits ($SWAN \geq 3$) were also associated with increased cognitive-adaptive discrepancy. Sociodemographic factors had smaller but still significant effects, with sex ($p < 0.001$) and age ($p < 0.001$) influencing cognitive-adaptive functioning discrepancy (male sex and younger age decreased the cognitive-adaptive functioning discrepancy).

Conclusions: The analysis demonstrated that cognitive abilities, social-communication differences, and inattentive traits are key drivers of cognitive-adaptive functioning discrepancies in neurodivergent children. This knowledge can inform clinical practice by guiding design of individualized support strategies to enhance adaptive functioning.

411.185 Exploring the Characteristics of Autistic Children with Discrepant Executive Functioning Reports and the Frequency in Which Discrepancies Occur between Teachers and Parents

L. A. Joyce¹, R. Lees², E. Ng-Cordell³, A. Zaidman-Zait⁴, I. M. Smith⁵, T. Bennett⁶, S. Georgiades⁷, P. Szatmari⁸, T. Vaillancourt⁹, L. Zwaigenbaum¹⁰, M. Elsabbagh¹¹, E. Duku¹², W. J. Ungar¹³, A. Richard¹⁴, R. Bedford¹⁵ and C. M. Kerns¹⁶, (1)Psychology, University of British Columbia, Vancouver, BC, Canada, (2)Psychology, University of Bath, Bath, UK, United Kingdom, (3)Psychology, The University of British Columbia, Vancouver, BC, Canada, (4)Tel-Aviv University, Tel-Aviv, ISRAEL, (5)Dalhousie University / IWK Health, Halifax, NS, Canada, (6)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (7)Centre for Addiction and Mental Health, The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Ottawa, Ottawa, ON, Canada, (9)University of Alberta, Edmonton, AB, Canada, (10)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (11)The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (12)Autism Research Centre, IWK Health Centre, Halifax, NS, Canada, (13)University of Bath, Bath, United Kingdom, (14)University of British Columbia, Vancouver, BC, Canada

Background: Executive function (EF) is linked to better outcomes for autistic children and likely contributes to heterogeneity in autistic traits, anxiety, and adaptive functioning. As children's EF and associated traits may present differently at school versus home, parent-teacher reports may not align. Nonetheless, data are limited on the frequency and associated characteristics of EF informant discrepancies in autistic children.

Objectives: Describe discrepancy in informant classifications of EF challenges and associated clinical characteristics in autistic preadolescents.

Methods: Participants were 210 preadolescents (85% male, $M[SD]_{Age}=8.08[0.54]$ years; $M[SD]_{IQ}=85.16[19.56]$) from the *Pathways* study, a longitudinal study of Canadian autistic youth, with concurrent parent- and teacher-reported Behavior Rating Inventory of Executive Function (BRIEF) at the earliest time point available between 7.5-11 years. Parent- and teacher-reported Social Responsiveness Scale (SRS), Vineland Adaptive Behavior Scales Second Edition (VABS-II; Adaptive Behavior Composite) and Child Behaviour Checklist (CBCL; Anxiety Problems) from that time point were also analyzed, along with IQ assessments (at 8.5-9 years) and Autism Diagnostic Observation Schedule (ADOS) severity scores (at 6.5-7 years). We categorized children as having elevated EF challenges (Global T score > 60) or not on both the parent- and teacher-reported BRIEF. Clinical characteristics were compared across groups via ANCOVAs (controlling for age) followed by Tukey post-hoc analyses with Holm-Bonferroni corrections.

Results: Inter-rater agreement between parents' and teachers' BRIEF reports was weak overall ($\kappa=.25$). 38% of children ($n=80$; $M[SD]_{Diff}=0.73[8.81]$) were above clinical cut-offs on both parent and teacher BRIEF and 25% ($n=53$; $M[SD]_{Diff}=2.33[7.14]$) below on both. Twenty-three percent ($n=49$; $M[SD]_{Diff}=15.51[8.91]$) were elevated on teacher BRIEF only and 13% ($n=28$; $M[SD]_{Diff}=14.00[7.08]$) on parent BRIEF only. Children who informants consistently identified as above clinical cut-offs had higher autistic traits (per SRS and ADOS) and anxiety, and lower adaptive functioning and IQ ($p<.01$). Comparing discrepancy groups, parent-rated autistic traits ($p=.01$) and anxiety ($p=.02$) were significantly greater for children whose parents (but not teachers) reported elevated EF (partial $\eta^2=.40$ and $.15$, respectively). By contrast, autistic traits (per ADOS [$p=.03$] and teacher-SRS [$p<.001$]) were rated significantly higher in children whose teachers (but not parents) reported elevated EF (partial $\eta^2=.09$ and $.31$, respectively). Discrepancy groups did not differ in adaptive functioning, teacher-rated anxiety, or IQ.

Conclusions: For most children, EF was consistently classified as elevated (or not) by parents and teachers. Children whom informants consistently identified as elevated in EF challenges were more symptomatic across mental health and IQ measures than discrepant or consistently non-elevated children. Notably, 37% of classifications were discrepant, with mean t-score differences of ~ 1.5 SD. Within this group, teacher (but not parent-rated) EF elevations were more common than vice versa and were associated with greater clinician-rated autistic traits (via ADOS). For this subgroup, school may pose particular EF-related behavior challenges, some of which may also be captured by or related to behavior assessed in the ADOS (e.g., behavioral flexibility or regulation differences affecting social reciprocity). Examining whether discrepancy patterns hold overtime may clarify the presence of consistent behavioral differences across contexts and inform context-specific supports.

411.186 Factor Structure of the Rosenberg Self-Esteem Scale in Youth with Autism Spectrum Disorder: Exploratory Factor

Analyses of Youth Self-Report Ratings and Parent Ratings

M. A. Volker, S. L. Brennan and K. M. Rispoli, *Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI*

Background: The Rosenberg Self-Esteem Scale (RSES; Rosenberg, 1965) is one of the most widely used measures of self-esteem in the world. It was originally intended to provide an overall score that reflects the global self-esteem construct (Rosenberg, 1965; Schmitt & Allik, 2005).

However, past RSES factor-analytic studies yielded mixed findings, as some studies produced the intended one-factor solution, while others produced a two-factor solution—with positively worded items on one factor and negatively worded items on the other. The RSES is typically used as a self-report measure of global self-esteem. However, when evaluating youth with autism spectrum disorder (ASD), some researchers have used both the standard self-report form for youth with ASD and a modified version of the RSES adapted to allow the parent to rate their child (e.g., see Van der Crujisen & Boyer, 2020).

Objectives: The purpose of the present study was to examine, via exploratory factor analyses (EFAs), the factor structure of the RSES for self-ratings of youth with ASD and for parent ratings of the youth with ASD. Although multiple EFAs and confirmatory factor analyses (CFAs) of the RSES exist in the literature, and despite the RSES having been used as a dependent measure in ASD studies (Van der Crujisen & Boyer, 2020), no prior factor analyses of the RSES with ASD samples have been reported.

Methods: Participants included 140 youth with ASD and their parents whose data were collected during the pretest period of three prior clinical intervention studies. Youth participants were all diagnosed with ASD and ranged in age from 7 to 16 years ($M=11.26$, $SD=2.15$); IQ $M=103.89$, $SD=13.67$; receptive language composite $M=97.71$, $SD=14.64$; and expressive language composite $M=102.56$, $SD=16.30$. Two forms of the RSES were examined—the original 10-item self-report rating form and the adapted 10-item parent-rating form. For each version, an EFA of the inter-item polychoric correlation matrix was performed using principal axis factoring with direct oblimin rotation. Number of factors retained was determined through a combination of parallel analysis, Velicer's MAP, Kaiser criterion, scree plot, and factor interpretability.

Results: EFAs yielded a single factor solution for the RSES parent rating form—consistent with the global self-esteem construct, and a two-factor solution for the youth self-report—consistent with two correlated method factors reflecting self-esteem assessed via positive or negative wording. Youth self-report results also revealed that items 1 and 8 were problematic, as they failed to load on either factor and their distributions and item content suggested likely confusion among youth respondents.

Conclusions: EFA results yielded a retained single-factor solution for the RSES parent report form, and a correlated two-factor solution for the youth self-report form. The two-factor solution appeared to reflect a method artifact—with positively worded items on one factor and negatively worded items on the other. Items 1 and 8 were problematic in the child self-rating context and should likely be dropped from the instrument or considered for revision or replacement.

411.188 Factors Associated with Teacher Social Responsiveness Scale (SRS): Age, Sex, and Challenging Behaviors

A. Dimachkie Nunnally^a, S. L. Birkeneder^a, J. C. Bullen^a, C. J. Alexander^a, K. G. Tena^a, N. Gillis^a, N. S. Tseng^a, P. Mundy^a and N. J. Sparapani^b, (1)UC Davis MIND Institute, M.I.N.D. Institute, UC Davis, Sacramento, CA, (2)School of Education, University of California, Davis, Davis, CA, (3)UC Davis, Davis, CA, United Kingdom, (4)School of Education, School Psychology, University of California, Riverside, Riverside, CA, (5)MIND Institute and Psychiatry & Behavioral Sciences, Center for Autism Research, Children's Hospital of Philadelphia, Sacramento, CA, (6)University of California, Davis, Davis, CA, (7)Teacher Education, University of California, Davis, CA, (8)Peter Mundy, Davis, CA, (9)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

Background: Diagnosing autism is a complex process. Currently, autism diagnosis involves a parent interview and a standardized clinical observation of the child. Most often used are the Autism Diagnostic Interview-Revised (ADI-R; Lord et al., 1994) and the Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2012). Yet, these measures are often time-consuming within educational settings and require trained clinicians to administer. As a result, screeners like the Social Responsiveness Scale, 2nd edition (SRS-2; Constantino & Gruber, 2012) are frequently employed to identify children for further in-depth assessment. Although the SRS-2 can be completed by multiple raters, such as parents and teachers, few studies have examined factors associated with teachers' ratings on the SRS-2.

Objectives: This study examines factors associated with teachers ratings on the SRS. Specifically, this study examines whether age, sex, and challenging behaviors, as measured by the Child Behavior Checklist - Teacher Rating Form (CBCL-TRF; Achenbach & Rescorla, 2001), are associated with total SRS-2 scores.

Methods: Participants were recruited as part of a larger 4-year IES-funded study examining teacher-student interactions among neurodiverse students in general education classrooms (R324A210288). This current study pulled data from year 3 of the larger study. Participants included 44 autistic ($n = 20$) and non-autistic ($n = 22$) students from Kindergarten to 3rd grade in inclusive general education classrooms. 13 teachers completed the SRS-2 ($n = 44$) and the CBCL-TRF ($n = 37$) on their students at the beginning of the school year. Bivariate Pearson correlations were conducted to examine associations between SRS-2 scores, chronological age, sex, and CBCL-TRF scores (Internalizing and Externalizing Scale scores). Linear regressions were conducted to examine the amount of variance contributed by additional variables.

Results: SRS-2 scores were significantly correlated with CBCL-TRF externalizing behaviors ($r = .58, p < .001$) and chronological age ($r = -.35, p = .02$) but not with CBCL-TRF internalizing behaviors ($r = .23, p = .18$) or sex ($r = -.13, p = .40$). Linear regressions showed chronological age was a significant predictor of teachers' ratings on the SRS-2 ($F(1, 35) = 4.98, p = .032$), accounting for 12.5% of the variance in teachers' ratings on the SRS-2 (adjusted $R^2 = .010$). After adding in the internalizing CBCL scores, 17.8% of the variance in teacher SRS scores were accounted for (adjusted $R^2 = 0.130$). After adding in the externalizing CBCL scores, 37.1% of the variance in teacher SRS scores were accounted for (adjusted $R^2 = .313$).

Conclusions: This study examines factors associated with teachers' ratings of autism symptomatology in their students in inclusive classrooms, finding that teachers report the highest autism features in younger students who have higher scores of challenging behaviors in the classroom. This study expands upon similar findings from studies examining factors associated with the parent SRS (Constantino et al., 2003; Hus et al., 2012). Future studies are needed to elucidate whether teachers are accurately perceiving autism symptomatology in their students by validating scores against clinical assessments of students' autism symptoms.

411.189 Factors Influencing Clinician Certainty in Diagnosing Autism Spectrum Disorder in Two-Year-Olds

F. Balsa¹, C. T. Christianson¹, J. Yurkovic-Harding^{1,2} and J. Bradshaw¹. (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Carolina Autism and Neurodevelopment Research Center, University of South Carolina, Columbia, SC

Background: Accurate and timely ASD diagnosis is crucial, especially for families with autistic children, as siblings have ~20% chance of also being diagnosed with ASD (Ozonoff et al., 2024). The complexity of diagnosing ASD in toddlers makes clinician certainty critical for ensuring accurate assessments. Understanding the factors that influence diagnostic certainty, and identifying potential sex and racial biases, is vital for improving assessment practices and addressing disparities in outcomes for autistic individuals. This research builds on previous studies, which have examined clinician certainty in community-referred settings (Klaiman et al., 2024) and in older children (Rødgaard et al., 2024).

Objectives: The current study explores factors influencing clinician certainty in making an ASD diagnosis in two-year-olds in prospective, longitudinal studies of infant siblings of children with ASD. We consider how demographic characteristics (sex and race), language level, and ASD features (ADOS-2 Toddler Module Calibrated Severity Scores (CSS) and individual items) influence certainty.

Methods: Participants included 109 two-year-old children who enrolled in the prospective longitudinal study prior to age 6 months ($n=64$ males, $n=45$ females; $n=70$ elevated (EL) familial ASD likelihood, $n=39$ low (LL) ASD likelihood). The sample consisted of 67 White children, 28 Black, 9 Mixed Race, 2 Asian, and 3 from unknown racial/ethnic backgrounds. At 2 years, licensed psychologists (ADOS-2 research reliable with ASD expertise) made diagnostic decisions using the clinical best-estimate procedures (Lord, et al., 2012) and rated their degree of diagnostic certainty (1-low certainty to 3-high certainty). We used multiple linear regressions to evaluate associations among sex, ADOS-2 CSS, race, and certainty in those with and without ASD. Fisher's Exact Tests and Spearman correlations were used to explore individual ADOS-2 items and certainty associations.

Results: Overall, 31% of participants ($n=18$ males; $n=16$ females) received an ASD diagnosis, and 53% of these diagnoses ($n=11$ males; $n=7$ females) were made with high certainty. Clinicians were equally confident in diagnosing and ruling out ASD ($p=.30$). Neither sex nor race was related to diagnostic certainty ($p=.54$; $p=.79$). Higher ADOS-2 CSS was moderately associated with more certainty in diagnosing ASD ($F(2,31)=5.49, p=.009$). Clinicians were less certain ruling out ASD for girls with higher RRB CSS ($F(2,69)=4.26, p=.02$; Fig. 1). Figure 2 shows specific ADOS-2 items predicting certainty. Lower language abilities (item A1 rating 3-4) correlated with a 64% increase in certainty for ASD diagnosis ($p=-.64, p=.0004$), while higher language abilities (A1 rating 0-2) correlated with an 18% increase in ruling it out ($p=.18, p=.01$), regardless of sex.

Conclusions: This study demonstrated that while sex and race do not directly influence clinician certainty in diagnosing ASD, sex plays a role in the diagnostic process, as clinicians exhibit less certainty when ruling out ASD in girls with higher RRBs. Consistent with previous studies of other ADOS-2 modules, certain items in the Toddler Module were stronger predictors of certainty, reflecting how clinicians weigh symptoms differently. As expected, lower language abilities correlated with greater certainty, indicating that children with higher language abilities are at greater risk of misdiagnosis or underdiagnosis. Addressing these factors may enhance diagnostic certainty, accuracy, and timely access to services.

411.190 Families' Implementation of Recommendations Provided in a Public Neurodevelopmental Assessment Service Whilst Awaiting Diagnostic Assessment.

S. Goldstein¹, A. Abbou², K. A. Boulton³, N. Silove⁴, G. Brooks⁵, A. J. Guastella⁶, S. Baracz⁵ and A. McCole⁷, (1)Child Development Unit and PECAT, The Children's Hospital at Westmead, Westmead, NSW, Australia, (2)Brain and Mind Centre, University of Sydney, Sydney, NSW, Australia, (3)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (4)Sydney Children's Hospital Network, Sydney, Australia, (5)Sydney Children's Hospital Network, Westmead, NSW, Australia, (6)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (7)Child Development Unit and PECAT, The Children's Hospital at Westmead, Sydney, NSW, Australia

Background: One in ten children worldwide meet criteria for neurodevelopmental conditions. There is an abundance of literature to support the significance of early diagnosis and intervention, but the wait for the diagnosis can be long. In New South Wales, Australia, public assessment services have waitlists that can range from 12-36 months. As well as impacting the child's access to early intervention these extended wait times can have significant impacts on stress levels experienced by families as well as their engagement with the provided services. Researchers have proposed focusing on simultaneously referring children for intervention while they are awaiting a diagnosis, and consumers also advocate for their preference to access supports whilst awaiting diagnostic assessment for their child. Neurodevelopmental assessments are effective in educating caregivers about their child's needs, as well as providing guidance on available supports and interventions. Despite the provision of actionable recommendations aimed at improving children's developmental outcomes the extent to which recommendations are implemented by families remains under-researched.

Objectives: We sought to investigate rates of implementation of financial, therapeutic, and educational recommendations provided in a public neurodevelopmental assessment clinic while families were awaiting a multi-disciplinary diagnostic assessment, approximately 12 months later. **Methods:** The study utilized a retrospective, quantitative design. Participants included 65 families whose children had attended both intake and assessment appointments at a tertiary neurodevelopmental assessment service between 2019 and 2022. This service offers an initial intake appointment where families are given recommendations around therapy, funding, and education to implement whilst awaiting diagnostic assessment. We extracted novel recommendations provided in intake reports and compared these to follow-up recommendations made in the diagnostic assessment reports to identify the rate of uptake and implementation of initial recommendations by families. We also assessed the effect of sociodemographic variables on implementation of recommendations.

Results: From the 65 participants, 50 (76.9%) received an ASD disorder diagnosis by the end of the diagnostic assessment. All remaining participants exhibited significant developmental delays in at least two areas. There was an average waiting period of 7.3 months between intake and assessment appointments (range: 1- 18 months). Children were aged between 22 months and 5 years ($M = 3.51$ $SD = 0.94$), 69% males and 31% females. A total of 170 novel recommendations were extracted from intake reports, and 57 (33.5%) of those recommendations were implemented by families during the waiting period. Thirty-eight (58.5%) of the 65 of families were given novel recommendations at their intake appointment, with 31 (81.6%) of these families implementing at least one novel recommendation while awaiting assessment. There was no statistically significant effect of sociodemographic variables (culturally and linguistically diverse status, maternal education, child's age at intake) on rates of implementation.

Conclusions: The results of this study provide information regarding rates of implementation of recommendations by families in neurodevelopmental assessment settings. Our results indicate most families are proactive about seeking appropriate supports and services for their children. Further exploration of the challenges and experiences of families with low implementation rates may offer valuable insights for improving the support provided.

411.191 Feasibility and Acceptability of 14 Days of Ecological Momentary Assessment with Ambulatory Psychophysiology in Autistic Adults

L. L. Manna¹, E. Nettesheim², J. Feldman³, M. J. Crown⁴, X. Hu⁵, C. M. Conner¹, C. A. Mazefsky¹, L. N. Scott¹ and L. M. Bylsma¹, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)UPMC Western Psychiatric Hospital, Pittsburgh, PA, (3)Department of Psychology, University of Pittsburgh, Pittsburgh, PA, (4)Department of Psychiatry, Boston University, Pittsburgh, PA, (5)University of Pittsburgh, Pittsburgh, PA

Background: Ecological Momentary Assessment (EMA) in combination with ambulatory psychophysiology provides insight into real-time psychophysiological changes (e.g. heart rate variability, electrodermal activity) and co-occurring self-reported subjective thoughts, feelings, and behaviors. No prior study has utilized EMA with ambulatory psychophysiology in autistic adults.

Objectives: We examined the feasibility of EMA with ambulatory psychophysiology for 14 days of data collection in an autistic adult sample. We aimed to examine feasibility and acceptability for use of ambulatory psychophysiological methods in autistic participants, including the potential association between self-reported sensory sensitivities and feasibility and acceptability.

Methods: Participants included 65 autistic and 20 non-autistic adults (M age =31.94, SD=10.08) who participated in a 14-day EMA protocol with heart rate variability (HRV) and electrodermal activity (EDA) continuous monitoring. Participants wore an electrocardiogram (ECG) sensor on their chest and EDA sensor on their ankle while responding to EMA surveys on a mobile device 8 times daily. Sensor wear compliance, physiological data quality, and EMA survey completion of the autistic adults were compared to the non-autistic adults using independent samples t-tests. Participants also completed a debriefing survey of 16 questions rated on a 5-point Likert Scale assessing physical discomfort, skin irritation, self-consciousness, impact on daily life, ease of use, and subjective feelings of stress while participating in the study. We examined bivariate correlations between the Comprehensive Autistic Trait Inventory (CATI) sensory sensitivity subscale and protocol compliance, data quality, and responses from the debriefing survey.

Results: No significant differences were found between groups for protocol compliance or data quality. Autistic adults had comparable rates of sensor wear, data quality, and EMA survey completion compared to non-autistic adults. Mean HRV compliance was 87.37% with validity of 78.17%, and mean EDA compliance was 85.57% with validity of 82.38%. Autistic adults in our sample had a higher mean subjective CATI sensory sensitivity score than non-autistic adults ($t(83) = 7.82, p < .001$). However, no significant correlation was found between CATI sensory sensitivity scores with protocol compliance (i.e., rates of sensor wear) or data quality. Debriefing questionnaire responses did not indicate excessive levels of physical discomfort from wearing the sensors. Positive correlations were observed between CATI sensory sensitivity scores and responses to debriefing questionnaire items assessing physical discomfort from sensor wear (r 's from .31 to .39, p 's $< .05$), indicating that individuals with higher self-reported sensory sensitivity report more physical discomfort from extended sensor wear. Nonetheless, compliance and data quality remained high and acceptable throughout the 14-day protocol in this autistic adult sample.

Conclusions: Our data suggest high compliance and data quality, indicating the feasibility and acceptability of EMA with ambulatory psychophysiological monitoring over the course of 14 days in autistic adults. It is important for researchers using these methods to consider sensory sensitivity and monitor participants' experiences to enhance compliance, data validity, and participant acceptability.

411.192 How Observed and Reported Measures of Sensory Processing Predict Physiological Measures in Autism Spectrum Disorder
A. Chaturvedi¹, S. Ramappa², M. Banchik³, U. Shah⁴, M. G. Craske⁵ and S. A. Green⁶, (1)Psychiatry and Behavioral Sciences, UCLA - Semel Institute, Los Angeles, CA, (2)UCLA CART (Center for Autism Research and Treatment), Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)UCLA, Los Angeles, CA, (5)Dept of Psychology, University of California, Los Angeles, Los Angeles, CA, (6)Dept of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

Background:

Sensory over-responsivity (SOR) is a heightened response to sensory stimuli commonly seen in autism spectrum disorder (ASD) and impacts daily functioning. Historically, parent-reported and observed behavioral assessments are used to study SOR, but are not correlated. This is possibly because they measure different aspects of sensory processing or because children inhibit their responses during a lab assessment. Physiological measures provide an objective measure of sensory reactivity, and atypical heart rate (HR) responses to aversive stimuli have shown to be related to SOR in ASD youth.

Objectives:

This study aimed to compare how reported and observed measures of SOR predict physiological measures of sensory reactivity, and to examine if the level of reported regulation in ASD youth affects how SOR behaviors on an observed measure correlate with physiological reactivity.

Methods:

In this study, 54 TD children and 83 ASD children completed the Sensory Processing 3-Dimensional Assessment (SP3-D); SOR responses (e.g., grimacing, clenching fists), to only auditory and tactile stimuli were measured (30-sec each of 3 brushes on arm and lips and 3 loud musical instruments). Electrocardiogram recordings, such as the change in inter-beat interval (IBI), were calculated as the difference between pre-stimulus resting IBI and IBI from ten time periods post-stimulus onset. The first 4 seconds post-stimulus onset were considered the "orientation phase," where HR typically decreases due to initial processing of the stimulus. The 4th through 10th seconds post-stimulus onset were categorized as the "acceleration" phase, when HR typically increases. Participants' parents completed the SP3-D Inventory Checklist to report on tactile and auditory SOR symptoms and the Child Behavioral Checklist (CBCL) Emotional Dysregulation Index to report on regulation.

Results:

Repeated-measures ANOVAs showed main effects of diagnosis on IBI for both auditory ($p=0.019$) and tactile ($p<0.001$) stimuli, with the ASD group having lower IBI (higher HR) across stimuli. Within the ASD group, results showed a three-way interaction between parent-reported SOR, observed SOR, and time for the tactile and auditory domains ($p=0.041$ and $p=0.002$, respectively). Post-hoc analyses indicated that ASD participants whose parents who reported they had high SOR in their daily life, and showed high observed SOR in the lab assessment, exhibited the highest HR responses (reduced orienting and increased acceleration). To follow up, we then examined the interaction between emotion dysregulation and observed SOR on HR orientation and acceleration slopes and found significant effects ($p=0.009$ and $p=0.03$, respectively). ASD participants who had higher emotion dysregulation had a stronger correlation between observed SOR behavior and atypical HR responses.

Conclusions:

This study's results support prior findings that ASD youth show higher HR responses to aversive stimuli. Furthermore, observed and parent-reported SOR interacted to predict HR, with those rated high on both measures showing the most atypical HR responses. Additionally, ASD youth reported as dysregulated by parents exhibited a stronger correlation between HR and observed SOR behaviors, indicating that observed SOR measures may be less accurate for ASD youth who are inhibiting their behavioral responses. This study illustrates how to integrate multiple measures of sensory reactivity to identify SOR in ASD youth.

411.193 Identifying Reliable Change in Outcome Assessments for Behavioral Interventions

C. Akouri¹, M. Helton², C. Schuppel³, S. Wohlwend⁴, M. Uljarevic³ and T. W. Frazier¹, (1)John Carroll University, Cleveland, OH, (2)Department of Psychology, John Carroll University, University Heights, OH, (3)Psychiatry & Behavioural Sciences, Stanford University, Palo Alto, CA, (4)Psychology, John Carroll University, Cleveland, OH

Background: Outcome assessments for effective behavior intervention approaches in autism spectrum disorder utilize skill-based and norm-referenced measures. Legacy outcome measures commonly-used in behavioral intervention practice often lack key information on whether client score changes are reliable.

Objectives: This study evaluated and compared three methods for determining reliable change: traditional reliable change indices (RCIs), practice-adjusted RCIs, and standardized regression-based (SRB) RCI norms, to the Neurobehavioral Evaluation Tool (NET V1.0 and V3.0) assessment data to inform future behavioral intervention outcome assessments.

Methods: Participants in the NET V1.0 sample (N=498) included individuals with neurogenetic and neurodevelopmental conditions, and their siblings, recruited through genetic syndrome foundations. Neurotypical participants were recruited through StudyKiK. NET V3.0 (N=125) parent/caregiver informants were recruited through Prolific. Informants for both versions provided demographic and health information. Clinical diagnoses were categorized into neurotypical, autism spectrum disorder (ASD), and other developmental disorders (DD). NET V1.0 included brief informant-report measures covering symptom and skill/functioning domains used in intervention studies in ASD and rare neurodevelopmental genetic syndromes. Measures featured 6 symptom and 5 skill domains, and were completed at baseline and 1-month and 4-month follow-ups. Analyses focused on sample characterization, identifying the appropriate test-retest interval and sub-sample for final norms and computed traditional RCIs, practice-adjusted RCIs, and SRB RCIs.

Results: NET V3.0 had a more diverse sample compared to NET V1.0, in terms of age, race, and ethnicity. The NET V1.0 sample had more participants with neurodevelopmental and neuropsychiatric conditions. NET V1.0 exhibited high test-retest reliability that was comparable across follow-up time points (1-month and 4-month), and NET V3.0 showed high test-retest reliability that was comparable across all sub-samples (NT, ASD, DD, ASD+DD). Mean changes were minimal across all domains in both versions Table 1. RCI norms were generated for 1-month follow-up with data combined across sub-samples. Traditional RCIs required a difference of 0.57 to 1.3 SDs from baseline to follow-up for reliable change in symptom reductions and skill improvements with minimal practice-adjustments. Baseline scores strongly predicted retest scores across all domains, highly influencing SRBs. Notably, age, speech levels, and cognitive levels were also significant predictors for selective measures. SRB RCIs tended to be slightly smaller than traditional RCIs, with similar variability across domain measures.

Conclusions: The norms presented can be used to inform and enhance behavioral interventions. Practice-adjusted RCIs may be preferred in clinical contexts, while SRBs may offer greater sensitivity to reliable change in many patients. Future research should incorporate more outcome assessment instruments to enhance the use of reliable change indices and explore the impact of other clinical factors on reliable change estimation. Additionally, it will be important to develop software with clinical decision support for easy implementation of RCIs in typical clinical practice. Provider education will be important for ensuring that reliable change indices are adopted and utilized to inform clinical management decisions.

411.194 Identifying the Unique Determinants Influencing Rural Families' Engagement with an Existing Tele-Assessment Approach for Autism Identification

L. Wagner¹, T. E. Foster², K. Bonnet³, D. Schlundt⁴, A. K. Spitzer⁵, A. R. Dixon⁶ and Z. Warren⁷, (1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)Division of Developmental Medicine, Vanderbilt University Medical Center / VKC TRIAD, Nashville, TN, (3)Vanderbilt University, Nashville, TN, (4)Psychology, Vanderbilt University, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN, (6)Vanderbilt, Nashville, TN, (7)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN

Background: Accurate identification of autism is a pressing challenge for rural, medically underserved communities. Even when diagnostic appointments become available, many multi-stressed, rural, or otherwise underserved families experience significant barriers to in-person assessment and treatment leading to disparities in age of identification and service access. Tele-assessment has potential to address these barriers, particularly for the 20% of children with developmental disabilities living in rural America and the estimated 50% of autistic children living in low-income households. Despite its promise, emerging work also highlights the potential for telemedicine to exacerbate existing care disparities for socioeconomically disadvantaged groups, particularly when approaches fail to address unique contextual factors surrounding implementation.

Objectives: This work systematically examined the factors that facilitate and hinder tele-assessment engagement (i.e., determinants) for families living in rural, medically underserved communities in order to identify targeted implementation strategies to promote equitable, sustained use.

Methods: As part of a larger ongoing state-wide initiative, we used a qualitative approach to identify factors influencing rural families' perceptions and use of tele-assessment, by interviewing caregivers of autistic children and community service providers living and working in rural, medically underserved areas in the Southeast region of the United States. As of this submission, we have interviewed 32 participants across two groups: 22 caregivers of autistic children, and 10 community providers serving autistic children or those with related disabilities (Table 1). We used author-created interview guides (structured using the Consolidated Framework for Implementation Research; CFIR) and interview transcripts to develop a hierarchical coding system. Two study authors coded all transcripts. To maintain trustworthiness throughout the coding process, another member of the study team read all transcripts and coded 50% of transcripts. An iterative inductive/deductive approach guided data analysis. Inductively, quotes were sorted by coding category to identify themes. Deductively, we were guided by the CFIR framework, the Health Belief Model, and the Social-Ecological model. We created a conceptual framework to visually present the focus group results.

Results: Preliminary data analysis reflected four core attitudes central to community perceptions, including 1) questions surrounding the validity (scientific legitimacy) of tele-mediated autism assessment; 2) level of trust in the evaluation process in general (and tele-assessment specifically); 3) beliefs about the feasibility of tele-assessment; and 4) concerns related to privacy. These attitudes and beliefs are influenced by determinants at multiple levels (child, family, system) and stages (e.g., referral, diagnostic visit), highlighting the need to adapt the existing tele-assessment approach by embedding implementation strategies that support multiple actors at each stage. As additional focus groups are conducted, our conceptual framework will be revised to incorporate new perspectives with specific focus on gathering additional input from linguistically, geographically, and socioeconomically diverse shareholders.

Conclusions: This work identifies important targets for ensuring equitable access to successful tele-assessment for rural families. Understanding and alleviating care disparities related to tele-assessment could fuel future health services research that seeks to understand telehealth appropriateness for diverse communities and disciplines.

411.195 Interpretation of Cognitive and Adaptive Traits in Individuals with Neurodevelopmental Conditions: A Comprehensive Assessment

T. Hagiwara¹, T. Eishi² and M. Katagiri², (1)Hokkaido University of Education, Asahikawa, Asahikawa, Hokkaido, JAPAN, (2)Hokkaido University of Education, Asahikawa, Asahikawa, Hokkaido, Japan

Background: To create appropriate, individualized support systems for individuals with neurodevelopmental conditions, whether diagnosed or not, comprehensive assessment using various tools is essential. While intelligence tests are commonly used, the assessment of adaptive behaviors should also be included, given the need to plan for social independence across all life stages. Cognitive and adaptive profiles should be central to these assessments, combining formal and informal tools tailored to individual needs.

Objectives: This study examined the relationship between cognitive and adaptive profiles in individuals with neurodevelopmental conditions through comprehensive assessment.

Methods: Eighty-one individuals from Japan, aged 4:1 to 42:6 ($M = 12:11$), participated in the study. All had full-scale IQ scores above 70 ($M = 94.27$). Each participant completed the Wechsler Intelligence Scales and Vineland-II Adaptive Behavior Scales (VABS-II), both translated and re-standardized for use in Japan. Analyses were conducted to examine the relationship between cognitive and adaptive traits.

Results: Correlation analysis showed that all VABS-II indexes were significantly negatively correlated with age (see Table 1). VABS-II Communication was significantly positively correlated with Wechsler FSIQ ($r = .40$, $p < .001$) and VCI ($r = .31$, $p = .008$). Among Communication subdomains, only Reading ($r = .44$, $p < .001$) showed a moderate correlation with VCI.

Participants were divided into four groups based on their VABS-II Adaptive Behavior Composite (VABS-II ABC) scores (see Table 2). One-way ANOVAs found no significant differences in FSIQ or VCI across the groups, but there were significant differences in all VABS-II domains: Communication ($F(3,77) = 73.83$, $p < .001$, $G\eta^2 = .74$), Daily Living Skills ($F(3,77) = 64.04$, $p < .001$, $G\eta^2 = .71$), and Socialization ($F(3,77) = 36.24$, $p < .001$, $G\eta^2 = .56$). Post-hoc analyses revealed that lower VABS-II ABC levels corresponded with lower scores in these domains.

Significant differences were also found in maladaptive behavior: Maladaptive Behavior Index ($F(3,76) = 10.67$, $p < .001$, $G\eta^2 = .3$), Internalizing ($F(3,76) = 6.78$, $p < .001$, $G\eta^2 = .21$), and Externalizing ($F(3,76) = 7.25$, $p < .001$, $G\eta^2 = .22$). Maladaptive Behavior Index and Externalizing scores were higher in groups with VABS-II ABC scores below 70, while Internalizing scores were higher in the group with VABS-II ABC scores of 85 or above.

Conclusions: The study provides insights into cognitive and adaptive traits in individuals with neurodevelopmental conditions. The negative correlation between age and VABS-II indexes suggests that adaptive skills may not develop with age. Although verbal cognitive ability and communication were positively correlated, the moderate to high correlations observed in previous studies were not found here, indicating a distinction between cognitive ability and daily communication. Lastly, an overall adaptive level of -2 SD below the mean may indicate a higher risk for maladaptive behaviors in this population.

**411.196** The Initial Report in Evaluating Autism Traits and Unusual Sensory Processing Profile in a Menopausal Autistic Woman Using the Autism Clinical Interview for Adults (ACIA) and Self-Reported Pre-Interview Questionnaires

A. Rynkiewicz^{1,2}, R. L. Moseley³, A. Brewer Curran⁴, K. Soh⁵ and E. Ferensztajn-Rochowiak⁶, (1)Department of Psychiatry, University of Rzeszow, Rzeszow, Poland, (2)Center for Diagnosis, Therapy and Education SPECTRUM ASC-MED, Gdansk, Poland, (3)Department of Psychology, Bournemouth University, Poole, United Kingdom, (4)Department of Pediatrics, University of Missouri, Columbia, MO, (5)ECHO Autism Communities, University of Missouri School of Medicine, Columbia, MO, (6)Department of Adult Psychiatry, Poznan University of Medical Sciences, Poznan, Greater Poland Voivodeship, Poland

Background: The hormonal changes of menopause present an emotional rollercoaster of particular significance for autistic women and other neurodivergent populations (Moseley et al. 2021; Rynkiewicz et al. 2024). Quantitative data suggest that autistic women experience more severe menopausal symptoms (Groenman et al. 2022; Rynkiewicz et al. 2023), and qualitative reports describe a breakdown in established coping skills, which can result in loss of employment, self-care and independent living skills, and can also be accompanied by dramatic increases in self-harm and suicidal behavior (Moseley et al. 2021; Rynkiewicz et al. 2024). There is still lack of reliable, valid, and appropriate diagnostic instruments for autistic adults (Wigham et al. 2020) and many women with this condition only get diagnosed often following a string of misdiagnoses (Rynkiewicz 2016; Kentrou et al. 2021). Autistic menopausal women may not be getting appropriate management and treatment for both symptoms of menopause or other physical and mental conditions.

Objectives: to evaluate the autism traits, unusual sensory processing and other symptoms in a menopausal autistic woman with hormone replacement therapy based on the semistructured interviews and self-reported questionnaires.

Methods: one case of the larger study on menopause in autism is presented. This is a white autistic person, assigned female at birth, identifying as a woman, with no intellectual disability (ID), diagnosed with ASD, with hormone replacement therapy (HRT). The case is ECHO Autism didactics. The Autism Clinical Interview for Adults (ACIA), an instrument still being assessed of its diagnostic utility and the standardized ADI-R, both from available and competent parent, ADOS-2 (Module 4) and self-reported questionnaires: Adolescent/Adult Sensory Profile (AASP), GQ-ASC/Q-ASC (Girls' Questionnaire for ASC) for adult women, Menopause-Specific Quality of Life (MENQOL) Questionnaire were used. The study was approved by the URBC (№ 2024/02/007) with patient informed consent. The researchers were formally trained on ACIA.

Results: ACIA identified autism traits relevant for a diagnosis, as well as the co-occurring conditions (e.g., anxiety in this patient) and supported the ADI-R scores. It confirmed the pattern of sociocommunicative and cognitive differences characteristic of autism, with clear evidence of unusual sensory interests albeit no self-injurious behaviour. The GQ-ASC demonstrated significant oversensitivity in touch and sound, and attempts to camouflage the autistic traits. The AASP results showed sensory processing profile of increased sensory sensitivity with sensation avoiding. Low registration and sensation seeking were in the average ranges, with a slight decrease for sensation seeking. The highest results in AASP were obtained for auditory and visual processing. The MENQOL results are presented in Table 1.

Conclusions: ACIA supported the ADI-R scores. It informed and enhanced diagnostic decision-making and treatment planning. The interplay with sensory processing and modulation worsen the menopausal symptoms and made daily functioning more difficult for this woman. The studies on small samples and even individual cases despite their limitations are worth reporting to increase knowledge on menopausal autistic people as the research of this area is still scarce. Our further research concerns higher number of autistic people with menopause.

411.197 Useful Factors in Determining an Adult Autism Diagnosis

K. Whaling¹, E. T. Crehan² and R. L. Loftin³, (1)Prosper Health, New York, NY, (2)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA, (3)Prosper Health, Chicago, IL

Background: Despite adults seeking evaluations at increasingly high rates, there are no established guidelines for adult autism diagnostic evaluations (Underwood et al., 2021). The best practice autism evaluation methods used with children are often impossible (e.g., deceased or otherwise unavailable caregivers to provide early history) or inaccessible (e.g., long wait times, limited insurance coverage, lack of clinicians with expertise in late diagnosis). Empirically investigating which factors are most influential in diagnosing autism is crucial to ethically and soundly meet the service needs of the increasing number of adults seeking evaluations for autism.

Objectives: To address the lack of available literature and contribute to studies on best practices in adult autism diagnosis, the present study uses an exploratory factor analysis on an autism diagnostic tools to create factors that can be used in determining a diagnosis of autism. Then, utilizing a stepwise regression, factors are analyzed to explore which factors are most strongly associated with an autism diagnosis. As this is an exploratory study, no hypotheses about specific factors are made. However, it is hypothesized that distinct factors will emerge and that some factors may be more useful than others in predicting an ultimate diagnosis of autism in adults.

Methods: Data from 100 adult autism diagnosis cases from varying demographic backgrounds have been completely collected, 75% diagnosed with autism and 25% not diagnosed with autism. The participants were age 18 - 60 (mean age of 26) and were diverse in race, ethnicity, and gender. Data collection is complete, but has not yet been analyzed. An exploratory factor analysis of the SRS-2, SCQ, and ratings from a structured clinical interview will be performed utilizing MPlus to identify factors relating to diagnosis. Then, a multiple linear regression (or stepwise regression) will be run to subsequently determine which factors most strongly predict a diagnosis.

Results: Data collection is complete, but analyses are unable to occur until after abstract submission. Results will discuss: (a) descriptive statistics of the population sample, (b) effect size, (c) power, (d) the distinct statistically significant factors that emerged from the exploratory factor analysis, (e) factors which most strongly predict or relate to an autism diagnosis in adults.

Conclusions: Multiple data sources will continue to be important in diagnostic evaluations, and much research on collateral report and collateral measurement is still needed. However, as these sources of data are often difficult to obtain in an adult assessment, more research is needed to better understand the self-report tools available. The identification of distinct and meaningful factors found by analyzing the SRS-2, SCQ, and ratings from a structured clinical interview and subsequently measuring their relative importance in the diagnosis of adult autism, can offer unique diagnostic information that is empirically sound to help improve and standardize adult autism diagnostic procedures. Specific implications based on the unique factors and their predictive power for researchers, clinicians, the autistic community, and other stakeholders will be discussed. Limitations and future research will be discussed.

411.198 Predictors of First-Time Adolescent Autism Diagnosis in a Clinical Sample

E. C. Kurtz-Nelson¹, C. James² and D. L. Reisinger³, (1)Indiana University School of Medicine, Indianapolis, IN, (2)Pediatrics, Indiana University School of Medicine, Indianapolis, IN, (3)Indiana University School of Medicine, Cincinnati, OH

Background: Late autism diagnosis is associated with co-occurring mental health and social challenges, which may worsen over time (Mandy et al., 2022). Simultaneously, co-occurring psychiatric symptoms may complicate differential diagnosis of autism in older children and adolescents (Duvall et al., 2024). Other characteristics may also contribute to late or complex autism diagnosis, including female sex assigned at birth and higher cognitive skills (Harrop et al., 2024; Hosozawa et al., 2020). In the context of high wait times for autism diagnostic evaluations, identifying factors that predict first-time adolescent autism diagnosis may inform triage models and improve access (Kanne & Bishop, 2021).

Objectives: To identify predictors of first-time autism diagnosis in adolescents presenting for an autism evaluation.

Methods: Participants were 56 individuals ages 13-17 years (mean age = 14 years, 29% female, 69% meeting criteria for autism) presenting for a first-time autism evaluation at an academic medical center. A referral from a medical provider was required for evaluation. All patients completed a diagnostic evaluation including the Autism Diagnostic Observation Schedule-2 (ADOS-2). Additional assessments typically included caregiver reported measures of adaptive skills (Vineland-3), autistic behaviors (BASC-3 Autism Probability Index), and emotional/behavioral problems (BASC-3 Internalizing and Externalizing Indices) as well as an appropriate cognitive measure. Chi-square and *t*-tests were used to identify predictors of autism diagnosis, and an exploratory logistic regression predicting autism diagnosis was conducted with variables potentially available prior to in-person autism assessment: age, sex assigned at birth, adaptive skills, caregiver ratings of internalizing, externalizing, and autistic behaviors, and diagnosis of intellectual disability.

Results: Participants diagnosed with autism had higher adaptive skills ($t(47) = -2.82, p = .003$) and ADOS-2 calibrated severity scores (CSS; $t(23.74) = -1.81, p = .04$) than participants who did not receive a diagnosis of autism. Other factors (age, sex, IQ, behavior problems, caregiver-rated autistic behaviors) did not significantly differ between diagnostic groups. In the logistic regression, while multiple factors approached significance (age, sex, adaptive skills, caregiver-rated autistic behaviors, and intellectual disability diagnosis), no single variable significantly predicted autism diagnostic outcome. The overall analysis predicted 73% of the variance in autism diagnosis (Nagelkerke R square) and had high sensitivity (96.3%) with adequate specificity (77.8%). Addition of ADOS-2 CSS to the model correctly classified all participants (sensitivity and specificity = 100%).

Conclusions: Results indicate that information gathered prior to in-person autism assessment, such as demographic factors, previous diagnoses, and caregiver ratings, could potentially be used to identify adolescents who are likely to meet criteria for autism. Adolescents with very low adaptive skills and no previous autism diagnosis may have alternate explanations for differences in social communication, such as intellectual disability or psychiatric diagnoses. However, the high rate of first-time autism diagnosis in this sample as well as reduced specificity of the overall model highlight the importance of timely access to autism evaluation for adolescents with clinical suspicion of autism.

Poster Session

412 - Genetics I

May 1st, 2025, 5:30 PM - 6:30 PM - Hall 4A

412.200 Autism-Relevant Skills and Behaviors in Angelman and Dup15q Syndromes

E. Taverna¹, I. M. Eigsti², T. Huedo-Medina³ and R. Fitch⁴, (1)Psychiatry, Massachusetts General Hospital, Boston, MA, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Department of Clinical, Health Psychology, and Research Methods, University of the Basque Country, Gipuzkoa, Basque Country, Spain, (4)Psychology, University of Connecticut, Storrs, CT

Background:

Angelman syndrome (AS) and Dup15q syndrome are rare neurogenetic disorders caused by abnormalities of chromosome 15, and characterized by intellectual disability (ID), motor impairments, and autistic behaviors. While autism is frequently diagnosed in both, the nature of autistic traits may differ; compared to idiopathic autism, individuals with AS exhibit high social motivation, frequent smiling, and laughing, with limited language and motor skills, and those with Dup15q exhibit greater social interest, again with language and motor delays. Autism diagnoses in AS and Dup15q may thus reflect motor and communication impairments, rather than the core symptoms of idiopathic autism. Assessing autism in genetic syndromes is challenging due to the presence of severe ID, motor impairments, and limited validation of diagnostic tools, which likely *overestimate* autism severity in individuals with significant delays.

Objectives:

This study examines autism-related skills and behaviors in children with Angelman syndrome (AS) and dup15q syndrome, comparing them to individuals with idiopathic autism and intellectual disability (ID). It also explores caregiver perceptions of autism diagnoses and access to interventions, with the goal of enhancing clinical understanding of how genetic differences influence autism characteristics.

Methods:

Participants included 110 children aged 2 to 11 years, with Angelman syndrome (AS; $n = 33$; 13 females), dup15q syndrome ($n = 20$; 6 females), or autism ($n = 57$; 11 females). Caregivers were recruited from syndrome organizations and SPARK. Caregivers completed questionnaires regarding sociodemographics, autism characteristics (SCQ, M-CHAT-R, RBS-R), and access to autism diagnoses and behavioral therapies. Group differences were analyzed using Kruskal-Wallis tests with Bonferroni corrections, and the SPIRIT Macro for differential item functioning on the SCQ and M-CHAT-R between syndromic and idiopathic groups.

Results:

The autism group had the highest SCQ scores (most autistic characteristics) relative to the AS group; scores in AS were higher than for dup15q, but did not reach significance. M-CHAT-R scores were similar across groups, but there were clear group differences in patterns of repetitive behaviors across groups (Table 1), with reductions in ritualistic/sameness, compulsive, and restricted interests and behaviors in AS relative to autism; the dup15q was intermediate. Social interest was a relative strength in the AS but not dup15q group, with “response to name” a salient weakness for AS and dup15q groups. Cluster analyses indicated that autistic traits were predicted by developmental level, communication abilities, motor skills across groups, and found a significant relationship between oromotor skills and autistic traits in AS and autism groups. Many in the syndromic groups had received an autism diagnosis, and parents generally felt that it was appropriate (Table 2).

Conclusions:

Profiles of autistic traits differed across groups, with more repetitive behaviors in the autism and dup15q versus the AS groups. Children with AS showed relative strengths in social interest, but weaknesses in motor and speech abilities, likely linked to developmental delays. Differences in behavior and therapy access emphasize the need for individualized support. These findings contribute to understanding UBE3A gene-related mechanisms in autism traits, and speak to the need for enhanced assessment tools in individuals with autism and ID.

412.201 Cathepsin B As a Pathogenic Factor and Lifelong Biomarker for Autism Spectrum Disorder: Evidence from Large-Scale Plasma Proteomic Analyses

W. Zhou, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, SHANGHAI, SHANGHAI, China

Background:

The lack of reliable biomarkers considerably impedes the diagnosis and early detection of autism spectrum disorder (ASD).

Objectives:

Identify potential biomarkers for ASD.

Methods:

We conducted a comprehensive study involving two populations: the UK Biobank ($n=36,134$) and an ASD children cohort ($n=296$). We analyzed 2,920 plasma proteins in the UK Biobank to characterize ASD-associated proteomic signatures. Potential ASD-associated proteins were validated in the ASD cohort. We performed multistage analyses, including neuroimaging, biochemical association analysis, and two-sample Mendelian randomization (MR).

Results:

Four proteins (CTSB, LRRC37A2, GYS1, and HLA-A) showed significant associations with ASD genetic risk. Functional analysis revealed enrichment in immune system processes. MR analysis suggested a causal relationship between CTSB (Cathepsin B) and ASD. In an independent Chinese cohort, autistic children exhibited elevated plasma CTSB levels, correlating with symptom severity. Elevated CTSB levels correlated with increased systemic inflammatory index and neurostructural alterations in brain regions associated with ASD. CTSB showed persistently high expression from infancy to adulthood, supporting its potential as a lifelong biomarker.

Conclusions:

Our multi-modal strategy provides convergent evidence implicating elevated CTSB in ASD pathogenesis, supporting its potential as a lifelong biomarker and treatment target for ASD.

412.202 Epigenetic Signature of Autism in Utero: Methylation Profiles of Circulating DNA from Maternal Blood Reflect Child Autism Diagnosis and Synaptic Gene Functions

L. A. Williams^a, O. Sharifi^a, J. S. Mouat^a, E. Angel^a, R. J. Schmidt^a and J. M. LaSalle^a, (1)Medical Microbiology and Immunology, University of California, Davis, Davis, CA, (2)University of California, Davis, Davis, CA, (3)Public Health Sciences, University of California Davis, Davis, CA

Background: As the prevalence of autism spectrum disorders (ASD) has risen substantially over the past few decades, more focus has been given to investigating gene by environmental interactions that associate with the likelihood of ASD diagnosis. Suspected environmental factors are hypothesized to increase ASD likelihood by altering gene regulatory networks in utero. Genome-wide DNA methylation signatures of ASD placenta show promise in reflecting gene networks relevant to the developing brain. Methylation analysis of cell-free DNA, which contains cfDNA from mother and cfDNA derived from fetal trophoblast, has the potential to provide unprecedented longitudinal insight into how environmental factors interplay with the regulation of gene networks involved in neurodevelopment.

Objectives: This project sought to determine if cell-free DNA methylation signatures from maternal blood plasma collected at delivery would distinguish ASD from Non-ASD pregnancies and include neurodevelopmental and synaptic gene networks.

Methods: CfDNA was collected from ~1 ml of delivery blood plasma of 51 participants in the MARBLES prospective elevated-likelihood ASD cohort study, representing 24 ASD and 27 Non-ASD pregnancies from which whole genome bisulfite sequencing (WGBS) from placenta was available. WGBS library preparation was performed on all cfDNA samples with the XGen Methyl-Seq Kit, and libraries were pooled and sequenced across 4 NovaSeq 6000 lanes. The resulting sequencing data was used to generate cytosine reports, which were then used to call differentially methylated regions (DMRs) between the ASD and Non-ASD samples using DMRichR. DMR analysis was performed using both sex-stratified and sex-adjusted strategies to minimize any potential interference of sex on detecting epigenetic signatures of ASD.

Results: We detected a stronger epigenetic signature of ASD in sex-stratified analysis of cfDNA, identified as 1436 ASD DMRs in the male dataset and 3113 ASD DMRs in the female dataset (Figure 1). Sex-stratified DMRs varied considerably in their genomic coordinates, direction of methylation, and genic annotation, but both sets of ASD DMRs showed significant enrichments for genes in pathways related to neurodevelopment such as 'calcium signaling pathway', 'glutamatergic synapse' and 'dopaminergic synapse' as well as enrichments for SFARI ASD genes (p-value = 2.5×10^{-4} for males, and p-value = 5.9×10^{-3} for females). CfDNA ASD DMR genes were also highly enriched for DMR genes identified in matched term placenta samples (p-value = 1.5×10^{-30} for males, and p-value = 5.7×10^{-39} for females), reinforcing the fetal relevance of cfDNA methylation. Despite differences in global directional patterns of DMR methylation, male and female DMR genes significantly overlapped with each other (p-value = 3.0×10^{-49}), indicating that prenatal ASD development may be associated with sex-specific dysregulation of similar gene networks.

Conclusions: An epigenetic signature of ASD is detectable in cfDNA isolated from low volume archived maternal plasma, and is characterized by sex-specific epigenetic dysregulation of gene pathways involved in neuronal synapses and neurodevelopment. Further investigations of the ASD cfDNA methylome hold the potential to illuminate complex ASD etiologies, including which gene networks may be susceptible to environmental factors. In the future, cfDNA methylomes may also be useful for designing early intervention strategies for ASD.

412.203 Genetic Disorders in Autism Spectrum Disorder: Findings from a Population-Based Surveillance System

S. Mermel¹, C. Louis¹, K. Sidwell¹, D. Rahama¹, L. Gomez Bustamante¹, T. Modla¹, J. Shenouda² and W. Zahorodny³. (1)Rutgers University, Newark, NJ, (2)Department of Pediatrics, Rutgers University, Newark, NJ, (3)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ

Background: Autism Spectrum Disorder (ASD) is an increasingly prevalent developmental disability characterized by deficits in communication, social interaction, repetitive behaviors and sensory processing. These deficits often overlap with other developmental disabilities, which may reflect underlying genetic disorders, in some. Individuals with ASD who also have intellectual disability (ID) associated with genetic disorders may have specific organic and functional profiles that influence treatment and outcomes. It has been estimated that using standard medical genetic evaluation techniques, a genetic cause can be identified in 20–25% of children on the autism spectrum. Knowing how many children with ASD have a specific genetic disorder may improve our knowledge of ASD, leading to more effective interventions and fruitful research. The association between ASD/ID in genetic disorders like Fragile X and Down Syndrome has been known for some time. Published estimates suggest that 10–25% of individuals with ASD may have co-occurring genetic disorders. Population-based estimates of the co-occurrence of known genetic disorders and ASD are needed to confirm this association and to provide baselines for future epidemiologic tracking.

Objectives: This study aimed to determine the occurrence of genetic disorders in a large, diverse, population of ASD children, examine demographic differences and describe the expression of ID in this population.

Methods: Case specific information was from population-based ASD surveillance in New Jersey. This study includes 8-year-olds with ASD identified through the most recent (2016, 2018, and 2020) cycles of comprehensive monitoring. 2016 surveillance encompassed 4 counties (Essex, Union, Hudson, and Ocean). The 2018 and 2020 cycles included Essex and Union counties. ASD cases were identified through the ADDM Network active, retrospective, multiple-source case-finding method, based on analysis of information from health and education sources.

Demographic and case-specific data, including diagnosed genetic conditions and level of intellectual ability, were described and analyzed.

Results: 2,071 children were identified with ASD. Among those, only 45 (2.2%) had a documented co-occurring genetic disorder. Males with a genetic disorder outnumbered females by 3:1. Approximately a third (31%) of ASD cases with genetic disorders had co-occurring intellectual disability (IQ ≤ 70); rates varied from 23% in 2016 to 42% in 2020. Most commonly-identified genetic disorders were: chromosomal abnormalities or duplication errors (n=14), Down Syndrome (n=8) and Fragile X (n=5).

Conclusions: Approximately 2% of 8-year-old children with ASD were determined to have a documented genetic disorder. The frequency of genetic disorders in ASD is lower than expected and may reflect a low rate of genetic testing. These results are preliminary, as they are based on evidence from a single monitoring region and may not be generalizable to other areas of the United States. Additional research, especially comparison to data from other ADDM Network states, is recommended.

412.205 Genomic Landscape of Autism Spectrum Disorder in the Indian Population: Insights from Whole Exome Sequencing and Copy Number Variation Analysis

S. Gulati¹, B. Kumar², V. Scaria³, S. Ojha⁴, S. Khan⁵, G. Kamila⁴ and A. Rohil⁶, (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, Ansari Nagar, New Delhi, India, (2)The Council of Scientific and Industrial Research- Institute of Genomics and Integrative Biology, Delhi, India, New Delhi, Delhi, India, (3)Karkinos Healthcare, Kochi, Kerala, India, (4)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (5)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (6)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India

Background:

Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by impairments in social interaction, communication, and repetitive behaviours. In this study, the limited availability of large-scale Whole Exome Sequencing (WES) was addressed and Copy Number Variation (CNV) was analyzed in the children with ASD among Indian population.

Objectives: The study objective was to identify the specific genomic markers associated with ASD among Indian children and adolescents

Methods:

Children and adolescents aged 18 months-18 years fulfilling the diagnostic criteria for ASD, as per DSM-V, were screened. Those who fulfilled the inclusion criteria and provided consent were included, while those with known genetic etiology and neurometabolic disorders were excluded. Around 3-5 ml blood was extracted through venepuncture. Whole Exome Sequencing (WES) was performed and the data was analyzed using a robust bioinformatics pipeline for variant identification, filtering, and annotation. Controls were healthy Indian individuals of varied age and sex who underwent whole genome sequencing.

Results:

Seventy-nine patients were enrolled in the study. A total of 637,681 unique variants were identified in the ASD cohort. After stringent filtering, 340 variants from a panel of 1,210 ASD-associated genes were prioritized. We identified 38 genes carrying pathogenic or likely pathogenic variants, including **HMGCL**, **AGL**, **POGZ**, **ASH1L**, **PTEN**, **OTOG**, **MYBPC3**, **TSC2**, and **NRXN3**. Variants in the **OTOG** gene were observed in four patients, while **ASH1L** variants were found in two patients. Additionally, CNV analysis of 67 samples uncovered 2,170 CNVs, of which five were classified as pathogenic or likely pathogenic. Comparative analysis with 100 Indian control samples identified 8,704 CNVs, of which 19 were significantly associated with ASD.

Conclusions:

This research uncovers a distinct genomic landscape in ASD within the Indian population, laying the groundwork for targeted diagnostic and therapeutic strategies. Ongoing studies aim to further elucidate the role of structural variations, complemented by functional evaluations.

412.206 Immunogenetic Association Supports the Involvement of IL-4 in Autism Spectrum Disorder

A. M. Persico¹, F. Chehban², I. Piras³, V. Napolioni⁴, A. Mavillonio⁵, R. Sacco⁶ and A. Grande⁶, (1)Dept. of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, MO, Italy, (2)Dept. of Biomedical, Metabolic and Neural Sciences, Child & Adolescent Neuropsychiatry, University of Modena and Reggio Emilia, Modena, MO, Italy, (3)Neurogenomics Division, TGen, Phoenix, AZ, (4)Genomic and Molecular Epidemiology Laboratory, School of Biosciences and Veterinary Medicine, University of Camerino, Camerino, MC, Italy, (5)Service for Neurodevelopmental Disorders, "Campus Bio-Medico" University Hospital, Rome, RM, Italy, (6)Dept. of Biomedical, Metabolic and Neural Sciences, Applied Biology, University of Modena and Reggio Emilia, Modena, MO, Italy

Background: Autism Spectrum Disorder (ASD) is often accompanied by immune dysregulation, encompassing neuroinflammation, systemic immune activation, abnormal adaptive and/or innate cellular response, allergies, autoimmunity. It is unclear whether immune dysregulation contributes to ASD pathogenesis or represents a collateral by-standing phenomenon.

Objectives: To search for genetic association between ASD and 34 functional SNPs (i.e., affecting gene expression or protein function), located in 26 genes involved in 16 different immune pathways, by investigating one experimental and two replica samples.

Methods: We performed a family-based genetic association study involving: (#1) an experimental sample of 502 Italian ASD families (484 simplex and 18 multiplex); (#2) a replica sample including 1,031 multiplex families with 1,553 affected offspring available from the AGRE collection; (#3) another replica sample, including 381 Italian families (359 simplex and 22 multiplex). After quality control, transmission disequilibrium was contrasted in ASD vs unaffected siblings (samples #1 and 2) or in ASD only (sample #3) using FBAT. Plasma concentrations of IL4, IL13, IL5 and GM-CSF were measured using the ELLA immunoassay system (BioTechnique). IL4 and IL4-R mRNAs were quantified in total RNA extracted from PBMCs by qPCR using TaqMan assays and applying the 2- $\Delta\Delta$ CT method after normalization with the housekeeping gene GAPDH.

Results: Sample #1: a significant association was found with IL-4 rs2243250 (Bonferroni adj P=2.0 x 10⁻⁴), CTLA4 rs231775 and LTA rs909253; Sample #2: genotypes at SNPs rs2243270 and rs11571292, in complete LD with rs2243250 and rs231775, confirmed a significant association with IL4 (FBAT p=0.027), but not with CTLA4; Sample #3 conclusively replicated the association with IL4 rs2243250 (FBAT P=0.037). The T allele at rs2243250, consistently overtransmitted from heterozygous parents to ASD offspring in all three samples, is associated with reduced IL-4 expression in live human tissues (enhanced expression only in EBV-transformed cells), but also with differential expression of the KIF3A, SLC22A5, SLC22A4, SEPT8 and HSPA4 genes (eQTL database). Plasma levels of IL-4 were significantly higher in 171 ASD children compared to 55 unaffected sibs (P=0.008) (ASD>sibs also in 58 intrafamilial pairs, p=0.046), and no association with rs2243250 genotypes was found. On the contrary, a significant decrease in IL-4 (p<0.05) and increase in IL-4R (p<0.01) mRNA levels was detected in PMBCs of 116 ASD vs 98 siblings. The phenotypes associated with rs2243250 include asthma, atopic dermatitis, and eczema (PheWAS), which also frequently occur in ASD. In our sample, association with the T-allele reaches a p<0.10 for presence of allergies and a p=0.001 for history of an autoimmune disorder in the patient.

Conclusions: The consistent association between ASD and the T allele at rs2243250 is likely mediated by differential IL-4 gene expression, although mediation by other genes cannot be excluded. The IL-4 pathway plays a pivotal role in Th2 immunity, but also directly influences brain functions, such as learning and memory. This role may be played during pregnancy and/or continue later in life. Further studies will need to address genotype effects and IL-4 functional roles in immune and neuronal cell models.

412.207 Investigation of Genetic Architecture of Autism and ADHD Using New Age at Onset of Walking GWAS Results Indicates Possible Distinct Developmental Pathways

M. Morgan¹, A. Ronald², A. Gui² and A. Hollowell³, (1)University of Surrey, Guildford, Surrey, United Kingdom, (2)University of Essex, Colchester, Essex, United Kingdom, (3)Birkbeck College, University of London, London, London, United Kingdom

Background:

Autism and attention-deficit/hyperactivity disorder (ADHD) are neurodevelopmental conditions that often co-occur and show considerable overlap in genetic influences. They both show associations with infant developmental milestones. A genome-wide association study (GWAS) of a key motor milestone, age at onset of walking, has recently been conducted. We investigated the relationship between the genetic architecture of age at onset of walking and neurodevelopmental conditions.

Objectives:

To investigate the underlying common variant genetic architecture of neurodevelopmental conditions.

Methods:

LDSC regression and GenomicSEM analysis were employed using the summary statistics of the latest GWASs of age at onset of walking, autism, attention deficit hyperactivity disorder and other neurodevelopmental conditions. We fitted models to estimate the shared common genetic variance between age at onset of walking and autism and ADHD after taking account of other conditions.

Results:

Age at onset of walking did not significantly associate with autism after taking account of the effects of ADHD and other conditions. Whereas, age at onset of walking did significantly associate with ADHD independently of effects of autism and the other conditions.

Conclusions:

Our results show that age at onset of walking shares genetic architecture with ADHD but not with autism. This result may indicate possible distinct early developmental pathways for autism versus ADHD.

412.208 Many Apparent False Negatives in Detection of Mutations in Gene Associated with Autism Spectrum Disorders

M. Hames¹, A. Kolevzon², E. Berry-Kravis³, J. Holder⁴, L. Glass¹, N. Jones¹, **B. Eisinger¹**, G. Bliss⁵, L. Squires¹ and T. Levy², (1)Neuren Pharmaceuticals, Camberwell, VIC, Australia, (2)Seaver Autism Center at Mount Sinai, New York, NY, (3)Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL, (4)Baylor College of Medicine / Texas Children's Hospital, Houston, TX, (5)CureSHANK, Beverly Hills, CA

Background:

Phelan-McDermid Syndrome (PMS) is a neurodevelopmental disorder caused by disruptions to the *SHANK3* gene on chromosome 22q13, encoding a scaffolding protein crucial for synaptic function and neuronal development. PMS presents with developmental delay, intellectual disability (ID), speech impairment or absence, hypotonia, and autism spectrum disorder (ASD) features. Deficiencies in *SHANK3* are caused by a variety of genetic abnormalities, including large deletions involving multiple genes, detectable by chromosomal microarray analysis (CMA), or smaller mutations affecting only *SHANK3*, requiring sequencing-based approaches. The prevalence of PMS is approximately 2.5-10 per million live births, yet mutations in *SHANK3* are among the most common genetic findings in people with ASD, affecting 1% of autism patients. There are no FDA-approved pharmacological therapies for PMS. As a rare disease, maximizing the rate of diagnosis is of the utmost importance for both treatment and recruitment for clinical trials. However, discrepancies exist across U.S. diagnostic laboratories in capabilities, quality, and practices in addressing the genetic complexity of PMS etiology. It is therefore likely that significant numbers of PMS patients go undiagnosed every year, representing a crucial unmet medical need for this rare neurological disorder.

Objectives:

This study aims to address this gap by evaluating U.S. commercial laboratories' *SHANK3* testing quality, identifying exemplary practices and areas for improvement, and disseminating actionable findings to laboratories, patients, caregivers and advocacy groups.

Methods:

To assess the degree to which U.S. laboratories are meeting the diagnostic needs of the PMS community, we established a set of criteria focusing on Next Generation Sequencing (NGS)-based approaches (Table 1). Information on each aspect of *SHANK3* diagnostic capabilities was gathered via web searches, inquiries, and direct communication with laboratories. Laboratories were classified as "optimal", "suboptimal", or "poor", with specific areas for improvement noted and testing volumes documented to assess overall impact.

Results:

Of 12 laboratories evaluated, 3 were classified as optimal, 6 suboptimal, and 3 poor for PMS testing (Table 2). Laboratories considered "poor" do not include *SHANK3* in panel-based testing or whole genome sequencing/whole exome sequencing (WGS/WES), making a positive PMS diagnosis impossible. Problematically, this omission often occurs in platforms advertised as being comprehensive for neurodevelopmental disorders. Suboptimally graded laboratories do include *SHANK3* in testing, but are impacted by incomplete gene coverage, a lack of deletion/duplication analysis, or non-comprehensive variant reporting. While precise testing volumes were not provided by all laboratories, range estimates varied across several orders of magnitude, and no correlation was observed between testing volume and quality classification.

Conclusions:

U.S. laboratories with poor *SHANK3* testing are likely failing to diagnose up to one-quarter of PMS patients, while suboptimal laboratories may be missing 2-3%. Considering testing volumes, it's probable that hundreds of PMS patients have been missed in recent years. Providing information about the most common pitfalls in PMS testing can inform laboratories' diagnostic workflow development, motivate remedial re-testing of previously negative ASD patients, and empower decision making by patients and health care providers.

412.209 Minerva: A Novel Public Web Resource for Learning about Autism Genetics

S. S. Kuo¹, C. van der Merwe², J. Fu³, F. K. Satterstrom⁴, M. E. Talkowski⁵, A. Thurm⁶, S. J. Sanders⁷, S. Bishop⁸ and E. B. Robinson³, (1)Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, (2)Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, (3)Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, (4)Analytic and Translational Genetics Unit, Broad Institute of MIT and Harvard, Boston, MA, (5)Division of Medical Sciences, Harvard Medical School, Boston, MA, (6)Office of the Clinical Director, National Institutes of Health - National Institute of Mental Health, Bethesda, MD, (7)Department of Psychiatry, Weill Institute for Neuroscience, University of Oxford, San Francisco, CA, United Kingdom, (8)Psychiatry and Behavioral Sciences, University of California, San Francisco, San Francisco, CA

Background: US professional medical guidelines recommend clinical genetic testing for all children with autism diagnoses, yet approximately only 3 in 100 autistic children have undergone first-line testing (i.e., chromosomal microarray and fragile X testing). Genetic testing can help explain co-occurring conditions such as seizures and metabolic disorders and suggest specific supports for mitigating these challenges. Although a genetic diagnosis can lead to tailored services for an autistic child, families and clinicians in the child's support network often lack access to reliable, accurate sources of information about clinical genetic testing.

Objectives: To empower learning about genetics tailored to autism, we are building a public, web-based suite of educational resources named MINERVA (Mapping Individualized Estimates to Rare Variants in Autism). In consultation with expert advisory groups and focus groups of parents and pediatricians supporting autistic children, MINERVA will provide several empirically supported resources centered on genetic heterogeneity and clinical genetic testing.

Methods: MINERVA resources include a novel prediction algorithm to estimate an autistic child's personalized probabilities of carrying a neurodevelopmental disability associated variant (NDAV). NDAVs were defined as *de novo* copy number deletions, as well as *de novo* protein truncating variants and disruptive missense variants in genes associated with neurodevelopmental disabilities (including intellectual disability and autism). To develop the prediction algorithm, we harmonized whole exome sequencing and phenotypic data in a combined sample of 3,440 autistic children aged 4-17 years from two independent, diverse North American cohorts. We conducted logistic regression models using multiple, easily accessible phenotypes (e.g., sex, age at walking) to estimate genetic diagnosis probabilities.

Results: We observed extensive heterogeneity in probability estimates throughout our sample, ranging from approximately 2% in males without congenital heart defect who walked at 12 months and had a cognitive score above 110, to over 50% in females with congenital heart defect who started walking at 30 months and had a cognitive score below 70. MINERVA will present genetic diagnosis probabilities for a child along with average probabilities across autistic people (7%) and their non-autistic / undiagnosed siblings (1%).

Conclusions: By providing genetic diagnosis probability estimates along with accessible guides to current scientific and clinical knowledge about autism genetics, MINERVA can help catalyze conversations about autism genetics and informed decision-making around clinical genetic testing for autistic children.

412.210 Molecular and Social-Environmental Factors Uniquely Contribute to Specific Cognitive and Adaptive Outcomes: A Case Study in Fragile X Syndrome

W. S. McKinney¹, A. Corsmeier², A. Dapore², C. Gross², K. Dominick², C. A. Erickson³ and **L. M. Schmitt⁴**, (1)Division of Behavioral Medicine and Clinical Psychology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH

Background: There is considerable phenotypic heterogeneity even among single gene causes of autism, like fragile X syndrome (FXS).

Approximately 30% of the variance in IQ among individuals with FXS is accounted for by familial genetic and molecular factors, including absence or reduction in fragile X messenger ribonucleoprotein (FMRP) expression. The remaining 70% of this variance is partially accounted for by social-environmental factors (e.g., education, access to therapies, home environment, nutrition) that have not yet been systematically examined in FXS.

Objectives: Identify the unique contributions of social-environmental and biological factors to individual differences in cognitive and adaptive behaviors in individuals with FXS.

Methods: 207 individuals with FXS (69% male) aged 4-72 years (mostly adults) completed the Stanford-Binet, Fifth Edition (SB-5) to estimate IQ. Participants' caregivers completed the Vineland-3 Comprehensive Interview to measure adaptive skills. FMRP was quantified using our validated Luminex-based assay. Standardized rankings of "neighborhood opportunity" were extracted based on participant home addresses at the time of testing using the Child Opportunity Index (COI), which ranks the economic, educational, and health/environmental resources of individual neighborhoods relative to national averages (higher scores reflect greater opportunities). We examined the variance in IQ and adaptive behaviors accounted for by neighborhood factors versus the variance accounted for by FMRP expression.

Results: Associations between positive neighborhood opportunities, higher IQ, and greater adaptive behaviors were significantly stronger in males with FXS than females. In males with FXS, even after controlling for age, FMRP accounted for about 3% of variance in IQ, with an additional 5% accounted for by access to healthcare resources (e.g., insurance availability; nearby healthcare nonprofit organizations). On the other hand, greater economic equity, employment opportunities, social-economic resources (e.g., multi-caregiver households; cross-income friendships), and educational resources (e.g., teacher experience) accounted for significant variance in adaptive skills beyond FMRP. Of these, the strongest predictor of overall adaptive behaviors were social-economic resources, which accounted for about 10% of the variance. In females with FXS, greater healthcare resources also were associated with higher IQ, although this association was no longer significant after accounting for FMRP expression.

Conclusions: Our findings show that distinct social-environmental factors contribute to individual differences in IQ and adaptive skills in FXS even after accounting for FMRP expression. Thus, similar social-environmental factors may contribute to individual differences in IQ and adaptive skills in other genetic and idiopathic ASDs. We also emphasize that although neighborhood-level opportunities are important, they are not universally related to cognitive and adaptive skills, and vary based on sex. Our finding that adaptive behaviors are most strongly related to social-economic supports warrants further investigation using narrowband measures and qualitative interviews with families to identify pathways through which these social-economic factors foster adaptive behaviors. Long-term, we hope this and follow-up studies will determine the extent to which findings are specific to FXS and which generalize across ASDs in order to enable the development of targeted interventions that combine both biological as well as family- and systems-level interventions to positive influence development.

412.211 Newborn Blood DNA Methylation Correlates Likelihood of Autism Spectrum Disorders with Grandparental Age, Alcohol Intake, and Cigarette Smoking

G. E. Kuodza¹, J. S. Mouat¹, N. Y. Krigbaum², V. Haghani¹, E. G. Thrall¹, R. Kawai¹, S. M. Hakam³, Y. J. Ludena¹, T. N. Sullivan¹, A. P. Mendiola¹, D. H. Yasui¹, T. A. Tran¹, O. Sharifi¹, A. L. Humphries¹, C. G. Torres¹, D. H. Bennett¹, R. J. Schmidt¹, M. A. La Merrill¹, P. M. Cirillo², I. Hertz-Picciotto¹, B. Cohn² and J. M. LaSalle¹, (1)University of California, Davis, Davis, CA, (2)Public Health Institute, Oakland, CA, (3)University of California, Berkeley, Berkeley, CA

Background: ASD is a group of neurodevelopmental conditions characterized by deficits in social reciprocity and communication, restricted interests, and repetitive behaviors. The etiology of most ASD cases is thought to be a combination of genetics, environmental factors, and gene-environment interactions that are poorly understood. Grandparental non-genetic factors, such as cigarette smoking during pregnancy and advanced age at conception, have been associated with increased risk of ASD in the grandchild, but potential molecular mechanisms and biomarkers have not been studied in a human cohort.

Objectives: In this study, we examine ASD versus typically developing (TD) newborn blood DNA methylation patterns to make biological connections between grandparental exposures and ASD diagnosis in the grandchild.

Methods: To conduct this study, we used two unique three-generation cohorts. The discovery dataset is from the Child Health and Development Studies (CHDS), which enrolled pregnant women in Oakland, CA from 1959-1967 and conducted follow-up studies with their children and grandchildren. The replication dataset is from the Child Autism Risks from Genetics and the Environment (CHARGE), which enrolled case-controls in the Sacramento region, CA from 2006 and conducted follow-up studies and asked grandparents for their participation. We obtained newborn dried blood spots (NBDS) from 196 CHDS grandchildren (84 ASD, 112 TD) and 174 CHARGE grandchildren (113 ASD and 66 TD) and assayed DNA methylation using whole genome bisulfite sequencing (WGBS). To analyze the newborn blood DNA methylation, we identified co-methylation modules using Comethyl, a weighted gene correlation network analysis (WGCNA) approach that has been optimized for WGBS data. Co-methylation modules consist of genomic regions with correlated methylation and can be reduced to single eigennode values that can be correlated with sample traits, including grandchild neurodevelopment and grandparental exposures (Figure 1).

Results: In the CHDS cohort we identified two co-methylation modules (orange and purple) that were significantly (Bicor=0.16, $p=0.026$) positively associated with ASD diagnosis, with ASD NBDS having higher methylation values than TD NBDS in both modules. We found that both ASD co-methylation modules were also significantly correlated with several grandparental traits, with different findings in maternal versus paternal lineages. Eigennode values from the orange module were negatively associated with maternal grandparent alcohol intake (Bicor=-0.27, $p=0.050$) and positively associated with paternal grandparent age at conception (grandfather Bicor=0.27, $p=0.00011$; grandmother Bicor=0.25, $p=0.0091$), while eigennode values from the purple module were positively associated with paternal grandfather cigarette smoking (Bicor = 0.21, $p = 0.0025$). The orange module mapped to genes *TLX3* and *RANBP17*, which have both been previously implicated in ASD, and *RANBP17* has been implicated in aging. The purple module mapped to genes *PTPRJ* and *TRIM49B* which have been previously linked to ASD. The analysis for the CHARGE cohort is ongoing as a replication for the CHDS findings.

Conclusions: The results from this study so far provide biological insight into grandparental factors associated with the likelihood of ASD and show that DNA methylation may be a mechanism by which factors such as age, alcohol intake, and cigarette smoking transfer the impact of these factors across generations.

**412.212** Non-Synonymous Variants' Enrichment Identifies Modules of Spatio-Temporal Co-Expressed Genes Functionally Associated with Autism Subtypes

A. Crippa¹, G. Scaccabarozzi², L. Fumagalli³, M. Mambretti³, R. Giorda³, M. Villa³, S. Busti Ceccarelli⁴, L. Villa⁵, E. Mani⁵, M. Nobile⁴, M. Molteni¹ and U. Pozzoli³, (1)Child Psychopathology Unit, Alessandro Crippa, Bosisio Parini, Lecco, Italy, (2)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy, (3)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy, (4)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (5)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy, Italy

Background: Given the heterogeneity of the condition, the identification of the functional implications of genes' variants related to autism commonly requires large-scale studies involving thousands of participants. An alternative perspective is to shift the focus from single genes to networks of genes that converge in functionally relevant biological processes, e.g. by using gene-set analysis. This approach permits to examine the combined effect of multiple DNA variants that cumulatively impact biological pathways potentially relevant to autism, reducing the impact of multiple testing and increasing effect size.

Objectives: In the present study, we aimed to explore whether an unbiased multi-step analysis could identify and functionally characterize gene-sets with relevance to autism subtyping in terms of different variants' load among two subgroups of autistic children.

Methods: After subdividing our sample of 71 autistic children (3-12 years) in two subgroups with higher (>80 ; $n=43$) and lower (≤ 80 ; $n=28$) intelligence quotient (IQ), a gene-set variants enrichment analysis was applied to identify gene-sets with significantly different incidence of non-synonymous variants between the two subgroups. Using a data-driven, unsupervised approach, gene-sets were then clustered into modules with more homogeneous enrichment scores. Next, to functionally characterize genes in the modules, we investigated their expression profiles according to the BrainSpan Atlas of the Developing Human Brain. Last, we considered an enlarged pool of genes by including those most correlated ($r>0.7$) with the genes in the modules. In this enlarged pool, we assessed gene spatio-temporal co-expression in BrainSpan Atlas, and protein-protein interactions according to the BioGRID database. Among them, we further explored the incidence of high-confidence autism-related genes as reported by the Simons Foundation Autism Research Initiative (SFARI) database.

Results: Our analysis identified 38 significant gene-sets (false discovery rate, $q<0.05$) with different variants' load in the two subgroups of autistic children. These gene-sets, which included 207 genes in total, were clustered in four modules representing specific biological processes, such as ion cell communication, neurocognition, gastrointestinal function, and immune system. Those gene modules were highly expressed in specific brain structures across different developmental stages, except for the immune module. When considering the enlarged pool of correlated genes, they were significantly spatio-temporally co-expressed and organized in three clusters. They also highly interacted at the level of protein-protein interactions (Fig.1). Moreover, among the entire pool of correlated genes, high-confidence SFARI genes were overrepresented ($OR=2.59$; $p=0.001$).

Conclusions: Our unbiased multi-step analysis could identify gene modules functionally meaningful to autism even in a relatively small set of participants. We further documented the brain expression of those genes, their spatio-temporal co-expression and functional interplay. Lastly, the relevance of the identified gene modules in autism manifestation was supported by their interactions with many SFARI genes. Although these observations should be considered with caution, future research could leverage the present approach to identify genetic pathways relevant to autism subtyping, towards the identification of distinct biotypes of patients.

412.213 Psychopharmacology in Children with Genetic Disorders of Epigenetic and Chromatin Regulation

S. Lenz^{1,2}, S. J. Goodman³, A. Sivaloganathan², C. Cytrynbaum¹, J. Rapley⁴, E. Canning⁵, R. Weksberg⁶ and D. A. Baribeau², (1)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Bloorview Research Institute, Toronto, ON, (5)Carleton University, Ottawa, ON, Canada, (6)Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada

Background: Over 100 neurodevelopmental disorders (NDDs - i.e. autism or intellectual disability) caused by variants in epigenetic or chromatin regulatory genes have been identified. Estimates of psychotropic medication use in children with NDDs range from 30-60%, and psychotropic polypharmacy is common. Yet, there are limited published clinical data, and no biomarkers, to guide psychotropic medication choice in NDDs. Whether individuals with genetic disorders of epigenetic/ chromatin regulation have differential responses to psychotropic medications, and whether methylation changes may serve as a biomarker of psychotropic treatment response in this population have not been examined.

Objectives: The objective of this study was to examine and compare behavioural profiles and longitudinal treatment patterns in children with epigenetic/chromatin disorders, other genetic NDDs, or no known genetic disorder.

Methods: Using the electronic medical records from a pediatric psychopharmacology program for children with NDDs, we compared clinical characteristics, longitudinal psychotropic medication profiles and reports of side effects across the three genetic groups. As an exploratory analysis, serial methylation analyses were conducted during pharmacotherapy trials in a child with ARID1B-related disorder (ARID1B-RD).

Results: A total of 331 children attended the program between 2019 and 2022. Nine children had variants in single genes known to have a primary epigenetic regulatory function (3%), and twenty-three children had other rare genetic NDD variants (7%). Developmental and psychiatric profiles were similar between groups, except for intellectual disability [epigenetic variant: 6/9 (66%), other variant: 12/23 (52%), no variant: 92/299 (31%), $p<0.01$]. Treatment patterns were similar, however side effect profiles differed: those with genetic variants were more likely to experience drowsiness (33 and 35% vs. 16%, $p<0.05$); those with epigenetic variants were more likely to experience weight gain (44%, vs. 9% and 21%, $p<0.05$). A methylation signature consistent with ARID1B-RD was detected; no methylation changes were associated with risperidone or methylphenidate.

Conclusions: Genetic classification of neurodevelopmental disorders may help anticipate treatment tolerability; the integration of diagnostic and therapeutic biomarkers merits further study.

412.214 Relative Diversity Associated with Neurexin Trajectories (RaDiaNT): A Protocol for a Family-Based Study of a Rare Genetic Condition

C. J. Molloy¹, H. Cahill², A. Miles³, F. Lelik⁴, T. Dinneen⁵, E. K. Baker⁶, L. Ristic³, A. T. Morgan⁷ and L. Gallagher⁸, (1)Psychiatry, Trinity College Dublin, Dublin, Dublin, Ireland, (2)Trinity College Dublin, Dublin, Dublin, Ireland, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Speech and Language, Murdoch Children's Research Institute, Parkville, VIC, Australia, (5)The Hospital for SickKids., Toronto, ON, Canada, (6)Genetics, Murdoch Children's Research Institute, Parkville, VIC, (7)Speech and Language, Murdoch Children's Research Institute, Parkville, VIC, Australia, (8)Psychiatry, University of Toronto, Toronto, ON, Canada

Background: *NRXN1* deletion (*NRXN1del*) is a rare neurogenetic condition associated with autism, intellectual disability and speech and language delay. The *NRXN1* gene encodes for a pre-synaptic cell adhesion molecule important for brain development and neurotransmission, providing a mechanistic pathway to investigate clinical outcomes. The Relative Diversity associated with Neurexin Trajectories (RaDiaNT) study is a family-based cross-sectional design that aims to examine the genetic heterogeneity contributing to variability in cognitive, language, social and mental health outcomes in *NRXN1del* carriers and family members. It is hypothesised that additional genetic factors may modify phenotypic outcomes. **Objectives:** To (1) refine a protocol to examine the prevalence of a range of neurodevelopmental and neuropsychiatric outcomes and traits in a large cohort of *NRXN1del* carriers and their family members; and (2) investigate the role of polygenic and rare variant burden in *NRXN1del* clinical outcomes.

Methods: Research sites include Trinity College Dublin, Ireland, The Hospital for Sick Children, Canada, and Murdoch's Children's Research Institute, Australia. The family-based design focuses on *NRXN1del* carriers, their parents, and nearest age sibling. Inclusion criteria are at least one family member with a clinical genetic diagnosis of *NRXN1del*. We have established a study protocol that includes online questionnaires, interviews and direct assessments to assess medical history, psychopathology, speech and language, cognitive ability, adaptive functioning, and quality of life across family members. We developed a measure of protocol feasibility to inform and refine family-based study designs including neurodiverse individuals. We record completion rates of cognitive and behavioural tasks within the protocol, and reasons measures are "partially complete" (inability to pay attention, tired/bored, got upset, behavioural issues, ran out of time), "complete but unsure about validity" (cognitive understanding, behavioural issues) and "not attempted" (refuse to complete, behavioural issues, tired/upset on day of visit). We also collect biosamples from all family members for whole genome and long read sequencing for copy number variant (CNV) breakpoint mapping and the identification of common and rare variation elsewhere in the genome. We will examine the influence of *NRXN1del* location and size, and common and rare genetic variation on clinical and behavioural outcomes.

Results: To date, 29 individuals from 8 families have been recruited at the TCD site; 13 *NRXN1del* carriers ($21.25 \pm SD = 13.97$; 7 male and 6 female) and 16 non carriers ($31.17 \pm SD = 26.66$; gender = 11 male, 5 female). Among children and sibling carriers of *NRXN1del*, 78% (n=7) had a parent-reported clinical diagnosis of autism, and 66% (n= 6) had an intellectual disability. Preliminary feasibility data indicate findings important for understanding accessibility of a battery of tablet-based cognitive tasks, with the battery partially completed by three participants due to frustration (n=1) or noise distraction (n=2), and not attempted by six participants due to cognitive and language level (n=5) and hyperactivity (n=1). **Conclusions:** Gene first approaches offer several advantages for studying rare neurogenetic conditions including important clinical and biological insights. The family-based design can enhance our understanding of genetic and environmental factors contributing to clinical outcomes.

412.215 Sexual Dimorphism in Autism: Exploring Gene Expression Differences As a Possible Etiological Factor.

K. Griesi-Oliveira and P. V. Visintin, Hospital Israelita Albert Einstein, São Paulo, Brazil

Background: Autism Spectrum Disorder (ASD) is a genetically heterogeneous condition, presenting with a notable sex bias, where males are diagnosed approximately four times more frequently than females. While various hypotheses attempt to explain this skewed sex ratio, the underlying physiological mechanisms remain elusive. Previous transcriptomic studies in neuronal cells of individuals with ASD have consistently identified dysregulation in modules of co-expressed genes. This observation raises the possibility that differences in the basal regulation of gene expression between males and females during neurodevelopment could contribute to the observed sex bias in ASD prevalence.

Objectives: We aimed to investigate whether gene co-expression modules, identified in fetal brains and enriched by ASD-associated genes, differ between sexes in terms of structural relationships or expression levels.

Methods: We utilized publicly available transcriptomic data from cortical regions of fetal brains (16-21 weeks of gestation), a critical period and region already implicated in ASD. Using Weighted Gene Co-Expression Network Analysis (WGCNA), we constructed gene co-expression networks for male and female brains independently and a consensus network in order to map the common and differential co-expression relationships, focusing particularly on those modules enriched by ASD-associated genes.

Results: We found 5 modules in the consensus network that are enriched by ASD-associated genes. A module related to cell migration and cell adhesion presented a higher level of expression in male brains. Additionally, some of these modules presented as a unique module in males, and as a distinct modules in females, and vice-versa, revealing differences in the structural organization of regulatory networks between the genders. Particularly, we found that, in male brains, a module related to expression regulation has an inverse correlation with the expression of a module enriched by genes related to synapse, while in female brains, the expression levels of these two modules are positively correlated.

Conclusions: The results obtained so far suggest that differences between sexes, both in terms of structure and gene expression profile in modules important for autism spectrum disorder, may be factors that contribute, at least in part, to the sexual dimorphism present in autism spectrum disorder, which is reflected in the more prevalent diagnostic ratio in men.

412.216 Somatic Variants in Autism Spectrum Disorder Revealed By Ultra-Deep Whole Genome Sequencing

A. Mo^{1,2}, A. Kriz², V. Viswanadham³, N. Engel³, J. Markowski³, H. Cline³, A. Lai^{1,2}, P. J. Park³ and C. A. Walsh^{2,4}, (1)Department of Neurology, Boston Children's Hospital, Boston, MA, (2)Division of Genetics and Genomics, Boston Children's Hospital, Boston, MA, (3)Department of Biomedical Informatics, Harvard Medical School, Boston, MA, (4)Howard Hughes Medical Institute, Boston, MA

Background: Non-inherited somatic variants that arise after fertilization have been identified by exome sequencing to contribute to 3-5% of simplex autism spectrum disorder (ASD) cases. A preliminary study using whole genome sequencing (WGS) further suggested that ASD brains may be enriched in non-coding somatic variants located in critical neural enhancers (Rodin et al., 2021). However, this study used bulk brain tissue instead of neurons and included only a small number of ASD cases.

Objectives: Here, we aimed to identify somatic variants in neurons from postmortem human brain tissue in ASD cases compared to neurotypical controls by using ultra-deep whole genome sequencing.

Methods: Frozen post-mortem frontal cortex from ASD cases (n=58) and control cases (n=48) were dissected and homogenized to isolate nuclei. To increase the sensitivity to detect clonal somatic variants that arose during fetal development, the time period of ASD pathogenesis, we used DNA from purified neurons rather than bulk brain tissue. Neuronal nuclei were separated from non-neuronal nuclei using fluorescence-activated nuclei sorting. DNA was extracted by phenol chloroform purification. WGS libraries were prepared and sequenced using 150bp paired-end reads to >210X coverage. Datasets were aligned to hg19 reference and preprocessed with GATK. Candidate somatic variants were initially identified using TNHaplotyper2 and then the callset was refined using MosaicForecast, a machine-learning based caller that is specialized for detecting variants with low variant allele fractions.

Results: Our preliminary analysis shows a greater number of potential somatic variants using WGS obtained from flow-sorted neuronal nuclei compared to previous datasets using bulk brain. Overall, WGS in neuronal nuclei identifies 62.8% more somatic single nucleotide variants than WGS using bulk brain tissue. Furthermore, WGS from flow-sorted neuronal nuclei identifies many lower allele fraction variants compared to bulk tissue.

Although the average numbers of somatic single nucleotide variants did not differ between ASD brains compared to control brains, ASD brains show significantly more variation in somatic single nucleotide variant counts than control brains. For example, one of the ASD brains exhibited ~2.5-fold more somatic variants than the average of either ASD or control donors. This brain shows a cluster of 72 predicted somatic variants spanning a 74-Mb stretch of chromosome 16. These variants show allele frequencies that likely correspond to mutations arising in the second and third cell divisions in early embryonic development.

Conclusions: We find evidence for differences in the distribution of somatic variants in ASD brains compared to control brains. Future analyses will focus on identifying the genomic context of somatic variants, comparing mutational signatures between ASD brain neurons and control brain neurons, and exploring the functional impact of somatic variation. This work has implications for understanding the mechanistic and genetic basis of ASD.

412.217 “We Need Community-Centred, Strongly Ethical Genetic Research”: A Qualitative Investigation of Community Attitudes Towards Autism Genetics

B. Johnson¹, K. Pugsley¹, G. A. Alvares², N. P. Stryj³, E. Baxter⁴, T. Chau⁴, L. Cooper⁴, S. Douglas⁴, K. J. Furley⁵, A. J. Guastella⁶, Z. Hawi¹, R. Keresztes¹, K. King¹, A. S. Rabba⁷, R. E. Poulsen⁸, H. Curd⁹, R. L. Gordon¹, M. Rose¹, J. Teo¹⁰, A. Ure¹¹, K. Williams¹², E. Pellicano¹³ and M. A. Bellgrove¹⁴. (1)Monash University, Notting Hill, VIC, Australia, (2)Telethon Kids Institute, Perth, Western Australia, AUSTRALIA, (3)Turner Clinics, Monash University, Notting Hill, VIC, Australia, (4)Department of Paediatrics, Monash University, Clayton, VIC, Australia, (5)Developmental Paediatrics, Monash University, Melbourne, VIC, Australia, (6)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (7)Monash University & Monash Health, Melbourne, VIC, Australia, (8)Department of Linguistics, Faculty of Medicine, Health and Human Sciences, Macquarie University, Sydney, NSW, Australia, (9)Monash Health, Clayton, VIC, Australia, (10)Murdoch Childrens Research Institute, Parkville, VIC, Australia, (11)Paediatrics, Monash University Department of Paediatrics, Clayton, VIC, Australia, (12)Paediatrics, Monash University & Monash Health, Melbourne, VIC, Australia, (13)Clinical, Health and Educational Psychology, University College London, London, London, United Kingdom, (14)Turner Institute for Brain and Mental Health, Monash University, Clayton, VIC, Australia

Background: Studies of the genetic aetiology of autism have attracted substantial research funding internationally. Translation of study findings into benefits for the Autistic community has lagged. Critically, the needs and priorities of the Autistic community with respect to autism genetics research are poorly understood.

Objectives: To explore the attitudes, experiences, and concerns of Autistic people and their parents/ carers towards autism genetics research.

Methods: We collected first-hand accounts of Australian Autistic individuals and their allies in a series of semi-structured interviews, focus groups, and qualitative surveys. The study design and interview schedule were co-produced with guidance from three separate advisory groups, including Autistic adults, parents of Autistic people, and autism research and healthcare professionals. Thirty-three community members took part in the study. Many held multiple simultaneous roles within the Autistic and autism communities. Twenty-eight participants (84.8%) identified as Autistic, 13 (39.4%) as parents of Autistic and/or neurodivergent children, and 12 (36.4%) as autism-related professionals (e.g., researchers, advocates, healthcare workers). Participants were an average of 38.9 years old at the time of their interview (range 21-76, SD = 13.3). The data were analysed within a critical realist framework using reflexive thematic analysis.

Results: Analysis of our interviewees' discussions about autism genetics research identified three main themes, and eleven sub-themes. The first theme related to autism genetics research having eugenic potential, and community concern for how it perpetuates negative attitudes about Autistic traits and people. The second theme focused on disillusionment and distrust towards the field of autism genetics research. Interviewees expressed a lack of trust of people in power stemming from their failure to integrate urgent community priorities within the research aims. The final theme focused on the positive potential of autism genetics research, with caveats. Community members believed that genetics knowledge could hold health benefits for the Autistic community. However, they felt these benefits could only be achieved through trust-building and improved engagement of Autistic voices in the research.

Conclusions: Our work outlines a path forward in co-design methodologies for undertaking community priority setting with respect to autism research. Our findings highlight the current relationship and perceptions that exist between community members and autism genetics researchers that need to be acknowledged and addressed in order for meaningful advances in this field. This research holds important implications for the design and conduct of future autism genetics research both locally and internationally.

Poster Session

413 - International and Cross-Cultural Perspectives I

May 1st, 2025, 5:30 PM - 6:30 PM - Hall 4A

413.218 How Do Transfronterizo Families Scaffold Their Autistic Children's Bilingual Language Interactions in Everyday Settings? **S. R. Cohen¹**, A. Wishard Guerra², M. J. Aragon³, A. Estrada⁴ and E. Lee⁵, (1)University of California, San Diego, San Diego, CA, (2)UC San Diego, La Jolla, CA, (3)Education Studies, University of California, San Diego, La Jolla, CA, (4)University of California, San Diego, La Jolla, CA, (5)UCLA, Los Angeles, CA

Background: Parents' language practices, quantity and quality of linguistic input, predict children's language outcomes (Anderson et al., 2021). For multilingual families, common misperceptions about language learning (e.g., "English only is best,") persist (Peña, 2016). These beliefs shape pedagogy, interventions, and recommendations by therapists, discouraging families from using their home language (Peña, 2016). Recent studies show cognitive benefits of bilingualism for autistic children (Peristeri et al., 2024). These benefits include improved cognitive flexibility and executive functioning outcomes, the ability to understand "false beliefs," and increased focus, as compared to their monolingual autistic peers (Ge, et al., 2023).

Objectives: This study aims to: (1) characterize families' language practices during daily routines; (2) explore how these language strategies vary by activity context; and (3) examine how parents' language scaffolding strategies relate to children's language production.

Methods: 179 video recordings were collected from five bilingual mother-child dyads living in transborder communities. Transcripts were categorized by activity setting: Daily Living, Reading/Homework, Family Mealtime, Play, or Transportation. Transcripts were separated by utterance then coded with one of four codes: scaffolding, contextualized reference, decontextualized reference (DR), and questions. Computerized Language Analysis (CLAN) software was applied to examine participants' language production. Language quantity was measured by number of words, number of utterances, and words per minute. Language quality was determined by mean length of utterance (MLU), type-token ratio (TTR), word variety, and the proportion of DR.

Results: Mothers used Spanish more than children, and their Spanish included significantly longer, and more varied utterances than their English utterances. Children had significantly more variability in their language use than their mothers. Children had significantly more DR ($M = 0.24$) than their mothers ($M = 0.20$), $t(107) = 1.96$, $p < 0.001$.

To examine the impact of families' activity settings on mothers' language practices, we conducted linear mixed effects models with four mother language factors across activity settings: (1) language quantity; (2) language quality; (3) acknowledge and extend; (4) questions. Interactions during transportation activities included significantly higher maternal language quality compared to reading/HW ($\beta = 0.99$; St Error = 0.24; CI: 0.52-1.47; $p < 0.000$). For aim three, mothers' use of DR, and the number of words that mothers used, predicted children's DR (quality: $\beta = 0.21$; St Error = 0.02; CI: 0.17-0.25; $p < 0.001$; quantity: $\beta = 0.04$; St Error = 0.02; CI: 0.004-0.08; $p < 0.05$). Mothers who acknowledged and extended their child's language had children who used more DR ($\beta = 0.04$; St Error = 0.02; CI: 0.00-0.07; $p < 0.05$).

Conclusions: Recent calls for "a contextually sensitive analysis" challenges researchers to consider how sociocultural context complicates autism research (Bottema-Beutel, 2024). Our study prioritized multilingual families' contexts and their linguistic resources to show that (1) bilingualism promotes daily complex language use; (2) distinct home activity settings moderate language interactions among autistic bilingual children and their mothers; and (3) variability in maternal language scaffolding optimize children's use of DR, or the language of abstract reasoning.

413.219 Autism Research Capacity Building in Northern Mexico: Continued Evaluation of an Ongoing Process

G. Perez Liz¹, A. B. Vega-Rivero², A. Vela Staines³, J. R. Maldonado Coronado⁴ and G. Vela⁵, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Universidad de Monterrey, Monterrey, NL, Mexico, (3)Colegio de Bioetica de Nuevo Leon, Monterrey, Mexico, (4)Universidad de Celaya, Celaya, GJ, Mexico, (5)Autismo ABP, Monterrey, NL, Mexico

Background: Research capacity (RC) is often measured with long-term outcomes of high-quality research, such as peer-reviewed publications or successful grant applications. This framework may not address relevant issues contributing to progress, particularly amongst the initial stages of development or when RC building occurs in Low-Middle Income Countries (LMICs). Perez-Liz et al. (2024) reported the sequential evaluation (2018, 2020, and 2022) of the RC building process in Northern Mexico. The report used a six-principle framework (Cooke et al., 2004) across four levels of development. The current study updates the former report as of October 2024.

Objectives: To evaluate the ongoing process of autism RC building in Northern Mexico, utilizing Cooke's framework, updated to October 2024 and analyze the progression of each level over the four time points collected (2018, 2020, 2022, and 2024).

Methods:

Six principles of RC building were evaluated along four levels of development activity (individuals, teams, caregiving organizations, and networks and support units): 1. Skills and confidence building; 2. Support of research 'close to practice'; 3. Linkages, partnerships, and collaborations; 4. Appropriate dissemination; 5. Continuity and sustainability; 6. Appropriate infrastructures. A matrix of criteria for each principle x level was defined by two founding members of the initiative and rated according to the development stage as of November 2018, December 2020, March 2022, and October 2024 as *Not started*, *In Progress*, or *Achieved* by two independent coders. Disagreements in coding were discussed between coders and resolved by one of the founding members. A comparison of the four time points was made and a summary including the accomplishments expected in the initial stages of RC building, and the identification of priorities for the next years was produced.

Results: Two new criteria were added to the existing list of 64 criteria originally identified guided by the model; of these, 31 (48.4%) were rated as *Achieved* or *In Progress* in 2018, versus 51 in 2020 (79.7%), 59 in 2022 (92.2%) and 64 in 2024 (97%). Consequently, the percentage of criteria rated as *Not Started* decreased from 51.5% in 2018 to 17.8% in 2020, to 7.2% in 2022, to 3% in 2024. By 2024, only two principles had items rated as *Not Started*: Principle 5 (Sustainability and Continuity), and Principle 6 (Infrastructure). Principle 4 (Appropriate dissemination and impact) continued to have the least number of items rated as *Achieved* in 2024 as compared to previous timepoints.

Conclusions: Cooke's framework has allowed a continued evaluation of the process of autism RC building in Northern Mexico at four time points: before starting their first research study in 2018, then in 2020, 2022, and 2024. Distinctively, principle 3 (Linkages, collaborations, and partnerships) was rated as the relative strength of this initiative from the launch of the first project and achieved most progress over the six-year comparison. Principle 4 (Appropriate dissemination and impact) continues to be an area of challenge. This ongoing evaluation will contribute to informing research efforts.

413.220 Autism Spectrum Disorder (ASD): The Situation Today in Libya: A Perspective

A. M. Zeglam¹ and N. E. Wahra², (1)Pediatric Neurology, Tripoli University Hospital, Tripoli, Libya, (2)Pharmacy, Department of Primary Health, Tripoli, Libya, Tripoli, Tripoli, Libya

Background:

Objectives:

Methods:

Abstract

Background Libya is a country in North Africa. It is bordered by the Mediterranean Sea to the north, It covers an area of almost 1.8 million square kilometers (700,000 sq mi). Libya is the 17th largest country in the world. The capital of Libya is Tripoli. Libya is a developing country ranking 92nd by The Human Development Index (HDI), the highest score in mainland Africa. While research on autism in Africa is increasing, current knowledge and information are still limited, with only about 1% of autism research originating from sub-Saharan Africa. This lack of representation is significant due to the inequalities in identifying and supporting individuals with autism and their families. There is a shortage of published research on autism in Africa, making the evidence basis for autism intervention and treatment insufficient.

Objectives: In Libya, the prevalence of ASD has risen significantly since 2005. A more recent hospital-based study conducted in 2023 at the neurodevelopment clinics of Tripoli University hospital, reported a prevalence of about 8:1000. These hospital-based studies highlight the substantial burden of ASD in Libya.

The purpose of this paper is to provide a thorough overview of the state of knowledge on ASD in Libya, along with recommendations for improving identification, assessment, management, and policy in these particular circumstances. In order to better understand the problem, efforts should be undertaken to raise awareness of ASD among families and to produce resources and educational materials that are both linguistically and culturally acceptable.

Methods: This is large hospital-based study. The study's two-stage sampling involved first studying the prevalence of ASD; and then All the families of children with ASD attended between Jan.2022 and Jun.2024 (445 children) weighted to be nationally representative of children with ASD were asked two specific questions related to ASD care and services. All children enrolled in this category did meet full DSM-V criteria for an ASD. All the studies were conducted at the pediatric neuro-development clinics of the two main teaching hospitals in Tripoli, Libya.

Results: This study revealed prevalence rates among children of 8:1000.74% of the families involved in the study were not happy about the service their children were receiving. They felt very socially isolated and started to adopt guilt and embarrassment. Of note, ASD rate in girls have steadily risen in recent years

Conclusions: These hospital-based studies highlight the substantial burden of ASD in Libya. There is currently a shortage of data on ASD in Libya, with the most of the information originating from HIC e.g. USA and Europe. Prioritizing funding for ASD will help to increase access to care, through the use of qualified medical personnel, specialist centers and schools, and the availability of relevant equipment and resources. In order to develop inclusive communities, children with ASD and their families should be given the full support they need.

413.221 Barriers to Autism Education: Professional Insights from across Latin America

R. E. Mitre¹, C. J. Fernandez Alvarez², K. Boles³, V. Nanclares-Nogues⁴ and K. Sohl⁵, (1)Fundación Neurodiversidad, Rosario, Argentina, (2)University of Salamanca, Salamanca, Spain, (3)Child Health, University of Missouri, Columbia, MO, (4)Pediatrics, University of Missouri - Columbia School of Medicine, Columbia, MO, (5)ECHO Autism Communities, University of Missouri School of Medicine, Columbia, MO

Background:

Autism spectrum disorder is a lifelong neurodevelopmental condition characterized by challenges in social communication and restricted behaviors. Globally, there is a shortage of professionals trained in autism diagnosis and intervention, leading to long wait times for services (Smith et al, 2020). In Latin America, this shortage is compounded by additional barriers such as limited resources, high training costs, and insufficient public policies supporting autism care. Prior research highlights that training deficits in neurodevelopmental conditions are common in medical and educational settings, particularly in low- and middle-income regions (Alvarez et al., 2024; Sohl et al., 2024). The need for specialized training is urgent, as studies show a clear link between professional development and improved care outcomes for individuals with autism (Mazurek et al, 2017; Buranova et al., 2022; Sohl et al., 2024).

Objectives:

This study aims to assess the main challenges and barriers faced by health professionals in Latin American countries in accessing specialized autism training and certification programs.

Methods:

ECHO Autism is an international capacity-building initiative designed to improve access to autism care by connecting specialists with local professionals through virtual mentorship and training. 108 responses were collected from the Minimum Data Set (MDS) is a standardized survey of various aspects of ECHO program implementation (Sohl et al., 2024). A more targeted survey of barriers to professional training (Alvarez et al., 2024) was conducted to gather additional information. Over 612 responses were collected from healthcare and educational professionals across 18 Latin American countries, including school teachers, therapeutic companions, and school psychologists, with over 20 other professions represented. Of the respondents, 62.2% reported having less than six months of autism training, 13.7% had 6 months to 1 year, and 24.1% had over 1 year of autism training.

Results:

Data from the MDS revealed that 96% of respondents felt their undergraduate training did not adequately cover autism, and 92% perceived a disparity between the financial investment required for specialized training and the compensation they received for providing autism-related services. Key barriers identified in the MDS also included the high costs of training opportunities and the lack of institutional and policy support for autism care. The broader barriers survey echoed similar concerns, with the top three challenges identified as the high costs of specialized training, insufficient autism-related content in undergraduate and graduate programs, and the overall lack of available training proposals in the region.

Conclusions:

This study provides valuable insights into the barriers that limit access to autism training for professionals across Latin America. The findings highlight the need for public policy reforms, enhanced institutional support, and more affordable and accessible training opportunities to expand the pool of qualified professionals. Addressing these barriers is critical for improving autism care, reducing wait times for diagnostic and intervention services, and ensuring that professionals are adequately prepared to meet the growing demand for autism-related services in Latin America. Implementing these changes will likely result in better care outcomes for individuals with autism, benefiting both families and healthcare systems across the region.

413.222 Best and Worst of Both Worlds: Experiences of Transfronterix Mothers Navigating Binational Autism Services

A. D. Duenas¹, F. A. Castellon², K. Valdez Lopez³, C. Orendain Soto⁴ and M. Valladares⁵, (1)*Counseling, Educational Psychology, and Special Education, SDSU, East Lansing, PA*, (2)*University of California Los Angeles, Los Angeles, CA*, (3)*Psychology, California State University Long Beach, Long Beach, CA*, (4)*Child and Adolescent Services Research Center, San Diego, CA*, (5)*San Diego State University, San Diego, CA*

Background: Binational collaboration is needed to address the unique needs of transfronterix families of autistic children. Transfronterix are dual US-Mexican citizens and/or residents who live in Mexico and travel to the U.S. for employment, health care, and community support. Reports from the Washington Office on Latin America show that on average 200,000 people cross the U.S.- Mexico border daily (Border Report, 2024, June 25). *Transfronterix* are a mix of privileged border commuters entering the U.S. with a Secure Electronic Rapid Inspection Card (SENTRI), and disadvantaged border residents who, after their return from the U.S., are barred from entering legally due to their immigration status, and may experience constant threats for deportation and criminalization. Transfronterix mothers of autistic children pursue various types of autism services in both Mexico and the U.S., and experience service unique disparities due to systemic barriers and lack of culturally sustaining care in both countries.

Objectives: The purpose of this study was to explore and document the 1) autism service experiences along the U.S.-Mexico border, 2) migratory motivations and reasoning of Mexican mothers of autistic children pursuing autism services in the U.S. and 3) socio-cultural factors that impact autism service access.

Methods: Following a Community-Based Participatory Research (CBPR) approach, researchers collaborated with community partners in the development of qualitative research materials while also supporting the purposeful recruitment of caregivers who: 1) had an autistic child or a child at risk for autism between 2-7 years of age, 2) crossed the US/Mexico border on a weekly basis to access autism-related services; and or 3) moved from Mexico to the US to receive autism services and continued to access other services in Mexico thus crossing the border on a weekly basis; and or 4) lived in the US and have looked for autism services in Mexico and cross the border on a weekly basis for family and other social supports.

Results: Findings highlight how the Mexican autism system is divided into public and private sectors resulting in families having to navigate both saturated systems with long waitlists, expensive fees, and slow child progress. Mothers capitalize on their transfronterix resources to pursue binational autism services through their willingness to engage in various sacrifices. Compounded by social pressure, stigma, and economic resources, mothers justify their decisions to pursue binational services as they recognize that both the U.S. and Mexico service systems are lacking and believe that this path will provide the best possible outcomes for their children.

Conclusions: The geographical proximity and scarcity of autism services at the US-Mexico border calls for extensive research on binational autism services. Increased collaboration is needed along the U.S./Mexico border to educate and support families navigating bicultural and immigration stressors, loss of social capital, and barriers to binational autism services in this region.

413.223 Concordance Values between Autism Symptoms Parental Interviews and Checklist Among Latino Children in the United States: Preliminary Results

G. Matheus¹, C. Montiel-Nava², A. C. Ramirez³, M. Montenegro³, V. L. Villarreal⁴, G. Perez Liz⁵ and E. Garza³, (1)*The University of Texas Rio Grande Valley, Edinburg, TX*, (2)*Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX*, (3)*University of Texas Rio Grande Valley, Edinburg, TX*, (4)*Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX*, (5)*A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Early detection of autism spectrum disorder (ASD) is fundamental for improved clinical outcomes. However, screening tools developed in English may not be as effective for Spanish-speaking populations. The Toddler Autism Symptom Inventory (TASI) and the Modified Checklist for Autism in Toddlers, Revised (M-CHAT-R) are validated instruments to screen autism in young children. However, there are no studies on their concurrent validity with other diagnostic measures in Latino children in the United States. Determining the psychometric properties of different screening and diagnostic instruments in culturally diverse populations of autistic children will decrease health disparities and barriers to accessing services in these often marginalized ethnic minorities.

Objectives: To examine the concordance values between the scores of the Spanish versions of the TASI with the ADOS-2 and between the M-CHAT-R with the ADOS-2.

Methods: This exploratory study is part of a broader project examining the psychometric performance of autism screeners in Latino children. Participants were recruited from local autism parent support group organizations in the Texas-Mexican border region, and the final sample consisted of 34 Spanish-speaking child-parent dyads ($n=34$), 13 females and 21 males with an average child's age of 60.56 months ($SD=12.49$). Participants completed the Spanish version of the TASI, the M-CHAT-R, and the ADOS-2 with bilingual examiners. Descriptive and bivariate correlation analyses examined the relationship between the Spanish TASI, the M-CHAT-R, and the ADOS-2 scores.

Results: For our sample, results indicated that a moderate positive correlation between the calibrated severity scores of the ADOS-2 and total scores of the Spanish TASI, ($r(34) = .481, p = .01$), and a strong positive association between the calibrated severity scores of the ADOS-2 and total scores of the Spanish M-CHAT-R, ($r(34) = .556, p = .01$). In terms of the ADOS-2 Social Affect domain, positive correlations were identified with the TASI-Social Communication domain ($r(34) = .553, p = .003$), and the M-CHAT-R mean score, ($r(34) = .370, p = .041$). However, there was no significant relationship between the ADOS-2 Restricted and Repetitive Behavior (RBB) domain and the RRB sections from the TASI or the M-CHAT-R.

Conclusions: Preliminary findings from this study suggest that the Spanish TASI and M-CHAT-R are valuable tools for the early detection of ASD in Latino children in the United States. Their use can help reduce barriers to autism diagnosis and support equitable access to early intervention and treatment.

413.224 Cross-Cultural Conceptualizations of Autism and Service-Use Decisions in the United States: A Systematic Narrative Review

A. Richardson¹ and L. Bennetto², (1)*Department of Psychology, University of Rochester, Rochester, NY*, (2)*Psychology, University of Rochester, Rochester, NY*

Background: Autistic individuals and their families face challenges accessing resources, diagnoses, and services due to several factors including limited autism knowledge, stigma, and a complex healthcare system. Black, Indigenous, and People of Color (BIPOC) individuals face additional barriers related to race and ethnicity, immigration status, and English proficiency.

Objectives: This review bridges a gap in literature through a comprehensive examination of autism in BIPOC families by: a) conducting a systematic narrative review of perceptions of autism and service-use decisions in BIPOC communities; b) discussing the clinical implications of these perceptions and decisions; and c) providing recommendations for more accessible information and care for these communities.

Methods: A comprehensive review of the literature was conducted using *PubMed*, *PsycInfo*, and *Web of Science*. Search terms included variations of “autism” and descriptors for race and ethnicity, alongside terms related to diagnosis and services. Eligible articles were reviewed for key findings. To identify the level of confidence in the results, the Let Evidence Guide Every New Decision (LEGEND) System (Clark, Burkett, & Stanko-Lopp, 2009) was used to evaluate each individual study. This evaluation aimed to determine both the quality of evidence for the overall body of work and for each specific racial/ethnic group.

Results: After screening, 73 articles (51 peer-reviewed, 22 dissertations) were retained and discussed through the Dis/ability and Critical Race Theory (DisCrit) Framework. BIPOC parents sought diagnostic clarity based on knowledge of autism, child development, and cultural expectations. Various etiologies (e.g., environmental, genetic, spiritual/karmic factors) were endorsed, with BIPOC parents overall being more likely to believe their child’s autism was temporary, particularly for immigrant parents. General perceptions of autism were impacted by systemic barriers (e.g., cost, geographic location, language) as well as differing levels of stigma within and outside of their community. Findings showed that applied behavior analysis, speech, and occupational therapies are being utilized across all BIPOC groups.

Unique beliefs emerged among specific racial/ethnic groups: for instance, Asian American families were reluctant to share autism diagnoses with others, including family, due to community stigmatization of autism, and had goals related to their child’s achievement. Black caregivers discussed treating their autistic child like any other child and strived to protect them from racism and ableism. Latine immigrant families were less likely to recognize and report symptoms, including speech delays, due to differing cultural expectations for development. Middle-Eastern/North-African (MENA) families did not widely endorse systemic barriers, implying they may be experiencing autism services differently than other BIPOC groups. Native parents felt health professionals lacked an understanding of their culture, which deterred them from accessing services.

Conclusions: Understanding the nuances of autism conceptualization is essential for ensuring that BIPOC autistic individuals and their families are respected, and their experiences acknowledged when planning/using services. This requires that providers not only be empathetic and culturally sensitive, but also be thoroughly informed about autism and its symptoms to effectively accommodate different knowledge levels across groups. This review highlights the need for continued research examining marginalized communities’ shared and unique perspectives to better inform accommodations and care.

413.226 Cultural Responsiveness of Autism Interventions: A Systematic Review of Adaptation Strategies

L. R. Gomez¹, A. K. Tero², N. Brunsting³ and C. Cummings³, (1)University of Florida, Gainesville, FL, (2)University of California, Davis - M.I.N.D. Institute, Sacramento, CA, (3)University of Florida, Gainesville, FL

Background: Autism interventions, primarily developed in Western contexts, often lack the cultural sensitivity needed to be effective with diverse populations. With increasing recognition of the importance of culturally responsive interventions, there is a need to explore how interventions and programs for autistic individuals across all ages are adapted to fit diverse cultural, linguistic, and social contexts. This systematic review addresses this gap by examining the strategies used to adapt autism interventions developed in Western contexts for diverse populations.

Objectives: The main objectives of this review are: (1) to identify existing research on the cultural adaptation of EBPs for autism since 2001, and (2) to explore the methods, strategies, or frameworks employed to facilitate these adaptations for diverse populations.

Methods: A systematic literature search was conducted using electronic databases including Academic Search Premier, APA PsycINFO, Education Source, and Psychology and Behavioral Science. Search fields were: (1) cultur* adapt* OR culturally sustain* OR culturally respons* OR CSP; (2) evidence-based practice* OR ebp, or evidence based or best practice OR intervention OR curricul* OR high leverage practice and (3) autism OR asd OR autism spectrum disorder OR PDD* OR Asperger OR Childhood Disintegrative Disorder. The search yielded 342 articles and after screening titles, abstracts, and full texts, 22 articles were selected for inclusion. The included articles met the following inclusion criteria: empirical article published in 2001 or after written in English or Spanish; conducted in or outside the U.S.; include individuals with autism across all ages as focal participants; include a description of an intervention or program originally designed in the U.S., that is being culturally adapted by healthcare or educational professionals, and delivered at a school setting, daycare, pre-K setting, home-based intervention, or community-based settings. Descriptive coding was used to classify the adaptation strategies and the degree to which cultural components (e.g., language, metaphors, social norms) were integrated.

Results: The review exhibits several strategies for cultural adaptation. Translation of materials, including intervention manuals and handouts, was the most common adaptation (n = 15). Some studies also incorporated back-and-forth translation to ensure linguistic and cultural accuracy.

Collaborative work with community members, caregivers, and local professionals played a crucial role in ensuring cultural relevance in seven articles. Interviews, focus groups, and surveys were used to gather insights on local social norms and participants’ language preferences.

Additionally, five pilot studies used feedback to refine adaptations before broader implementation. The Ecological Validity Framework (EVF) was employed in five studies, guiding the adaptation process across dimensions such as language, context, and metaphors.

Conclusions: Cultural adaptations of autism interventions are essential when implementing them with diverse populations. The strategies identified in this review demonstrate a growing recognition of the importance of cultural responsiveness. However, there is a need for more systematic approaches and rigorous reporting of cultural adaptation processes. This review contributes to understanding how interventions can be tailored to diverse populations and to provide pragmatic and effective ways to implement adaptations in practice. Additionally, this review offers practical insights for future research in autism interventions globally.

413.227 Culturally Adapted Social Communication Interventions for Autistic Individuals: A Systematic Review and Quality Appraisal

V. Rajesh Kumar¹, A. Iyer¹, T. Pham¹, M. Y. Savundranayagam², S. T. Moodie³ and J. Oram¹, (1)School of Communication Sciences and Disorders, Faculty of Health Sciences, Western University, London, ON, Canada, (2)School of Health Studies and Sam Katz Community Health and Aging Research Unit, Faculty of Health Sciences, Western University, London, ON, Canada, (3)School of Communication Sciences and Disorders and The National Centre for Audiology, Faculty of Health Sciences, Western University, London, ON, Canada

Background: Social communication interventions to support autistic individuals are primarily developed and tested in Western countries with predominantly White, English-speaking participants. This limits the generalizability of these interventions to diverse cultural groups and underserved communities, both within and outside Western countries. Cultural adaptation becomes necessary when there is an intervention-consumer mismatch, i.e., when the originally developed intervention is not relevant to a specific cultural group. Although numerous frameworks have been developed to culturally adapt interventions for diverse ethnocultural groups, the quality of these adaptations is not well understood. Understanding key aspects of cultural adaptations - what, when, why, how, and by whom - can ensure methodological rigor and allow for examination of the impact of cultural adaptations on intervention outcomes.

Objectives: This review sought to identify which social communication interventions designed for autistic individuals have been culturally adapted and to identify frameworks that researchers have used to guide their cultural adaptation process. This review also aimed to evaluate the quality of cultural adaptations of social communication interventions for autistic individuals using the Cultural Adaptation Checklist (CAC; Lee et al., 2023). The CAC was developed to not only serve as a tool to culturally adapt intervention programs intended for diverse and/or marginalized populations, but also to systematically appraise the quality of cultural adaptations.

Methods: This systematic review was pre-registered on PROSPERO (CRD42024531743). Searches were conducted in eight databases (ERIC, CINAHL, EMBASE, PsychINFO, MEDLINE, Scopus, Web of Science, and Nursing and Allied Health) to identify culturally adapted social communication interventions for autistic individuals delivered by professionals. The methodological quality of the studies was assessed using QualSyst, and the data were analyzed through narrative synthesis.

Results: 16 studies involving a total of 474 participants met the inclusion criteria. Included studies reflected seven different culturally adapted interventions delivered across 12 countries in 11 languages. All studies had at least adequate methodological quality, but only three reported using a specific framework to guide the cultural adaptation process. The quality of cultural adaptations varied, with fulfillment of CAC items across studies ranging from 44% to 91%. The CAC context dimension (i.e., cultural adaptation of the intervention environment) was the most frequently addressed across studies and the methods dimension (i.e., cultural adaptation within intervention planning and procedures) the least.

Conclusions: The current review highlights the need for an increased number and improved quality of cultural adaptations to best support the global autistic community. In particular, there is a need for further attention to the full range of cultural adaptations in future research; the CAC offers a useful framework to facilitate this process. Future research should focus on exploring to what extent, and which types of cultural adaptations are needed to achieve desired intervention outcomes.

413.228 Culturally Responsive Strategies for Autism Interventions in Adulthood in Real-Life and through Virtual Settings

V. D. Grillo^{1,2} and P. Venuti¹, (1)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto, Trento, Italy, (2)Fondazione Bruno Kessler, Povo, Trento, Italy

Background:

Autism research is increasingly focused on developing personalized interventions tailored to individual needs; however, cross-cultural perspectives remain underrepresented. Additionally, there is a significant gap in effective and validated social skills interventions and communication outcomes for adults, both in In-Real-Life settings and through virtual reality (Monahan et al., 2021). In fact, autistic adults represent an underserved neurodivergent population within society (e.g., Laugeson et al., 2015). This gap suggests the need for interventions that specifically address the social needs of adults in real-world contexts (Balderaz, 2020), as current studies predominantly center on children and adolescents (e.g., Oh et al., 2021).

Objectives:

We engaged both autistic and neurotypical psychologists and psychotherapists to gather insights for creating a personalized (virtual) intervention for autistic young adults (L1, ages 18-40) using their clinical expertise. Our goal was to also integrate and compare Italian data with data from other countries to identify any cultural influences on intervention strategies.

Methods:

Following initial desk research, we conducted nine semi-structured focus groups with Italian professionals who work with autistic young adults (18-40 y.o.) in different regions (Veneto, Trentino, Lazio). In parallel, we conducted individual in-depth interviews with professionals from other countries (e.g., U.S.A., Australia). All qualitative data are analyzed using a mixed thematic analysis approach (Braun & Clarke, 2023), employing NVivo coding software by QSR. Two independent coders were assigned to ensure data reliability. For robustness, we triangulated the data through both theoretical and investigator approaches.

Results:

Findings reveal a range of insights, from professionals' perceptions of autism and neurodiversity to effective strategies for social skills development. Key elements needed to create a virtual environment tailored to individual needs have been identified. Discussions also touched on potential challenges and solutions for implementing virtual reality interventions, and best practices to support this population also in real life. Additional topics emerged organically from group conversations, underscoring the value of cross-regional and cross-cultural perspectives.

Conclusions:

This study includes step-by-step guidelines to implement virtual reality interventions, actionable strategies to address potential challenges, and best practices for supporting autistic young adults in In-Real-Life and in virtual settings. Overall, findings indicate that developing interventions based on individual interests, sensory preferences, and social needs can significantly improve social skills and overall well-being. Further research should implement these guidelines and investigate their effectiveness through quantitative data analysis.

413.229 Development of a Cross-Culturally Validated Measure of Autism Knowledge (PAK-M) with a Neurodiverse Team: Exploration of Items across Cultures and Levels of Expertise

A. M. Schwartz¹, S. Y. Kim², S. M. M. Taresh³, G. Y. H. Lam⁴, A. Gurba⁵, S. Saade⁶, R. Obeid⁷, E. Cappe⁸, E. Bastan⁹, B. Kofner¹⁰, T. Waisman¹¹, Z. J. Williams¹², K. Gillespie-Lynch¹³, K. Trice¹⁴, M. Graham¹⁵, A. Nanou¹⁶ and V. S. Velonaki¹⁶, (1)Department of Physical Therapy, Movement & Rehabilitation Science, Northeastern University, Boston, MA, (2)Korea University, Seongbuk-gu, Seoul, Korea, Republic of (South), (3)Taiz university, Yemen, Taiz, Yemen, (4)Department of Educational and Psychological Studies, The Chinese University of Hong Kong, Tampa, FL, Hong Kong, (5)Psychology and Brain Sciences, AJ Drexel Autism Institute, Philadelphia, PA, (6)Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (7)Case Western Reserve University, Cleveland, OH, (8)Laboratoire de Psychopathologie et Processus de Santé, Université Paris Cité, Boulogne-Billancourt, Île-de-France, France, (9)Psychology, Karadeniz Technical University, Trabzon, Trabzon, Turkey, (10)College of Staten Island, Staten Island, NY, (11)Adapt Coaching & Training, Vancouver, BC, Canada, (12)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (13)Department of Psychology, CUNY Graduate Center, Staten Island, NY, (14)Department of Psychology, Northeastern University, Boston, MA, (15)Boston University, Boston, MA, (16)Department of Nursing, National and Kapodistrian University of Athens, Athens, Athens, Greece

Background: Greater knowledge about autism is associated with reduced stigma and increased societal acceptance of autistic individuals, making it essential to accurately measure autism knowledge. Sensitive measures are crucial for evaluating educational programs' impact and understanding people's misconceptions. However, existing tools often lack cross-cultural validity, contain ambiguous items, and use response formats that limit their utility. This project aims to develop a more inclusive, valid measure to address these issues.

Objectives: This study aims to adapt the Participatory Autism Knowledge-Measure (PAK-M), originally developed with input from autistic individuals in the US, to 1) address community members' priorities, 2) be culturally valid, 3) distinguish between varying levels of expertise and, 4) demonstrate strong psychometric properties.

Methods: The iterative adaptation process of PAK-M has thus far involved nine datasets and five item sets, with data from 2,888 participants, including undergraduate students, clinical professionals, and the general public from South Korea and the US (Table 1). To establish content validity, a team of autistic and non-autistic researchers rated each round of items. Final item selection retained the best-performing items, focusing on reducing ambiguity and grounding items in research evidence. The first four datasets initially used a 5-point Likert scale but later versions explored True/False responses with confidence and importance ratings. Versions ranged from 27 to 92 items. We calculated internal consistencies using Cronbach's alpha and examined ceiling effects by calculating the percentage of participants who got each item correct. We also examined how different scoring systems were correlated and analyzed the relationships between confidence, importance, and accuracy.

Results: Internal consistency for the 5-point Likert scale ranged from .50 to .88, True/False from .41 to .57, and confidence ratings from .93 to .98. Among the general public, no items reached a ceiling effect, while among speech pathologists, ceiling effects ranged from 8% to 30% of items, suggesting the scale captures expertise well. Average correctness per item varied from 50% to 83%, highlighting gaps in autism knowledge. In American samples, reverse-coded items had higher internal consistency than non-reversed items, whereas in Korean samples, reverse-coded items showed lower consistency. In the most recent data, we compared responses using an Agree/Disagree binary option with a Likert-based importance rating to a True/False binary with a Likert-based confidence rating. We found significant correlations between confidence and importance ratings in 17 of 56 items after Bonferroni corrections. True/False and Agree/Disagree responses were strongly correlated ($r = .73, p < .001$), but not identical.

Conclusions: The process of refining the PAK-M involved selecting items and refining their phrasing to capture expertise and ensure clarity and research support across the measure. Findings reveal variations in internal consistency due to differences in response scales, item phrasing, cultural background, constructs measured, and clinical training. Ceiling effects suggest that the measure requires further refinement, especially to identify appropriate response options, differentiate knowledge of the text of the diagnostic criteria from knowledge of (continuously updated/improved) research findings, address cross-cultural differences, and develop a reliable and valid measure of autism knowledge.

**413.230** Disparities in Autism Classifications: Racial and Ethnic Differences in Special Education Designation over Two Decades
H. Kim, Department of Teaching Learning and Educational Leadership, Binghamton University, Binghamton, NY

Background: Recent prevalence studies indicate a resurgence of racial and ethnic disproportionality in autism, highlighting complex temporal and spatial variations. Understanding these patterns is crucial for identifying factors contributing to shifts in autism prevalence.

Objectives: This study explores racial and ethnic disparities in autism prevalence over two decades, using data from three National Longitudinal Transition Studies (NLTS). We examined: 1) changes in the educational labels assigned to students with a medical diagnosis of autism over time, and 2) the disparities in these changes across different racial and ethnic groups.

Methods: We conducted a secondary data analysis using the SPSS Complex Samples module, focusing on the percentage distribution of educational labels over time as reported in the longitudinal NLTS data. The NLTS surveys have documented a significant increase in the number of students with a clinical diagnosis of autism studied over time: from 40 in the original NLTS to 1,020 in NLTS2, and 1,710 in NLTS2012.

Results: Analysis reveals that students diagnosed with autism are often categorized under various special education categories including autism, other health impairments, intellectual disabilities, speech and language impairment, and emotional disability (see Figure 1). From 2001 to 2012, there was a decrease in all racial groups being formally recognized under the autism special education category, with representation stabilizing at approximately 52% across White, Hispanic, Black, and Asian groups as shown in Figure 2. In 2001, a significantly large proportion of Hispanic students with a medical diagnosis of autism were more likely classified under intellectual disability (ID) and speech and language impairment (SLI) categories. While these proportions decreased by 2012, a significant number remained classified under the ID and specific learning disability (SLD) categories. NLTS2 data from 2001 showed that a relatively larger percentage of Black students clinically diagnosed with autism were placed in the emotional disability (ED) and SLD categories. By 2012, there was an increase in the other health impairment (OHI) category designation for this demographic, with a considerable portion persistently classified under the ID category. Although sample sizes for Asian students were limited, it was noteworthy that in 2001, those clinically diagnosed with autism were significantly more likely to be categorized under the autism label for special education purposes. By 2012, this trend had decreased dramatically, aligning the proportion with that of other groups.

Conclusions: The study suggests that racial disproportionality in the autism category in special education has diminished over time. However, notable disparities in special education categorizations, especially in SLD and ID, and OHI designation, persist across different racial and ethnic groups despite changes over time.

413.231 Evaluating the Effectiveness of a Training for Caregivers on Using Read and Remove, Ask, Answer, Prompt (R2AAP) Strategy during Shared Adapted Book Reading with Their Children with Autism Spectrum Disorder (ASD).

N. Muttiah¹, M. E. Proulx² and N. Perera³, (1)Department of Disability Studies, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka, (2)SUNY Cortland, Cortland, NY, (3)Department of Disability studies, Faculty of Medicine, University of Kelaniya, Ragama, western province

Background: Children with autism often face significant communication challenges, emphasizing the crucial need for effective interventions, particularly in early childhood (Reichle et al., 2016). Augmentative and alternative communication (AAC) has emerged as a vital support for individuals with complex communication needs (CCN) such as autism (ASHA, 2009).

Caregivers' active involvement in communication training programs is pivotal, such as what has been demonstrated with strategies such as Read, Ask, Answer and Prompt (RAAP) during shared book reading (Kent-Walsh, Binger, & Hasham, 2010). Read, Ask, Answer, Prompt (RAAP) is an evidence-based storybook reading instructional strategy that uses a least-to-most prompting procedure to teach language support strategies to communication partners (Kent-Walsh, Binger, & Malani, 2010). The RAAP strategy has displayed promising effects on parent strategy use during instructional programs and has improved the communication skills of children who use AAC during shared book reading activities (Dodge-Chin et al., 2022).

Adapted books are modifications that are made to books to make them easier to access and more interactive for children. The current study adapted books to have removable picture elements in it. For example, an illustration of a dog in the book may be photocopied, laminated, and attached to the book by Velcro; the caregiver can then physically manipulate this picture element.

The purpose of the current study was to evaluate the effectiveness of an online training for caregivers on using adapted books during interactions with their children with autism. Specifically, caregivers were trained on using adapted books and implementing the R2AAP strategy. The R2AAP strategy stands for: Read and Remove, Ask, Answer and Prompt. The study aimed to answer the following research question: what is the impact of training caregivers on using adapted books during interactions with their children with ASD and complex communication needs (CCN). A total of three caregivers participated in the training, two from the US and one from Sri Lanka.

Objectives: To determine the effectiveness of an online communication partner training on caregivers' ability to use R2AAP strategy during adapted book reading with their children with autism.

Methods: Single subject multiple probe across participants design.

Results: All three caregivers implemented the R2AAP strategy between 50% to 100% of the time while reading adapted books with their children. They all implemented the strategy at or above the mastery criterion that was set for the study.

Conclusions: The current study presents an innovative training model that is self-paced and online at the convenience of caregivers. A unique aspect of this study is the cross-cultural component of having implemented the training with caregivers across two different countries, the United States and Sri Lanka. Although, these countries differed significantly in terms of context and resources this type of an online training indicated the potential to be successful across both contexts. In addition, there is currently no research on using adapted books with children on the autism spectrum. The interactive elements and movement of the adapted books could lend itself to support communication and engagement for children with autism.

413.232 Examining a Decade of Changes in Autism Identification and Inclusion By Race and Ethnicity in California Education System

Y. Yu¹, P. Schetter², M. Melgarejo³, J. Suhrheinrich³, J. Holmes⁴, J. Gonsier-Gerdin⁵ and A. C. Stahmer⁶, (1)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Placer County Office of Education, Sacramento, CA, (3)San Diego State University, San Diego, CA, (4)Disability Advocacy Services, Sacramento, CA, (5)California State University, Sacramento, CA, (6)UC Davis MIND Institute, University of California at Davis MIND Institute, Sacramento, CA

Background: The number of children on the autism spectrum receiving special education services in public schools in the United States has increased exponentially. Disparities exist in autism identification and service access in public schools. Over- or under-identification of autism may limit access to appropriate services and requires ongoing investigation.

Objectives: This study examined racial and ethnic differences in autism identification, general education inclusion and service access in California education system and examined trends in autism identification by race and ethnicity in special education from 2008 - 2018.

Methods: The secondary data analyses were based on data obtained from a publicly available database (DataQuest) or provided by the California Department of Education. Various student counts by race and ethnicity, educational identification, and special education services were collected. The likelihood of being in a certain group was indicated by the risk ratio (RR). A p-value and 95% confidence interval for each risk ratio were computed based on a normal approximation (Jewell 2004); a significant p-value (<0.05) indicates a RR different from 1.

Results: Asian (RR = 1.24), Black (RR = 1.28), and White students (RR = 1.17) had elevated likelihood of meeting an educational eligibility for autism than others ($p<0.001$). Hispanic/Latinx (RR = 0.71, 95% CI=0.71-0.72) and Native Hawaiian or Other Pacific Islander students (RR = 0.75, 95% CI=0.69-0.83) were less likely to receive autism identification as the primary condition. Black autistic students were less likely to be included in general education settings (RR = 1.60 when LRE was Less than 40%; RR = 2.19 for Separate School). The under-representation in Native Hawaiian or Other Pacific Islander students was evident in all six educational services examined compared to their peers (behavioral intervention services, individual counseling, language and speech therapy, mentoring, occupational therapy, specialized academic instruction), although mentoring was not significantly different than other groups (RR=0.60, 95% CI=0.35-1.04) and the under-representation in Hispanic/Latinx students was seen in five out of the six services examined. The risk ratios in all groups, except in White students, have increased over the years (see Figure 1).

Conclusions: While progress has been made in reducing disparities in autism identification, significant challenges persist. Addressing these disparities requires a comprehensive effort that involves policy changes, practitioner training, and ongoing research to ensure that all students, regardless of their racial and ethnic background, have equal access to appropriate services and educational opportunities.

413.233 Feasible Solutions: Ensuring Autism Care Access for All

K. Boles¹, R. E. Mitre², V. Nanclares-Nogues³, M. Mahurin⁴, A. Brewer Curran⁵ and K. Sohl⁶, (1)Child Health, University of Missouri, Columbia, MO, (2)Fundación Neurodiversidad, Rosario, Argentina, (3)Pediatrics, University of Missouri - Columbia School of Medicine, Columbia, MO, (4)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (5)Department of Pediatrics, University of Missouri, Columbia, MO, (6)ECHO Autism Communities, University of Missouri School of Medicine, Columbia, MO

Background:

Autism care access remains a significant challenge in many regions, particularly in underserved areas. Disparities in training, resources, and support systems further exacerbate these challenges, making it difficult for professionals to provide adequate care for autistic individuals. The ECHO Autism community, spanning North, Central, and South America, seeks to address these barriers by offering standardized, scalable training programs that equip healthcare providers with the skills and confidence to improve autism care access in their local contexts. In 2023, a new standardized metric for evaluating ECHO Autism programs was introduced to assess the impact of ongoing training ECHOs across different regions, focusing on key factors such as self-efficacy, barriers to care, and practice changes among participants.

Objectives:

- To evaluate the effectiveness of ECHO Autism training programs in increasing self-efficacy among healthcare providers across the Americas.
- To assess regional differences in barriers to autism care and identify how these barriers evolve following program participation.
- To compare the impact of training programs in Latin America (LATAM) and the United States (US) by examining changes in participants' practices and their interactions with autistic individuals.

Methods:

Participants in ECHO Autism programs across North, Central and South America were asked to self-report their demographics, self-efficacy, barriers, and changes in practice in survey form. Data were collected prior to and following attendance in ECHO programs from 2023-2024. Results were aggregated and visualized for comparison and assessment.

Results:

There were 979 responses to LATAM surveys and 741 responses to US surveys. Psychologists were the largest group of participants in LATAM programs (22%), whereas physicians made up the largest proportion of US program participants (31%). Prior to attending, 25% of LATAM program attendees had no training in Autism compared to 21% of attendees in US programs. Following participation, all respondents indicated either no change or an increase in the number of autistic individuals they interact with (LATAM n=108, US n=116). In general, LATAM participants indicated all barriers were more severe than US participants, and US participants indicated a larger decrease in severity of barriers in comparison to LATAM participants. Participants in both LATAM and US indicated an increase in self-efficacy and high satisfaction with the program(s) they attended.

Conclusions:

The results demonstrate that ECHO Autism training programs are effective in improving self-efficacy and reducing barriers to autism care across diverse regions. While significant progress was made, regional differences suggest that barriers to care remain more pronounced in Latin America, highlighting the need for continued focus on addressing these challenges. Nonetheless, the increase in interactions with autistic individuals and the high levels of satisfaction among participants in both regions underscore the value of these programs in fostering more inclusive, informed autism care practices.

413.234 From Conferences, Consultations to Care: Outlining Autism Trends in Nigeria

T. Faloughi-Ekezie¹, L. Duyile² and J. Anokwuru³, (1)Simone's Oasis Foundation, Lagos, Lagos, Nigeria, (2)Consultant, Lagos, Lagos, Nigeria, (3)Independent Consultant, Lagos, Lagos, Nigeria

Background:

Despite global advancements in ASD awareness, Nigeria faces challenges in translating awareness into care due to cultural stigma, economic constraints, and limited medical infrastructure. Since 2011, the annual Guaranty Trust Holding Company (GTCO) Autism Conference has sought to bridge this gap by providing two days of presentations followed by a five-day consultation period, where specialists offer diagnostic and therapeutic guidance to Nigerian families. The conference has grown in attendance from 300 in 2011 to 6,000 in 2024 (hybrid). Attendees include parents, caregivers, educators, and professionals, but the long-term outcomes on sustainable care remain uncertain.

Objectives:

This study evaluated whether the rise in Autism-related conferences in Nigeria has improved care or primarily served as awareness platforms to families. Additionally, we explored the role of the GTCO Autism Conference in lowering barriers to knowledge and care, and examined obstacles families face. Lastly this study proposed strategies to better align awareness efforts with hands-on interventions that lead to lasting improvements.

Methods:

This study is based on narrative and case study analysis, drawing from parents, advocates, and active collaborators experiences at the GTCO Autism Conference over the past 14 years. We collected qualitative data through informal and formal discussions with 30 parents, professionals, and other participants recruited via purposeful sampling. Data was gathered through surveys, questionnaires, observations, and interviews. Our thematic analysis incorporates reflections on conference structures, session formats, and content presented by both local and international experts. We focused on identifying the tangible benefits provided to families during the event and the sustainability of those benefits post-conference.

Results:

Our findings reveal a complex picture of the role of autism-related conferences in Nigeria. While the GTCO Autism Conference successfully raised awareness and reduced social stigma, bringing together diverse stakeholders, its direct impact on improving ongoing care remains limited. Families reported significant benefits from the diagnostic consultations and expert advice provided during the five-day consultation period, as they received immediate guidance and coping strategies for managing ASD. However, many struggle to access continuous support after the event, and lack resources for follow-up care. Despite growing awareness, gaps remain, such as a shortage of local service providers trained in autism care, limited funding for community-based programs, and insufficient policy support for ASD services. Consequently, while families leave conferences with valuable information, they often struggle to implement sustainable care solutions, limiting the long-term outcomes.

Conclusions:

There is a pressing need to transition from awareness-focused events to initiatives providing continuous support for families dealing with ASD in Nigeria. While conferences such as the GTCO Autism Conference play a key role in raising awareness and offering temporary support, they must be complemented by scalable, long-term interventions. We propose that policymakers, healthcare providers, and educators collaborate to develop community-based interventions that extend beyond conferences. Integrating Autism Speaks' Caregiver Skills Training into the autism conference framework could equip families with practical skills applicable at home and in their communities. Additionally, establishing regional support groups or resource centres could provide ongoing assistance and reduce reliance on annual events for ASD care.

413.235 Globalizing the Boscc: Adaptation, Training, and Implementation in India's Low-Resource Context

A. Kaur¹, R. Roy², K. Leadbitter³, J. Green⁴, G. Divan⁵ and M. Balabanovska⁶, (1)Sangath, New Delhi, Delhi, India, (2)COMPASS, Sangath India, New Delhi, Delhi, India, (3)University of Manchester, Manchester, UNITED KINGDOM, (4)University of Manchester, Manchester, United Kingdom, (5)Child Development Group, Sangath India, New Delhi, India, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, London, United Kingdom

Background:

The Brief Observation of Social Communication Change (BOSCC) is a play-based, video-coded assessment designed to detect subtle changes in social-communication behaviors. It involves semi-structured play sessions between a child and an adult (typically a researcher). Reliability training and inter-rater consistency are essential for accurate implementation. BOSCC has been validated for minimally verbal individuals (Module 1/MV) and phrase speech/young fluent individuals (Module 2/PSYF). Developed in high-income country, its application in low- and middle-income countries (LMICs), such as India, must consider cultural and contextual differences. This study explores barriers and facilitators to BOSCC implementation within the Communication-centred Parent-mediated treatment for Autism Spectrum Disorder in South Asia (COMPASS) trial in India, which recruited 261 autistic children, aged 1-9 years. BOSCC assessments were conducted at three time points, totalling 547 MV and 151 PSYF assessments.

Objectives:

1. To examine the adaptation process of BOSCC for LMIC use, focusing on training, assessment administration, and reliable coding.
2. To investigate challenges and facilitators encountered during implementation, providing insights for broader application in low-resource environments.

Methods:

Sample: The study involved 26 participants, including 4 team members responsible for training and supervision, 16 involved in BOSCC administration, 3 engaged in coding, and 3 who did not achieve coding reliability. Data collection and analysis are currently ongoing, with preliminary insights guiding the adaptation process and informing further iterations.

Measures: A structured, open-ended questionnaire was administered to capture reflections on BOSCC implementation experiences, including challenges, adaptive strategies, and recommendations for enhancing cross-cultural applicability. Feedback was also collected from team members who did not achieve coding reliability, focusing on specific difficulties encountered.

Analysis: Thematic analysis summarized experiential data regarding facilitators and barriers to BOSCC implementation, as well as adaptations made to maintain coding effectiveness while ensuring confidentiality.

Results:

Preliminary data indicated that while the core training process for BOSCC remained unchanged, additional training was required to align team members with the prescribed interaction style. Guidance was specifically needed for transitioning from directive to non-directive, child-led play, which is less familiar in traditional Indian contexts. Supportive supervision emerged as a critical facilitator, ensuring high-quality implementation. Varying levels of experience among team members and exposure to participant population were notable barriers. These were mitigated through structured supervision and continuous support, which fostered skill development and confidence. Feedback from coders highlighted the need for clearer decision-making frameworks to enhance coding reliability. Coders took 3 to 5 months to achieve reliable assessments, primarily due to discrepancies in interpretation and limited familiarity with specific cases. Weekly supervision sessions facilitated ongoing discussions to clarify complex concepts, with relevant video resources suggested to enhance understanding.

Conclusions:

This study provides insights into the challenges and facilitators of implementing BOSCC in low-resource settings like India. The findings regarding training, cultural adaptation, and barriers offer valuable lessons for future BOSCC applications globally. Further research should explore the broader applicability of these adaptations in other LMIC settings, potentially expanding BOSCC as a measure for assessing social communication changes in ASD interventions.

414.236 A Father-Implemented Enhanced Milieu Teaching Intervention for Young Children with Autism Delivered Via Telehealth Practice-Based Coaching

E. Shannon, AARTS Center, Rush University Medical Center, Chicago, IL

Background: Individuals with autism spectrum disorder (ASD) experience deficits in social communication skills, but the literature suggests that addressing early communication at a young age can result in a myriad of positive outcomes later in life. Early intervention and intensive applied behavior analysis therapy have become commonplace for many, but those supports are costly and may not be accessible to all. Additionally, even for those that do have access, an emphasis is being placed on caregiver-mediated interventions (CMIs) that can be implemented outside of sessions with service providers. Research indicates that CMIs can help children generalize skills to routines and contexts within their natural home environment. CMIs that directly target natural play routines, such as Enhanced Milieu Teaching (EMT), have been repeatedly implemented successfully by caregivers to improve both caregiver implementation outcomes and child expressive communication.

Objectives: Despite the benefits, most CMI interventions for children with ASD have been delivered primarily to mothers, although fathers have reported that they also want access to supports. Barriers that prevent all caregivers from engaging in CMIs are extensive, but additional hurdles exist for fathers, including providers not prioritizing their access to relevant information, inflexible in-person session hours, and provider biases. Many of these barriers can be addressed through the use of modifications and telehealth service delivery. This study aimed to explore the effectiveness of a father-mediated telehealth EMT intervention delivered via a collaborative practice-based coaching (PBC) partnership.

Methods: We incorporated modifications of typical caregiver-mediated interventions to meet the specific needs and desires of fathers, including short weekly coaching sessions over Zoom, flexible scheduling inside and outside of traditional business hours, initial background information on ASD and the principles of operant conditioning, a focus on typical father-child play routines, asynchronous supports to supplement coaching sessions, and video training models of fathers acting as the intervention agent. Three father-child dyads completed the study, which utilized a multiple baseline across behaviors design with four intervention tiers to teach separate EMT implementation strategies. Fathers uploaded two 5-min videos engaging with their child in a chosen play routine each week, and implementation fidelity and child expressive communication were coded. Visual analysis of father data and descriptive analysis of child communication were used to determine the effects of the intervention. Additionally, father well-being and ASD knowledge were assessed via pretest and posttest surveys. Participants remained in the study for up to 15 weeks.

Results: Results indicate that fathers can successfully implement the EMT intervention with their children with ASD. As a result of improvements in father implementation, substantial increases in child expressive communication occurred. However, the intervention may not have had an influence on father well-being outcomes, as survey responses were mixed across participants.

Conclusions: This study provides evidence that EMT delivered to caregivers—and particularly fathers—via telehealth-based PBC may be ideal to address the needs of children with ASD and their families.

414.237 A Four-Year Follow-up Study of the Early Start Denver Model in Taiwanese Children with Autism Spectrum Disorder: Preliminary Analysis of the Development of Cognitive, Language and Adaptive Behaviors

Y. S. Tang¹, C. H. Chiang², T. H. Tseng² and I. S. Cheong³, (1)Department of Psychology, National Chengchi University, Taipei, Taipei, (2)Department of Psychology, National Chengchi University, Taipei, Taiwan, (3)Department of Psychology, National Chengchi University, Taipei, Taipei, Taiwan

Background:

In recent years, the prevalence of Autism Spectrum Disorder (ASD) has been increasing both domestically and internationally. Early diagnosis and intervention have gained growing attention, and there is an increasing focus on whether the effects of interventions can be sustained over time. However, long-term follow-up studies on early interventions, both locally and globally, remain limited and show inconsistent results. The Early Start Denver Model (ESDM) is an evidence-based, comprehensive early intervention model that integrates behavioral, developmental, and relationship-based approaches. Our team previously conducted a short-term, low-intensity individual-implemented ESDM intervention study (Chiang, et al., 2023), which found that compared to the control group, the ESDM group showed greater improvements in overall Development Quotient (DQ) and non-verbal DQ from pre- to post-intervention. However, these differences did not sustain at the 6-month follow-up. Therefore, it is necessary to conduct a long-term follow-up study to address the issue.

Objectives:

This study aims to follow up with the children from Chiang et al. (2023)'s study four years later to examine their cognitive, language, and adaptive behaviors and to explore whether this individual ESDM intervention has long-term effects.

Methods:

This study employs a quasi-experimental design, with participants being children with ASD who received either individual-implemented ESDM intervention or standard early intervention services between the ages of 2 to 4 (ESDM group and community group). Data collection was conducted at three time points (T1: pre-intervention; T2: post-intervention; T3: 6 months follow-up). Four years after the intervention (T4), both groups (17 participants each, with an average chronological age of 99.05 and 99.30 months, respectively) were assessed on cognitive, language, and adaptive behavior measures. Cognitive and language abilities were assessed using the Mullen Scale of Early Learning (MSEL), Wechsler Preschool & Primary Scale of Intelligence-Fourth Edition (WPPSI-IV), and Wechsler Intelligence Scale for Children-Fifth Edition (WISC-V), with overall DQ and language DQ calculated. Adaptive behaviors were measured using the Adaptive Behavior Assessment System, Second Edition (ABAS-II).

Results:

The interaction between group and time point for cognitive, language, and adaptive behaviors was not significant. Both groups showed improvements in cognitive and language abilities over time. In terms of cognitive ability, the ESDM group showed significant improvements compared to T1, while the community group showed significant improvements compared to both T1 and T3. For language ability, both groups showed significant improvements compared to T1 and T3. In terms of adaptive behaviors, both groups showed a decline, but the magnitude of the decline between time points was not statistically significant.

Conclusions:

The effects of the short-term, low-intensity individual-implemented ESDM intervention on cognitive and language abilities were sustained four years later; however, there were no significant differences compared to the community group. This suggests that early intervention, whether through ESDM or community-based services, has long-term benefits for the children with ASD.

414.238 A Mixed Methods Investigation of Providers' Intent to Use Caregiver-Implemented Reciprocal Imitation Teaching with Children with Social Communication Delays in the Public Early Intervention System

K. M. Frost¹, S. R. Edmunds², A. Bravo³ and D. J. Abate⁴, (1)Pediatrics, University of Massachusetts Chan Medical School, Worcester, MA, (2)Psychology, University of South Carolina, Columbia, SC, (3)College of Education, University of Washington, Seattle, WA, (4)E. K. Shriver Center, E. K. Shriver Center, University of Massachusetts Medical School, Worcester, MA

Background:

Evidence based practices (EBPs) for supporting social communication development among toddlers with a high likelihood of autism are not routinely implemented in community-based early intervention (EI) settings. According to the Theory of Planned behavior, provider factors (e.g., skills, norms, attitudes) impact their *intent to use* a new EBP, which predictive of subsequent implementation. Understanding whether and how providers intend to use an EBP, and predictors of that intent, are important for understanding the scalability of EBPs. Data for this study were obtained in the context of an ongoing hybrid implementation-effectiveness trial ("RISE") of the caregiver-implemented Reciprocal Imitation Teaching (CI-RIT), an early social communication intervention, within the publicly funded Early Intervention system in four US states.

Objectives:

We used a mixed methods approach to understand providers' intent to use CI-RIT, how it might relate to perceived social validity of CI-RIT, how it compares with their usual approach to EI (TAU), and their skill in implementing CI-RIT during the study.

Methods:

Qualitative data: A subset of EI providers who had delivered the CI-RIT curriculum to at least 2 families on their caseload in the research trial ($n = 13$) completed semi-structured interviews about their usual practice, how CI-RIT sessions compare to their usual practice, and their intent to use CI-RIT in the future. Qualitative data were analyzed using a rapid qualitative analysis approach (Hamilton, 2013) in which transcripts were summarized and consolidated in a descriptive matrix (Averill, 2002) prior to thematic analysis. Four researchers independently reviewed the data matrix and developed themes, and themes were then compared and consolidated into a final set of themes by the lead author.

Quantitative data: Providers completed the CI-RIT Social Validity Scale and two items on future intent to use 12 months after enrolling in the study, with all items rated from 1 (low) to 7 (high). Fidelity of implementation of CI-RIT was also rated on recorded videos of early intervention sessions. All three measures were available for 27 providers; data collection is ongoing.

Results:

A description of qualitative themes and subthemes are presented in Figure 1 and Table 1. Primary themes were that (1) Usual care is less structured and focused than CI-RIT, and that providers described (2) Intent to use in a condensed, piecemeal, or general way. In a mixed methods analysis, splitting interviewees by their perceptions about social validity and observed fidelity ratings (above/below median) did not indicate meaningful differences in intent to use. Finally, in our preliminary quantitative analysis, mean intent to use was high ($M=6.18$, $SD=.67$) and perceived social validity was significantly correlated with intent to use ($r = .472$, $p = .013$) while fidelity of implementation was not ($r=.232$, $p=.244$).

Conclusions:

While providers in our sample tended to rate their intent to use CI-RIT very highly on a Likert rating, qualitatively, they rarely planned to implement the intervention as intended and rather described incorporating some general principles that they indicated were a change from their usual practice.

**414.239 A Pilot Trial of the Social ABCs in Israel**

T. Nitzan¹, T. Matz Vaisman², T. David Cohen³, M. Ilan⁴, M. Faroy⁵, G. Meiri⁶, I. Dinstein⁷ and J. Koller², (1)Azrieli National Centre for Autism and Neurodevelopment Research, Student at Ben Gurion University of the Negev, Beer Sheva, Israel, (2)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (3)Hebrew University, Jerusalem, Israel, (4)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (6)26 YA'ARA ST., Beer-Sheva, Israel, (7)Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel

Background: Studies have demonstrated that autistic children can exhibit delay in language development and social-communication skills (Brian et al., 2015). The Social ABCs, a parent-mediated intervention for toddlers originally developed in Canada (Brian et al., 2016), targets early functional verbal communication and positive affect sharing in the context of play and caregiving activities.

Objectives: The aim of the current pilot study was to evaluate the impact of the intervention in Israel on various child and parent variables, using both standardized tools and questionnaires.

Methods: Participants were 17 autistic children aged 19-39 months ($M=26.4$, $SD = 5.61$; 94.1% male) who participated in the Social ABCs in two sites in Israel. The current study followed the group Social ABCs protocol, which includes 6 online parent group sessions, and 9 frontal coaching parent-child sessions. Children were administered a gold-standard evaluation prior to the intervention and 6 weeks after completion of the protocol. Relevant measures included assessments of autism symptom severity (ADOS-2); developmental screening (Communication and Symbolic Behavior Scales Developmental Profile; CSBS-DP), lexical capacity, (Hebrew Communicative Development Inventory (HCIDI); parenting stress (PSI-SR), and aberrant behaviors (ABC).

Results: Of 25 families who met inclusion criteria, 20 (80%) elected to participate in the intervention program, and 17 completed the intervention. Parents rated the intervention as highly satisfactory ($M=33.13$, $SD = 2.78$, of a maximum score of 35). Children's vocabulary increased significantly from pre- to post-intervention both for expressive ($t(14)=-4.11$, $p=0.001$) and receptive vocabulary ($t(14)=-3.94$, $p=0.002$) with large effect sizes ($d>1.0$). We found no statistical change in the ADOS Social Affect Calibrated-Severity-Score, but significant gains were observed both for the social ($t(14)=-2.90$, $p=0.012$) and speech composites ($t(14)=-2.20$, $p=0.045$) of the CSBS-DP. A significant decrease in parenting stress scores occurred in the Parent-Child Dysfunctional Interaction (PCDI) subscale ($t(16)=3.25$, $p=0.005$), indicating lower stress during parent-child interaction. ABC scores showed a significant decrease in the Social Withdrawal subscale ($t(16)=2.42$, $p=0.028$), indicating increased social involvement of the child.

Conclusions: This study provides evidence that the Social ABCs is feasible, acceptable, and satisfactory in Israel. In the current pilot study, improvement was noted in child social functioning and language development, and reduced reported dysfunctionality in parent-child interactions.

414.240 A Preliminary Study of the Impact of Very Early Intervention with Esdm for ASD on Sensory Problems

Y. Tateno¹, Child psychiatric clinic, Tokiwa Child Development Center, Sapporo, Hokkaido, Japan; Graduated school of Education, Hokkaido University, Sapporo, Hokkaido, Japan

Background:

The Early Start Denver Model (ESDM) is a Naturalistic Developmental Behavior Intervention (NDBI) that uses natural reinforcers in child-selected activities. ESDM follows a manual (Rogers & Dawson, 2009). Curriculum checklists are used to provide a comprehensive view of a child's development in various domains (receptive communication, expressive communication, social skills, cognition, play, fine motor, gross motor, and personal independence).

Regarding the evidence for ESDM, Dawson conducted the world's first randomized controlled trial (RCT) of a very early intervention for ASD in 2010, showing that ESDM improves intellectual function, including language function, and prevents the deterioration of adaptive behaviour (Dawson, Rogers, Munson et al., 2010).

The Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) was used as the diagnostic criteria for ASD in the study. However, the DSM-IV does not include sensory problems to criteria for ASD, therefore sensory assessment was not performed in clinical studies of ESDM.

Objectives:

The aim of this study is to investigate whether ESDM has a positive effect on sensory problems in ASD.

Methods:

We compared the intervention and control groups to see if there were any changes in scores on the Japanese version of the Infant Sensory Profile (ITSP) before and after the ESDM intervention. Children aged 19-36 months attending outpatient clinics at medical institution, 17 children who had been implemented with ESDM (intervention group) and 14 children who had not been implemented with ESDM (control group). Both group were administered the ADOS-2, the new version of the K-type Developmental Test 2020, and the Vineland-II adaptive behavior scale and there was no significant difference between the two groups. ITSP was administered before the start of ESDM (Pre) and after 60 minutes of individual therapy with parent once a week for 6-9 months (Post), and the differences in ITSP scores between Post minus Pre were compared between groups. The Mann-Whitney U test. EZR (version 1.63) was used for statistical analysis (Kanda, 2013), with a risk rate of 5% as statistically significant and 10% as a significant trend.

Results:

All of the subjects in this study had been diagnosed with ASD, and the results suggest that atypical sensory processing can be seen in children with ASD from as early as 36 months of age.

The results showed that among the four quadrants of ITSP, the change in sensation avoiding ($U = 73.5, p = .073$) tended to be statistically significant in the control group. The analysis of each sensory processing in that same group showed a significant difference in oral sensory processing ($U = 69.5, p = .05$) as well as a significant trend in tactile processing ($U = 74.5, p = .080$).

Conclusions:

Future research should focus on examining sensory evaluation at an objective behavioral level to accumulate more findings. The ITSP evaluation method measures highs and lows with an emphasis on averages; therefore, analysis should incorporate both quantitative and qualitative methods. Further studies are needed to explore the effects of very early intervention with ESDM on sensory problems and to compare these effects with other measures.

414.241 An Expert Panel to Identify Essential Support Strategies to Promote Autistic Preschoolers' Language Skills

A. B. Ford¹, R. Senter², D. Pfeiffer³, J. Artis⁴, A. Foltz-Hottle¹, H. Spencer¹ and S. Peele⁵, (1)Communication Sciences and Disorders, University of Cincinnati, Cincinnati, OH, (2)Communication Sciences & Disorders, DeSales University, Center Valley, PA, (3)Old Dominion University, Norfolk, VA, (4)University of Maryland, College Park, MD, (5)Lakota Public Schools, Liberty Township, OH

Background: Previous research has identified several barriers for practitioners implementing evidence-based practices (EBPs) with autistic students. These barriers include practitioners reporting that existing EBPs are too complicated, not clearly defined or described, and lack feasibility within the real-world context (Barry et al., 2020). Thus, we must identify, define, and guide early childhood educational teams on essential support strategies they should adopt and deliver to promote language outcomes for autistic preschoolers (Damschroder et al., 2009). Essential support strategies—called core components or active ingredients—are the observable, discrete, indispensable elements, strategies, and intervention mechanisms essential for change that may stand alone or be present within established EBPs (Blase & Fixsen, 2013). To date, however, no systematic investigations have sought to identify these essential support strategies for promoting language in autistic preschoolers.

Objectives: Our investigation aims to identify a simplified, preliminary set of essential support strategies that promote the language of autistic preschoolers using an electronic Delphi Method (McMillan et al., 2016).

Methods: We are engaging an expert panel in multiple rounds of information gathering to narrow the field of support strategies and reach a consensus on those deemed most essential. Our 28 panelists are early childhood researchers ($n=13$) and practitioners ($n=15$); three identify as autistic. All panelists have expertise and at least five years of experience in early language development, autism, and implementing evidence-based language practices for autistic preschoolers in the classroom. Our research team represents researchers and practitioners with expertise in researching and implementing EBPs with autistic preschoolers; two identify as autistic.

There are three rounds of asynchronous data collection, with data analysis by our team between each round (see Figure 1). For Round 1, we created an online survey in which experts generated an exhaustive list of essential support strategies, defined them, and provided examples. Our experts generated 376 essential support strategies, which our team coded using conventional content analysis procedures (Hsieh & Shannon, 2005). We narrowed the list to 96 unique support strategies that anonymously reflect all experts' suggestions and integrated definitions from the literature when available.

For Round 2, we created another online survey and asked panelists to review the consolidated list of 96 support strategies and their definitions. They reviewed a table with the frequency with which the strategy occurred (e.g., experts mentioned *visual supports* 55 times). Table 1 provides a sample of the strategies, definitions, and frequency. Panelists then rated and ranked the support strategies to narrow the field to those most essential.

Results: Our panelists completed Round 2. We are analyzing and summarizing the data in preparation for Round 3, where we will ask panelists to narrow down the strategies and definitions in another online survey. We expect the third and final round of data analysis in January 2025; we will present the full E-Delphi results at INSAR.

Conclusions: Educational teams must know which strategies are essential to use in the classroom to promote the language of autistic preschoolers. To facilitate this process, we will share our panel's final recommendations and facilitate a conversation with attendees.

414.242 Association between Parent-Child Joint-Engagement States and Parents' Implementation of Incredible Years® (IY-ASLD) Strategies

I. Knoll¹, L. Lerma², J. Pattammady³, L. B. Jahromi⁴ and M. Brassard⁵, (1)*Barnard College, New York, NY*, (2)*Teachers College Columbia University, New York, NY*, (3)*Health Studies & Applied Educational Psychology, Teachers College Columbia University, New York, NY*, (4)*Teachers College, Columbia University, New York, NY*, (5)*Brassard Practice, New York, NY*

Background:

Autism Spectrum Disorder is categorized by differences in social communication and reciprocity and repetitive and/or restrictive behaviors and interests. The Incredible Years® Parent Program is a group-based parenting curriculum that was developed to reduce parental stress and improve wellbeing, foster parents' use of developmentally appropriate strategies and improve children's social-emotional development for children with disruptive behaviors (Webster-Stratton et al., 2001). A new version of this program (Incredible Years-ASLD®; Webster-Stratton et al., 2018) was adapted for parents of children with ASD and/or language delay. Given that IY-ASLD strategies are designed to sustain positive parent-child interactions, an important question is whether these strategies are temporally related to the parent-child dyad's joint engagement states.

Objectives:

Little research has assessed whether parent-child engagement states are related to parents' implementation of IY-ASLD® behavioral strategies. This study aims to investigate the relationship between parents' use of IY-ASLD behavioral strategies and joint engagement states of the dyad. These findings will help elucidate discrete strategies that may help sustain the interactions of parents and their autistic children.

Methods:

Parents (n=17) of preschool aged children who met criteria for ASD (Child Autism Rating Scale-2) and/or language delay (e.g., IEP or IFSP with speech services) were included in the study. Parents attended the 12 week Incredible Years-ASLD® telehealth intervention. Parent-child interactions were recorded for 12 minutes while they played together in structured play (5min), free play (5min), and clean up (2min) at baseline. Play interactions were coded in 15-second intervals to assess parents' use of strategies taught in the program and the dyad's level of joint engagement in the same interval (see Tables). Analyses explored the total number of strategies used by the parent within each interval as well parents' use of individual strategies at the interval level.

Results:

There was no significant correlation between the dyad's overall level of joint engagement and the *total number* of different IY strategies the parent used in a 15-second interval, $r(765) = .053, p = .143$. However, when individual strategies were examined, a significant negative correlation emerged between JE level and parents' use of active ignoring $r(765) = -.158, p < .001$ and redirection of attention $r(765) = -.144, p < .001$. Additionally, there was a significant positive correlation between JE level and use of descriptive comments $r(765) = 0.078, p = .031$.

Conclusions:

The results suggest that the effectiveness of strategies in supporting a state of JE may not be dependent on the total number, but rather on the quality of specific strategy implementation. Active ignoring and redirection of attention were both negatively associated with JE. This may be because these strategies tend to coincide with children's negative behaviors. In contrast, descriptive comments is a strategy that entails following of the child's lead, suggesting that descriptive commenting usage could help promote a JE state. Through understanding the relationships between JE and IY-ASLD strategies, clinicians may better prepare parents for the application of curriculum to real-life interactions with their children.

**414.243 Building Bridges! Children with Autism Spectrum Disorder and Their Transition from Kindergarten to School**

S. Chahboun, *Pedagogy and long life learning, NTNU, Trondheim, Norway*

Background:

It is well documented that transitioning to school supposes an immense and stressful change for children with Autism Spectrum Disorder. Adapting to a new setting, with new rules, new challenges and demands can be both physically and mentally exhausting for the child, his/her family and the school staff.

Objectives:

The goal of this study was to map the research on the transition from kindergarten to school for children with autism spectrum disorder (ASD). Further, the goal was to identify the elements influencing the transition process as well as the variables that would promote a smooth and positive transition experience for the children in question. The study also aimed to identify knowledge gaps on the subject and the current practice in the field.

Methods:

The study is a scoping review that includes peer reviewed articles from the databases ERIC, Google scholar, PsycINFO and Web of Science and the search was restricted to articles in English from 2019-2024. The search terms used were autism spectrum disorder, autism, transition, preschool, ECEC, inclusion, education intervention, early childhood, early education and kindergarten. After identifying and screening current articles from the databases, the articles were ascertained for relevance in three stages. In phase one, the title was considered. Phase two consisted of reviewing the abstract, and the final stage was to review the full text. At each stage, articles that did not prove relevant to the goal of the study were excluded. This left us with thirteen articles for inclusion in this article.

Results:

In the selected articles the following elements are necessary for children with autism to have a positive transition from kindergarten to school: 1) School readiness skills and school inclusiveness, 2) Comparable educational opportunities and psychological support, 3) Collaboration and professional competence, 4) A balance to ensure a better transition, and 5) Inclusion and support and 6) Children's perspectives.

Conclusions:

The research gaps identified were: 1) that few studies take the child's perspective into account, and 2) that there is an overemphasis on subjective experiences of effectiveness, and a lack of focus on measurable effects within studies on transition and inclusive education.

414.244 Caregivers Skills Training in Brazil: A Follow-up Analysis

A. M. Choinski¹, M. D. F. J. Minetto², G. M. S. Doria³, E. Matos⁴, R. Massuda³ and E. Cassanho⁵, (1)*Education, Federal University of Parana, Curitiba, Brazil*, (2)*Education, Federal University of Parana, Curitiba, Brazil*, (3)*Psychiatry, Federal University of Parana, Curitiba, Brazil*, (4)*Founder, Ico Project Foundation, Curitiba, Brazil*, (5)*Federal University of Parana, Curitiba, Parana, Brazil*

Background:

Caregivers Skills Training (CST) is a World Health Organization program developed to assist caregivers of children with developmental delays and teach them to stimulate the development of children's skills. The program is implemented in more than thirty countries and evidence points to an improvement in both training objectives. In Brazil, the CST was adapted and validated, and is being disseminated in the public health context. However, despite the positive results of the program at the end of the training, we need more data from the impacts of the CST after training.

Objectives:

This research aimed to evaluate and compare the perception of the impacts of the CST 6, 12 and 18 months after completing the training.

Methods:

Thirteen caregivers participated from three different CST family groups (two online and one in-person training courses). The groups had different periods elapsed since they completed the training (6, 12 or 18 months) from when data was collected. A focus group with each group was conducted, these were recorded, transcribed, and analyzed using Content Analysis.

Results:

The results from the Content Analysis indicate that caregivers from all groups cited as positive impacts of the program: the development of the child's new skills; a greater empowerment by the caregiver; a better management of problem behaviors; a more organized of the environment and routine; healthier family relationships; and establishment of a positive support network. Some caregivers commented that they got back to the print guides to review the materials and suggested friends, or other family members, read them to deal with some problem.

The differences found between the groups can be associated with the modality of training (online or in-person). The group with in-person training cited a more established relationship than the online ones, this relationship extrapolated the CST sessions to frequent conversations and mutual support. As for the online groups, a reminder of the caregivers and child's names before the focus groups was needed at the beginning of the session. In the focus group session with the in-person trained group there were more parallel conversations and discussions about non-related topics.

The caregivers also made suggestions for the CST such as including at least one moment to talking about toilet training and food selectivity; holding meetings after the end of the CST to review the topics and strengthen their support network; and that some materials for easy access with key messages and tips would be useful as a reminder strategy.

Conclusions:

These findings suggest that the main goals of the CST were maintained even months after the end of the training, that the strategies taught during the training were useful for the families on many occasions and that the families benefited from the online training, even though there were some drawbacks that can be related to this training modality. The sample size from this study is small, so other research with similar objectives and different methodologies are essential for further comprehension of the CST impacts.

414.245 Characterizing Federally Mandated Early Intervention for Children with Social Communication Delays: A Mixed Methods Analysis

Y. Dai¹, K. M. Frost², E. R. Britsch³, E. M. Harrington⁴, Y. S. Stern⁵, B. R. Ingersoll⁶, A. Wainer⁷, W. L. Stone⁸, S. Broder-Fingert⁹ and A. S. Carter⁹, (1)Psychology, Florida International University, Miami, FL, (2)Pediatrics, University of Massachusetts Chan Medical School, Worcester, MA, (3)Psychology, University of Washington, Seattle, WA, (4)Psychology, Michigan State University Psychology Department, East Lansing, MI, (5)Psychiatry and Behavioral Sciences, Rush University Medical Center, Chicago, IL, (6)Psychology, Michigan State University, East Lansing, MI, (7)Department of Psychiatry and Behavioral Sciences, Rush University Medical Center, Chicago, IL, (8)UMASS Medical School, Boston, MA, (9)Department of Psychology, University of Massachusetts Boston, Boston, MA

Background: The most common way for toddlers with social communication delays to receive intervention is through Part C early intervention (EI). However, little research has characterized the structure, content, or quality of interventions. Available studies focus on caregiver coaching and reveal discrepancies between provider-reported and observed levels of caregiver coaching during EI (Arranbarri et al., 2021; Lee et al., 2022; Pellecchia et al., 2023).

Objectives: Utilizing a mixed methods approach, our team characterized provider practices during EI sessions with children with social communication delays across four United States. Specifically, we (1) described caregiver coaching based on (a) provider report and (b) observations of EI sessions, and (2) characterized the structure and content of EI sessions.

Methods: Participants were drawn from an ongoing multi-site clinical trial examining the effectiveness of Reciprocal Imitation Training (RIT). EI providers randomized to the treatment-as-usual condition, who enrolled at least one family into the larger study by January 2024 ($n = 33$; 32 females; 26-61 years old) were included. Providers completed the Provider Services Questionnaire (PSQ) at baseline, which asked about their frequency of caregiver coaching practices during typical EI sessions, and recorded three EI sessions with each family enrolled in the larger study. One session per provider was randomly selected for coding by raters masked to group. Sessions were coded for quality and quantity of evidence-based caregiver coaching strategies using the Parent Empowerment and Coaching in Early Intervention (PEACE) caregiver coaching fidelity tool (Pellecchia et al., 2023). The PSQ and PEACE use a 5-point Likert scale (0 = Never, 5 = Always). Additionally, an adapted Rapid Qualitative Coding approach (Hamilton & Finley, 2018; Nevedal et al., 2021; Vindrola-Padros & Johnson 2020) was used to summarize the content of sessions and other intervention strategies (beyond parent coaching) that were used during session.

Results: Providers self-reported greater use of caregiver coaching, relative to video coding by researchers (see Table 1). Rapid coding revealed that providers consistently use developmental strategies (e.g., child-led play, labeling, modeling) and behavioral strategies (e.g., prompting, reinforcement). Notably, although certain behavioral strategies were frequently used, the coding team rarely observed effective use of sequenced behavioral teaching approaches. For example, providers often cued children to say or do something, but did not provide support or follow-through (e.g., repeated prompts, scaffolding) if the child did not respond. Similarly, providers maintained a positive attitude and frequently praised children, but praise was general rather than specific, and positive reinforcement was not consistently contingent upon children's actions. Additionally, there was substantial variation in observed session duration, structure, and caregiver and child engagement.

Conclusions: This study replicates previous findings that EI providers report greater use of caregiver coaching than is observed, and provides information about other types of interventions delivered to children with social communication delays in Part C. It highlights that providers are already utilizing many evidence-based strategies to support children's development. However, opportunities remain to further enhance and standardize practices to ensure the provision of the most efficacious interventions during a time of heightened brain plasticity.

414.246 Determinants of Improved Outcomes One Year Post-Initiation of Applied Behavioral Analysis in a Sample of Turkish Autistic Children

H. Aslan Genc^a, E. Sever^a and T. Mutluer^a, (1)Child and Adolescent Psychiatry, Koç University School of Medicine, Istanbul, Turkey, (2)Koç University School of Medicine, Istanbul, Turkey

Background: Applied behavior analysis (ABA) is a leading evidence-based intervention for autism spectrum disorder (ASD), yet it is often out of reach for families in low- and middle-income countries (LMICs). Recent research has explored the relationship between the age at which early interventions are initiated and their impact on outcomes for children with ASD. These studies emphasize the importance of examining multiple predictor variables to fully understand treatment outcomes.

Objectives: The study aims to build on this by examining pre-treatment factors influencing ABA treatment outcomes.

Methods: The records of 223 individuals receiving ABA therapy at a special education center in Istanbul, Türkiye were reviewed. From this population, 64 children diagnosed with ASD who had completed at least 12 months of ABA therapy were initially selected for the study. After excluding children without pre-therapy assessment data, the final sample comprised 50 children (45 males, 5 females) with a mean age of 6.1 years ($SD = 2.0$). Sociodemographic and clinical history, including information on medication use and psychological test results, were obtained for all participants. The Gilliam Autism Rating Scale-2 (GARS-2) was administered to assess the initial symptom severity of the participants. Additionally, the Psychoeducational Profile-Revised (PEP-R) was employed to evaluate developmental functioning at baseline (T0) and after one year (T1) of ABA therapy.

Results: The sociodemographic characteristics and scale results are presented on Table-1. The weekly session number was 5.18 ± 3.39 , the use of any regular medication was 44% ($n=22$) and psychotropic medication was 22% ($n=11$). Among the variables age of the participant ($r=-0.308, p=0.026$), GARS-2 autism index score ($r=-0.309, p=0.037$) and GARS-2 stereotyped behaviors score ($r=-0.373, p=0.019$) had negative low correlation with the difference in total PEP-R scores. GARS-2 autism index score was negatively correlated with difference in PEP-R imitation ($r=-0.343, p=0.024$), perception ($r=-0.414, p=0.005$), cognitive performance ($r=-0.365, p=0.015$) and cognitive verbal scores ($r=-0.357, p=0.045$). GARS-2 stereotyped behaviors score was negatively correlated with difference in PEP-R imitation ($r=-0.347, p=0.038$), perception ($r=-0.374, p=0.023$), cognitive performance ($r=-0.524, p<0.001$) and cognitive verbal scores ($r=-0.391, p=0.048$). In multiple regression analyses, younger age of the participant, lower GARS-2 autism index score and lower GARS-2 stereotyped behaviors score at the initiation of the treatment predicted better outcomes following a year of ABA treatment in autistic children ($f(3,35)=4.342, p=0.011, R^2=0.271$).

Conclusions: The findings highlight that the effectiveness of ABA therapy for autistic children is influenced by several factors, including the age of the child and the severity of symptoms as measured by the GARS-2 autism index and stereotyped behaviors. Our findings indicate that younger children with lower autism severity at the start of treatment show better developmental improvements over a year of therapy even in low intensity settings. It is important to note that the average weekly session frequency in our sample was significantly below the optimal level of 20 sessions per week, which is recommended for maximizing ABA's efficacy. This underscores a critical gap in service provision, especially in LMICs, where access to the recommended level of therapy may be limited. Future research should aim to explore the impact of achieving optimal session frequency on treatment outcomes and address the barriers to accessing adequate levels of ABA therapy in these settings.

414.247 Development and Usability Testing of a W.H.O. Caregiver Skills Training Smartphone Application (Kica)

E. Salomone¹, M. Vanoncini¹, G. de Leonardis¹, M. Fioravanti¹, A. Arnoldi¹, A. Gabbiadini¹ and L. Zampini², (1)Department of Psychology, University of Milan-Bicocca, Milan, Italy, (2)Department of Psychology, University of Milan-Bicocca, Milan, Milan, Italy

Background: Mobile-health approaches to parent-mediated interventions (PMIs) hold great potential for implementation scale-up. However, essential phases of an application development cycle, such as stakeholders consultations for needs assessment and usability testing, are often overlooked. Findings of a previous consultation with professionals and caregivers about a to-be-developed mobile application based on the WHO Caregiver Skills Training (CST) indicated that it should be suitable for parental self-directed use regardless of previous exposure to PMIs and employ easy-to-use, engaging and customizable activities to: 1) provide psychoeducation; 2) support home practice and 3) promote psychological well-being.

Objectives: To report on the development process of Kica, a novel mobile application based on CST (Phase 1), and to explore caregivers' views on the prototype's design, content, and usability (Phase 2).

Methods:

[Phase 1] The app was designed with a user-centered approach, tailored to stakeholders' needs. It adapts CST contents and learning activities into 6 lessons covering engagement, communication, and routines. Each lesson includes a Learning Mode for psychoeducation, a Practice Mode with guidance on interaction strategies with children, and Wellbeing Mode for self-care (Figure 1, part A). Gamification elements were added to enhance engagement and motivation, including quizzes, self-assessment graphs for tracking strategy use, micro-learning videos, and skills demo-clips.

[Phase 2] Participants in the usability tests were 19 parents (with at least intermediate proficiency in Italian; 84% mothers) of 2–6-year-old autistic children ($M=53$ months, $SD=14$), recruited from public health services in Northern Italy. On their first interaction with the prototype, participants either received the Cognitive Walkthrough (CW; Polson et al., 1992; $n=11$), which assesses success rates (success; partial success; failure) on 18 app navigation tasks and self-reported difficulty (7-point scale), or the Think-Aloud task (TA; Charters, 2003; $n=8$), providing feedback in design, content, and usability. The two groups were balanced on background characteristics (gender, nationality, education, income, all $ps > .05$). All participants were then asked to rate the overall usability on the 10-item, 5-point-scale System Usability Scale (SUS; Brooke, 1996).

Results: The average task success rates in the CW was 85% ($SD=19$), with significant differences by Italian proficiency in the 3 tasks with suboptimal ($<60\%$) success rates (all $ps < .05$; Table 1). Task difficulty ratings were in the 'low' range ($M=2.44$, $SD=1.84$). Thematic analysis (Brown & Clarke, 2012) of TA transcripts supported these findings: participants appreciated the videos and visual aids, the scheduling features for daily activities, and the focus on routines to promote relationship with the child and communication. Suggestions for improvement included enhancing progress tracking and feedback, and personalized features based on child's needs. Usability issues mainly concerned poor graphic contrast and navigation difficulties. Total SUS ratings ($M=81.44$, $SD=14.89$) indicated overall acceptable usability.

Conclusions: Usability testing highlighted strengths and areas for improvement. Adjustments to the prototype included simplifying and minimizing language, redesigning the home screen, enhancing visual cues for progress and activity tracking, and clarifying previously hidden or misleading functionalities (Figure 1, part B). Overall, the findings indicate good acceptability and support formal testing of feasibility and preliminary clinical efficacy through pilot testing.

**414.248** Development of Telehealth Parent-Mediated Intervention for Young Children with ASD in Taiwan: A RCT Study

C. H. Chiang¹, T. H. Chen² and K. H. Cheng³, (1)Department of Psychology, National Chengchi University, Taipei, Taiwan, (2)Department of Psychiatry, China Medical University Hsinchu Hospital, Hsinchu, Hsinchu, Taiwan, (3)Department of Psychiatry, National Yang Ming Chiao Tung University Hospital, Yilan, Yilan county, Taiwan

Background: Due to the COVID-19 public health crisis, in-person interventions became largely infeasible from 2020 to 2022 in Taiwan. As a result, it is crucial to develop an evidence-based, telehealth, parent-mediated intervention for young children with autism spectrum disorder (ASD) that includes cultural adaptation.

Objectives: This study aimed to examine the intervention effects on children's outcomes between self-directed and coach-assisted groups.

Methods: A randomized controlled trial (RCT) was conducted with 36 parents and their children with ASD (aged 20 to 47 months), recruited between 2020 and 2023, and randomized into coach-assisted and self-directed groups. The intervention lasted 13 weeks, with online courses adapted primarily from the Early Start Denver Model (ESDM) parent manual. Parents in both groups were asked to complete weekly online courses, while parents in the coach-assisted group also received an additional 1-hour coaching session via videoconference. Assessments were conducted at baseline, immediately post-intervention, and three months post-intervention. Outcome measures included parental knowledge of intervention strategies, ESDM fidelity, and children's spontaneous functional communication and joint engagement.

Results: The results indicated the following: (1) Both groups of parents improved their knowledge of intervention strategies post-intervention. However, only parents in the coach-assisted group showed significant improvement in ESDM fidelity, with the benefits sustained three months post-intervention. (2) Regarding child outcomes, only children in the coach-assisted group demonstrated a significant increase in the variety of communication functions, and this effect was maintained three months post-intervention. Additionally, both groups of children exhibited a significant increase in the proportion of high-level joint engagement during the intervention period, although this effect was not sustained three months post-intervention.

Conclusions: The results revealed that the online coaching program for parents can enhance the quality of parent-child interaction and improve children's communication abilities at home. Moreover, both the self-directed and coach-assisted groups showed potential for improving the social communication skills of children with ASD.

414.249 Differential Response to Early Intervention between Autism Subtypes Defined Based on Non-Core Language, Intellectual, Motor, and Adaptive Functioning Features.

V. Mandelli¹, M. Godel², F. Robain³, Y. Sinai-Gavrilov⁴, T. Gev⁵, L. Ruta⁶, O. Golan⁷, G. Vivanti⁸, E. Courchesne⁹, K. Pierce¹⁰, M. Schaer² and M. V. Lombardo¹¹, (1)Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto, Italy, (2)Department of Psychiatry, University of Geneva, Geneva, Geneva, Switzerland, (3)Department of Psychiatry, University of Geneva School of Medicine, Geneva, Switzerland, Geneva, Switzerland, (4)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel, (5)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (6)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy (CNR), Messina, Italy, (7)Department of Psychology, Bar-Ilan University, Department of Psychology, Ramat-Gan, ISRAEL, (8)A.J. Drexel Autism Institute, AJ Drexel Autism Institute, Philadelphia, PA, (9)Neuroscience, Eric Courchesne, San Diego, CA, (10)Autism Center of Excellence, Department of Neurosciences, University of California San Diego, San Diego, CA, (11)Laboratory for Autism and Neurodevelopmental Disorders, Italian Institute of Technology, Rovereto, Trento, Italy

Background:

While difficulties in social-communication and restricted repetitive behaviors hallmark core features of autism, they do not capture other important features that distinguish young autistic children. Non-core features such as language, intellectual, motor, and adaptive functioning (LIMA) separate autism into a type I versus type II distinction. These subtypes separate autism into types with relatively high (type II) compared to low (type I) levels of LIMA scores. The subtypes are also meaningful for predicting differential early developmental trajectories and functional and structural neuroimaging phenotypes (Mandelli, Severino et al., 2024). However, it is unclear whether they also point to a distinction that is relevant for understanding who benefits most from early intervention.

Objectives:

In this work we aim to test whether type I versus type II autism subtypes will differentially respond to early intervention. Specifically, we examine whether the Early Start Denver Model (ESDM) or community-based treatment-as-usual (TAU/COM) intervention programs show differential responses as a function of subtype.

Methods:

We pool data from 7 studies on early intervention in autistic children, collected over 8 sites internationally (USA, Switzerland, Israel, Australia) and comprising $n=361$ (female $n=77$) participants (age = 11-60 months). Participants received from 6 to 27 months of intervention, with variable levels of intensity, and were enrolled in either ESDM ($n=170$) or TAU/COM ($n=191$) interventions. Longitudinal data common to most datasets included Mullen Early Scales of Learning (MSEL), Vineland Adaptive Behavior Scales (VABS), and ADOS. Subtypes were predicted using pre-treatment MSEL and VABS data in a subtype prediction model validated in prior work (Mandelli, Severino et al., 2024). Linear mixed effect models were used to predict trajectories of MSEL age-equivalent scores, VABS domain standardized scores, or ADOS calibrated severity scores, with random effects of dataset and age grouped by subject, fixed effects of treatment type, subtype, age, and their interactions, and other covariates such as treatment intensity, sex, age at treatment start, and pre-treatment developmental quotient. Control for multiple comparisons was achieved using FDR $q<0.05$. Follow-up analyses tested for the effect of treatment type within each subtype separately using the same mixed effect modeling framework.

Results:

After controlling for several covariates (e.g., sex, treatment intensity, age at treatment start, pre-treatment developmental quotient), we observed age-related interactions with subtype on all MSEL subscales and on VABS communication and motor domains, as well as with treatment type on MSEL receptive and expressive language and VABS communication scales. Explaining the age*subtype interactions, we find that type II individuals generally have faster growth trajectories compared to type I. To explain the age*treatment type interaction, we find that expressive and receptive language growth is facilitated more by ESDM than COM/TAU specifically in the type I subtype ($p = 0.02$), but not in type II ($p = 0.47$).

Conclusions:

This work suggests that in addition to being developmentally sensitive, LIMA-defined early autism subtypes may be treatment-relevant. Both ESDM and COM/TAU tend to work similarly on both subtypes. However, there is a subtle facilitative effect for ESDM on expressive and receptive language in type I individuals.

414.250 Does Baseline Expressive Language Ability Predict Early Intervention Outcomes? Evidence from the Social ABCs

S. Daoud¹, K. Bernardi², E. M. Dowds³, S. Macwilliam⁴, S. Jilderda⁵, L. Zwaigenbaum⁶, I. M. Smith⁷ and J. A. Brian⁸, (1)Autism Research Centre, Holland Bloorview, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehab Hospital - ARC, Toronto, ON, Canada, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (4)IWK Health Centre, Halifax, NS, CANADA, (5)Alberta Health Services, Edmonton, AB, Canada, (6)University of Alberta, Edmonton, AB, Canada, (7)Dalhousie University / IWK Health, Halifax, NS, Canada, (8)Holland Bloorview Kids Rehab Hospital, Toronto, ON, Canada

Background:

The Social ABCs is a caregiver-mediated early intervention for toddlers showing social-communication challenges that may be signs of autism spectrum disorder (ASD). With a large research evidence base and widely offered community-based services, children with varying language skills are accessing the program. In clinical application of this work, whether children with lower baseline language abilities benefit from caregiver-mediated early interventions that focus on vocal communication targets remains a question.

Objectives:

To support clinicians who refer children to caregiver-mediated early interventions, this study aims to determine whether children with lower expressive language skills benefit from programs such as the Social ABCs.

Methods:

67 families (62 mothers, 4 fathers and 1 grandmother) participated in a randomized control trial of the Social ABCs. Before starting the program all toddlers (52 boys, 15 girls; mean age: 25.95 months; range: 18-32 months) were assessed using the Mullen Scales of Early Learning. Expressive Language scale age- equivalent (AE) scores were categorized into three AE bands: 0-11 months, 12-17 months, and 18-36 months. Video-coded data were used to calculate child responsivity, child initiations, orienting to caregiver, shared smiling, and caregiver implementation fidelity before and after intervention, and change scores for these target skills were examined.

Results:

An ANOVA of change scores showed gains across all toddler variables for all age bands with no significant differences. Caregiver implementation fidelity showed a significant effect between groups ($F(2,47) = 5.11, p = .010$). All groups gained in implementation fidelity; post hoc analysis showed a significant difference ($p = .008$) in caregiver fidelity for toddlers in the 12–17-month AE band ($M = 44.03$) compared to the 18+ AE band ($M = 28.34$). These findings suggest that the Social ABCs is beneficial regardless of baseline expressive language abilities.

Conclusions:

These findings contribute to a larger understanding of which toddlers and families benefit most from participating in early intervention programs. Toddlers with very low expressive language skills at baseline can still benefit from early caregiver-mediated interventions such as the Social ABCs. Regardless of baseline expressive skills, all children in this study had an equal opportunity to make gains in the areas of responsivity, child initiations, orienting to caregiver and shared smiling. Caregiver implementation fidelity increased for all groups, with a notably larger increase for the 12–17-month AE group. One possibility is that caregivers of toddlers who have relatively lower language abilities at baseline may be uniquely motivated to learn the intervention strategies. We will explore this in further analyses. This information may be helpful in informing clinical triage decisions.

414.251 Early Child-Clinician Patterns of Acoustic Synchrony Predict Outcome of Autism Intervention

G. Bertamini^{1,2,3}, **S. Perzoli**¹, **A. Bentenuto**⁴, **M. Chetouani**³, **C. Furlanello**^{5,6}, **D. Cohen**⁷ and **P. Venuti**¹, (1)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto (TN), France, (2)Department of Child and Adolescent Psychiatry, Hôpital Universitaire Pitié-Salpêtrière, Sorbonne University, Paris, France, (3)Institut des Systèmes Intelligents et de Robotiques, CNRS UMR 7222, Sorbonne University, Paris, France, (4)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto (TN), Italy, (5)LIGHT Center, Brescia, Italy, (6)HK3 Lab, Rovereto, Italy, (7)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto, Trento, Italy

Background: Patient-therapist dynamics is a core component of psychotherapy. However, the way it contributes to outcomes remains largely unknown. Fine-grained research on mechanisms of action in psychotherapy is time-consuming and labor-intensive because of human data annotation, and it suffers from poor quantification. This is also the case for developmental approaches in the context of neurodevelopmental conditions like autism, where research is stressing the role of the interpersonal interplay as an active element, e.g., of Naturalistic Developmental Behavioral models of Intervention (NDBIs). **Objectives:** In this study, we evaluated whether changes in the child-clinician acoustic synchrony dynamics during the first few months of autism NDBI predicted the outcome at one year with a computational approach. **Methods:** We followed 25 autistic preschool children and 17 therapists during recommended developmental intervention over one year and video-recorded two 60-min sessions for each child: one at baseline and one at three months, for a total of 50 videos. We developed a fully automated pipeline based on deep learning and affective computing to automatically segment and annotate children's and therapists' voices and to quantitatively model child-clinician acoustic synchrony in order to predict intervention outcome (developmental learning rates) at one year through logistic regression. We modeled synchrony at different levels of sophistication, including a complex dynamical system perspective by means of Recurrence Quantification Analysis. We employed a rigorous pipeline to perform feature selection, model development and model evaluation through nested leave-one-out cross-validation and machine learning algorithms. We further included a data augmentation analysis to test result generalization. **Results:** We found that early changes in child-clinician acoustic synchrony accurately predicted the clinical response (Bal accuracy=0.96; F1=0.96, sensitivity=1; specificity=0.92; precision=0.92; MCC=0.92; AUCROC=0.99; PRROC=0.99). Specifically, a better response trajectory was predicted by (i) patterns of synchrony concurrently displaying increased variability, predictability, and organization of their internal structure; and (ii) acoustic features mainly related to emotional engagement. Interestingly, non-responders showed complementary patterns with respect to the evolution of these variables. **Conclusions:** We conclude that our non-invasive system is accurate and applicable to large amounts of naturalistic data. It can also be flexibly adapted to different developmental clinical settings. For autistic children, it supports the role of interpersonal synchrony and emotional engagement as key elements to promote intervention efficacy, as well as the pivotal role of the early months for intervention efficacy. Implications include the possibility to develop a "therapeutic feedback", implement systematic treatment monitor, and the disclosure of interaction features that may allow for efficacy maximization and treatment individualization .

414.252 Effectiveness of a Caregiver-Involved Group-Based Ndbi Program for Autistic Preschoolers: Preliminary Analysis of a Pilot Randomized Controlled Trial

G. J. Seng^{1,2,3,4}, J. Y. Lin³, H. Y. Lai³, W. C. Kao³, W. L. Huang³, H. L. Chen² and S. S. F. Gau⁵, (1)Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan, Taiwan, (2)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, Taiwan, (3)Department of Psychiatry, National Taiwan University Hospital Yunlin Branch, Yunlin, Taiwan, Taiwan, (4)Department of Psychiatry, College of Medicine, National Taiwan University, Taipei, Taiwan, Taiwan, (5)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan

Background:

Naturalistic Developmental Behavioral Interventions (NDBIs) are highly effective in enhancing cognitive and social communication skills in autistic children. Caregiver involvement in these interventions further amplifies their effectiveness. Additionally, some specific NDBI models delivered in group-based contexts suggest that such settings can foster autistic children's development and may be more practical for community-based implementation, facilitating the translation of early intervention research into real-world practice. However, most existing evidence is derived from one-on-one NDBI programs, which require certified therapists and maintain a high staff-to-child ratio. Therefore, developing and evaluating the effectiveness of group-based programs that adhere to open-access NDBI fidelity guidelines, involve caregivers, and operate with a lower staff-to-child ratio is necessary to provide a more feasible model for clinical practice.

Objectives:

This study aims to evaluate the effectiveness of a caregiver-involved group-based NDBI program for autistic preschoolers in improving (1) development, (2) social communication, and (3) adaptive functioning.

Methods:

We recruited autistic children aged 2-4 years and randomly assigned them to either (1) a group-based NDBI program (experimental group) where one therapist led five caregiver-child dyads or (2) a one-on-one NDBI program (active control group). Both interventions were delivered twice a week, with each session lasting 1 hour, for 12 weeks. Intervention fidelity was maintained using the NDBI-Fi for the one-on-one program and an adapted group-based NDBI-Fi for the group program. All children were assessed using the Autism Diagnostic Observation Schedule (ADOS) and clinically diagnosed by a child psychiatrist. Outcome measures included assessor-blinded Individual Growth and Development Indicators (Early Communication Indicators and Early Social Indicators), the Mullen Scales of Early Learning (MSEL), and the caregiver-reported Vineland Adaptive Behavior Scales, Third Edition (VABS-3). Repeated measures ANOVA was used to compare time effects and time-by-group interactions.

Results:

Five children (four boys and one girl), aged 27 to 46 months (mean = 38.8 months, SD = 7.4), were assigned to the group-based NDBI program, while five children (three boys and two girls), aged 29 to 44 months (mean = 38.8 months, SD = 5.9), were assigned to the one-on-one NDBI program. There were no significant differences between the groups at baseline regarding age, sex, ADOS Calibrated Severity Score, or developmental quotient (DQ). In the MSEL, a significant time effect was found for verbal DQ ($F = 12.55, p = 0.008$) and overall DQ ($F = 19.24, p = 0.002$), with a significant time-by-group interaction for overall DQ ($F = 6.25, p = 0.037$). A significant time effect was observed for Early Social Indicators ($F = 8.80, p = 0.018$), though no time-by-group interaction was found. No significant time or time-by-group effects were found for Early Communication Indicators or the VABS-3.

Conclusions:

Preliminary findings suggest that the caregiver-involved group-based NDBI program yields benefits similar to those of individual interventions in verbal development and early social functioning for autistic preschoolers. The integration of caregivers, adherence to open-access NDBI fidelity, and a lower staff-to-child ratio suggest that this program is feasible for clinical implementation while maintaining its therapeutic effectiveness.

414.253 Effectiveness of a Early Intervention Model for Children with Autism and Family Outcomes: A Repeated Measurement Study

S. Zeng, *Curriculum and Instruction, University of Massachusetts Boston, Boston, MA, China*

Background: Early intervention has been shown to improve outcomes for children with autism, particularly in areas such as language development, social skills, and adaptive behavior (Dawson et al., 2010; Reichow et al., 2012). However, evaluating the long-term effectiveness of these interventions presents unique challenges. A repeated measurement study design, which includes multiple time points, is essential for capturing the dynamic nature of intervention effects on both children with ASD and their families.

Objectives: The purpose of this study was to evaluate the effects of an early intervention model based on the principles of Naturalistic Developmental Behavioral Intervention (NDBI) on young children with autism spectrum disorder (ASD) and family outcomes in China.

Methods: We used quasi-experimental design for two groups and conduct repeated measurement at baseline, post, and 8-week follow up. The sample ($N = 60$) mean age was 4.8 years old ($SD = 1.1$) in this study. Children in the treatment group received the culturally adapted intervention 3 hours per day, 15 hour per week. Children in the control group received public-funded intervention services for 3 hours per day, 15 hours per week for a total of 8 weeks. To assess changes over time and differences between groups at the follow-up stages, we used mixed effect models to fixed effects.

Results: Findings demonstrated a significant decrease in autism symptoms and improved severity categorization for children in the intervention group, compared with the control group in both post and the follow up phrase. The treatment group showed a greater improvement ($b [SE] = 0.31[0.05], t = 36.3, p < .001, d = 0.65$) based on the overall ATEC score and CARS score ($b [SE] = 0.83[0.05], t = 2.87, p = .011, d = 0.37$). Also, there were positive changes for the treatment group's parental stress and anxiety levels. In the pre-post comparison, there was a significant improvement in the treatment group ($b [SE] = 0.16[0.05], t = 9.5, p = .002, d = 0.73$) for the SAS overall score. The largest effect was seen in the PSI overall score, where the treatment group showed a significant coefficient of 1.62 ($SE = 0.12, t = 17.3, p = .001, d = 0.49$). In the follow up comparison, there was a significant improvement in the treatment group ($b [SE] = 0.21[0.04], t = 12.3, p < .001, d = 0.78$) for the SAS overall score. The largest effect was seen in the PSI overall score, where the treatment group showed a significant coefficient of 1.95 ($SE = 0.21, t = 13.4, p < .001, d = 0.51$).

Conclusions: This study contributes to the growing body of evidence that early intervention is critical for improving outcomes in young children with autism. The improvements observed in communication, sociability, and sensory awareness, along with the sustained long-term benefits and positive impacts on parental stress, underscore the importance of early, targeted interventions. It also highlights the broader family benefits, emphasizing the need for a holistic approach to autism care that supports both the child and the parents.

414.254 Engaging Stakeholders to Adapt Ndbi Parent Coaching Interventions for Use in Early Childhood Education Settings

R. Gonzalez¹, A. Alenizi¹, S. M. Nichols² and M. Siller³, (1)University of North Texas, Denton, TX, (2)University of North Texas Kristin Farmer Autism Center, Denton, TX, (3)Emory University School of Medicine, Atlanta, GA

Background: Naturalistic Developmental Behavioral Interventions (NDBIs) provide a promising framework for early autism intervention research. Researchers have begun to specify and measure essential elements of evidence-based NDBI parent coaching interventions, both at the clinician-parent (Edmunds et al., 2022) and at the parent-child level (Frost et al., 2020). Many of these strategies align broadly with Developmentally Appropriate Practice guidelines published by the National Association of the Education of Young Children (NAEYC), which emphasize the importance of fostering reciprocal partnerships with families in preschool settings (Siller et al., 2023).

Objectives: To gather input from multi-setting and multi-level stakeholders to adapt NDBI parent coaching interventions for use in authentic ECE settings.

Methods: Participants were $N=34$ stakeholders, including ECE system leaders ($n=6$), program directors or principals ($n=6$), teachers ($n=11$), and parents ($n=11$). Ninety one percent (91%) of participants were female and ranged in age from 21 to 65 years ($M=42.5$, $SD=11.4$). Ethnic and racial diversity included 85% White, 15% Hispanic or Latino, 9% Asian, and 6% Black or African American. Stakeholders represented multiple ECE systems, including public school-based ECE (43%), Head Start (22%), and private ECE centers (48%). Following an initial survey, $n=31$ participants (91%) completed structured interviews, probing for experiences, opportunities, and barriers related to engaging parents of children with social-communication challenges in ECE settings. Interviews were transcribed and coded by two doctoral students using qualitative content analysis.

Results: Qualitative analyses revealed four content domains: (1) target population, (2) parent education format, (3) parent education content, and (4) feasibility and barriers. Interviews reveal that ECE settings educate children with a broad range of social-communication challenges, including children with high likelihood of autism. In terms of parent education format, stakeholders emphasized the potential of in-person opportunities for learning, practice, and coaching (e.g., literacy night), compared to didactic workshops (online or in-person). When questioned about learning content, stakeholders prioritized a broad range of strategies for promoting engagement (e.g., focus on the child, responding to and expanding children's communication), over more structured teaching strategies (e.g., prompting hierarchies, reinforcement analysis). Finally, the main barrier reported by preschool staff and parents was time, emphasizing that parent engagement opportunities in ECE should be limited in frequency and duration.

Conclusions: Stakeholder input was used to adapt NDBI parent coaching strategies for use in authentic ECE settings to develop Family-School Partnership Intervention (FSPI). Key components of FSPI include (1) opportunities for practice and coaching are embedded in a playgroup format where teachers guide parents through a small number of familiar routines shared at home and at school (e.g. book reading, chore, play, and snack); (2) program intensity is limited to three 90-minute playgroups scheduled over the course of a school year; (3) the intervention content focuses on six engagement strategies to promote children's investment, independence, and initiations; and (4) the program is implemented by preschool staff and targets children with a variety of social-communication challenges. A feasibility trial of FSPI is currently underway.

414.255 Estimating Individualized Intervention Effects of a Parent-Implemented Social Communication Intervention in Autistic Preschoolers: A Randomized Controlled Trial

L. Wang¹, Y. Shi², H. W. Hirai³, H. C. So² and P. Wong⁴, (1)Brain and Mind Institute, The Chinese University of Hong Kong, Hong Kong, HK SAR, (2)School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong SAR, HK SAR, China, (3)Brain and Mind Institute, The Chinese University of Hong Kong, Hong Kong, HK SAR, China, (4)Brain and Mind Institute, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong

Background:

Autistic individuals show significant variability in social communication skills, and parent-implemented interventions have demonstrated positive developmental impacts. However, such interventions often lead to heterogeneous effects across individuals. While randomized controlled trials (RCTs) traditionally focus on group-level outcomes, individual variability in response to interventions may be obscured, especially when group-level effects are driven by a subset of highly responsive individuals. Understanding individualized effects is essential for tailoring interventions to those most likely to benefit.

Objectives:

This study aimed to estimate the individualized intervention effects of a parent-implemented social communication intervention in autistic preschoolers. We sought to identify child- and parent-related characteristics that predict better outcomes, moving beyond average treatment effects (ATE).

Methods:

A total of 112 minimally verbal autistic children aged 2-5 years from Mainland China participated. Children with listening or visual impairments or neurological/psychiatric conditions were excluded. One of their parents participated in a randomized controlled trial, with families randomly allocated to either the SLT (speech-language therapist) -Led or the Self-Study Group using a minimization method (see Table 1). In the SLT-Led Group, parents participated in 20 weeks of online lessons led by an SLT, during which they learned seven key communication strategies and received feedback on weekly video submissions of interactions with their children. In the Self-Study Group, parents received bi-weekly reading materials on the same communication strategies over 20 weeks but did not submit videos or receive therapist feedback. Outcomes were measured using ADOS-2 and Vineland-3 Communication scores in 12 months.

Results:***Predicted Individual Intervention Effects***

Machine learning models (T-Learner and X-Learner) were used to estimate individualized intervention effects. While no significant group-level effects were found, individualized effects revealed higher intervention benefits for the SLT-Led group compared to the Self-Study group (**ADOS CSS**: ATE = -0.10, 95% CI [-2.03-1.83] in T-Learner, ATE = -0.11, 95% CI [-1.69-1.47] in X-Learner; **Communication Score**: ATE = 1.36, 95% CI [-17.45-20.17] in T-Learner, ATE = 1.63, 95% CI [-12.70-15.95] in X-Learner).

Child- and Parent-Related Characteristics Associated with Individualized Effects

Among child- and parent-related characteristics in Table 1, parental BAPQ scores, child age, PSS, Child SCQ and parental sex were the most important characteristics influencing the individualized intervention effects on the ADOS CSS. For the communication, parental BAPQ scores, PSS, child age, household income levels, and POSC were most important characteristics. Notably, these relationships were not linear as suggested by previous studies. For example, as shown in Figure 1, the association between parental BAPQ and ADOS CSS was a U shape, suggesting scores ranged between 3-3.5 took more benefit from the SLT-Led course.

Conclusions:

Our findings highlight the importance of individualized analyses in intervention research. While average effects may be negligible, individual responses vary significantly, with specific child- and parent-related characteristics predicting better outcomes. These insights can help inform personalized intervention strategies, ultimately enhancing intervention scalability and effectiveness for a wider range of autistic children.

414.256 Evaluating the Effectiveness of Telehealth-Delivered Parent-Implemented Esdm on Developmental Outcomes and Maternal Anxiety in Young Autistic Children.

C. Carrozza¹, F. I. Famà¹, A. Campisi², E. Leonardi¹, S. Aiello¹, T. NEST Team¹, S. Campisi³, R. Bruschetta⁴, G. Tartarisco⁴, G. Pioggia⁴, M. Mastrogiuseppe⁵ and **L. Ruta¹**, (1)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy (CNR), Messina, Italy, (2)University of Trieste, Messina, Italy, (3)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy (CNR), Messina, Sicily, Italy, (4)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy, Messina, Italy, (5)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy (CNR), Messina, sicily, Italy

Background:

Early intervention for autistic children increasingly emphasizes the importance of embedding learning opportunities within everyday routines and naturalistic environments. By actively involving parents in the intervention process, parent-mediated approaches create unique opportunities to integrate skills and strategies into daily life. Research has demonstrated that these interventions positively impact children's communication, social interaction, and behavior (Cheng et al., 2023), while also empowering parents by boosting their sense of efficacy and helping them manage stress and anxiety (Pacia et al., 2022). Moreover, the use of telehealth modalities for delivering parent coaching enhances accessibility and flexibility, reducing barriers such as travel and scheduling, and providing real-time support and feedback directly within the family's natural environment (Pan et al., 2023).

Objectives:

Building on this evidence, our study aims to compare the effects of a parent-implemented Early Start Denver Model (PESDM) and Therapy As Usual (TAU) on child developmental outcomes and maternal anxiety, exploring how different intervention modalities delivered with similar low intensity influence both child and caregiver well-being.

Methods:

Participants were young children diagnosed with autism according to DSM-5 criteria. The PESDM group included 52 children (39 males), aged 16–37 months (mean=26.48; SD=4.7), while the TAU group comprised 27 children (26 males), aged 19–39 months (mean=30.92; SD=5.3). TAU children received three 1-hour one-on-one therapy sessions per week through public services. The PESDM group received a mixed-modality intervention: two 1.5-hour one-on-one ESDM sessions at CNR-IRIB facilities and one remote parent coaching session using video feedback. Child development was assessed with the Griffiths Mental Development Scales (GMDS), and maternal anxiety with the State-Trait Anxiety Inventory (STAI). A linear mixed-effects model analyzed developmental trajectories, controlling for age and developmental quotient at intervention start.

Results:

The findings revealed a significant effect of intervention modality on the overall score and all developmental domains assessed by the GMDS (General: $F(1,152)=10.83$, $p=0.001$; Locomotor: $F(1,152)=12.67$, $p<0.001$; Personal-Social: $F(1,152)=10.75$, $p=0.001$; Hearing-Language: $F(1,152)=4.25$, $p=0.04$; Eye-Hand Coordination: $F(1,152)=5.58$, $p=0.01$; Performance: $F(1,152)=5.06$, $p=0.02$), with children in the PESDM group showing greater developmental gains compared to the TAU group (Fig. 1). Additionally, mothers in the PESDM group demonstrated a reduction in anxiety levels after the 6-month intervention period, approaching significance (STAI: $F(1,112)=4$, $p=0.048$) (Fig. 2).

Conclusions:

This study underscores the efficacy of a parent-implemented ESDM intervention delivered via tele-health using a video-feedback approach, demonstrating significant enhancements in early developmental outcomes for children and reductions in maternal anxiety. These findings suggest that mixed-modality, parent-focused interventions can effectively improve developmental trajectories in young children with autism while supporting parental well-being, ensuring that autistic children receive support that is aligned with their natural experiences and environments.

414.257 Examining Parent Fidelity in Reciprocal Imitation Teaching: Challenges and Gaps in Implementation

C. Perryman¹, D. M. Tagay² and W. L. Stone³, (1)University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA

Background: Parent fidelity in implementing Naturalistic Developmental Behavioral Interventions (NDBIs) is essential because it ensures that intervention strategies are delivered as designed, which directly impacts child progress (Roberts et al., 2019). Consistent and accurate use of these techniques by parents has been linked to better outcomes in areas such as social communication, imitation, and language development (Ouyang et al., 2024). Without high fidelity, the effectiveness of NDBIs may be compromised, limiting potential benefits for children.

Objectives: The objective of this study is to examine parent fidelity of a specific NDBI, Reciprocal Imitation Teaching (RIT), following caregiver coaching from a Part C Early Intervention provider. Specifically, this study aims to understand which components of RIT are not being completed in a subsample of caregivers who had low fidelity.

Methods: This project stems from a larger RCT examining a brief, inexpensive training in RIT, compared to an active control condition, on EI providers' implementation of RIT and downstream child outcomes. Specifically, this study examined behaviorally coded fidelity data from caregivers who received training in RIT at two timepoints (T2: 3 months after training and T3: 6 months after training). Fidelity was coded via a 6-minute observational sample in which caregivers were instructed to use strategies they were learning with their EI provider. Caregivers were rated on their use of the various components of RIT "None of the time" (0), "Some of the time" (1), or "Most of the time" (2) over the 6 minutes. RIT fidelity components were: (1) Imitates child's play or gestures; (2) Models new actions for the child; (3) Physically prompts the child to imitate; and (4) Praises the child's imitation. The number of full RIT cycles caregivers used (defined as using all components in succession) was also coded. Repeated measures ANOVAs were utilized to determine if caregivers were completing certain fidelity components more frequently than others.

Results: Nineteen caregivers were trained in RIT. Eighteen completed a fidelity assessment at T2 and fifteen completed a fidelity assessment at T3. At T2 78% of caregivers were classified as having low fidelity (defined as not completing at least one RIT cycle during the observation). At T3, 67% of caregivers were classified as having low fidelity. Results of the ANOVA showed a significant effect of fidelity component type on frequency of caregiver use at T2 (See Figure 1). Post hoc comparisons revealed that at T2, parents with low fidelity were more frequently modeling new actions, and less consistently imitating, physically prompting, and praising. Results did not show a significant effect of fidelity component type on frequency of caregiver use at T3 (See Figure 2).

Conclusions: Results suggest that certain components of RIT are consistently more challenging for caregivers to implement. However, this study had a low sample size. Future work in this area should aim to determine if additional coaching or practice for caregivers in specific areas can improve fidelity in a larger implementation study. Future research could also serve to determine if additional coaching leads to downstream effects on child outcomes.

414.259 Examining the Effect of Parental Involvement on Child and Parent Outcomes in the PEERS for Preschoolers (P4P) Social Skills Intervention: A Randomized Controlled Trial

L. Oliver Aronson¹, T. Gev^{2,3}, E. A. Laugeson⁴ and O. Golan^{3,5}, (1)Department of Psychology, Bar Ilan University Israel, Ramat-Gan, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (3)OTI - The Israeli Autism Association, Givat-Shmuel, Israel, (4)UCLA Semel Institute for Neuroscience and Human Behavior, UCLA PEERS® Clinic, Los Angeles, CA, (5)Department of Psychology, Bar-Ilan University, Department of Psychology, Ramat-Gan, ISRAEL

Background:

Involving parents in social-skills training for autistic children is known to improve intervention effectiveness (DeRosier et al., 2011), since parents facilitate social learning opportunities for their children, and improve the maintenance and generalization of treatment gains (Siller et al., 2018). Parents may also benefit themselves from participating in these interventions (Solomon et al. 2008). The Program for the Education and Enrichment of Relational Skills for Preschoolers (PEERS for Preschoolers; P4P, Laugeson et al., 2024) is a 16-week research-supported, parent-assisted social-skills training program for young autistic children. In P4P, parents attend parallel sessions to their children, learning strategies to support skill practice and facilitate peer-interactions. Previous studies of P4P have demonstrated concurrent improvements in social and caregiving skills (Factor et al., 2022), which were maintained at follow-up (Antezana et al., 2022).

Objectives:

To conduct an Israeli randomized controlled trial, comparing the effects of the parent-supported P4P program to those of a P4P program with minimal parent involvement (P4P-MPI) on children's social-skills and on skills' generalization to school settings.

Methods:

Sixty-nine participants (9 females) aged 4-7 ($M=5.29$, $SD=0.98$), diagnosed with ASD without intellectual disability, were randomly assigned to the standard P4P intervention ($n=34$) or the P4P-MPI ($n=35$). In the P4P-MPI condition, parents received handouts summarizing didactic lessons instead of attending parent sessions. Each intervention group included up to 10 children. Conditions were comparable on age, sex, cognitive abilities, and ADOS-2 scores. Parents and teachers reported pre- and post-intervention on the Social Skills Improvement System (SSIS; Gresham & Elliott, 2008) and the Social Responsiveness Scale, 2nd ed. (SRS-2; Constantino & Gruber, 2012). Parents also completed the Quality of Play Questionnaire (QPQ; Frankel & Mintz, 2011) and the Parenting Stress Index (PSI; Abidin, 2006).

Results:

In the P4P condition, but not in the P4P-MPI, parents reported on improved social-skills, self-control, and empathy and of reduced ASD symptoms of their children on the SSIS. Parents reported no significant changes on the SRS-2. In addition, parents in both groups reported elevated stress across all three PSI subscales (Parental Distress, Difficult Child, and Parent-Child Dysfunctional Interaction), but these increases were statistically significant only in the P4P-MPI condition.

Teachers reported on significant intervention effects for all SSIS subscales, but the P4P condition showed significant improvements on children's communication, responsibility, and engagement, while the P4P-MPI condition showed improvements on children's empathy and self-control. On the SRS-2, teachers of children in the P4P condition reported improvements on the SRS-2 total score and on the Social Communication and Interaction index, and the Social Awareness, and Social Cognition subscales, whereas teachers of children in the P4P-MPI condition reported improvements on the Social Communication and Restricted Interests and Repetitive Behavior subscales.

Conclusions:

Results support the cross-cultural efficacy of P4P and highlight the importance of parental involvement in social-skills interventions for autistic children. Results also indicate that participation in social-skills interventions increases parental stress, but that this stress is moderated when parents participate in the intervention. Moreover, parental involvement appears to enhance the generalization of some learned skills to school settings.

**414.262** Exploring the Intersection of Emotion Dysregulation and Intervention Use in Autistic Children

A. Saunders, C. A. Mazefsky and J. B. Northrup, Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: Emotion dysregulation (ED) is common in children on the autism spectrum, and can present in a variety of ways in early childhood. Despite the prevalence of ED in autistic children, it is often not the target of early interventions—in fact, none of the most commonly-used interventions are designed to target ED (Beck et al., 2020). That said, ED may have an impact on access to interventions, and existing interventions may already impact ED in a positive or negative way. Understanding the association between ED and receipt of various types of interventions in young autistic children is a first step towards delineating these possible processes.

Objectives: This study aimed to describe receipt of various interventions in a large, diverse sample of autistic preschoolers, and examine associations between intervention use and ED severity.

Methods: The data for this study came from an online, national sample of parents of children ages 2- to 5-years with autism (N=853; Mean age = 4.6, SD= 1.1; 24% female). ED was measured using the Emotion Dysregulation Inventory-Young Child (EDI-YC), a parent report measure characterizing the severity of dysregulation across two dimensions: reactivity (fast, intense emotional reactions) and dysphoria (low positive affect, sadness, unease).

Parents answered questions about the intervention services their child currently receives and any services they have received in the past. They also completed questionnaires regarding child demographics, speaking ability, and autism symptoms.

We calculated the percent of the sample receiving each type of intervention, both in the past and currently. ANOVAs determined whether EDI scores differed between children who were or were not receiving each service type (currently or in the past). Finally, a regression analysis examined unique predictors of EDI scores, including all significant service types, while controlling for variables that were known to be associated with either ED or service use (i.e., income, autism symptoms, parental education, speaking ability).

Results: Speech (77% currently enrolled), occupational (64% currently enrolled), and behavioral (55% currently enrolled) therapy were the three most common therapies, while counseling interventions were uncommon (~5% currently enrolled; see Figure 1). There were several associations between specific interventions and EDI scores (see Figure 2). Children who received behavioral or physical therapy in the past, but not currently, had higher reactivity scores. Children currently receiving counseling services or social skills interventions had higher reactivity and dysphoria. On the other hand, children who received speech therapy, either currently or in the past, had lower reactivity and dysphoria.

Conclusions: Results suggest associations between ED and various intervention types, even when ED is not a direct target. Speech therapy—the most common intervention type—was associated with lower ED, even when controlling for speaking ability. Other intervention types, such as counseling interventions and social skills groups, were associated with increased ED. Although the current study cannot speak to directionality or causality of effects, it is a first step towards understanding the ways ED intersects with early intervention. Future prospective and longitudinal research is needed to continue to better understand these associations.

414.263 Exploring the Relation between Fidelity and Adaptation: Implementing an Ndbi within a Hybrid Type I RCT across Four Public Early Intervention Systems

S. R. Edmunds¹, K. M. Frost², A. R. Borowy³, Y. S. Stern³, E. M. Harrington⁴, A. S. Carter⁵, W. L. Stone⁶, S. Broder-Fingert⁷, R. C. Sheldrick⁸, A. Wainer⁹ and B. R. Ingersoll¹⁰, (1)Psychology, University of South Carolina, Columbia, SC, (2)Pediatrics, University of Massachusetts Chan Medical School, Worcester, MA, (3)Psychiatry and Behavioral Sciences, Rush University Medical Center, Chicago, IL, (4)Psychology, Michigan State University Psychology Department, East Lansing, MI, (5)Department of Psychology, University of Massachusetts Boston, Boston, MA, (6)Psychology, University of Washington, Seattle, WA, (7)UMASS Medical School, Boston, MA, (8)Boston University School of Public Health, Boston, MA, (9)Department of Psychiatry and Behavioral Sciences, Rush University Medical Center, Chicago, IL, (10)Psychology, Michigan State University, East Lansing, MI

Background: Providers often modify evidence-based practices (EBPs) when implementing them in community practice. Modifications to EBPs can be characterized as “fidelity-consistent” and “fidelity-inconsistent” (Wiltsey-Stirman et al., 2019). However, few studies exist to validate this way of thinking, and the true relation between fidelity and modification may be more complex. For example, while implementing core components of an EBP to fidelity may be essential for effectiveness, insisting on fidelity to the adaptable periphery may stifle innovation critical for personalizing care to individuals’ and families’ diverse identities and achieving successful community implementation. This study explores whether different types of modifications complement or detract from fidelity, which will inform future hybrid effectiveness-implementation trials and ultimately help providers make useful modifications.

Objectives: The objective of this study was to assess the relation between ratings of providers’ fidelity of caregiver-implemented reciprocal imitation teaching (CI-RIT) coaching and the amount and type of modifications they made. Does modifying an EBP always affect fidelity? Is our trial’s measurement of modifications capturing our intended construct, or simply measuring low fidelity?

Methods: Within a hybrid type 1 effectiveness-implementation trial (“RISE”), early intervention (EI) providers in the Washington, Michigan, Illinois, and Massachusetts public EI systems were trained in and provided CI-RIT as part of their regular practice. Providers’ ($n=47$) CI-RIT coaching fidelity and modifications were coded from families’ ($n=83$) EI session videos by trained observers. Providers completed surveys on the types of modifications (informed by the FRAME and MADI adaptation frameworks) they made for each family. Providers rated the extent to which they modified CI-RIT on a Likert scale from 1 (“never”) to 5 (“always”). We calculated an overall sum, and sums for items reporting “augmenting” and “reducing” modifications (Lau et al., 2017). Data collection is ongoing.

Results: Providers’ fidelity in CI-RIT coaching was negatively correlated with the overall amount of modification they reported making for that family, $r=-.331$, $p=.008$, such that those who were rated as having high fidelity reported making fewer modifications. While providers’ CI-RIT coaching fidelity was not significantly correlated with their augmenting modifications, $r=-.084$, $p=.510$, it remained negatively correlated with reducing modifications, $r=-.343$, $p=.006$.

Conclusions: Researchers are only recently exploring how to recognize and react to distinct types of modifications that providers regularly make when implementing EBPs in real-world settings (Yu et al., 2021), which has far-reaching implications for EBP effectiveness. Overall coaching fidelity was significantly associated with low modification. This suggests that, as measured in this study, fidelity and modification—especially modifications in which providers remove or reduce CI-RIT coaching elements—are on the same continuum rather than two unique constructs. However, the lack of association between coaching fidelity and modifications in which providers *added* elements to their CI-RIT coaching suggests that augmenting modifications may be somewhat separable from fidelity. Future work for this INSAR presentation will examine additional data on observed (rather than self-report) modifications. We will discuss whether the utility of modifications may vary based on which EBP component is modified, and whether augmenting modifications may enhance CI-RIT effectiveness or implementation within the EI system.

414.264 Facilitating Joint Attention in Young Children with Autism: A Parent-Mediated Intervention Approach **M. Garcia, G. M. Garcia and A. Mastergeorge, Human Development and Family Sciences, Texas Tech University, Lubbock, TX**

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by deficits in social skills, communication, cognitive abilities, and behavioral competencies, with particular difficulties in developing joint attention (JA). JA is a pivotal skill that emerges in infancy, with the ability to share focus on an object or event with others. It plays a foundational role in early communication development. When JA fails to develop, infants encounter difficulties in communication and social interaction, which can have long-term consequences for developmental trajectories. Since JA activities occur in everyday interactions, parent-mediated interventions often focus on enhancing these skills through everyday parent-child contexts.

Objectives: This study aims to examine the effects a play-based parent-mediated JA-based intervention has on parent verbalization frequency during parent-child social interactions, and to examine possible differences across types of verbalizations and play activities.

Methods: This 16-week parent-mediated intervention study focused on 12 parent-child dyads. The study included two distinct JA play activities: (1) constructing a face on a Mr. Potato Head toy with parent scaffolding the child in a problem-solving activity, and (2) playing with a dump truck, which included activities such as dumping objects in and out and rolling the truck back and forth to encourage turn-taking skills. The Dyadic Parent-Child Interaction Coding System (DPICS) was utilized to assess parent-child social interactions, with a focus on parental verbalizations. These verbalizations included: Acknowledgment, Total Praise, Total Descriptions, Total Questions, and Total Commands. Implementing multiple Wilcoxon Signed-Rank tests, the frequencies of each parent verbalization category were compared across time for the two play activities. Coder inter-rater reliability was conducted on reviewed videos segments based on DPICS criteria and Cohen’s Kappa was 80% for rater agreement. For the purposes of this study, pre-intervention frequencies were compared to the last four weeks of the scaffolding problem-solving activity, the last four weeks of the turn-taking activity, and post-intervention scores. This allowed for an analysis of changes in parent verbalizations within the two activities over the intervention period.

Results: Wilcoxon Signed-Rank test analyses of pre-intervention and post-intervention scores indicated no significant changes in any parent verbalization frequency. However, comparison of pre-intervention and the last four weeks of the scaffolding problem-solving activity scores indicated that Acknowledgment was significantly more prevalent ($z=-2.536$; $p=0.011$) while Total Descriptions ($z=-2.394$; $p=0.017$), Questions ($z=-2.516$; $p=0.012$), and Commands ($z=-2.041$; $p=0.041$) were significantly higher during the pre-intervention phase. Comparison of pre-intervention and turn-taking activity scores indicated that Total Descriptions ($z=-2.810$; $p=0.005$), Questions ($z=-2.703$; $p=0.007$), and Commands ($z=-2.675$; $p=0.007$) were significantly higher during the pre-intervention phase. Total Praise was not significantly different between pre-intervention and activity periods.

Conclusions: While unexpected, the overall decrease in parent verbalizations may be an indicator of increased child verbalizations and dyadic engagement. This highlights the importance of utilizing alternative analytical methods to examine JA and dyadic engagement within parent-mediated interventions. Furthermore, the decreases in parental descriptions, questions, and commands may suggest parental adaptations to increases in child verbal social cues and responses, resulting in fewer prompts and promoting dyadic synchrony.

414.265 Preschool Children with Autism Are More Likely to be Placed in Special Education If They Exhibit Low Cognitive Abilities and Aberrant Behaviors

M. Bachrach¹, **M. Ilan**², **D. Waissengreen**³, **T. Nitzan**⁴, **L. Baram**⁵, **L. Zelikovich Moyal**⁶, **M. Faroy**⁷, **D. Zagdon**⁸, **A. Michaelovski**⁹, **Y. Sadaka**¹⁰, **D. A. Zachor**¹¹, **J. Koller**¹², **I. Menashe**¹³, **I. Dinstein**¹⁴ and **G. Meiri**¹⁵, (1)Ben Gurion University in the Negev, Beer Sheva, South, Israel, (2)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Israel National Autism Research Center, Be'er Sheva, Israel, (4)Azrieli National Centre for Autism and Neurodevelopment Research, Student at Ben Gurion University of the Negev, Beer Sheva, Israel, (5)Negev Autism Center, Ben Gurion University of the Negev, Israel, Beer Sheva, Israel, (6)Azrieli National Centre for Autism and Neurodevelopment Research, Ben Gurion University of the Negev, Beer Sheva, Negev, Israel, (7)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (8)4. Zusman Child Development Center, Soroka University Medical Center, Beer Sheva, Negev, Israel, (9)Child Development Center, Soroka University Medical Center, Beer-Sheva, Israel, (10)Child Development Center, Ministry of Health, Beer Sheva, Israel, (11)ALUT The Israeli Society for autistic children, Tel-Aviv, Israel, (12)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (13)Department of Epidemiology, Biostatistics, and Community Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, (14)Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel, (15)26 YA'ARA ST., Beer-Sheva, Israel

Background: In many western countries autistic children can be placed in either special or mainstream preschool educational settings. These settings often differ dramatically in their cost, exposure to typically developing children, expertise and size of the educational staff, and their ability to incorporate structured autism intervention. Surprisingly little research has examined how placement decisions are made or what child characteristics predict placement in one setting versus the other. Previous studies have reported that children with lower cognitive abilities were more likely to be placed in special rather than mainstream preschool settings.

Objectives: To identify the strongest predictors of first year preschool educational placement in special versus mainstream education in Israel.

Methods: We recruited 165 children with autism as they entered their first year of kindergarten, at an average age of 37.86 (SD=4.4) months (i.e., 3-4-years-old). Of these children, 120 (73%) were placed in special education and 45 (27%) in mainstream education. All children completed the Autism Diagnostic Observation Schedule (ADOS-2), and most completed assessment of cognitive abilities with the Bayley or Mullen (n = 114), adaptive behaviors with the Adaptive Behavior Rating Scale 3rd edition (ABAS-3) (n = 113), and aberrant behaviors with the Aberrant Behavior Checklist (ABC) (n = 126). We used t-tests to compare children placed in mainstream versus special education settings and multiple logistic regression to determine the relative contribution of assessment scores in predicting educational placement. We also performed the same comparison across educational settings only with children without intellectual disability (NID, cognitive scores > 80).

Results: Children placed in special education exhibited significantly lower cognitive scores [80.8 vs 68.7; p=0.014], were diagnosed at an earlier age [33.8 vs 30.2; p=0.014] and their mothers had fewer years of education [14.7 vs 13.6; p=0.04]. There were no significant differences across settings in ADOS-2 Calibrated Severity Scores (CSS), ADOS-2 social affect (SA) CSS, ADOS-2 restricted and repetitive behaviors (RRB) CSS, ABAS-3 general score and all 5 subscales of the ABC. However, when isolating the analysis to NID children, those placed in special education exhibited significantly higher ABC: Irritability scores [7.29 vs 14.2; p=0.012]. A logistic regression analysis revealed that ADOS RRB-CSS (OR = 10.98, p = 0.009) and ABC: Irritability scores (OR = 7.01, p = 0.013) were both significant predictors of placement.

Conclusions: These findings suggest that early placement decisions for children with ASD entering kindergarten are primarily influenced by cognitive abilities. However, for children without intellectual disability, severity of repetitive behaviors and irritability are predictors of placement. In contrast the severity of core autism social symptoms does not seem to be a significant factor in placement decisions.

414.266 Assessing Geographic Provider Access By Therapist Type for Children with Autism in Missouri

K. Sohl¹, **A. James**², **A. R. Guhlincozzi**³, **C. McMahon**⁴, **R. Riley**⁵, **A. Abu-Shanab**⁶, **S. Greer**⁶, **M. H. Palmer**³ and **A. Brown**⁷, (1)ECHO Autism Communities, University of Missouri School of Medicine, Columbia, MO, (2)MU Peds, 65212, MO, (3)Geography, University of Missouri, Columbia, MO, (4)University of Missouri, Columbia, MO, (5)University of Missouri, Columbia, MO, (6)Medicine, University of Missouri, Columbia, MO, (7)University of Missouri School of Medicine, Columbia, MO

Background:

Children diagnosed with Autism Spectrum Disorder (ASD) may require specialized therapy or care not as widely available as other forms of care. Limited numbers of therapists can hinder access, especially in rural areas, or with marginalized communities. Understanding where different types of therapists are in relation to such communities is critical for gaining insight into where targeted support can be provided for improving access to specialized healthcare services for autistic children.

Objectives:

This study's objective was to analyze the distribution of four different types of healthcare services supporting children diagnosed with Autism Spectrum Disorder (ASD) throughout the state of Missouri: applied behavior analysts (ABA), occupational therapists (OT), physical therapists (PT), speech language pathologists (SLP), in relation to children with an IEP code for ASD by their local school district, in the year 2020. We hypothesized a clear need for all 4 types of healthcare providers throughout the state of Missouri, with concentrations in underserved rural areas and densely populated urban areas.

Methods:

By examining the amount of this population group with ASD in Missouri in relation to these four therapy types, a needs assessment can be performed to find health care gaps. This project is modeled from previous geographic needs assessments done in rural communities around care distribution (Carson et al 2021). An additional layer added to this analysis is the inclusion of multiple therapist types by all counties in Missouri. The count of each therapist by county was identified using the Summarize Within tool in ArcGIS Pro, and then compared to the number of children identified in the county listed having ASD, with the number of hours a child with ASD is recommended to spend with each therapist.

Results:

All counties required at least 1 ABA therapist to adequately service the number of students with an IEP for Autism (Figures 1 & 2). OTs (Figures 3 & 4) were needed in the rural northern and southern regions of Missouri and the need for more OTs was clearly relegated primarily to these rural northern and southern areas, with a band of adequate numbers stemming through the middle of the state from St. Louis to Kansas City. PTs (Figures 5 & 6) were clearly needed in rural areas, despite a broader distribution of at least one county retaining a PT, only in the urban areas of the state are there more than enough PT options. For SLPs (Figures 7 & 8) need is concentrated in the urban areas.

Conclusions:

While need for a range of services is clearly an issue throughout the state, there is a clear urban-rural divide dependent on the type of service. St. Louis, Kansas City, Columbia, and Springfield – state population centers – lack ABA and SLPs, with adequate PT and OTs. Although ABA therapists are most starkly needed in urban areas. Understanding access to care requires a spatio-temporal perspective recognizing the tensions between distance, time, and need. Future research will investigate these spatial patterns with more advanced methods, such as the 2-Step Floating Catchment Method.

Poster Session**415 - Interventions - Social, Cognitive, Behavioral and Educational - School-Age, Adolescent, Adult I**

May 1st, 2025, 5:30 PM - 6:30 PM - Hall 4A

415.267 "It Fostered a Greater Appreciation for My Little Corner of the World": A Feasibility Study of a Therapeutic Photography Intervention for the Well-Being of Autistic Youth

M. Charalampopoulou¹, A. Ibrahim², N. Eddy³, L. Panetta⁴, H. Prime¹, H. M. Brown⁵, S. Desai⁶, N. Khanlou⁶, C. McMorris⁷, K. Tiliczek⁸, A. Tint⁹, P. G. Ritvo⁶ and J. A. Weiss¹, (1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, Canada, (3)Psychology, University of Calgary, Toronto, ON, Canada, (4)Psychology, York University, North York, ON, Canada, (5)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (6)York University, North York, ON, Canada, (7)Department of Paediatrics, University of Calgary, Calgary, AB, Canada, (8)York University, Toronto, ON, Canada, (9)University of Calgary, Calgary, AB, Canada

Background: There is a shortage of interventions addressing the promotion of positive emotional (hedonic) and psychological (eudaimonic) states for autistic youth. Therapeutic photography (TP), referring to self-initiated photo-taking paired with mindful reflections of the photographs, has the potential to provide an accessible and scalable approach to promote positive mental health for autistic people.

Objectives: The current study employed a mixed methods approach to evaluate the feasibility of a novel TP intervention aimed at increasing hedonic and eudaimonic well-being among autistic youth.

Methods: Forty-one autistic youth 16 to 25 years of age ($M_{age} = 20.87$; 39% cis-female; 56.1% White; 97.6% with a professional diagnosis of autism) completed a four-week TP intervention. Each week, participants photographed and reflected on a different aspect of positive well-being. Intervention feasibility was determined according to intervention demand, implementation, acceptability, practicality, and preliminary effects (Bowen et al., 2009). Demand and implementation were assessed according to recruitment numbers, participant adherence, and engagement in TP. Practicality was determined according to two items from the Implementation Acceptability Scale (Lee et al., 2022). Acceptability was assessed using the 4-item Acceptability of Intervention Measure (AIM; Weiner et al., 2017), the 4-item Intervention Appropriateness Measure (IAM; Weiner et al., 2017), and the 20-item Negative Effects Questionnaire (NEQ; Rozental et al., 2019). Changes in hedonic and eudaimonic well-being were captured using the 20-item EPOCH Measure of Adolescent Well-being (Kern et al., 2016), the 4-item Meaning and Purpose Scale (PROMIS-MP; Salsman et al., 2020), the Generalized Anxiety Disorder 7-item Scale (GAD-7; Spitzer et al., 2006), and Patient Health Questionnaire 9-item Scale (PHQ-9; Kroenke et al., 2001). Qualitative findings were gathered using semi-structured interviews surveying the benefits, challenges, and possible adaptations for the intervention.

Results: Recruitment efforts were successful and intervention adherence and engagement were high (Figure 1). Participants indicated high levels of acceptability on the AIM ($M = 4.06$, $SD = .80$) and the IAM ($M = 3.86$, $SD = .90$). Fifteen participants (41.7%) attributed at least one negative effect to TP on the NEQ; however, the average negative impact of these effects was very low ($M = 0.67$, $SD = 1.43$). On the IAS, 94.4% of participants noted that they did not have to give up resources to participate in TP and 80.6% found the amount of effort required for TP to be acceptable. In terms of preliminary effects, repeated measures ANCOVAs, controlling for FSIQ, indicated significant improvements in full scale EPOCH scores ($F(1,34) = 10.17$, $p = .003$, $\eta^2 = .23$). Paired samples t -tests revealed significant improvements in experiences of meaning and purpose (i.e., PROMIS-MP; $t(35) = 2.71$, $p = .01$, $d = .45$) and no significant differences between pre- and post-intervention in anxiety and depressive symptoms ($p > .05$). Qualitative reports provided valuable insights regarding benefits, challenges, and future adaptations for TP (Figure 2).

Conclusions: Therapeutic photography is a promising and feasible novel intervention for the promotion of well-being for autistic youth. Future research efforts should be invested in examining the feasibility of an RCT and exploring mechanisms of change related to TP.

415.268 A 12-Month Reading Intervention for Autistic Students That Require Augmentative and Alternative Communication: A Multiple Single-Case Design

A. Nordahl-Hansen¹, K. Larsen², A. Dechsling³, L. B. Ulriksen⁴ and M. Bilet-Mossige⁵, (1)Østfold University College, Halden, Norway, (2)Oslo university hospital, Oslo, Norway, (3)Faculty of Teacher Education and Languages, Østfold University College, Fredrikstad, Norway, (4)Department of Educational Science, University of South Eastern Norway, Fredrikstad, Østfold, Norway, (5)Department of Education, ICT and Learning, Østfold University College, Fredrikstad, Norway

Background: For autistic children, requiring augmentative and alternative communication (AAC) reading skills are key to achieve higher levels of communication, for example from AAC systems that use graphic symbols to orthography (Caron et al., 2018), and to independently express themselves (Light & McNaughton, 2020). For this population there may be many barriers to developing reading skills, and previous research has mainly focused on those with verbal communication skills (Westerveld et al., 2017).

Objectives: This study investigated effects of a reading skills intervention for autistic students who require AAC. The research questions were: Is there a functional relationship between the use of the reading material "Reading for all" and increased accuracy of a) sound blending, b) letter sound correspondence, c) phoneme segmentation, d) improved acquisition of recognition of sight words, and e) decoding.

Methods: This study was conducted with a multiple single-case design with multiple randomized baselines. A total of 26 students (6-13 years, 21 boys, 5 girls) diagnosed with autism (13 with intellectual disability) and requiring ACC were included in the present analysis. The majority of the sample was minimally verbal. Both parents and teachers consented to participation. The reading material "Reading for all" is based on the research of Accessible Literacy Learning (ALL) (Light & McNaughton, 2011). The intervention targeted phonological awareness skills, letter-sound correspondence, shared reading, recognition of sight words and word decoding for 12 months. Oral responses were not required for the students. Direct and systematic instruction, explicit instruction, scaffolding, immediate and corrective feedback, cumulative review and practice were emphasized. Primary outcomes were assessed 12 times in equidistant time points across the 12 months. All the tests were developed by the researchers (described in Ulriksen et al., 2023). The students were assessed in letter sound correspondence, sound blending, and phoneme segmentation each month (12 times), and assessed in sight words and decoding in months 1 and 12. Baselines were randomized using PASS23 via Wei's urn algorithm that minimizes unbalanced groups (Wei & Lachin, 1988). This is an open-label study, hence not possible to mask intervention start (baseline) for the students. However, two assessors coded outcomes independently.

Results: The data indicates that many students have achieved early literacy skills, such as phonological awareness and letter sound skills, which is necessary for later reading skills. Several students have also demonstrated reading skills, phonologically. Analyses of effect-change will be presented at INSAR. The results are presented in graphs that demonstrate each student's development.

Conclusions: Due to lack of competence, evidence-based reading programs and expectations, it is crucial to emphasize the importance of such reading interventions. To raise awareness and expectations that students with limited or missing speech ability can acquire functional reading skills is essential, and can change the individual's opportunities in many areas.

415.269 Pilot Study of a Brief Inclusive Peer Intervention in Middle School: Staff and Student Perspectives on Inclusion

S. Thompson-Hodgetts¹ and E. Grauer², (1)Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (2)Faculty of Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada

Background: Peer relationships are essential to every child, yet students with neurodevelopmental disabilities (SWDs) are frequently isolated due to limited opportunities for SWDs to interact with peers in general, including in extracurricular activities, and few school staff taking responsibility to facilitate or plan these opportunities. Educating classroom peers about disabilities and facilitating interactions between SWDs and their classroom peers can improve peer perceptions of disability and the social lives of SWDs. However, there is a scarcity in these interventions in middle school and high school despite evidence that shows that older students tend to hold more negative attitudes towards SWDs.

Objectives: This pilot study explored experiences with and the effects of a brief peer-focused intervention in a middle school. The intervention incorporated (1) education to peers (and educators) about disability and strategies to engage with SWDs, and (2) facilitated opportunities for social interactions between peers and SWDs through activity-based recess clubs. Specific research objectives were: (1) to explore the effects of the intervention on peer attitudes towards SWDs and (2) to understand SWDs, classroom peers, and staff perspectives of the intervention on understanding, acceptance, and social in/exclusion of SWDs.

Methods: A mixed-methods, convergent parallel design was used. Participants were three SWDs (two in one classroom, one in another), and their classroom peers and teachers. Peer attitudes towards SWDs were measured using the Revised Chedoke-McMaster Attitudes Towards Children with Handicaps Questionnaire (CATCH-R) pre and post the educational intervention. Wilcoxon test was used to analyze pre-post differences overall (all students combined) and the Mann-Whitney test was used to analyze pre-post differences by class and for students who did and did not choose to participate in the recess club. Rank biserial correlation was calculated as the effect size for the Mann-Whitney test. Thematic analysis of data from semi-structured interviews with SWDs, peers, and school staff following the recess clubs explored perceived impacts of the multi-component intervention on inclusion.

Results: CATCH-R scores indicated a significant difference in peer attitudes towards SWDs post-educational intervention between students who did ($n = 13$) and did not ($n = 21$) choose to participate in the recess club ($U = 197.500$, $N1 = 13$, $N2 = 21$, $p = .029$). Interviews (2 SWDs, 8 peers, 2 school staff) generated three themes: (1) *Increased knowledge and understanding about SWDs*, (2) *Structured activity increased interaction between SWDs and peers*, (3) *More in-depth class education and recess club sessions are needed to influence inclusion*.

Conclusions: This intervention was novel in that it included both the class-wide intervention and the small-group intervention, that it was targeted to middle school, and that it was done during the school day (a real-life context) and led by school staff. Overall, findings indicate that a brief peer-focused intervention that includes class-wide educational and facilitated social interaction components can support social inclusion for SWDs in middle school. This has important implications for planning interventions to support social inclusion for SWDs in middle school in the future.

415.270 Enhancing Caregiver Wellbeing: A Scoping Review of Group-Based Mental Health Interventions for Parents of Autistic Children

I. Sansone¹, K. Garibian¹, A. Lucas¹ and J. E. Crasta², (1)The Ohio State University, Columbus, OH, (2)Physical Medicine and Rehabilitation, The Ohio State University, Baltimore, MD

Background: The mental health of caregivers of children on the autism spectrum is often overlooked, despite research showing elevated levels of stress, anxiety, and depression among these caregivers. Interventionists and therapists typically focus on the needs of the child, neglecting the crucial role caregivers play in supporting the child's wellbeing.

Objectives: This scoping review aims to explore group-based mental health interventions for caregivers of children on the autism spectrum to identify strategies that reduce caregiver stress, anxiety, and depression while improving their overall quality of life.

Methods: The review was conducted following the Preferred Reporting Items for Scoping Reviews (PRISMA) guidelines and included articles in English that examined randomized control trials (RCTs), controlled clinical trials (CCTs), cohort studies, and qualitative studies with caregiver interventions in group settings. Two reviewers independently screened titles, abstracts, and full texts in Covidence. The inclusion criteria focused on studies involving caregivers of children over 10 years old on the autism spectrum and interventions aimed at improving caregiver mental health. Articles were sourced from PubMed, CINAHL, and PsycINFO, with searches conducted in August 2024.

Results: A total of 24 studies were included in this review. Various themes emerged from a thorough analysis of the articles including mindful movement, parent to parent interventions, mindfulness-based parenting, and cognitive change. Mindfulness-based interventions, involving both parents and children, were the most effective in reducing caregiver stress and improving wellbeing. Interventions focused on peer support also showed positive mental health outcomes but had mixed results in reducing stress.

Conclusions: The findings suggest that group-based interventions, particularly those focusing on mindfulness and peer support, can significantly improve the mental health of caregivers of children on the autism spectrum. However, the evidence regarding the reduction of parenting stress remains mixed across studies. Future research should further investigate the most effective group intervention components and the potential role of OTPs in supporting caregiver mental health, to enhance family wellbeing.

415.271 A Preliminary Look at Unique and Shared Influences on the Implementation of Two Middle School Programs for Autism

J. Jarrett¹, J. R. Steinbrenner², B. Kraemer³, A. Sam⁴, S. L. Odom⁵, L. J. Hall⁶ and K. S. Dickson⁶, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Special Education, San Diego State University, San Diego, CA, (4)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (6)San Diego State University, San Diego, CA

Background: Schools play a critical role in caring for autistic youth, often serving as the primary setting where services are delivered. As the number of autistic students in schools continues to grow, ensuring that schools are equipped to deliver effective, evidence-based services is essential. This is especially crucial during the middle school years when many autistic students, particularly those accessing the general curriculum, increasingly experience social communication and executive functioning challenges that hinder academic performance, peer relationships, and overall functioning. This underscores the importance of schools implementing programs that address these specific areas of need. However, the range of social skills and executive functioning programs available—particularly those relevant for and effective in middle schools—remains limited. Research examining these programs in real-world school settings, particularly with a focus on factors that influence successful implementation, is needed to inform ongoing and future efforts to enhance school services for autistic students.

Objectives: The current study aims to examine the unique and shared factors (i.e., barriers and facilitators) influencing the implementation of the *Program for the Education and Enrichment of Relational Skills (PEERS)* social skills and *Unstuck and On Target (Unstuck)* executive function programs in public middle schools.

Methods: Data are drawn from a larger multisite cluster randomized control trial of *PEERS* and *Unstuck* in public middle schools. Qualitative interviews with school-based implementers (n=23, 96% female, 48% Non-Hispanic White, 61% special educators and 17% speech language pathologists) who received training in and delivered *PEERS* or *Unstuck* with participating autistic students were conducted. Interviews gathered perspectives regarding implementers' experiences delivering *PEERS* and *Unstuck* and factors that influenced their delivery. Data were analyzed using a rapid qualitative assessment process (Hamilton, 2020) that yielded themes regarding barriers and facilitators of implementation.

Results: Results indicated several shared facilitators of implementation for both *PEERS* and *Unstuck*, including the manualized nature of the program and availability of corresponding materials (e.g., PowerPoints, videos) that aided ease of delivery as well as a focus on skill areas extremely relevant for autistic students. Shared implementation barriers included the repeated focus on certain skill areas across lessons that made it challenging to maintain student engagement. For *PEERS*, unique barriers included challenges implementing the motivational system and homework extensions specified in the curriculum while the specified behavioral rehearsals activities specified facilitated implementation. For *Unstuck*, the number and varying nature of prespecified activities were often challenging, representing an implementation barrier, while the multimodal approach and scripted vocabulary integrated across lessons facilitated delivery.

Conclusions: Findings highlight key shared and unique influences of program implementation in middle schools. Findings from this study have the potential to significantly inform ongoing and future efforts to translate evidence-based programs into schools on a broader scale and address issues of feasibility. By identifying the factors supporting or hindering program implementation, researchers and educators can better ensure that autistic students receive the high-quality, targeted support they need. In the long term, this research could lead to more effective strategies for delivering evidence-based practices in schools, ultimately improving outcomes for autistic youth across the country.

415.272 A Qualitative Exploration of Autistic Perspectives: Experiences with Mathematics Education

G. Yakubova¹, T. Vyas², B. B. Chen³, M. Duranti⁴, Y. Lee⁵, V. Y. Kang⁶ and T. Proulx⁶, (1)Counseling, Higher Education, and Special Education, University of Maryland, College Park, MD, (2)University of Maryland, College Park, College Park, MD, (3)Special Education, Towson University, Towson, MD, (4)University of Maryland at College Park, College Park, MD, (5)Counseling, Higher Education, and Special Education, University of Maryland at College Park, College Park, MD, (6)University of Oklahoma, Norman, OK

Background: While previous research has examined challenges autistic students experience in mathematics education, studies examining mathematics challenges from the perspectives of autistic youth are scarce. Thus, we conducted a study to highlight the unique perspectives and experiences of autistic young adults in K-12 mathematics education to raise awareness, promote inclusive and effective teaching practices.

Objectives: The aim of this study was to qualitatively explore the experiences of autistic youth in k-12 mathematics education in the US. Specifically, we examined the supports autistic youth received and challenges they experienced during their mathematics education.

Methods: In this exploratory study, we employed semi-structured in-depth interviews with 11 autistic young adults (ages 18-28). Participants were recruited through snowball sampling via online networks, including disability advocacy groups and social media platforms. The eligibility criteria included both, self-identified and formally diagnosed autistic individuals. Data collection took place through Zoom interviews, which were recorded, and then transcribed for coding and analysis. The data was analyzed using inductive thematic analysis.

Results: The findings from the interviews revealed several key themes related to their experiences in K-12 mathematics education. Participants reported that their challenges in math often stemmed from difficulties with processing abstract mathematical concepts, and inconsistencies in teacher support. Many expressed that traditional teaching methods, which heavily rely on verbal explanations and abstract reasoning, were difficult to follow. Instead, they found visual aids, step-by-step instructions, and hands-on activities to be more effective in enhancing their understanding. Additionally, they appreciated the use of interactive technologies such as math apps or digital manipulatives, which allowed them to work at their own pace and revisit concepts as needed. Social interactions in the classroom also presented a challenge. Participants mentioned that group work or having to explain their reasoning in front of the class heightened their anxiety. Overall, participants expressed a desire for teachers to be more aware of and responsive to their needs, offering accommodations that reduce stress and allow for better focus and engagement.

Conclusions: The results of this study contribute valuable insights into the experiences of autistic youth in K-12 mathematics education. By identifying key challenges and supports, this research will help inform the development of more inclusive mathematics curricula and teaching practices. Moreover, the study highlights the importance of incorporating the perspectives of neurodiverse individuals when designing educational interventions, particularly in mathematics, where autistic students do not feel supported.

415.274 A Special Educator-Mediated Training Program Improves the Ability to Recognize Basic Emotion in Adolescents with Autism: Results from a Pilot Study

E. Grossi¹ and S. Poletti², (1)Autism Research Unit, Villa Santa Maria SCS, Tavernerio, Como, Italy, (2)Autism Research Unit, Villa Santa Maria SCS, Tavernerio, Italy

Background:

Emotions are vital indicators of the psycho-physiological state of humans and can greatly help in improving intelligent healthcare services. In children with autism there is significant impairment in recognizing and understanding basic facial emotions and prototypical feelings. This "Emotional misunderstanding" directly affects social interaction.

Objectives:

The aim of the study is to investigate three emotion-related constructs in children with ASD, namely: emotion recognition, emotional regulation and understanding of emotions, and to carry out training aimed at increasing knowledge of emotions and learning useful techniques for controlling negative feelings such as fear, anger and anxiety.

Methods:

Eighteen subjects (15 males and 3 females) aged between 13 and 18 years participated in the research (mean age = 15.2; ds = 1.44) with severe (No.9) or moderate (No.9) disability at Developmental Disability Child Global Assessment Scale (DD-CGAS).

The special training program educator mediated, consisted in twenty weekly sessions each lasting approximately two hours, conducted using two protocols inspired by Rational Emotional Therapy of Albert Ellis: "Exploring Feelings", and "The ABC of my emotions: socio-affective literacy program".

The training aimed at enhancing the knowledge of the main emotions and learning effective cognitive strategies to overcome and manage negative thoughts and moods, aiming to increase pleasant ones in everyday life.

The Test of Emotion Comprehension (TEC) was applied before and after the training program.

Results:

The training program was associated to a significant improvement of the Total score of TEC, which increased from (mean(SD)) 4.27(2.21) to 5.33 (2.40); $p < 0.001$; with an effect size of 0.45. Most participants (15 out of 18) showed a positive change in the TEC total score. The magnitude of score change was higher in the severe disability group with a 47.6% improvement (from 2.33 to 3.44) in comparison with moderate disability group, with a 16% improvement (from 6.22 to 7.22).

Conclusions:

An intensive training educator mediated based on Rational Emotional Therapy seems effective in improving emotion comprehension in adolescent with autism, especially in those with severe disability. These evidences support the planning of a randomized study.

415.275 Identifying Challenging Environments: Designing a Virtual Reality Intervention for Adolescents with Autism Spectrum Disorder through Their Perspective

M. Hochhauser^a, E. Ben-Itzhak^a and O. Rubin^a, (1)Department of Occupational Therapy, Ariel University, Ariel, Israel, (2)Bruckner Center for Autism Research, Department of Communication Disorders, Ariel University, Ariel, Israel

Background:

Individuals with autism spectrum disorder (ASD) face significant challenges in social skills and executive functions, affecting daily functioning and quality of life. Existing interventions often show limited effectiveness with poor generalization to real-life scenarios. There is a pressing need for interventions tailored to adolescents with ASD, incorporating training in realistic environments that include their input.

Objectives: 1) To explore adolescents with ASD's perspectives on social skills and executive function challenges by mapping challenging environments, difficulties, and needs. 2. To compare these perspectives with those of parents and therapists. These insights will inform the design of a Virtual Reality (VR) intervention.

Methods: Participants included 40 adolescents with ASD (34 boys, six girls; mean age 15.3), 36 parents (20 men, 15 women, 1 non-binary; mean age 47.07), and 36 health/education professionals. All completed a specially designed questionnaire assessing challenging environments, their characteristics, and associated difficulties.

Results:

A mixed two-factor ANOVA with repeated measures examined the functional importance of environments for adolescents with ASD from the perspectives of three groups of evaluators (adolescents, parents, and caregivers). Significant main effects were found for group [$F(2,109) = 12.06$, $p < .001$, $\eta^2p = 0.18$], environment type [$F(8,872) = 16.61$, $p < .001$, $\eta^2p = 0.13$], and a significant group x environment interaction [$F(16,872) = 3.91$, $p < .001$, $\eta^2p = 0.67$]. Adolescents consistently rated environments less important than parents and caregivers, with social media, school, and shopping malls ranked highest. In contrast, parents and caregivers rated public transportation and supermarkets as significantly more important ($p < .01$) than adolescents. Adolescents identified schoolyards during recess, mall food courts, and cashier interactions as most challenging. Their greatest difficulties included self-explanation, initiating contact, or responding to unfamiliar people, with sensory stimuli such as noise, crowding, and large groups as most disturbing. Parents prioritized youth movement as an important and preferred VR training environment, while therapists emphasized supermarkets and rated difficulties the highest across all areas. Both parents and therapists emphasized public transportation as important. Despite the differences between evaluators, agreement was found in several key environments, including the school cafeteria, social media, and shopping malls, as well as on key challenges (coping with new situations) and disturbing sensory stimuli (noise and overcrowding).

Conclusions:

The findings reveal a discrepancy between evaluators, with adolescents rating their challenges as less severe and prioritizing training environments lower than parents and therapists. This highlights adolescents' distinct perspectives and the need to integrate their unique viewpoints into intervention designs. Despite differences, there was agreement on key environments such as schools and shopping malls and consensus on challenges, such as sustainable peer interaction, which provide a foundation for designing VR environments that target social skills and executive functions, incorporating sensory stimuli to enhance real-world generalization. Recommendations include developing a VR environment centered on school settings (recess, classrooms, cafeterias), where skills training focuses on self-explanation, coping with new situations, and managing sensory stimuli such as noise and crowding.

415.276 A Systematic Review of Oral Care Interventions for Autistic Individuals across the Lifespan

L. I. Florindez^a, D. H. Como^a and L. I. Duker (Stein)^b, (1)Nursing Research and Performance Improvement, Cedars-Sinai Medical Center, Los Angeles, CA, (2)Division of Occupational Science and Occupational Therapy, University of Pittsburgh, Pittsburgh, PA, (3)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

Background:

Oral health is important to both physical and psychological health. Certain populations, such as autistic individuals, experience greater oral care disparities as compared to typically developing individuals, suggesting that innovative and efficacious interventions to facilitate care are needed. However, little research currently exists examining oral interventions for autistic individuals.

Objectives:

The primary research question that guided this systematic review was: What are the impacts of non-pharmacological oral care interventions for autistic individuals? In addition, we asked: What is the methodological strength of the research reported in each study?

Methods:

Systematic review methodology as outlined in the Cochrane Handbook for Systematic Reviews of Interventions was used for this paper. Six electronic databases were searched, including: PubMed, CINAHL, Web of Science, Clinical Trials, COCHRANE, and PsycINFO using the keywords “oral/dental health/care,” “intervention,” and “autism.” Inclusion criteria for article selection included: (1) implementation and investigation of a home and/or dental office intervention to impact oral care health and/or experiences, (2) participants diagnosed as autistic, (3) published in a peer-reviewed journal, and (4) published in English, Spanish and/or Portuguese. No restrictions were placed on year of publication or level of evidence, but pharmacological interventions were excluded. Two reviewers independently screened all articles for inclusion. Of the articles included, three reviewers independently extracted data. Methodological quality of studies was assessed by two reviewers using Reichow, Volkmar, & Cicchetti’s Evaluative Method for Determining Evidence Based Practice (EBP) in Autism; disagreements were resolved by a third reviewer to reach consensus.

Results:

The search produced 545 articles, with 36 studies meeting all inclusion criteria. Using the EBP guidelines, methodological quality of the articles were assessed as “strong” (n=5), “adequate” (n = 8), or “weak” (n = 23). The studies focused on improving home-based oral care skills and routines, and reducing fear, anxiety, and/or negative behaviors in the dental clinic. Studies incorporated preparatory interventions to support home-based hygiene activities or improve an approaching dental encounter (n = 29), most often using visual aids, and/or strategies to manage behavioral difficulties exhibited in the dental office (n = 17). Some studies used both approaches (n = 10), combining visual aids prior to a visit with behavior management in the dental office. Only one study purposefully recruited autistic adults and no studies included intervention elements tailored to race/ethnicity, culture, and/or socioeconomic status with the others focused solely on pediatric autistic populations.

Conclusions:

Findings provide preliminary support for preparatory homebased visual interventions to improve toothbrushing and/or ready patients for dental visits, and distraction or sensory reducing interventions to improve experiences in the dental clinic. Only one study purposefully recruited autistic adults and no studies included intervention elements tailored to race/ethnicity, culture, and/or socioeconomic status. This review highlights the need for high-quality studies investigating the impact of oral care-related interventions for autistic individuals and identifies a gap in interventions for autistic adults and those from minoritized populations.

415.277 ADAPT: A Mixed-Methods Pilot Test of an Intervention to Address Substance Use Disorders Among Autistic Adults

L. Graham Holmes¹, K. Wyka², L. Valvano³, M. Mueller⁴ and E. F. Rothman⁵, (1)*Silberman School of Social Work, Hunter College, CUNY, New York, NY, (2)Epidemiology and Biostatistics, City University of New York School of Public Health, New York City, NY, (3)Department of Psychiatry, CUNY Graduate Center, New York City, NY, (4)Columbia University, New York, NY, (5)Occupational Therapy, Boston University, Sargent College, Boston, MA*

Background:

Unhealthy substance use is a public health problem with serious implications for relationships, education prospects, employment and health. Substance use disorders (SUDs) may be just as prevalent, or even more prevalent, among autistic adults versus non-autistic adults. For example, a population-based case-control study ($n=29,986$) found that autistic people had double the risk of alcohol use disorder compared to neurotypical family members. Studies suggest that some autistic people use substances to cope with co-occurring mental health conditions, perceived social difficulties, and sensory sensitivities, and using alcohol to cope is a risk factor for unhealthy use.

There are no evidence-based SUD interventions established to be effective for autistic people. The Alcohol and Drug Choices for People on the Autism Spectrum (ADAPT) workshop is an online, group-based intervention comprising six 90-minute weekly sessions for autistic people who want more control over their substance use. ADAPT was developed in collaboration with an autistic advisory board, and all ADAPT sessions are facilitated by an autistic substance use expert.

Objectives:

To test the feasibility, acceptability, and preliminary efficacy of ADAPT.

Methods:

We recruited 40 adults (Mean age=34, SD=10) with formal (65%) or self-diagnosis (35%) of autism to participate in a waitlist-controlled trial evaluation of ADAPT, delivered via Zoom in April-August 2023. Participants signed up for their desired timeframe and were therefore considered active treatment (April, June) or waitlist control (May, August). Each group (three total) consisted of 15-20 participants. Facilitators presented didactic content on substance use norms, creating personal goals, strengthening motivation, social support, coping with cravings, healthy lifestyles, and setbacks/relapse strategies.

We collected data from autistic participants on ADAPT feasibility and acceptability. We also collected self-report data to assess primary (e.g., coping with cravings) and secondary outcomes (e.g., social isolation, depression).

Data from participants in the active treatment condition were compared to waitlist control data using appropriate statistical analyses (e.g., chi square, t-test), placing emphasis on effect size versus p-values using Hedge's g within group effect size metric (0.2=small, 0.5=medium, 0.8=large).

Results:

Overall, 40 of 64 screened individuals enrolled (Table 1). Of these, 88.2% ($n=35$) completed 5-6 sessions and were included in analyses. There were no statistically significant differences in demographics or outcome measures at baseline for active treatment versus waitlist control groups. Participants rated the workshop overall 8 out of 10 (with 10 being more positive). 90% said it helped them get in touch with motivation to change, 87% that it helped increase motivation to change and helped them create goals for substance use, and 74% that it helped improve their ability to cope with cravings. Preliminary tests of efficacy suggest that the active treatment group experienced improvements in use of coping strategies for cravings ($g=1.05$), social isolation ($g=0.54$), and depression symptoms ($g=0.50$). Participants in the active treatment group improved on depression symptoms compared to waitlist controls, and results were statistically significant ($p=.042$; Table 2).

Conclusions:

ADAPT is a promising treatment for substance use problems among autistic adults. Additional research that uses more rigorous methods, such as RCT, is a logical next step.

415.278 ADEPT-2 Randomised Controlled Trial of a Low-Intensity Psychological Intervention for Autistic People Experiencing Depression: A Qualitative Evaluation

A. X. Realpe^{1,2}, A. Russell³, K. Cooper⁴, A. Georgakopoulou¹ and J. Horwood¹, (1)University of Bristol, Bristol, United Kingdom, (2)NIHR Bristol Biomedical Research Centre, Bristol, United Kingdom, (3)Centre for Applied Autism Research, Psychology, University of Bath, Bath, UNITED KINGDOM, (4)University of Bath, Bath, UNITED KINGDOM

Background: Autistic adults frequently report high rates of depression. The differences in social communication, neurocognition, and emotional awareness within autistic individuals underscores the need to adapt psychosocial treatments. Studies consistently show that healthcare clinicians often possess limited knowledge about autism, while autistic individuals face significant barriers in accessing mental healthcare. Consequently, there is a clear need for an empirically supported psychological intervention specifically tailored to address depression in autistic adults. The multi-centre Autism Depression Trial (ADEPT-2) was a randomised controlled trial (RCT) designed to evaluate an adapted low-intensity psychological intervention (Guided Self-Help) for depression in autistic adults.

Objectives: This qualitative evaluation aimed to investigate the views and experiences of the ADEPT-2 RCT and the guided self-help intervention.

Methods: Autistic adults experiencing depression (PHQ-9 score ≥ 10)—were randomly assigned to either Guided Self-Help (GSH), a low-intensity psychological intervention based on Behavioural Activation adapted for autistic adults, or NHS Treatment as Usual (TAU). A total of 37 trial participants (23 in GSH, 14 in TAU) and 12 low-intensity psychological therapists (or "coaches") were interviewed, with their transcripts analysed thematically.

Results: Participants and coaches both expressed positive attitudes towards the research, acknowledging the importance of an intervention for depression tailored to autistic adults. Online processes and clear communication with the research teams helped facilitate their participation in the trial. Participants in the TAU arm reported difficulties in accessing mental health services, as well as inconsistencies in healthcare professionals' awareness of autism. Conversely, GSH arm participants valued the sessions with coaches who demonstrated a strong understanding of autism and made adjustments to meet their needs. Many GSH participants continued using the skills they had learned to manage their depressive symptoms and reported feeling better equipped to cope with challenges after completing the intervention. Coaches indicated that the training and supervision provided were comprehensive, and they were able to maintain fidelity to treatment principles within the trial protocol. Suggestions for improvement included offering more flexibility in pacing (adapting session speed to individual needs), splitting sessions when necessary, and providing optional follow-up sessions.

Conclusions: The qualitative assessment demonstrated that it is feasible to deliver an RCT to evaluate the effectiveness of a new low-intensity psychological intervention for depression in autistic adults. Further adaptations outside the constraints of a trial protocol could enhance the accessibility of GSH to a broader and more diverse range of autistic individuals. If the trial demonstrates that GSH is effective, the GSH materials could be implemented by mental healthcare providers.

415.279 AI-Based Auditory Intervention for Autistic Individuals with Decreased Sound Tolerance: Improved Comfort in Virtual Reality and Community Settings

M. Waite¹, B. Bahmei², A. Ansarmohammadi², G. Iarocci¹, S. Arzanpour² and E. Birmingham³, (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Mechatronic Systems Engineering, Simon Fraser University, Surrey, BC, Canada, (3)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada

Background: Decreased sound tolerance (DST) is a common sensory sensitivity in autism, where everyday noises can be overwhelming and upsetting for those affected (Williams et al., 2021). DST causes significant emotional discomfort and limits engagement in daily activities (Scheerer et al., 2022). Consequently, creating interventions to improve comfort and auditory accessibility for autistic individuals experiencing DST is crucial.

Objectives: The aim of this study was to investigate the effectiveness of an AI-based auditory intervention on comfort levels in autistic youth and adults with DST.

Methods: The current study evaluated an auditory intervention across two phases. For Study 1, 20 autistic participants with DST (9 male, 8 female, 3 agender/nonbinary), ages 12 to 47 years old ($M=19.45$, $SD=10.82$) were exposed to a series of auditory trials within virtual reality (VR) environments. Participants rated their comfort with these trials using a five-point scale (1=Very Comfortable, 3=Neutral, 5=Very Uncomfortable). These trials included exposure to aversive sounds presented unaltered, with a masking sound, with active noise cancellation (ANC) or filtered out using the technology. Filtration, masking, and ANC either occurred throughout the trial or were activated only once the software detected the aversive sound.

For Study 2, 10 autistic participants with DST (3 male, 3 female, 4 agender/nonbinary) ages 14 to 52 years old ($M=23.50$, $SD=11.12$) participated in a field-testing session to test the sound management technology in the community. Participants accessed the technology on a mobile app, where they set their preferred sound management method. When the software detected an aversive sound, participants could choose to have it respond by automatically turning on ANC, a masking sound, or both. Participants rated their comfort with listening to prerecorded aversive sounds and with naturally occurring aversive sounds while using the mobile app.

Results: For Study 1, participants' comfort ratings varied significantly across intervention types, $F(6,114)=11.54$, $p<.001$. Specifically, participants reported greater comfort listening to aversive sounds when the software detected and responded to the aversive sound by turning on filtration, masking, or ANC, compared to listening to aversive sounds unaltered. Similarly, in Study 2, participants reported greater comfort listening to prerecorded aversive sounds while using the sound management technology ($M=2.64$) compared to when listening to the sounds unaltered ($M=3.56$) while in a public community setting, $t(9)=4.12$, $p=.003$. Qualitative feedback gathered from both studies support the utility of this technology (e.g., "takes away the piece about having to predict what is going to happen") and provides directions for further development (e.g., "more masking sounds and more kinds of sounds it blocks").

Conclusions: This study evaluated the effectiveness of an AI-based auditory intervention at increasing comfort for autistic individuals with DST when exposed to aversive sounds. In Study 1, the sound management technology improved comfort levels during virtual reality trials in the lab. In Study 2, the sound management technology improved comfort in a noisy community setting, providing support for the intervention's practical application in everyday environments. These findings support the effectiveness of an AI-based auditory intervention for improving comfort in autistic individuals with DST.

**415.280** Adaptability and Efficacy of LEGO Therapy in Italy: A Randomized Controlled Trial

A. Narzisi¹, F. Barbetti², R. Muccio³, C. Cristofani², E. Martinelli², F. Pizzino², M. Fabbri-Destro⁴, A. Milone³ and G. Masi³, (1)Department of Child Psychiatry and Psychopharmacology, Antonio Narzisi, Pisa (Calambrone), Pisa, Italy, (2)ircs stella maris, PISA, Italy, (3)IRCCS Stella Maris Foundation, Pisa (Calambrone), Italy, (4)Istituto di Neuroscienze, Consiglio Nazionale delle Ricerche (CNR), Parma, Italy

Background: Interventions aimed at enhancing social skills are critical for improving the quality of life in individuals with Autism Spectrum Disorder (ASD), especially during adolescence, a period marked by increased social demands. LEGO Therapy, a play-based intervention using LEGO building activities, has emerged as a promising approach to foster social skills in children with ASD. While preliminary evidence supports its effectiveness, rigorous RCT are necessary to validate these findings.

Objectives: The primary objective of this study was to evaluate the efficacy of LEGO Therapy in improving social communication and interaction skills in adolescents with ASD aged 11 to 13. Specifically, the study aimed to compare the social outcomes of boys who participated in LEGO Therapy to those who received no such intervention. Secondary objectives included evaluating the intervention's acceptability and feasibility, as well as understanding the impact of therapy on the severity of social symptoms, as measured by standardized autism diagnostic tools.

Methods: This randomized controlled trial included 48 boys diagnosed with ASD, aged between 11 and 13, divided into an experimental group (n=24) and a control group (n=24). The experimental group participated in LEGO Therapy sessions, while the control group received no specific intervention. The two groups were matched for autism severity, intellectual functioning, and age and no significant differences were showed. The intervention consisted of 12 weekly 60-minute sessions over three months, with four groups of six children. Each group was conducted by two specialized educators, and one LEGO brick model builder facilitating each session. Outcome measures were assessed at baseline (T0) and post-intervention (T1, after three months) using the ADOS-BOSCC/FP2 (provided by WPS for the sole purpose of this study) and other standardized tests such as: Social Responsiveness Scale; Stanford Social Dimensions Scale (SSDS); This study was registered at ClinicalTrials.gov (registration number: NCT06641583).

Results: Attendance was high, with 18 children attending all sessions and 6 children missing only 2 sessions. The LEGO Therapy group demonstrated significant improvements in social communication behaviors compared to the control group. Specifically, the experimental group showed a marked improvements in attention skills, turn-taking, and cooperative play behaviors. The control group, by contrast, exhibited no significant changes in these domains over the study period. Attendance and engagement in the sessions were high, supporting the feasibility of LEGO Therapy as a group intervention. No significant adverse events were reported, and feedback from parents and educators indicated a high level of satisfaction with the intervention.

Conclusions: This randomized controlled trial provides evidence supporting the efficacy of LEGO Therapy in enhancing social skills in boys with ASD. The intervention led to significant improvements in social communication and interaction, as reflected in standardized outcome measures. The high level of participant engagement and positive feedback from educators and parents further support the feasibility and acceptability of LEGO Therapy as a social skills 'Naturalistic Developmental Behavior Intervention' for children with ASD. Future research should explore long-term outcomes and the potential for scaling this intervention to other age groups and settings.

415.281 Adapting Evidence-Based PTSD Interventions for Individuals with Neurodevelopmental Disabilities: Exploratory Findings on a Social Story Framework for Post-Disaster Recovery

M. Matheis¹ and **R. Lou²**, (1)Center on Disability Studies, University of Hawaii, Honolulu, HI, (2)Center on Disability Studies, UNIVERSITY OF HAWAII, Honolulu, HI

Background:

The August 8, 2023 wildfires in Maui exposed critical gaps in disaster recovery for individuals with autism and other neurodevelopmental disabilities (NDD). Traditional post-traumatic stress disorder (PTSD) interventions often lack accessibility for this population, highlighting the need for adapted, trauma-specific tools that integrate both mental health and disability support needs. This research explores the adaptation of evidence-based PTSD interventions for individuals with NDD, utilizing a social story framework and approach grounded in Dissemination & Implementation (D&I) science to ensure scalability and real-world impact.

Objectives:

This exploratory research aims to:

1. Adapt elements of evidence-based PTSD interventions to meet the specific needs of individuals with NDD.
2. Develop and implement a social story workbook as a trauma support tool for use by individuals with NDD, families, support staff, and mental health clinicians.
3. Assess initial effectiveness and satisfaction with the adapted intervention.

Methods:

A toolkit was developed through a collaboration between the University of Hawai'i Center on Disability Studies (CDS) and the Department of Health Developmental Disabilities Division (DDD). It incorporates "active ingredients" from evidence-based PTSD practices into a social story format to enhance accessibility. The toolkit includes separate workbooks for children and teens/adults, along with supplementary materials for caregivers and support staff.

Workshops utilizing the toolkit were conducted at adult day health programs, such as Easterseals Hawaii and Arc of Maui, with 60 individuals with NDD and their support staff participating. Additionally, webinars targeting a broader audience of 146 participants, including families, individuals, support staff, and clinicians, were conducted. Data were collected via post-session satisfaction surveys and qualitative feedback from participants, focusing on usability, content adaptation, and perceived benefits.

Results:

Preliminary results show high levels of satisfaction with the social story workbooks across both workshops and webinars. Participants found the format accessible, clear, and relevant in responding to traumatic stress. Qualitative feedback from individuals with NDD and their families emphasized the workbook's ease of use and ability to foster a sense of control during recovery. Support staff noted improvements in communication and engagement during trauma recovery discussions with their clients.

Although quantitative data on long-term impacts are still being gathered, these initial findings suggest that the workbook intervention has strong potential as a scalable and accessible resource for individuals with NDD in post-disaster recovery.

Conclusions:

This exploratory research demonstrates the feasibility of adapting evidence-based PTSD interventions for individuals with NDD through a social story framework. High levels of satisfaction and positive feedback from participants suggest the promise of this approach. Further research, including longitudinal studies, is needed to evaluate the toolkit's long-term effectiveness and its broader applicability to other traumatic contexts. Expanding the toolkit's dissemination through webinars and community outreach represents a scalable model for disaster recovery support tailored to individuals with NDD.

415.282 Adapting Universal Design for Learning to the Informal Learning Environment with Autistic Teens and Museum Educators
S. Tumolo¹, **W. Martin²**, **S. Letourneau³**, **T. Z. Henderson⁴**, **A. Barandiaran⁵** and **E. Whyte⁵**, (1)Education Development Center, Waltham, MA, (2)Education Development Center, New York, NY, (3)Research and Development, New York Hall of Science, Corona, NY, (4)Education, Explora, Albuquerque, NM, (5)Children's Museum of Pittsburgh, Pittsburgh, PA

Background:

While Universal Design for Learning (UDL) has become prevalent in formal learning environments, little research has been conducted on how UDL can be expanded into the informal learning sector, where many challenges prevent its implementation. Instead of designing museum exhibits and experiences with autistic learners in mind, many museums offer select times where sensory triggers are reduced, and where supports are provided to create an inclusive learning experience. While this can be beneficial to some, it can also isolate autistic individuals from their neurotypical peers, and prevent individuals who may not have a diagnosis (or who are not comfortable with disclosing diagnosis) from accessing the supports they need.

Objectives:

The objective of this project is for researchers and museum educators to collaborate with autistic teens to create a set of UDL guidelines and training materials for informal learning environments that support belongingness for autistic learners. In Year 1, three museum sites across the US hired a cohort of 5-14 paid autistic teens to serve as codesigners. The codesigners examined existing engineering-design activities at each museum site, and provided feedback, redesigns, and suggestions to make the experience more inclusive. Combined with interview findings and discussion questions focused on learning differences and belonging, the codesign team created a set of suggestions for inclusive program design. In Year 2, these suggestions will be incorporated into activities in each museum site, which will undergo several testing and iteration cycles.

Methods:

Interviews with children and caregivers about museum experiences (n=12)

Interviews with codesigners about the belongingness in museums and ideas about activity design and UDL (n=24)

Museum staff reflections documented after each co-design session

Results:

Through family and codesigner interviews and reflections on the codesign process, we have identified preliminary themes needed to create a universally-designed informal learning experience.

- Make the environment easier to understand and embed intuitive wayfinding in each activity space
- Design activities where visitors have freedom to work at their own pace
- Be clear (but flexible) about learning goals
- Leverage and guide social interactions, allowing visitors to choose social and solo experiences
- Provide opportunities for independent exploration and choice
- Make goals and instructions more clear by breaking them down into steps and including visuals
- Embed visitor interest and encourage them to connect activities to personal experiences
- Provide multiple modalities for engaging with content
- Consider creative ways to display examples and celebrate visitor work
- Re-consider capacity and limit the amount of individuals at a workstation
- Provide time to increase familiarity with the space, activities, facilitation
- Provide smaller and intimate spaces with lighting that isn't too bright
- Be clear about who and how to ask for help

Conclusions:

While there are many challenges that prevent informal learning environments from being inclusive to autistic individuals, there is also a lot of flexibility and freedom in program design that doesn't exist in most formal learning environments. By utilizing findings created in collaboration with autistic youth and embedding UDL principles, informal learning environments can support belonging and learning for autistic museum visitors.

415.283 Addressing Social Skills and Anxiety in Autistic Adolescents: A Systematic Review of Interventions.

N. Buranova, Special Education, University of Missouri, Columbia, Columbia, MO, Kazakhstan

Background: The prevalence of autism spectrum disorder (ASD) continues to rise in the U.S. (Maenner et al., 2021). Social skills deficits are a key characteristic of ASD, and autistic individuals also experience higher levels of anxiety compared to their neurotypical peers (Croen et al., 2015; Russel et al., 2016; Roux et al., 2017; Mazurek & Handen, 2019). Adolescence is a crucial period for developing social relationships, which can have long-term effects on individual outcomes (Shattuck et al., 2012). Autistic adolescents are at increased risk of bullying (Sterzing et al., 2012; Zablotsky et al., 2014), which is associated with elevated anxiety (Weiss et al., 2015). To address these issues, this systematic review will examine existing interventions that target both social skills and anxiety in adolescents with ASD. Prior research highlights the importance of addressing these areas, given the close relationship between mental health—particularly anxiety—and social skills performance in this population (Briot et al., 2020; Pickard et al., 2017; Factor et al., 2022; Fuselier et al., 2024).

Objectives: The aim of this systematic review is to synthesize evidence on the effectiveness of interventions that address both social skills and anxiety in adolescents with autism spectrum disorder (ASD) and to outline implications for practice.

Methods: A systematic search was conducted to identify peer-reviewed, English-language publications from 2013 to 2024. Inclusion criteria required participants to be adolescents (ages 10-19) diagnosed with autism spectrum disorder (ASD) or eligible for special education under Autism. The interventions needed to target both social skills and anxiety, with outcome measures reporting on both. Databases searched included ERIC, Academic Search Elite, Academic Search Premier, APA PsycArticles, APA PsycInfo, CINAHL, Education Full Text (H.W. Wilson), and MEDLINE. The initial search, conducted between July 22nd and August 2nd, 2024, yielded 1070 articles. After removing duplicates, 659 articles remained. Abstracts of these 659 articles were scanned, and 59 studies were selected for full-text review. Of these, 25 met the inclusion criteria. An ancestral search added six more articles, resulting in 31 articles included in the final analysis. A second observer coded 20% of the studies at each stage, with inter-observer agreement (IOA) ranging from 98% to 100%.

Results: The review synthesizes and describes key features of the interventions: intervention method, agent, tools, setting, duration, research methodology, and key findings. The studies included varied in methodology, intervention types, countries and represent a culturally diverse sample of participants. Out of the 31 studies included in the final analysis, the majority demonstrated a positive impact of interventions on both social skills and anxiety in autistic adolescents. However, fewer studies addressed the generalizability of the interventions, emphasizing the need for future research to explore this area more thoroughly.

Conclusions:

This systematic review highlights the potential of integrated interventions addressing both social skills and anxiety for autistic adolescents. While several interventions showed promise, there remains a need for more comprehensive and long-term studies to determine lasting outcomes.

415.284 An Exploratory Study into the Utility of Toca Boca's Creative Play Model for Autistic Children

B. Laboret, E. Moore, J. Koehler and M. I. Hopkins, Psychology, The University of Alabama at Birmingham, Birmingham, AL

Background:

Autistic children often exhibit differences in social skill development and creative play compared to their typically developing peers. Technology-based interventions have been proposed as a potential way to address these developmental gaps. There are over 455,000 "educational" apps available in various app stores, but very few are properly evaluated for their effectiveness, particularly for autistic children. Ultimately, a well-designed app, informed by developmental science could offer significant benefits compared to other screen media by providing convenient, passive support for social skill development.

Toca Boca World (TBW), a creative play app with over 100 million downloads, has shown promise in promoting active learning, engagement, and social interaction, aligning with Meyer et al.'s (2021) four pillars of learning framework. However, few studies have examined its effectiveness in fostering social or creative play skills, particularly in autistic children. This study aims to explore the utility of TBW as a tool to support these skills in autistic youth.

Objectives:

The primary objective of this study is to determine whether participation in a TBW intervention improves social skills in autistic children aged 4-13. The secondary objective is to assess the participants' enjoyment of the app. A third objective is to explore improvements in creative play skills across the intervention sessions.

Methods:

We recruited 95 autistic children aged 4-13 and their primary caregivers. Pre- and post-intervention social skills were measured using the Social Skills Rating System (SSRS) and a Social Skills Observation form (via playground observations). The intervention consisted of eight TBW play sessions, each lasting 5-10 minutes over four weeks. Enjoyment after each session was measured using a five-point Likert-type scale, where higher ratings indicated greater enjoyment, comfort, and desire for future play. Paired samples t-tests were used to analyze pre/post changes in social skills and enjoyment.

Results:

Preliminary results from four children who have completed the intervention indicate significant improvements in overall social skills, particularly in cooperation ($t(3) = -4.33, p < .05$), assertion ($t(3) = -4.04, p < .05$), and self-control ($t(3) = -3.66, p < .05$), as measured by the SSRS. The children also consistently reported high levels of enjoyment during the sessions. They expressed happiness ($M = 4.34, SD = 0.77$), comfort ($M = 4.20, SD = 0.90$), and a strong desire to continue playing TBW ($M = 4.23, SD = 0.97$).

Conclusions:

Although data collection is ongoing, preliminary findings suggest that TBW may be a valuable tool for enhancing social skills in autistic children, particularly in cooperation, assertion, and self-control. If these trends hold as more participants complete the intervention, TBW could represent an effective, accessible means of supporting social development in this population. Moreover, the high levels of enjoyment reported by participants highlight the potential for sustained engagement, making it a promising tool for further research and potential use in developmental and educational settings. These findings have important implications for future work exploring TBW and its potential role in social skills development for autistic children.

415.285 An Implementation Process Evaluation of a Treatment Comparison Efficacy Trial: Establishing the Implementation Variable

S. L. Odom¹, K. S. Dickson², L. J. Hall³, J. Jarrett⁴, H. Spitzer⁴ and J. R. Steinbrenner⁵, (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (2)San Diego State University, San Diego, CA, (3)Special Education, San Diego State University, San Diego, CA, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Although RCTs are thought to be the gold standard in efficacy research of autism interventions, they may not tell the whole story. Increasingly in other fields (such as education science in the UK) researchers are using implementation process evaluations (IPEs) to understand the dynamic associations of factors affecting implementation of complex interventions in complex settings. IPEs, however, are used sparingly in autism intervention research. The current IPE study is being conducted in parallel with a multisite CRCT designed to assess the efficacy of two intervention programs [PEERS-focusing on social relationships and Unstruck and On Target (UoT)-focusing on executive functioning]. These programs were structurally similar (group based, similar number of lessons), which allowed them to serve as contact controls, but they addressed different high needs areas for autistic middle schoolers. This IPE began with the identification of research questions, which then lead to an initial conceptual map highlighting possible factors, or interactions of factors, possibly associated with implementation. To conduct such an analysis, however, one must establish the variable(s) that would constitute the implementation construct, which is the anchor of the IPE analysis. **Objectives:** To determine the key variable(s) that would represent the implementation construct in an IPE study of a CRCT intervention comparison.

Methods: To date, researchers have randomly assigned 12 schools to the PEERS condition and 9 schools to the UoT condition. Schools were located in Southern California and North Carolina, and 4-8 autistic students per school participated. Two primary implementation variables were examined. The first was the proportion of the intervention lessons completed by the end of the year (a content variable). The second variable was a quality rating from a scale consisting of 13 items in a 0-2 Likert-type format. On five occasions, intervention coaches completed the scale after observing implementer's lesson delivery, their mean rating was calculated, and the proportion high possible score (2.0) was calculated. Inter-rater agreement was conducted on more than 25% of the ratings with agreement about the 80% criterion. In addition, a composite score was calculated by multiplying the quantity X quality ratings.

Results: Table 1 lists the proportion of lessons covered, quality metric (the mean rating divided by 2.0 to establish a metric comparable to the content variable), and the implementation composite metric. The composite metric was then used to rank the schools on level of implementation. For UoT, a clear difference on the composite metric allowed ranking four schools as higher implementers and five schools as lower implementers. For PEERS the composite scores were more continuous so the top six schools were identified as higher implementers and the lower six schools were identified as lower implementers

Conclusions:

Establishing the implementation variable is an essential first step in conducting this IPE. It will now allow examination of process variables that could be associated with high and low implementation and similarities/differences between the two intervention programs. This is the next step in the full mixed-method IPE.

**415.286** Analysis of Effective Intervention Strategies within a Play-Based Intervention for Children with Developmental Disorders

R. A. Gordon¹, L. Himmelf², S. W. Russ³ and A. Dimitropoulos³, (1)Psychological Sciences Clinical Psychology, Case Western Reserve University, Cleveland, OH, (2)Case Western Reserve University, Cleveland, OH, (3)Psychological Sciences, Case Western Reserve University, Cleveland, OH

Background: Pretend play interventions hold preliminary efficacy for improving cognitive and affective skills in children with Prader-Willi Syndrome (PWS) and autism spectrum disorder (ASD; Dimitropoulos et al., 2021, 2023; Doernberg et al., 2021; Lifter, Mason, & Barton, 2011). However, it is unknown what components of these play-based interventions truly contribute to growth and development, as children with developmental disabilities respond differentially to various facilitation strategies, such as modeling, prompts, or praise. Previous studies have analyzed moment-to-moment interactions of children with developmental disabilities in response to adult facilitators, suggesting that adults who match the level of support needed provide effective care (Gordon et al., 2023; Hoffmann, 2016; Trawick-Smith & Dziurgot, 2011).

Objectives: As such, the present study uses a method of moment-to-moment analysis in which child and interventionist interactions were recorded, transcribed, and coded based on level of support and skills targeted.

Methods: Participants included 28 children ages 6-12 with PWS who completed a remotely delivered pretend play intervention for 6-8 weeks.

Participants demonstrated clinically significant impairments in social, cognitive, and adaptive skills, including overlapping ASD symptoms. Four sessions per child were transcribed and coded for type, level, and frequency of interventionist facilitation strategies (prompt, question, modeling, reflection/behavioral description, praise, or watching) and child play behaviors (pretend play, affect in play, imagination in play, and non-play).

Analyses of Variance (ANOVA) examined moment-to-moment responses of the child to the interventionist. Pearson's correlations and Hierarchical Linear Modeling (HLM) examined patterns of strategy and child target behaviors across the course of the intervention program.

Results: Findings supported the utility of the Interventionist-Child Dyadic Coding System and this method of analyzing moment-to-moment and between-session patterns of dyadic behavior. Results revealed that reflection and behavioral description (for example, commenting, "the girl is crying because she's sad," or "now he's driving the car"), and modeling strategies (such as, "this block can be the table"), most often preceded child's pretend play and may predict increases in these skills over time (75.74% and 75.03% of the time, respectively, $p < .01$). Prompts demonstrated mixed utility and were most effective when eliciting affect in play (50.82% of the time), while questioning was related to non-play ($p < .001$). Results did not vary for children with greater ASD symptomatology as indicated by the Social Communication Questionnaire.

Conclusions: This method represents a novel and efficacious mode of identifying how children respond to various adult intervention strategies, informing the mechanisms by which evidence-based interventions successfully scaffold child skill growth. The present study illuminates how non-directive strategies, such as modeling and reflection or behavioral description, may be essential facilitation techniques that help children with developmental disabilities improve their pretend play. Further, this method of analysis identifies how play and social cognitive skills may most effectively be scaffolded over the course of an intervention program. Future efforts to engage and support the PWS and ASD populations can be enhanced by capitalizing on these digital analysis methods and subsequently harnessing identified evidence-based techniques to refine interventions and provide more sensitive care.

415.287 Applying a User-Centered Approach to Inclusive Education Teacher Training: Teach Input from the U.S. and Netherlands
A. J. Harrison¹, K. Bowman², A. K. Smit³ and A. de Bildt⁴, (1)Educational Psychology, University of Georgia, Athens, GA, (2)TEACCH Autism Program; Psychiatry, University of Georgia, Chapel Hill, NC, (3)Accare UCKJP, Groningen, Netherlands, (4)Department of Child and Adolescent Psychiatry & Accare Child Study Center, University Medical Center Groningen, Groningen, NETHERLANDS

Background:

Teachers globally receive insufficient training to teach autistic students in inclusive classrooms, leading to limited use of evidence-based practices for inclusion (EBI) and an inability to meet student needs. Teacher trainings to augment knowledge of autism and EBIs are essential and must be designed to align with teacher-reported needs to increase training engagement. Implementation science supports that trainings have a higher likelihood of changing behavior when stakeholders (i.e., teachers) participate in user-centered intervention design (Byrne, 2019; Pérez Jolles et al., 2022). As this is a global need, trainings developed with the input of international teachers can ensure cross-cultural feasibility and acceptability at the development stage.

Objectives:

To employ user-centered development of an intervention to globally support general education teachers, the current study sought teacher perspectives from the US and Netherlands on preferences for EBI content and training modalities.

Methods:

10 US and 17 Dutch current or preservice teachers completed a qualitative interview. Coded themes assessed inclusive teacher experiences and training needs/preferences. All participants also completed Likert questions (scale 0-10) assessing knowledge and attitudes toward *EBI training content* derived from the literature from multiple orientations and on different *instructional modalities* (e.g., decisional flow charts, vignettes, video modeling). Training preferences were ordered from most to least familiar (knowledge) and acceptable (attitudes) and were compared across the two countries.

Results:

Given several non-normal variables, a Wilcoxon Sign test was used to show the relative positioning of all 11 topics in terms of attitudes (M_{att}) and knowledge (M_k) compared to a neutral median Likert of 5. For EBI content, all teachers had negative opinions about self-regulation ($M_{att} = 4.67$; $M_k = 4.00$). The most preferred content included TEACCH strategies ($M_{att} = 7.67$; $M_k = 7.00$) and behavioral rewarding ($M_{att} = 7.67$; $M_k = 7.50$). In terms of modality preferences, teachers had low rankings for a behavioral flow chart ($M_{att} = 4.0$; $M_k = 3.50$) and motivational interviewing ($M_{att} = 4.67$; $M_k = 2.50$), and high rankings for diagnostic vignettes ($M_{att} = 7.67$; $M_k = 7.00$). Next, we compared mean attitude scores on the normally distributed variables between countries. Analyses revealed that Dutch teachers had more negative attitudes than US teachers on behaviorism $t = 1.77, p < .05$ and a behavioral flow chart $t = 1.72, p < .05$. Qualitative themes revealed most teachers had negative experiences with autistic students (22/27). This was higher among reporting US teachers. With equal distribution across countries, most teachers described using TEACCH strategies (22/27) and approximately half of teachers described using strategies consistent with NDBI (16/27), but very few had used peer interventions (3/27). Almost all teachers expressed the desire to learn more about autism (24/27) but less expressed the need to learn differentiated instructional strategies (12/27).

Conclusions:

Dutch and US teacher input about training content and modality preferences were closely aligned. However, data will be collected from additional countries (Malaysia & South Africa) to ensure we have international teacher opinions to shape the development of an EBI intervention that considers teachers needs and incorporates strategies identified as feasible and acceptable.

415.288 Are the Outcomes of PEERS for Adolescents Equivalent across Modality? an Examination of in-Person and Telehealth Intervention

E. J. Adler^{1,2}, S. A. Lehman², H. K. Schiltz³, D. M. Glad⁴, M. K. Guell², M. Simons² and A. V. Van Hecke², (1)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Psychology, Marquette University, Milwaukee, WI, (3)University of Washington, Los Angeles, CA, (4)University of Wisconsin-Milwaukee, Milwaukee, WI

Background: During the Covid-19 pandemic, many healthcare services transitioned to telehealth, and some caregivers were concerned if telehealth services were efficacious (White et al., 2021). There is a growing body of literature supporting the effectiveness of in-person social skills interventions, however research on telehealth administration of social skills intervention is more limited. The research team associated with the PEERS® creators published data indicating similar social outcomes across treatment modality (Estabillo et al., 2022), and our research team published pilot data demonstrating similar social changes across telehealth groups (Adler et al., 2022). This study serves as the first independent replication of telehealth PEERS® to not only look at social changes across treatment modality but extend to the mental health and family impact.

Objectives: This study evaluated if the telehealth version of PEERS® has equivalent effects for autistic adolescents as the originally developed in-person modality. Change in social, familial, and emotional-behavioral factors over the course of intervention and across delivery method was analyzed via adolescent- and caregiver-reported measures. Additional factors not previously addressed in the literature, including intolerance of uncertainty and perceived treatment acceptability, were explored within telehealth groups.

Methods: 181 adolescents aged 11-17 ($M=13.49$, $SD=1.58$) and their families were included in the current analysis. Participants were enrolled based on documentation of autism diagnosis, $IQ \geq 70$, and other inclusion criteria (for full details, Schohl et al., 2014; Adler et al., 2022). Participants completed PEERS® for Adolescents via in-person or telehealth modalities ($n_{telehealth}=53$, $n_{in-person}=66$, $n_{waitlist}=62$). Questionnaires were completed by adolescents and their caregivers before and after PEERS® provision (Table 1 & 2). Using SPSS 28.0, 2x3 mixed model ANCOVAs, controlling for age, examined change across time (pre, post) and group (in-person, in-person waitlist, telehealth) for social (get-togethers, social knowledge and competency, social responsiveness, social problems), familial (environmental stress/disorder, parenting stress, parenting self-efficacy), and emotional-behavioral (anxiety, depression) factors. For telehealth only, paired samples t-tests examined intolerance of uncertainty change across intervention and descriptive statistics explored treatment acceptability.

Results: Findings indicated successful replication of positive improvements over the course of in-person and telehealth PEERS®, including get-togethers, social skills knowledge and competency, social responsiveness, social problems, parenting stress, and anxiety and depression symptoms; improvement in environmental stress/disorder was only observed in telehealth groups (Table 1). Furthermore, the changes in social skills knowledge, social competency, social responsiveness, get-togethers, social problems, and withdrawn/depressive symptoms were deemed statistically equivalent across modality, based on post hoc equivalency testing. Results examining only telehealth groups suggested improvements in caregiver-reported adolescent intolerance of uncertainty following PEERS® (Table 2), and families found telehealth PEERS® to be an acceptable intervention.

Conclusions: Overall, this study suggested that families will receive similar, if not equivalent, social, familial, and emotional-behavioral benefits from participating in either in-person or telehealth modalities of PEERS® for Adolescents. Additionally, caregivers reported a perceived improvement in adolescent intolerance of uncertainty following telehealth PEERS®. Importantly, families perceived the telehealth format of PEERS® to be acceptable. These findings may encourage healthcare providers to expand access to evidence-based intervention by offering telehealth services to the wider autism community.

415.289 Association between Improvements in Executive Functioning and Depression Among Autistic Adolescents Who Completed a Mindfulness-Based Intervention

M. Mitchell¹, **H. Honda²**, **A. Malligo³**, **S. Boyd²**, **B. B. Braden⁴**, **B. A. Pagni⁵** and **N. L. Matthews²**, (1)Research, Southwest Autism Research and Resource Center, Phoenix, AZ, (2)Southwest Autism Research and Resource Center, Phoenix, AZ, (3)Southwest Autism Research & Resource Center, Phoenix, AZ, (4)College of Health Solutions, Arizona State University, Tempe, AZ, (5)Arizona State University, Tempe, AZ

Background:

Many autistic adolescents experience challenges with executive functioning (EF) and mood symptoms (Camillone & Cragin, 2022). Mindfulness-based interventions (MBI) may yield improvements in both areas in autistic adults and non-ASD samples (e.g., Bockmann & Yu, 2023; Pagni et al., 2023), but less is known about autistic adolescents. Initial findings from our pilot randomized controlled trial (RCT) of a novel 8-week MBI for autistic teens and their parents demonstrated significant improvements in adolescent depression and a composite measure of EF in the treatment group (Matthews et al., under review). The current study examines treatment-related improvements in specific EF domains and potential associations among improvements in EF domains and depression. A better understanding of the relationship between improvements in EF and depression will provide insight into the mechanism by which these key areas may benefit from mindfulness training.

Objectives:

1. Compare change in EF domains between adolescents who completed an 8-week MBI and a delayed treatment control (DTC) group.
2. Examine associations among treatment-related improvements in EF domains and depression.

Methods:

Data were drawn from a pilot RCT of an 8-week telehealth MBI for autistic adolescents and their parents. Participants were 39 adolescent-parent dyads who were randomly assigned to the MBI ($n = 19$; adolescent M age = 15.32, 1.60; 68.4% male) or a DTC group ($n = 20$; adolescent M age = 15.10, $SD = 1.55$; 60% male) and completed data collection at both time points. Treatment group dyads attended weekly group meetings for 8 weeks to learn mindfulness and habit formation strategies. Participants were asked to practice mindfulness outside of group sessions using a mindfulness meditation app. Parents completed the Behavior Rating Inventory of Executive Function, Second Edition (BRIEF-2; Gioia et al., 2015) and the Children's Depression Inventory, Second Edition (CDI-2; Helsel & Matson, 2024) at baseline and program exit.

Results:

The treatment group demonstrated significant improvements on the BRIEF-2 inhibition ($t(37) = -2.71, p = .01$) and emotional control (Mann-Whitney: $z = 2.18, p = .03$) clinical scales relative to DTC. Group comparisons on the other clinical scales were not significant. Reported in Table 1, there were positive and statistically significant associations between improvements in inhibition and emotional control and improvements in depression in the treatment group.

Conclusions:

Findings suggest that treatment-related improvements in overall EF were driven by improvements in inhibition and emotional control. These findings are consistent with previous research in other populations indicating associations between mindfulness and inhibitory control (Pozuelos et al., 2019) and mindfulness and emotion regulation (Kral et al., 2018). Program strategies related to focused attention, acceptance of moment-to-moment experience, and the STOP (Stop, Take a breath, Observe, Proceed) Method likely facilitated these improvements. Improvements in inhibition and emotional control had moderate and strong associations, respectively, with improvements in depression in the treatment group. This suggests potential mechanisms by which mindfulness may improve mood symptoms in autistic adolescents. Future research with a larger sample size should examine whether improvements in inhibition and/or emotional control mediate improvement in depression symptoms or vice versa.

415.290 Autism Transition to Adulthood Groups (ATAG): Feasibility RCT of a New Peer-Group Intervention to Promote Successful Transition to Adulthood for Autistic Young People

K. Cooper¹, A. Burnley², L. Allain², B. Beresford³, L. Crane⁴, M. Vazquez Morales⁵, L. Portway², B. Redmayne⁶, A. Russell⁷ and W. Mandy⁸,

(1)University of Bath, Bath, UNITED KINGDOM, (2)University of Bath, Bath, United Kingdom, (3)University of York, York, United Kingdom, (4)University of Birmingham, Birmingham, Birmingham, United Kingdom, (5)Bristol Trials Centre, University of Bristol, Bristol, Bristol, United Kingdom, (6)Ambitious about Autism, London, London, United Kingdom, (7)Centre for Applied Autism Research, Psychology, University of Bath, Bath, UNITED KINGDOM, (8)Research Department of Clinical, Educational & Health Psychology, University College London, London, United Kingdom

Background: Autistic individuals without intellectual disabilities often face barriers to positive adult outcomes and are at high risk for poor health, including mental health issues, which could be mitigated by improving well-being. Autistic individuals who receive a diagnosis of autism in childhood do not always receive formal support to learn about autism. Young people should receive support to increase their well-being during the transition to adulthood, when social and family support often reduces.

Objectives: We conducted a feasibility randomised controlled trial (RCT) of an online peer-group intervention, "Understanding You, Discovering You" (UYDY), which aimed to support autistic young people during the transition to adulthood.

Objectives included assessing (1) recruitment and retention rates; (2) the acceptability of randomisation and outcome measurement procedures; (3) Care as Usual (CAU) accessed by participants; (4) acceptability of the interventions; (5) clinical outcome measure variances.

Methods: This 2-arm parallel feasibility RCT included a nested qualitative evaluation. Seventy participants aged 16-25 years old with a clinical autism diagnosis were randomised on a 1:1 basis to UYDY or CAU. Exclusion criteria included risk of harm to self or others, receipt of post-diagnostic support in the past 12 months, and literacy levels such that the written session materials were not accessible. Participants were recruited from England and Wales via charities and NHS services.

UYDY, a six-week co-designed online peer-group intervention, covered topics such as understanding autism, problem-solving, and accessing services, and was facilitated by an autistic person and social care professionals. Clinical outcomes were measured at baseline, and 8-, 16-, and 24-weeks post-randomisation. The primary clinical outcome was well-being, assessed using the Warwick Edinburgh Mental Wellbeing Scale (WEMWBS). Secondary clinical outcomes included autism social identification, quality of life, social support, and loneliness. Adverse events were monitored and reported. Carer impact was also measured. Qualitative interviews were conducted to explore the acceptability of trial participation including randomisation and the interventions.

Results: A total of 314 potential participants expressed interest in the study, and 80 (25%) of these attended a baseline appointment, with 70 (22%) taking part. We therefore recruited the full target sample. Seventy-four percent of participants randomised to UYDY attended at least three of the six sessions. Initial qualitative interviews (n=19) indicated that participants generally had positive experiences of the UYDY groups. Two preliminary themes were (1) *a new perspective*; some participants felt their self-understanding improved through learning about autism, while others felt they benefitted by building useful practical skills such as problem solving. Theme (2), *collective support*, focused on positive experiences of being in a group with other autistic young people, and with autistic facilitators, and that this could improve well-being and self-acceptance.

Conclusions: Preliminary analyses indicate that a full trial of UYDY is feasible, and that the trial design is acceptable to participants. Data collection is ongoing and will be complete in early 2025. Results will inform the design of a full RCT.

415.291 Autistic-to-Autistic Peer Mentoring: Using Double Empathy to Foster Relationships, Self-Advocacy, and Identity Development

D. D. Onwumere¹ and **K. P. Patten²**, (1)*New York University, NY, NY*, (2)*Occupational Therapy, New York University, New York, NY*

Background: Recent studies report an increase in autism diagnoses among individuals aged 14 to 17, a crucial time for college preparation (Bakker et al., 2023). This trend highlights the urgent need for effective support systems to help autistic students transition to adulthood. Only 39% of autistic students complete a college degree within eight years of finishing high school, compared to 52.4% of their non-autistic peers (Newman et al., 2024). This gap emphasizes the unique challenges autistic students face in higher education. Peer mentoring is a promising approach to support autistic college students (Siew et al., 2017). With transitional programs and self-advocacy skills, autistic students can achieve similar success rates to non-autistic peers (Bublitz et al., 2015). The Double Empathy Theory (DET) suggests that communication difficulties between autistic and non-autistic individuals result from differences in perception (Milton, 2012). These challenges decrease when autistic individuals communicate with each other, improving information exchange (Crompton et al., 2020; Chen et al., 2021). Self-Determination Theory (SDT) emphasizes fostering autonomy, competence, and relatedness (Deci and Ryan, 1980). The Making Mentor program integrates DET and SDT to foster supportive, neurodiversity-affirming relationships. Autistic college students mentor autistic high school students. The program trains autistic college students, primarily STEAM majors, to mentor autistic high school students by sharing knowledge on self-advocacy and preparing for the transition to higher education. Mentors receive training from an autistic consultant on effective mentoring techniques and boundary setting.

Objectives: 1) Investigate self-advocacy outcomes within the context of the mentoring program. 2) Examine the experiences and perspectives of autistic participants using a mixed-methods approach.

Methods: This mixed-methods pre/post study included 6 autistic mentees and 10 autistic mentors from large urban universities and public schools; mentors and mentees were matched based on shared interests. Quantitative data were collected through surveys using the Self-Determination Inventory (SDI) (Shogren et al., 2017) for mentors/mentees and the Disability Identity Development Scale for mentors (DIDS, Forber-Pratt et al., 2022). Qualitative data were collected through interviews and analyzed using thematic analysis.

Results: Quantitative Analysis: Mentee Outcomes: The surveys revealed a large effect size in self-advocacy ("Advocate") ($d=0.82$), demonstrating a strong program impact. Moderate improvements were noted in "Strength" and "Interest" ($d=0.65$), while "Accommodations" showed modest gains ($d=0.38$). The combined effect size for Advocacy, Interest, and Strength was large ($d=0.91$), suggesting a meaningful impact despite the p-value not reaching significance. **Mentor Outcomes:** Mentor surveys showed slight improvements in "Interest" and "Strength" ($d=0.30$) but small declines in "Advocate" ($d=-0.25$) and "Accommodations" ($d=-0.27$), suggesting a decrease in self-advocacy and perception of accommodations. Improvement in the DIDS scores were noted. **Qualitative Analysis:** Four key themes emerged: (1) mutual understanding, (2) self-advocacy, (3) knowledge acquisition, and (4) self-identity (see Figure 1 for exemplars).

Community Engagement: The project includes autistic advisory board to guide program development and ensure content aligns with autistic needs and perspectives. Autistic mentors create resources and share their experiences at conferences, demonstrating meaningful community engagement.

Conclusions: The mentoring program demonstrated positive outcomes in self-advocacy and identity, with mentors and mentees benefiting from the program.

415.292 Behavior on Performance-Based Tasks of Pragmatic Language and Safety for Digital Romantic Encounters Is Related to Autism Features

M. Armstrong¹, N. Sheikhi², Z. Xie³, Y. Lee⁴, C. Nigzus⁵, N. Toumanios⁵, E. T. Crehan⁶ and S. Faja⁷, (1)Labs of Cognitive Neuroscience, Boston Children's Hospital, Boston, MA, (2)Laboratories of Cognitive Neuroscience, Boston Children's Hospital, Brookline, MA, (3)Boston Children's Hospital, Brookline, MA, (4)Developmental Medicine-Laboratories of Cognitive Neuroscience, Boston Children's Hospital, Brookline, MA, (5)Tufts University, Boston, MA, (6)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA, (7)Boston Children's Hospital Laboratories of Cognitive Neuroscience, Brookline, MA

Background: A growing literature investigating the sexual health and romantic relationships of autistic adults, including the emergence of interventions in this domain, highlight the need for robust assessment. A previous study determined autistic adults have impaired pragmatic language skill compared to their counterparts and a lower number of partner experiences (Kohn 2022). To look further, we developed a novel set of performance-based tasks. These assessments include a pragmatic language task with text exchanges to potential intimate partners and a task assessing the safety of dating app profiles.

Objectives: To explore the relation between features of autism and performance on two novel assessments of performance in the context of romantic and sexual relationships.

Methods: To date, 77 adults (18 autistic) have completed the battery as part of an ongoing study. Groups did not differ in age or cognitive ability, although the non-autistic group had a higher proportion of women. All participants completed the Autism Quotient (AQ) to assess self-report of autistic features; scores were significantly higher for the autistic group ($M = 32.8$) than the non-autistic group ($M = 16.2$). Participants completed two novel tasks: (1) the Texting Pragmatics Task that assesses pragmatic language in the context of text exchanges with potential partners via 10 multiple choice and 10 free response items; and (2) the Trustworthiness Task assesses judgment about the safety of potential partners on 20 dating app profiles. We analyzed bi-variate correlations between the AQ and performance on the tasks to understand whether higher levels of autism features corresponded with different social behaviors.

Results: On the Texting Pragmatics Task, the AQ corresponded with performance on the free response items, $r(69) = -.27, p = .025$, but not the multiple choice items, $r(74) = -.08, p = .52$. Adults with higher levels of autism features demonstrated less effective pragmatic skills in the context of texting a partner when they were required to generate a free response but not when asked to select the best multiple-choice response. On the Trustworthiness Task, the AQ corresponded with safety ratings, $r(24) = -.46, p = .019$. Adults with higher levels of autism features rated the dating app profiles as being generally less trustworthy than adults with lower levels of autism features.

Conclusions: Two novel assessments of performance in the context of romantic and sexual relationships were sensitive to differences in the level of autism features, suggesting that the tasks may be useful in detecting individual differences that could be supported by dating and sexual health interventions for autistic adults. The tasks suggest that in the context of digital exchanges with romantic and sexual partners, adults who identify as having higher levels of autism features are less able to generate pragmatically effective responses to text exchanges and may be less trusting of potential partners. These differences provide useful information about the specific needs of autistic adults related to social aspects of intimate relationships and provide the possibility of more objective and inclusive assessments of these needs.

415.293 Building Connections: Peer-Mediated Instruction to Enhance Social Communication for Students with Autism in General Classrooms

J. Z. Zanuttini, *Special and Inclusive Education, University Of Sydney, Sydney, NSW, Australia*

Background: For many individuals with autism, social impairment is one of the most challenging characteristics of their diagnosis. For school-students with autism in Australia, social impairments commonly limit the extent to which they participate in general education schools and classrooms. Due to the growth in the proportion of students with autism entering general education, it is becoming increasingly challenging for general educators to address the unique and diverse needs of the students in their care. Unfortunately, there remains a separation between empirical research and teacher practice, with many teachers finding it difficult to sacrifice class time for social and emotional interventions.

Objectives: Primarily, this study aimed to determine the effect of peer-mediated time-delay instruction, embedded within typical academic learning tasks, as support for the social communication development of students with autism. In addition, this study aimed to investigate other potential impacts as a result of the peer-mediated intervention, including impacts on academic progress and their general enjoyment of the intervention.

Methods: Three single-case designs, each involving a multiple-baseline-across-behaviours design for a target participant with autism, were used to investigate the effect of the peer-mediated intervention on both the frequency and quality of targeted social communication behaviours. The peer-mediated time-delay instruction was embedded by same-age peers without disability during teacher-led learning sessions. Partial-interval recording procedures were used to collect observational data. Visual data analysis and IQR_Md quantification processes were used to analyse observational data of the target students. A fidelity checklist was used to monitor the intervention's implementation by peers throughout this investigation.

Results: Data show that the intervention had some positive effects on several of the social communication behaviours targeted during the study. However, due to small-scale intervention effects, variable data patterns, and inconsistent effect replication, a functional relationship between the intervention and the targeted social communication behaviours could not always be established. Implementation fidelity data demonstrated that trained peers accurately delivered the intervention, with an increase in accuracy over time. Academic monitoring showed that there was no regression in academic outcomes for any participating student. At the completion of the intervention, participants' self-reports revealed that their experience was positive, resulting in improved social communication skills and confidence.

Conclusions: In conclusion, the peer-mediated intervention demonstrated some positive effects on social communication behaviours among students with autism. The fidelity of implementation by trained peers improved over time, and no adverse effects on academic outcomes were observed for any participants. Additionally, the intervention was positively received by both students with autism and their peers, suggesting that integrating social communication strategies into academic learning can offer meaningful social benefits without compromising academic progress.

415.294 Capturing Autistic Students' Anxiety: Application of the PARS-ASD in a School-Based Comparative Effectiveness Trial.

K. M. Russell¹, A. Losh², K. Cosgrove³, S. Nickles³, L. G. Klinger⁴, K. Pickard⁵ and J. Reaven⁶, (1)UC Santa Barbara, Santa Barbara, CA, (2)JFK Partners, University of Colorado, Anschutz Medical Campus, Aurora, CO, (3)CU Anschutz, Denver, CO, (4)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (5)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (6)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Anxiety is common in autistic children (Salazar et al., 2015) and may negatively impact school functioning (Reyes et al., 2021). The SCARED (Birmaher et al., 1999) is often used to measure anxiety in school-aged children, including autistic youth (Stern et al. 2014) but was not designed specifically for autistic youth. The recently developed PARS-ASD (Maddox et al., 2020) is a brief caregiver interview designed to assess anxiety in autistic children that may be both useful and feasible in research contexts compared with lengthier semi-structured interviews (e.g., ADIS-ASA; Kerns et al. 2014) or objective measures alone. This study explores the application of the PARS-ASD in a school-based comparative effectiveness trial.

Objectives:

- 1) Examine the feasibility and utility of the PARS-ASD with autistic students.
- 2) Examine relations between the PARS-ASD and teacher (SAS; Lyneham et al., 2008), caregiver (SCARED), and child (SCARED) rating scales. It was hypothesized that the PARS-ASD would be (1) feasible due to its brevity and will have good utility, given the autism-specific items and range of anxiety symptoms assessed; and (2) positively correlated with the caregiver SCARED, but not correlated with reports from other informants.

Methods: Participants were 127 autistic children with anxiety aged 8-15 years ($M=10.9$, $SD=1.7$), their caregivers, and teachers. Participants were diverse across gender and racial and ethnic identities (see Table 1). Participants were recruited through an ongoing multi-site, cluster randomized comparative effectiveness trial examining Zones of Regulation (Kuyper, 2011) and Facing Your Fears in School (Reaven & Blakeley-Smith, 2024) for autistic students. Caregiver, teacher, and child report measures of anxiety were collected at baseline. For Aim 1, PARS-ASD subscale endorsements, administration time, and anxiety domains measures across instruments were obtained. For Aim 2, correlations of total scores for each measure were conducted.

Results: PARS-ASD mean administration time was 24 minutes, 13 seconds ($SD=7:38$) and 91% of participants completed the PARS-ASD at baseline. The administration time paired with unique anxiety symptom domains promotes the utility of the PARS-ASD. Descriptives in this school-based sample ($M=11.3$; $SD=5.5$) were very similar to clinical samples (Maddox et al., 2020). See Table 2 for PARS-ASD, SCARED, and SAS administration modality, measured anxiety constructs, and sample items. Of the anxiety domains unique to the PARS-ASD, 75.6% of caregivers endorsed specific phobia(s), 52.8% endorsed anxiety symptom(s) related to health and the body, and 88.2% endorsed anxiety surrounding need for sameness/routine. Bivariate Pearson correlations revealed that the PARS-ASD total score was significantly correlated with caregiver SCARED Total Score ($r=.61$, $p<.001$), but not child SCARED or teacher SAS (Table 3).

Conclusions: Results suggested that the PARS-ASD is time efficient, had a high completion rate in this trial, and captures anxiety symptom domains not assessed by some other common measures (Specific Phobia(s), Health and the Body, and Sameness/Need for Routine). The PARS-ASD was only significantly correlated with the caregiver SCARED measure, though the caregiver SCARED was significantly correlated with all other measures. These results highlight the potential unique benefits of PARS-ASD utilization within school-based anxiety research. Limitations and future directions will be discussed.

415.295 Caregiver Perspectives on an Adapted CBT Intervention for Autistic Adolescents with Intellectual Developmental Disability: Facing Your Fears-IDD

N. Reyes¹, C. Middleton², L. Hayutin², S. Sharif¹, J. Reaven⁴, A. Meyer² and A. Blakeley-Smith³, (1)University of Colorado, Anschutz Medical Campus, Aurora, CO, (2)University of Colorado Anschutz Medical Campus, Aurora, CO, (3)JFK Partners, University of Colorado School of Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO, (4)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Autistic adolescents with intellectual developmental disability (IDD) are an underserved population at high risk for anxiety. However, they tend to have limited treatment options (Skwerer et al., 2019), and they are frequently excluded from treatment trials (Rosen, Connell, & Kerns, 2016). Adapting Cognitive Behavior Therapy (CBT) approaches for the full spectrum of autistic youth reflects a key step in enhancing mental health treatment options. Caregivers' perspectives may inform what CBT components are most and least effective and what adaptations and refinement are needed for this population.

Objectives: Caregivers were interviewed to gauge information about their experiences after participating in Randomized Controlled Trial (Facing Your Fears: Intellectual Developmental Disability (FYF:IDD, Blakeley-Smith et al., under review). FYF:IDD is a CBT based intervention designed to address anxiety symptoms in autistic youth with IDD. Thus, this qualitative investigation aimed to understand caregiver perceptions of a CBT based group intervention.

Methods: One family per FYF:IDD group ($n=16$ families; 21.9% of sample) was randomly selected to participate in a 30 minute "Exit interview" 6 months after completing FYF:IDD. This semi-structured exit interview was conducted with caregivers to examine their perceptions about FYF:IDD, including aspects such as CBT components, caregiver involvement, and treatment modality. Exit interview questions were developed in line with other treatment adaptations (e.g., Reaven et al., 2023). Interviews were recorded and transcribed. Transcripts were analyzed using rapid qualitative analysis to determine themes about perceptions of FYF:IDD.

Results: Analyses yielded four overarching themes: (1) "*Intervention required practice beyond group sessions*" - Caregivers reported that after participating in FYF:IDD, they needed practice outside group to increase teens' use of the strategies learned. (2) "*Importance of individualizing strategies*" - Caregivers stated that FYF:IDD needed to individualize strategies for their teens. (3) "*Caregiver involvement to enhance accessibility and generalization*" - Caregivers mentioned that they often needed to be highly involved to increase accessibility and generalization. (4) "*Weighing the pros and cons of a group modality*" - Caregivers reported benefits and challenges of a group modality for them and their teens.

Conclusions: When trying to expand evidence-based anxiety interventions to support autistic teens with IDD and their families, it is critical to understand caregiver perspectives of the intervention. Results from this study suggest that when using CBT approaches, repetition and long-term practice of skills is pivotal, adaptations of CBT strategies may be needed to match the unique needs of each teen, caregiver involvement is necessary, and group modality may be the best fit for some families, but not others. In the future, thoughtful tailoring of both CBT strategies and group constellation is necessary for families to experience belonging and to support accessibility and generalization of treatment components. This study reflects an important step in further adaptations and refinement of FYF:IDD. Future directions and recommendations will be discussed.

415.296 Changes in Heart Rate Variability in Autistic Youth Following a Therapeutic Photography Intervention

L. Panetta¹, J. A. Weiss², M. Charalampopoulou², A. Ibrahim³ and N. Eddy⁴, (1)Psychology, York University, North York, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)York University, Toronto, ON, Canada, (4)Psychology, University of Calgary, Toronto, ON, Canada

Background: Research indicates that autistic youth are disproportionately impacted by a lack of access to evidence-based supports while also experiencing many health conditions and social challenges. These challenges can also be compounded by intersecting identities that can place an individual at even greater risk of marginalization (e.g., identifying as LGBTQ2S). Consultations with the autistic community reveal a desire to prioritize research and supports that focus on mental health. Within this context, we evaluated the potential of an easily-implemented intervention for autistic youth, therapeutic photography (TP) to improve well-being.

Objectives: To determine if autistic youth (age 16-25 years) show differences in their physiological experience of well-being after participating in a therapeutic photography intervention.

Methods: Forty-one autistic youth were recruited from a variety of sources including community organizations, online advertising, and social media. Thirty-four participants visited the lab before and after completing the 4-week TP intervention, where they took photographs of contexts that were associated with happiness, connectedness, optimism, and engagement/perseverance and completed the physiological measurement. Gender identity varied considerably, with 57% identifying as cis-gender and 43% as gender diverse (i.e., transgender, non-binary, agender, and genderqueer). Well-being was measured through vagal tone as operationalized by heart rate variability (HRV). During lab visits, HRV was measured at rest and during mild stress (i.e., a computerized version of the Mirror Tracing Task) using electrocardiogram data collected via electrodes placed on participants wrists and ankle. HRV was operationalized using the root mean square of successive differences (RMSSD) of the intervals between heartbeats.

Results: In the overall sample, there was no significant change in baseline HRV before and after the intervention ($p = .45$). When change in baseline HRV was examined by gender group, cis-gender participants showed no significant difference ($p = .78$), while participants who did not identify as cis-gender showed an increase in baseline HRV after the intervention that approached significance ($p = .05$).

Conclusions: Results may suggest that gender identity had an important association with how responsive participants were to the intervention at a physiological level, and also may have different resting state HRV in general. Potential interpretations of the results and implications for informing interventions and supports for autistic youth will be discussed. It is important to consider gender differences beyond looking at cis-male and cis-female distinctions when considering gender in autistic research.

415.297 Changes of Brain Connectivity after Social Skills Training in Autistic Adults

S. S. F. Gau¹ and Y. L. Chien², (1)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (2)National Taiwan University Hospital, Taipei, Taiwan

Background: Autistic adults suffered from social communication difficulties. Evidence-based social skills training may significantly improve social function impairment, reduce social interaction anxiety, stimulate motivation for social interaction, and acquire social skills knowledge. Whether the social skills training change the structural connectivity of the brain is largely unknown.

Objectives: This study aims to investigate the changes of white matter integrity by diffusion tensor imaging (DSI) after social skills training in autistic adults.

Methods: This study recruited 28 autistic adults, who completed 16-week The Program for the Education and Enrichment of Relational Skills® social skills training. DSI images was collected before and after the training in each participant. Repeated measure analysis of variance was performed to compare the DSI parameters (including generalized fractional anisotropy [GFA], fractional anisotropy [FA], radial diffusivity [RD], axial diffusivity [AD] and mean diffusivity [MD]) before and after the training.

Results: Preliminary analysis revealed that the DSI parameters of several tracts may change after the training, including left thalamic radiation of ventrolateral prefrontal cortex (GFA), right thalamic radiation of dorsolateral prefrontal cortex (AD), and right perpendicular fasciculus (AD and MD). However, most findings did not pass multiple test comparison. Of note, several non-gaussianity parameters changed after the social skills training. The statistical power may be limited by smaller sample size.

Conclusions: Preliminary findings revealed that social skills training may change white matter integrity in autistic adults. However, most findings did not survive multiple test correction. These initial findings warrant further investigation by novel methods. Besides, other brain structural parameters such as cortical/subcortical volumes may be worth investigation.

415.299 Community-Partnered Development and Feasibility Testing of a Brief Motivational Interviewing Intervention to Support Autistic Young Adults with Motivation to Complete Daily Living Skills

E. A. Kaplan-Kahn¹, A. Garagozzo², B. E. Yerys², E. S. Kushner³, M. Leach² and J. Gettings⁴, (1)Center for Autism Research, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Departments of Radiology and Psychiatry, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Children's Hospital of Philadelphia, Philadelphia, PA

Background: Many autistic adults demonstrate a notable gap between their cognitive skills and consistent completion of daily living skills (DLS) needed to live independently. (Kraepel et al., 2017). Under-developed DLS may arise from problems with either *capacity* (skill acquisition) or *consistency* (skill execution). Diminished motivation to complete DLS may drive poor consistency, but no existing DLS treatments for autistic young adults addresses DLS consistency. Motivational Interviewing (MI) is an evidenced-based therapeutic style that honors autonomy and personal values and aims to promote behavior change. MI has been used successfully to promote change across a range of health behaviors in young adults (Cushing et al., 2014). Thus, MI is a theoretical framework that may be well suited to support autistic young adults with their DLS consistency.

Objectives: 1) Use a community-partnered research approach to develop an MI-based intervention for improving consistency with DLS; 2) Assess feasibility and acceptability of the new intervention

Methods: We developed a 5-session intervention, Motivational Interviewing for Daily Living Skills (MI-DLS) based on a brief motivational enhancement therapy for alcohol abuse program (Miller et al., 1999). Core tenets of MI-DLS include exercises to identify values, explore ambivalence about change, and provide autonomy support around DLS selection and execution. We then conducted individual semi-structured interviews with an advisory board of nine transition-age autistic youth, caregivers, and service providers to garner feedback content, and the perceived utility and accessibility of the intervention. Advisor feedback was integrated into a revised treatment manual. We piloted MI-DLS with 10 autistic young adults (17-21 years) to evaluate its acceptability and satisfaction. Acceptability was measured through session attendance. Satisfaction was rated on a 1 to 7 scale through self-report and caregiver-report.

Results: Manual Development – Community consultants requested revisions related to: (1) addressing sensory and executive functioning challenges that influence motivation to conduct DLS, (2) clarifying ambiguous language, (3) ensuring that autistic young adults are present in the room for all conversations with caregivers. These revisions were integrated into the MI-DLS manual. **Feasibility**– 10/10 participants completed all five MI-DLS sessions. Participants took an average of 5.9 weeks to complete the 5 sessions due to participant scheduling conflicts. **Acceptability** – Across sessions, autistic youth (N=10) and caregivers (N=7) reported high levels of satisfaction and perceived helpfulness. Both autistic youth and caregivers also reported high likelihood of consistently using MI-DLS strategies to complete their target DLS as well as other DLS (see Table 1 for all ratings). Autistic youth additionally reported high levels of empowerment in sessions.

Conclusions: To our knowledge, our study is the first to employ an intervention rooted in MI principles for autistic people. Community-partners optimized the utility and accessibility of our intervention by identifying the need for accommodations for executive function and to minimize sensory discomfort. Preliminary data suggests MI-DLS is feasible with high levels of acceptability and satisfaction. Future research will pilot MI-DLS in a larger sample to evaluate preliminary treatment efficacy.

415.300 Comparing Sensitivity of Social Communication Measures Following a Trial of PRT

S. Park¹, E. Gray² and P. E. Ventola³, (1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Ventola Lab - Yale Child Study Center, New Haven, CT, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

Background:

Pivotal Response Treatment (PRT) is an evidence-based behavioral intervention aimed to improve social communication skills in autistic children. While social skills may improve with intervention, quantifying these changes may be challenging due to limitations in existing assessment tools (Bishop et al., 2019). The Vineland Adaptive Behavior Scales, Third Edition (Vineland-3) and the Social Responsiveness Scale, Second Edition (SRS-2) are widely used standardized parent-report questionnaires for assessing social communication improvements. Although the validity and reliability of these measures have been studied, there is continued need to evaluate their sensitivity in detecting changes in social communication skills following PRT.

Objectives:

This study aimed to compare the sensitivity of the Vineland-3 and SRS-2 in detecting change in social communication skills following a trial of PRT.

Methods:

This study included 51 children aged 4-9 years old with an ASD diagnosis confirmed by the ADOS. Families participated in a 16-week trial of PRT. Sessions were 6 hours weekly and consisted of direct work with the child and parent guidance. Parents completed the Vineland-3 and SRS-2 at baseline and at the end of treatment.

Results:

Following PRT, improvements were seen in Vineland-3 domain standard scores (Communication: $p = 0.004$, $t(39) = -3.039$; Socialization: $p = 0.006$, $t(39) = -2.889$) and subdomain age equivalents (Receptive Communication: $p = 0.028$, $t(39) = -2.278$; Play and Leisure: $p < 0.001$, $t(39) = -5.271$). Improvements were also seen in SRS-2 domain raw scores (Awareness: $p = 0.005$, $t(48) = 2.979$; Cognition: $p = 0.032$, $t(48) = 2.214$, Communication: $p < 0.001$, $t(48) = 4.198$; Motivation: $p = 0.029$, $t(48) = 2.248$), and T-scores (Communication: $p < 0.001$, $t(48) = 5.464$, Motivation: $p = 0.001$, $t(48) = 3.408$). There were no differences observed between changes in Vineland-3 standard scores and SRS-2 T-scores. The magnitude of change in Vineland-3 age equivalent scores across social communicative subdomains (Receptive Communication, Expressive Communication, Interpersonal Relationships, Play and Leisure) were greater than the changes observed in SRS-2 raw domain scores (Social Awareness, Social Communication, Social Cognition, Social Motivation), $p < 0.001$.

Conclusions:

The Vineland-3 and SRS-2 both measured improvements in social communication skills of autistic children following a trial of PRT. Change was detected across Vineland-3 domain raw scores and subdomain age equivalent scores as well as SRS-2 raw domain scores and T-scores. The Vineland-3 age equivalent scores demonstrated the greatest magnitude of change. This provides evidence that the Vineland-3 age equivalent scores may be of increased sensitivity to change. This could be due to how the Vineland-3 is a clinician administered interview, where the clinician is able to probe for changes even of small magnitude. Overall, although the greatest magnitude of change was detected in the Vineland-3 age equivalent scores, the Vineland-3 standard scores and SRS-2 domain-level raw and T-Scores also detected change in this sample. It is critical to continue investigating outcome measures such as the SRS-2 and Vineland-3 to further refine outcomes and determine which are the most fit for a given trial.

415.301 Concept Structuring Analyzing Task (ConSAT) - a Methodological New Tool for Revealing Interviewees' Perceptions about Educational Inclusion of Students with ASD

M. Blumenfeld^{1,2} and **E. Dromi¹**, (1)Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel, (2)Kibbutzim College of Education, Technology and the Arts, Tel Aviv, Israel

Background:

All over the world, educational inclusion has become an established philosophy and a common placement practice for students with ASD in elementary schools. While the philosophy of inclusion is advanced by clinicians, parents and educators, very little is known about the implementation of its principles by educational teams who take part in this complex process. Previous studies used questionnaires and interviews with direct questions on the subject. In the present study the ConSAT methodology was utilized for the investigation of interviewees' perceptions about the inclusion of students with ASD in their classrooms, and how they perceive their roles in it.

Objectives:

To explore the perceptions of various educational team members: 1) school principals, 2) teachers and 3) paraprofessional aids about their role in the inclusion process in which they take part.

Methods:

39 educational educators: 10 school principals, 11 teachers and 18 paraprofessional aids, participated in the study. ConSAT interviews were conducted with each of them. Each participant was asked to create a visual map that represents its ideas about the inclusion of students with ASD in regular classrooms. In addition, each participant was asked to define 19 concepts that appeared in their own map (attached an example of one map)

Results:

Findings revealed that the school principals, the teachers and the paraprofessional aids did not share views on the inclusion process, and their respective tasks. Differences were identified with respect to the role of the included student, the relationships among the educational team members, and the functions of the paraprofessional aides. Our results shed light on how the educational teams defined all the stakeholders that are involved in the inclusion process, and how they viewed the various activities that are required for the inclusion to succeed.

Conclusions:

1. The ConSAT methodology significantly advance our understanding of the complexity of the inclusion process
2. This is a useful methodology for capturing interviewees' perceptions about inclusion without leaning on direct questioning.
3. Our results point to the need to define the distribution of responsibilities within the school and ensure that the philosophy of inclusion is familiar and shared by those who take part in it.
4. We suggest to expand the training programs of educational teams to include theory and practice about successful inclusion of students with ASD in regular school systems.

415.302 Coping with Uncertainty in Everyday Situations (CUES©): The First U.S. Trial

S. A. Lehman¹, **M. K. Guell¹**, **M. Berman²** and **A. V. Van Hecke¹**, (1)Psychology, Marquette University, Milwaukee, WI, (2)Psychology, Marquette University, Milwaukee, WI

Background: Approximately 40% of autistic youth are diagnosed with at least one DSM-5 anxiety disorder (van Steensel et al., 2011). The presence of anxiety often amplifies the social and functional difficulties faced by autistic youth, exacerbating poor outcomes. Intolerance of uncertainty (IU) has been identified as a key mechanism to the development and maintenance of anxiety in both neurotypical and autistic populations (Jenkinson et al., 2020; Osmanağaoğlu et al., 2018). Of note, autistic youth demonstrate higher rates of IU compared to their neurotypical counterparts (Boulter et al., 2014; Chamberlain et al., 2013; Neil et al., 2016). As such, autistic youth who experience anxiety may benefit from interventions that specifically target IU. Coping with Uncertainty in Everyday Situations (CUES©; Rodgers et al., 2017) is the first intervention for autistic youth that treats anxiety via IU. Preliminary data show decreased child IU and anxiety as well as increased parental self-efficacy following participation in CUES© (Rodgers et al., 2022). However, these data have yet to be replicated. Further, CUES© has yet to be implemented in the U.S.

Objectives: The objective of the present study is to (1) implement minor content adaptations while still maintaining the integrity of the CUES© treatment, (2) assess whether U.S. families find CUES© to be an acceptable intervention, and (3) determine whether treatment outcomes from the CUES© origin site can be replicated in the U.S.

Methods: The CUES© parent-facing didactic content was adapted for U.S. populations through group consensus with a certified CUES© provider. Three groups with approximately 8 participants each will take place: one in the fall of 2024 and two in the spring of 2025. Assessment measures will be used at baseline to confirm autism diagnoses (BOSA; Lord et al., 2020), evaluate cognitive function (KBIT-2, Revised; Kaufman & Kaufman, 2022), and screen for comorbid anxiety (ADIS-ASD; Kerns et al., 2024). Outcome measures will be implemented pre- and post-treatment to examine changes in parent-reported IU (IUS-P; Comer et al., 2009) and parent-reported anxiety (ASC-ASD; Rodgers et al., 2016). Intervention acceptability will be assessed post-treatment (CEQ; Devilly & Borkovec, 2000).

Results: Adaptations ($N = 164$) primarily addressed differences in phrasing (51.23%) as well as differences in spelling (26.83%) between British English and American English. For example, changing "Why not have a go" to "Give it a try" or "Mum" to "Mom". Images were also changed to better match the racial-ethnic demographics of the midsized midwestern city where groups will be held. The first CUES© cohort is currently underway, which includes the parents of 8 autistic children and adolescents aged 7-17 ($M = 12.13$; 87.5% male). On the ADIS-ASD, 40% met criteria for 2-3 clinical modules and 40% met criteria for 4 or more clinical modules.

Conclusions: Complete pre- and post-treatment data for the IUS and ASC-ASD will be available for approximately 24 participants at conference time along with data for the CEQ. Analyses and descriptives will indicate whether U.S. families find the intervention to be acceptable and whether it had an impact on parent-reported IU or anxiety.

415.303 Correlates of Attrition Status in a 12-Week Non-Inferiority Trial Comparing Telehealth Versus in-Person Parent-Mediated Intervention for Autistic Toddlers

R. Reetzke^{1,2}, H. Stalknecht¹, V. Singh¹ and R. Landa^{1,2}, (1)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD

Background:

Randomized controlled trials offer families of autistic children free access to evidence-based interventions, which have been associated with improved outcomes. However, dropout occurs, particularly for low-income populations (Carr & Lord, 2016). In an ongoing federally-funded autism early intervention clinical trial providing in-home parent coaching for 12 weeks, we have observed unexpectedly high attrition. The trial's design, where all families receive the intervention, allows us to examine a myriad of factors associated with attrition. Identifying these correlates may help inform the development of family-centered supports to maximize participation, and ultimately, child outcomes.

Objectives:

To define associations among child-, parent-, and family-level factors and attrition status in an ongoing non-inferiority trial comparing a telehealth versus in-person parent-mediated intervention for autistic toddlers.

Methods:

Participants included 113 autistic toddler-parent dyads (autistic toddler age range: 24–36 months; male: 93, 71.5%; female: 37, 28.5%). At baseline, parents completed family and child questionnaires, and research-reliable examiners conducted Autism Diagnostic Observation Schedule (ADOS) and Mullen Scales of Early Learning assessments. Participants were categorized into one of four attrition status groups: attended no intervention sessions ($n = 15$), attrition after 1-2 sessions ($n = 17$), attrition after 3+ sessions ($n = 17$), or no attrition (completed intervention) ($n = 64$). Chi-square tests assessed associations between attrition and categorical variables (e.g., intervention modality, sex assigned at birth, race, family income, mother/father education, mother/father work status, child co-residence with mother/father), while ANOVAs examined differences in continuous variables (e.g., Mullen and ADOS scores, parent motivation, child behavior).

Results: Attrition was significantly associated with intervention modality ($p = 0.012$), with higher attrition rates observed prior to intervention onset in the telehealth (66.7%) compared to the in-person intervention arm. Reasons for attrition varied by attrition status ($p = 0.002$): families citing obstacles/life stressors were more likely to attrit after 1-2 sessions (58.8%) or 3+ sessions (47.1%), while families with attrition before completing any sessions were mostly passive (66.7%), providing no reason for leaving the study. Family income ($p = 0.004$), father's education ($p = 0.013$), and child co-residence with father ($p = 0.034$) were significant correlates of attrition status, with lower income and lower father education, and child not co-residing with father being associated with higher attrition. Parents in the completion group had greater coach-coded motivation compared to attrition groups ($p < 0.001$). While ADOS CSS and Mullen scores showed no group differences, children with attrition without receiving any sessions exhibited more repetitive behaviors ($p = 0.035$).

Conclusions:

These findings highlight the need to tailor supports, particularly for telehealth interventions, and to consider family dynamics and socioeconomic context to reduce attrition. Despite significant correlates, child-level factors (ADOS, Mullen) scores were not significantly associated with attrition status, suggesting that family-level factors may play a more substantial role in trial participation. Providing targeted engagement strategies for low-resourced families may support retention and child intervention access in similar trials.

415.304 Development and Evaluation of a Training Course Using Embodied Virtual Reality for University Staff to Make Universities More Inclusive for Autistic Students

E. Cappe^{1,2}, K. Lamore³, E. Boujut⁴, M. H. Plumet⁵, S. Zorn⁶, A. Arguel⁷, C. Hoffert⁸ and C. Clément^{9,10}, (1)Laboratoire de Psychopathologie et Processus de Santé, Université Paris Cité, Boulogne-Billancourt, Île-de-France, France, (2)Institut universitaire de France (IUF), Paris, Île-de-France, France, (3)Université de Lille, Lille, Hauts-de-France, France, (4)Laboratoire Cognition Humaines et Artificielles, CY Cergy Paris Université, Cergy, Île-de-France, France, (5)Université Paris Cité, Boulogne-Billancourt, Île-de-France, France, (6)INSEI, Suresnes, Île-de-France, France, (7)Université de Toulouse, Toulouse, Occitanie, France, (8)Université Paris Nanterre, Paris, Paris, France, (9)Université de Strasbourg, Strasbourg, Grand Est, France, (10)STRAS&ND, Strasbourg, Grand Est, France

Background: University education is a crucial means for autistic adults to achieve social participation. However, France lags behind in the education of autistic adults, even though it is a national priority. Evidence from the literature has shown the positive effect of specialized training on teachers' attitudes toward the inclusion of students with disabilities. However, it also points to the need for practices that emphasize experimentation. It has also been shown that embodied virtual reality (EVR) is a more effective method of eliciting awareness than traditional perspective-taking.

Objectives: We have developed a training course in autism for university teachers and staff, combining a classic learning environment with theoretical presentations and a learning environment using EVR, and we propose to test its effects in terms of improving awareness, via pre/post-test and comparison conditions protocols. To meet this objective, our project includes 3 studies. This paper will present the results of study 1 and the methodology of studies 2 and 3.

Methods: The methodology is based on the ORBIT model of intervention development and evaluation (Czajkowski et al., 2015). The first study aims to develop the training course. To identify the needs of university teachers and staff and define the content of the training course, individual research interviews with 15 autistic student-experts enrolled in 5 French universities, and 26 university teachers and disability service staff from 14 universities, have been carried out. Collaborative workshops to produce EVR content were planned with autistic students (they took part in creating the scenarios and were actors in the films). The second and third studies aim to test its impact. Study 2 aims to conduct a preliminary evaluation via a pilot study using a pre/post-test protocol on 30 participants. The protocol will include different evaluations: self-reported questionnaires (knowledge about autism and inclusive practices, beliefs and attitudes towards autism and school inclusion, empathy, and social desirability), implicit association testing (measuring implicit bias), problem-solving exercises regarding academic inclusion, and research interviews (exploring satisfaction with the training course format and content). Fidelity implementation will also be assessed. Study 3 is a randomized controlled trial on a larger population. The protocol will be the same as that of the pilot study but will include two comparison conditions.

Results: The results of the interviews highlighted the various difficulties encountered by French autistic students, particularly in their interactions with university staff, as well as the need for support for professionals, particularly due to their lack of resources and training. Three 360-degree EVR film prototypes have been first produced, in collaboration with 12 autistic students, confirming technical feasibility. A first version of the theoretical training content (manual and PowerPoint) has been produced and validated by the experts (autistic students and professionals). The scenarios have also been co-constructed and reviewed with the experts. Participative and collaborative workshops for producing EVR content (shooting 360-degree EVR films) were done with neurotypic students and autistic student.

Conclusions: The effects of this project are both scientific and societal, and address issues of inclusion and digital innovation in university training.

415.305 Do Autism and ADHD Play a Role in Teachers' Burnout in France?

E. Cappe^{1,2}, V. Nieuwenhuys³, D. Ridremont⁴, J. Despax¹ and E. Boujut¹, (1)Laboratoire de Psychopathologie et Processus de Santé, Université Paris Cité, Boulogne-Billancourt, Île-de-France, France, (2)Institut universitaire de France (IUF), Paris, Île-de-France, France, (3)Laboratoire Cognition Humaines et Artificielles, CY Cergy Paris Université, Cergy, Île-de-France, France, (4)Laboratoire de Psychologie et d'Ergonomie Appliquées, Université Paris Cité et Université Gustave Eiffel, Boulogne-Billancourt, Île-de-France, France

Background: The teaching profession is particularly vulnerable to stress and burnout, with over 50% of teachers in France reporting these issues. Burnout manifests through emotional exhaustion, depersonalization, and reduced personal accomplishment. Various factors contribute to its development, as explained by Bruchon-Schweitzer and Boujut's transactional and integrative model, which emphasizes the interplay of personal antecedents, dispositional variables, and transactional processes between the individual and their environment. Understanding these interactions is crucial, especially as burnout often arises when teachers perceive stress without adequate coping mechanisms. The factors influencing teacher burnout can be classified into four categories: socio-demographic factors, aspects of the professional and organizational environment, personal characteristics of the teacher, and student-related factors. Understanding the dynamics that affect teachers' well-being is essential, as it directly impacts student welfare. In France, the school enrollment rate for children with neurodevelopmental disorders has risen due to legislation aimed at promoting inclusion. This requires teachers to adapt their methods for students with special needs, potentially increasing their stress and risk of burnout.

Objectives: The study aimed to 1) assess the risk of burnout among mainstream teachers in France and 2) identify predictors of burnout in these teachers. The investigation focused on variables such as teachers' socio-demographic characteristics, work context, individual psychological variables and the characteristics of their students, particularly emphasizing the presence of at least one pupil with autism or with attention deficit hyperactivity disorder (ADHD).

Methods: A sample of 347 French mainstream teachers took part in the study: 214 teachers without students with disabilities, 69 with at least one student with autism, and 64 with at least one student with ADHD. Participants completed a questionnaire that included standardized scales (assessing perceived stress, generalized self-efficacy, perceived social support, coping strategies and burnout) along with questions about their socio-demographic characteristics and working conditions. Multiple linear regressions were conducted to analyze the predictive effects of socio-demographic characteristics, dimensions of perceived stress, generalized self-efficacy, dimensions of perceived social support and coping strategies on each of the three burnout dimensions.

Results: The results indicated a high prevalence of burnout among all teachers (whether or not they have a student with autism or ADHD), with 46.4% of the total sample displaying at least one dimension of high burnout. Negative predictors identified included perceived stress as a threat, low self-efficacy, low perceived social support, emotion-focused coping strategies, being female, having low seniority, and teaching in primary education. Notably, having a student with autism or ADHD did not emerge as a predictor of teacher burnout; rather, it served as a protective factor for those with ADHD.

Conclusions: The findings underscore the urgent need for public policy interventions to address teacher burnout in France. Our findings suggest that neither student's autism nor student's ADHD were predictors of burnout among French teachers, highlighting the success of inclusion policies in France. Nevertheless, these results put in light the need for better support in stress management and social support strategies to address the high overall prevalence of burnout among teachers working with students with special needs.

415.306 Does Formal Training Matter? How Training in Manualized Programs Impact Interdisciplinary School Provider Attitudes Toward Evidence-Based Practice

C. Middleton¹, A. Losh¹, L. Hayutin¹, L. DeVries², S. Nickles³, K. Pickard⁴, L. G. Klinger⁵ and J. Reaven⁶, (1)University of Colorado Anschutz Medical Campus, Aurora, CO, (2)University of Colorado School of Medicine, Aurora, CO, (3)CU Anschutz, Denver, CO, (4)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (5)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (6)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Anxiety is common in autistic students and disrupts daily and school functioning (Adams et al., 2019). Schools may be the ideal setting for addressing anxiety and emotion dysregulation in students (Zablotsky et al., 2015). While there are commercially available school-based manualized programs for anxiety, it is unclear whether providers receive formal training in these interventions and/or how much they are implemented. Lack of training may limit program delivery and reduce intervention fidelity, negatively impacting student outcomes (Kern et al., 2017). There is some evidence that provider attitudes play a critical role in training participation and EBP use (e.g., Locke et al., 2019) and may lead to better implementation and delivery (Barnett et al., 2018); however, it is unclear how these factors impact EBP use within the context of school mental health services for autistic youth.

Objectives: (1): To understand whether interdisciplinary school providers (ISPs; e.g., counselors, special educators) receive formal training in manualized programs for anxiety and emotion dysregulation and assess the frequency of specific program usage. It is hypothesized that most ISPs will not have received formal training in manualized programs, but may still have high rates of use. (2): To understand whether provider attitudes toward EBPs relate to their training in and use of manualized programs. We hypothesize that having formal training in any program will be related to more favorable attitudes toward EBPs overall.

Methods: Elementary and middle school ISPs (N=129) were enrolled in an ongoing cluster, randomized comparative effectiveness trial of two school-based anxiety interventions, *Zones of Regulation (ZOR)* and *Facing Your Fears in School (FYF-S)* for autistic students (Table 1). At baseline, ISPs reported prior formal training in and current use of popular manualized school-based programs, and the Evidence-Based Practice Attitudes Scale (EBPAS; 2004). Frequency of formal training in and use of manualized programs was determined. An independent samples t-test was used to compare total scores on the EBPAS between ISPs with any formal training and those without.

Results: Formal training in and use of programs are reported in Figure 1. ISPs reported receiving formal training in and using ZOR and Social Thinking most frequently. ISPs were least likely to have training in or to use MATCH-ADTC. For all programs except MATCH-ADTC, more ISPs used the program regardless of whether they received formal training. ISPs who reported receiving *any* formal training had significantly more positive attitudes about evidence-based practice use ($m=49.9$; $SD=5.8$) than ISPs with no formal training ($m=47.3$; $SD=7.1$): $t(110)=2.0$, $p<.05$).

Conclusions: Results indicated that ISPs often use manualized programs without formal training. They receive the most formal training in ZOR and Social Thinking and use them most often. ISPs with formal training held more positive attitudes toward EBPs, suggesting formal training may be linked to willingness to learn new programs. Alternatively, ISPs with more positive EBP attitudes may be more likely to seek formal trainings. Further research is needed to examine the directionality of this relationship and how formal training relates to other implementation variables, such as intervention fidelity.

**415.307 Does Inclusion Promote Postsecondary Success? a Study of Autistic High School Leavers**

E. Kim¹ and C. Kasari², (1)UCLA, Los Angeles, CA, (2)Education and Psychiatry, University of California Los Angeles, Los Angeles, CA

Background: Autistic high school graduates have been less likely to prepare for college in high school compared to their neurotypical peers (Longtin, 2014). Recent initiatives to improve college attendance among this group have led to a significant increase in rates of autistic young adults enrolling in college (Bakker et al., 2019). Factors such as academic performance, parents' expectations, high school type, and annual household income have all been identified as significant predictors of participation in postsecondary education (Chiang et al., 2011). While previous studies have highlighted the benefits of high school inclusion for postsecondary outcomes for those with learning disabilities or emotional disabilities (Rojewski et al., 2013), little is known regarding autistic high school graduates.

Objectives: To close the research gap, this study examines whether time spent in general education predicts autistic high school graduates' enrollment in post-secondary education.

Methods: This study used longitudinal administrative record data (2005-2018: pre-pandemic) from a large urban school district in the southwest United States. For this study, out of 140,947 with primary eligibility of autism, we selected a total of 932 participants, excluding those that had missing values. Participants were ages 14-22, predominantly male (82.94%), low-income (53.43%), and racially and ethnically diverse (54% Hispanic, 20% White, 11% African American, 8% Asian, and 6% other.). Logistic regression analysis was conducted.

Results: The logistic regression analysis revealed a significant intercept ($B = -2.64$, $SE = 0.47$, $z = -5.64$, $p < 0.001$), indicating that the log odds of attending college significantly differed from zero when controlling for participants' gender, English language learner, ethnicity, and household income. Time spent in general education (GE) was a significant predictor of college attendance ($B = 1.54$, $SE = 0.29$, $z = 5.33$, $p < 0.001$), with the odds of attending college increasing by 4.65 times for each additional unit of GE ($OR = 4.65$, 95% CI [2.64, 8.21], $p < 0.001$). Following the time spent in GE, participation in GE curriculum also significantly predicted college attendance ($B = 2.54$, $SE = 0.22$, $z = 11.52$, $p < 0.001$), with the odds of attending college increasing by 12.63 times compared to students in the alternative curriculum ($OR = 12.63$, 95% CI [8.29, 19.69], $p < 0.001$).

Conclusions: The results demonstrate that spending more time in GE and participating in GE curriculum significantly predict post-secondary education involvement for autistic high school graduates, aligning with previous research that highlights academic performance as a significant predictor of college attendance for autistic high school leavers (Chiang et al., 2011). While this study does not account directly for the participants' academic performance, prior research suggests that autistic students who were included in GE had better academic achievement compared to those in self-contained classrooms (Kurth & Mastergeorge, 2010). Limitations were: there were many participants that the school could not reach, and we did not have IQ scores of participants, which in the past have shown an association with their educational placement. Future studies on the influence of inclusion in long-term outcomes are needed.

415.308 Effects of an Internet-Delivered Psychosocial Program for Parents of Children with Autism and ADHD: A Randomized Controlled Trial

C. Berenguer¹, A. B. Salamanca², M. C. Santamarina-Siurana³ and I. Fortea⁴, (1)Developmental Psychology and Education, Universitat de València (VAT ESQ4618001D), Valencia, Spain, (2)University of Valencia, Valencia, Spain, (3)Universidad Politécnica de Valencia, Valencia, Spain, (4)Catholic University of Valencia, Valencia, Spain

Background:

Recent research indicates that psychosocial interventions incorporating psychoeducation and cognitive-behavioral training for parents can effectively manage children with autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) (Young et al., 2020). These interventions empower parents to regulate their children's behavior, positioning caregivers as agents of change. However, traditional interventions often face limitations, such as non-randomized study designs and accessibility barriers for families (Tan-McNeill et al., 2021). In-person formats can pose logistical challenges, particularly for families in rural areas or those struggling with work-life balance, which restricts access to evidence-based treatments. Despite the proven benefits of structured interventions, many children with ASD, ADHD, or both still lack access to these essential psychosocial supports (Danielson et al., 2018).

Objectives: This study aimed to assess the effects of an internet-delivered psychosocial program on parenting stress, coping strategies, and the social-behavioral outcomes of children with ASD and ADHD.

Methods: Parents of children aged 7 to 11 years with ASD and ADHD were randomly assigned in a 1:1 ratio to either the Psychosocial Program group (n=42) or a Control group (n=40). The psychosocial program was delivered remotely online. Parent-reported measures of parenting stress, coping strategies, and children's social behavioral problems were assessed at three time points: before the intervention (T1), immediately after the intervention (T2), and six months post-intervention (T3). Two-way mixed analysis of variance (ANOVA) was conducted with group (intervention vs. control) as the between-subjects factor and time (pre-, post-intervention, and follow-up) as the within-subjects factor.

Results:

Parents in the Psychosocial Program group reported significantly lower levels of parenting stress and higher positive coping strategies at T3 compared to the Control group. Additionally, improvements in child social behavioral problems were observed in the intervention group at T2 and T3.

Conclusions:

The findings suggest that this internet-delivered psychosocial program is a promising and accessible approach for empowering parents, reducing parenting stress, and enhancing coping strategies. The program may be particularly beneficial for families with limited access to traditional services, as it can be completed at home. Overall, the online psychosocial intervention for parents of children with ASD and ADHD appears to be an effective and accessible strategy for improving the well-being of both parents and their children.

415.309 Engaging Caregivers in Child Mental Health Services: An Exploration of Provider Strategies and Differences in Hispanic/Latinx Families

T. Holt¹, J. Lopez², R. Haine-Schlagel² and K. S. Dickson², (1)SDSU, San Diego, CA, (2)San Diego State University, San Diego, CA

Background: Caregivers play a critical role in their child's mental health therapy. Not only are caregivers facilitating access and attendance to services, meaningful engagement in their child's therapy session is a key component to their child's overall treatment (Haine-Schlagel et al., 2016). For some, socio-cultural factors may contribute to the caregiver's engagement in their child's therapy including, but not limited to, racial, ethnic, or language differences distinct from that of the provider and therapy setting. Research has shown that low-income and/or Hispanic/Latinx families, are more likely to have more limited engagement in their child's mental health treatment compared to their non-Hispanic/Latinx white counterparts (Haine-Schlagel et al., 2022; Dickson et al., 2017; Reyno & McGrath, 2006). Additionally, the quality of care can differ when there is a cultural mismatch between the caregiver and provider of the child's treatment (Kapke & Gerdes, 2016). This highlights the need to examine the use of mental health provider engagement strategies and gaps in caregiver participation to better support mental health services for Latinx autistic youth.

Objectives: Explore mental health provider use of parent engagement strategies in community-based child mental health services for autistic youth and examine differences in caregiver engagement based on ethnicity and cultural match with provider. Differences in therapist and caregiver engagement behaviors were examined by ethnicity and cultural match.

Methods: Data were drawn from a larger project testing an adapted version of an executive functioning intervention, *Unstuck and On Target* (*Unstuck*), for mental health settings. Therapist training of the adapted version of *Unstuck* included evidence-based parent engagement strategies (Haine-Schlagel et al., 2018). Community mental health providers (N=26, 88% female, 61% Non-Hispanic/Latinx White) were videorecorded providing psychotherapy to participating autistic clients and their caregivers (N=32, 90% female, 62% Hispanic/Latinx). Observational coding of a subset of recorded sessions were completed assessing therapist use engagement strategies along with the caregiver's in session attendance and participation in child's therapeutic activities using the established Therapist Alliance, Collaboration, and Empowerment and Parent Participation Engagement coding systems (Haine-Schlagel & Martinez; 2014a,b).

Results: Results from our multilevel analyses indicated significant differences in therapist use of engagement strategies (p 's <.05), with higher therapist use of alliance ($M_{\text{Hispanic/Latinx}}=2.69$, $M_{\text{Non-Hispanic/Latinx}}=1.39$) and attending to the feasibility of home action ($M_{\text{Hispanic/Latinx}}=1.03$, $M_{\text{Non-Hispanic/Latinx}}=2.10$) with Hispanic/Latinx versus Non-Hispanic/Latinx caregivers. Similarly, analyses indicated higher use of caregiver discussion of home action plans among Hispanic/Latinx ($M_{\text{Hispanic/Latinx}}=1.03$) versus Non-Hispanic/Latinx ($M_{\text{Non-Hispanic/Latinx}}=2.10$) caregivers, ($p<.05$). In contrast, Non-Hispanic/Latinx caregivers demonstrated significantly more participation in therapy activities ($M_{\text{Non-Hispanic/Latinx}}=3.47$) compared to Hispanic/Latinx caregivers ($M_{\text{Hispanic/Latinx}}=2.12$; $p<.05$). Further analyses exploring further caregiver and therapist demographic factors as well as differences by treatment condition will also be examined.

Conclusions: Overall and in contrast to prior literature, results indicate higher therapist use of engagement strategies and some higher caregiver engagement behavior, particularly around home-action planning. However, non-Hispanic/Latinx caregivers demonstrated overall higher participation in therapeutic activities, which is consistent with prior work in this area. Findings point to key areas for further efforts to develop and target strategies to support successful engagement of Hispanic/Latinx families in mental health services.

415.310 Engaging Neurodivergent Learners through Gamified Quiz Platforms: An Approach to Inclusive Education

K. Hamad¹, K. Chapman² and X. Page², (1)Brigham Young University, Provo, UT, (2)Computer Science, Brigham Young University, Provo, UT

Background: Tests are subject to being biased due to factors like increased anxiety and boredom (Meijer, 2007; Goetz, 2023). These difficulties may be even more severe for autistic individuals who have an increased likelihood of anxiety (White, 2009). As such, it could be highly beneficial to find nontraditional mechanisms for test-taking that encourage student participation. Prior work with neurotypical students has identified that gamification may motivate and improve understanding of educational materials (Borges, Durelli, Reis, & Isotani, 2014). While the majority of previous work on gamification has studied neurotypical individuals, newer work has similarly shown that autistic individuals are also more inclined to focus on study material when it is gamified. (Rodríguez Jiménez & Ramos Navas-Parejo, 2019).

Objectives: To determine whether gamified quizzes can improve engagement and thus measured learning outcomes for autistic young adults.

Methods: We piloted the use of competitive, gamified quizzes to test knowledge. The gamified quizzes allow students to earn points based on a combination of correctness and speed. 8 autistic young adults (ages 18-29) with level 2 support needs (1 with and 7 without intellectual disabilities) participated in these quizzes to test their knowledge in context of a social media literacy course. This was done for various concepts during several hour-long educational sessions. Participants could also select which character to use for their player icon and a leaderboard displayed the character of the leading student. All participants were classmates from the previous semester and were starting their second semester at their residential program. We audio recorded and analyzed student's utterances during the gamified quiz.

Prior to the INSAR, we will deploy a full study for a 14-week long full social media literacy course. A new set of students will be recruited from the residential facility and divided into two classes of 8 students each. One class will use the traditional quiz format for their knowledge tests of social media literacy, while the other class will use the gamified quiz format. To evaluate whether students perform better with the gamified quiz, we will compare pre- and post- test improvement between the two classes using the Wilcoxon Signed-Rank test. To compare whether the gamified quiz led to significantly better scores, we will use the Mann-Whitney U test.

Results: Preliminary findings indicate that utilizing gamification results in greater improvement in knowledge test scores. Qualitative insights suggest that a reason for this improvement is because students were more excited about the competitive aspect of the gamified version. For example, when students did well, they would often share that with other students, "I was on fire." We are still running this study and will report the full results at the conference.

Conclusions: Our initial results indicate that gamification can be a beneficial educational tool for measuring knowledge with autistic young adults who know one another. This work suggests another way educators can motivate their emerging adults to take knowledge tests in an educational setting.

415.311 Enhancing Executive Functioning: Online Caregiver Training and a Project Extension for Community Healthcare Outcomes-Based Maintenance Program

D. J. Magin¹, K. N. Drapalik², H. W. Kent³, M. Rinaldi² and K. V. Christodulu², (1)Center for Autism and Related Disabilities/University at Albany, Albany, NY, (2)Center for Autism and Related Disabilities/University at Albany, Albany, NY, (3)Center for Autism and Related Disabilities-University at Albany, Albany, NY

Background:

Executive function-related challenges are common in autistic children and adolescents (Pellicano, 2012). Parent-mediated interventions are an evidence-based practice used to provide caregivers the tools to best support their children (Tarver et al., 2019). Recent research has shown promising results in using this technique in an online format to teach parents skills to aid their children's executive functioning differences (Kenworthy et al., 2023). Further research in the parent training literature indicates the potential long-term benefit of "booster sessions" in maintaining the skills learned in parent-mediated interventions (Van Kamp et al., 2008).

Objectives:

- 1) The first study seeks to provide additional support for the online *e-Unstuck and on Target* program combined with a weekly, telehealth group parent coaching session (Kenworthy et al., 2014, 2018).
- 2) The second study seeks to examine preliminary acceptability data related to an extension of this program for previous participants, designed to facilitate maintenance and generalization of skills learned using the Project Extension for Community Healthcare Outcomes (Project ECHO) model (Arora et al., 2016).

Methods:

STUDY 1: 73 parents of children and adolescents age 5-14 ($M = 9.37$, $SD = 2.64$) with ASD were randomly assigned to either a waitlist control ($N = 38$) or a training and coaching group ($N = 35$). Parents in the parent coaching group were asked to complete one module, weekly, of the *e-Unstuck and On Target* parent training program over the course of 9 weeks, while the waitlist control group completed these modules following their 9-week waiting period. The *Behavior Rating Inventory of Executive Function- Second Edition (BRIEF-2)* (Gioia et al., 2015) was completed pre- and post-program participation as well as before and after the waitlist time period.

STUDY 2: Previous participants in the *e-Unstuck and On Target* program were invited to participate in a four-part series of hour-long trainings using the Project ECHO framework as a maintenance tool for executive-functioning related parenting skills. Preliminary qualitative and quantitative acceptability data were analyzed.

Results:

STUDY 1: An independent sample t-test was conducted comparing change scores on the *BRIEF-2* Global Executive Composite between the waitlist control group and the parent coaching group. Results revealed no significant differences between the BRIEF-2 scores in the waitlist and the parent coaching group ($p > .05$).

STUDY 2: Preliminary program satisfaction data found that 89% of participants either agreed or strongly agreed with the statements, "I and/or my child benefitted from the program", and, "this program helped me more effectively support my child's executive functioning."

Conclusions:

There were no differences between the parent coaching group and waitlist groups in parent-reported executive functioning outcome data, indicating that the program did not significantly improve child executive functioning relative to the waitlist control. High satisfaction ratings of the Project ECHO-based extension of the program indicate that this add-on maintenance program was acceptable for previous participants in the program. Future studies should evaluate whether participants in this maintenance program experience improvement in their child's executive functioning to assess for the delayed impact of the skills learned in the program.

415.312 Enhancing Sexual and Reproductive Health Support for Adolescents with Autism Spectrum Disorder in Ethiopia: A Culturally Tailored Multi-Intervention Model

E. Damtew Asfaw¹, W. A. Zeleke² and K. Tumoro Petros³, (1)Joy Center For children with Autism, Nia Foundation, Addis Ababa, Addis Ababa, Ethiopia, (2)Counseling, Psychology and Special Education, Virginia Commonwealth University, Pittsburgh, PA, (3)Joy Center for Children with Autism, Nia Foundation, Addis Ababa, Addis Ababa, Ethiopia

Background: The Joy Center for Children with Autism, a pioneering organization established in 2002 in Ethiopia, has been dedicated to providing interventions for children with autism and supporting their families in Ethiopia. As one of the first centers of its kind in the country, the Joy Center developed culturally responsive strategies to address the unique needs of autistic youth, particularly in the area of sexual and reproductive health (SRH). Adolescents with autism spectrum experience typical sexual development, but their understanding and expression of sexual feelings can differ significantly from their neurotypical peers due to challenges in social comprehension, sensory processing, and emotional regulation. At the Joy Center, these differences manifest in behaviors such as public displays of sexuality, difficulties in interpreting social cues, and heightened vulnerability to exploitation, posing unique challenges for caregivers and educators. This presentation will share the results of culturally sensitive multi-model interventions to address these complex SRH needs, showcasing our approach within the Ethiopian context.

Objectives: This presentation will discuss our experiences and outcomes of a comprehensive multi-tiered intervention addressing the SRH needs of autistic adolescents. Participants will acquire practical insights into implementing similar interventions tailored to the social, cultural, and developmental requirements of autistic youth.

Methods: We implemented a multifaceted culturally responsive intervention encompassing the following:

- **Development of SRH Knowledge Materials:** Customized training manuals for educators, parents, and health professionals were developed to address the specific SRH needs of adolescents with ASD.
- **Training Programs:** Comprehensive training sessions were conducted for parents, educators, and healthcare providers, focusing on ASD-specific SRH education and a Specialized SRH
- **Education Room:** A sensory-friendly environment equipped with visual aids, anatomical models, and audiovisual resources was established to facilitate SRH learning in a structured and sensory-appropriate setting.
- **Coordinated Clinical Support:** Clinical teams collaborated to manage behavioral instability and address hyperactive sexual behaviors through targeted medical and behavioral interventions.
- **Data was collected through monthly community discussions—"Saturday Coffee Mornings"—conducted over one year with 60-100 participants, including parents, educators, caregivers, and staff. The recorded discussions and facilitator notes were analyzed using content analysis, providing valuable insights into the program's effectiveness from a community perspective.**

Results: Preliminary findings from our initiative demonstrate notable improvements in caregivers' and professionals' understanding of the SRH needs of adolescents with autism. The sensory-friendly SRH education room effectively reduced inappropriate behaviors and increased student engagement. The training programs empowered caregivers and educators with practical skills, whereas media outreach raised societal awareness and fostered greater empathy around the SRH challenges faced by autistic youth.

Conclusions: This presentation offers a roadmap for supporting youth with autism in their sexual and reproductive health needs, stressing cultural sensitivity, caregiver empowerment, and sensory-friendly resources. Attendees will gain a practical, adaptable model emphasizing cultural sensitivity and community involvement to support the SRH needs of autistic youths. This approach underscores that, even in low-resource settings, structured interventions can significantly enhance the well-being and social inclusion of neurodivergent youth.

415.313 Evaluating How Interdisciplinary School Providers Preliminarily Deliver and Adapt Two Manualized Programs Rooted in Cognitive Behavior Therapy (CBT) for Autistic Students with Anxiety

N. Islam¹, S. Valladares Ortiz², L. G. Klinger³, J. Reaven⁴ and K. Pickard⁵, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (4)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

Background:

Implementing cognitive behavior therapy programs (CBT) in schools may increase access to mental health services for autistic children (Reaven et al., 2024). Although a growing body of research is evaluating the effectiveness of CBT when delivered in schools, less is known about how well these programs are implemented and whether they are adapted within schools. The current study sought to address this gap as part of a comparative effectiveness trial evaluating two CBT programs implemented in elementary and middle schools, Facing Your Fears in Schools (FYF-S) and Zones of Regulation (ZOR).

Objectives:

- Evaluate Interdisciplinary School Providers' (ISPs) fidelity and adherence to FYF-S and ZOR.
- Explore how ISPs adapt FYF-S and ZOR during implementation.

Methods:

This study includes preliminary data from 56 ISPs across 26 school teams who were randomized to deliver FYF-S or ZOR to anxious autistic students ages 8-14 years. Sixteen school teams comprising of 36 ISPs were trained in FYF-S, and 10 school teams comprising of 20 ISPs were trained in ZOR. ISPs across both conditions submitted recordings from 322 FYF-S or ZOR sessions. Fidelity was scored by trained raters for 132 sessions using program-specific tools. Fidelity scoring accounted for adherence to specific program activities (i.e., percent of activities completed), in addition to the quality of program activities rated on a 5-point Likert scale (i.e., fidelity). Additionally, scored sessions were rated for the presence of adaptations based on the Framework for Reporting Adaptations and Modifications, Expanded (FRAME). Descriptive statistics were used to summarize adherence, fidelity, and adaptations across FYF-S and ZOR, along with average number of lessons completed and average duration of lessons.

Results:

Schools assigned to FYF-S completed an average of 11/ 12 lessons, where each lesson was M=40.71 minutes; Schools assigned to ZOR completed an average of 15/ 18 lessons where lessons were M=29.71 minutes. Schools across both interventions adhered to core components similarly with FYF-S at M=75.09% and ZOR at M=73.55%. Similarly, school teams' average FYF-S fidelity was 72.21% and was 71.72% for ZOR. However, for FYF-S specifically, fidelity was notably higher for psychoeducation-based lessons (M=76.41%) in comparison to exposure-based sessions (M=66.33%). Regarding adaptations, FYF-S teams split lessons across group sessions 16 times whereas ZOR teams only did once. In contrast, ZOR teams were more likely to combine ZOR lessons and did so a total of 12 times, where FYF-S schools combined lessons only once.

Conclusions:

Preliminary data indicates similar FYF-S and ZOR adherence and fidelity when delivered to anxious autistic students within schools. Despite some differences in session length, autistic students appeared to receive similar intervention quality regardless of study condition. However, results highlighted more prominent differences in the adaptations made by ISPs across the programs. Findings also suggest that FYF-S may become more difficult to deliver as the lessons change from psychoeducation to exposure and may indicate that ISPs need more support delivering graded exposure within school settings. Future research will evaluate predictors of FYF-S and ZOR fidelity and will evaluate the relationship between program fidelity and student outcomes.

415.314 Evaluating Student Profiles at an Autism Summer Treatment Program: Analysis of Stress and Belongingness

N. Cristallo¹, L. Allen², J. Marlhoury A Canafuego² and A. Matlack¹, (1)School Psychology, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA

Background:

A sense of belongingness describes an individual's feeling that they are respected and accepted by others in a particular environment based on shared experiences and beliefs (Mahar et al., 2013). A strong sense of belongingness is a human need and plays a role in healthy development and is associated with higher subjective well-being for youth (Afroz & Tiwari, 2021). Conversely, a sense of thwarted belongingness for children is associated with negative mental health outcomes including higher rates of anxiety (Timmons et al., 2011). Research has shown that autistic youth feel higher rates of anxiety and lower rates of belongingness than their allistic peers (VanderBroek Stice, L., Lavner, J.A., 2018). Little research has explored interventions to increase perceived belongingness in autistic youth. Similarly, reported anxiety is higher in autistic youth than typically developing populations and research shows that direct intervention is a useful tool to provide autistic youth with coping strategies for anxiety (Sohmaran & Shorey, 2019).

Objectives:

1. Evaluate the effects of a summer treatment program on child-perceived belongingness and anxiety.
2. Explore the relationship between belongingness and anxiety.
3. Evaluate parent concerns with observable camper behavior to create camper behavior profiles (internalizing vs. externalizing).

Methods:

This study evaluated 23 participants between 7-13 ($M=9.81$, $SD=2.69$) with a diagnosis of autism at a summer treatment program (STP). The STP's activities were based on Cognitive Behavior Therapy (CBT) and Applied Behavior Analysis (ABA). Over 4 weeks, participants engaged in intervention to develop social and emotional regulation skills. Caregivers received training around social-emotional health and behavioral interventions to generalize impact at home. Data collection happened weekly and was overseen by research staff.

Repeated measures ANOVAs were conducted to analyze mean score improvement on the Screener for Child Anxiety Related Disorders (SCARED) and Sense of Social Fit Scale (SSFS). Pearson correlations analyzed the relationship between belongingness and stress. Qualitative data was taken from parents and observed participant behavior to analyze who exhibited more internalizing or externalizing behaviors. Pearson's correlations were conducted to evaluate the relationship between externalizing and internalizing behaviors and stress and belongingness.

Results:

One Way ANOVA results indicated that camper anxiety] fell over the course of the STP ($F(2,50)=6.12$, $p<0.05$). Campers reported increases in belongingness, however, these increases were not statistically significant ($F(2,50)=1.47$, $p=.239$). Anxiety and belongingness were not significantly correlated ($r^2=.05$, $p=0.61$). However, anxiety was correlated with age such that older campers felt more anxiety ($r^2=0.23$, $p=0.04$). Caregiver data suggests that concerns were primarily challenging behavior (i.e. physical aggression) and social skills training.

Conclusions:

Results indicate that participation in a STP can reduce stress reported by autistic youth and marginally increase perceived belongingness. Parent reports and staff observations reveal that autistic youth with more internalizing behaviors were at risk for more anxiety and less perceived belongingness. Exploratory analyses showed that participants felt less stress the longer they participated in the STP. Results should be replicated with a larger sample over a longer period of time and should evaluate the long term effects of STPs on stress and belongingness.

415.315 Evaluating the Feasibility, Safety, Efficacy, and Neural Correlates of Accelerated Continuous Theta-Burst Stimulation Targeting the Left Primary Motor Cortex to Improve Social Communication Impairment in Autistic Children: An Open-Label Trial
H. Tan¹, T. Ren², M. Xu³, L. Deng⁴, C. Miao⁵ and F. Li⁶, (1)Developmental and Behavioral Pediatric Department & Child Primary Care Department, Brain and Behavioral Research Unit of Shanghai Institute for Pediatric Research and MOE Shanghai Key Laboratory for Children's Environmental Health, Xinhua Hospital, Shanghai, Shanghai, (2)Developmental and Behavioral Pediatric Department & Child Primary Care Department, Brain and Behavioral Research Unit of Shanghai Institute for Pediatric Research and MOE Shanghai Key Laboratory for Children's Environmental Health, Xinhua Hospital, Shanghai, Shanghai, China, (3)Shanghai Jiaotong University School of Medicine Xinhua Hospital, Shanghai, Shanghai, China, (4)Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, Shanghai, China, (5)Institute of Science and Technology for Brain-Inspired Intelligence, Fudan University, Shanghai, Shanghai, (6)Developmental and Behavioral Pediatric Department & Child Primary Care Department, Brain and Behavioral Research Unit of Shanghai Institute for Pediatric Research and MOE Shanghai Key Laboratory for Children's Environmental Health, Shanghai, Shanghai, China

Background:

Social communication impairment is a core symptom of autism spectrum disorder (ASD) for which there is currently no effective treatment. Repetitive transcranial magnetic stimulation (rTMS) is a promising intervention, but no effective protocol has been validated.

Objectives:

This study investigated the feasibility, safety, efficacy, and neural correlates of accelerated continuous theta-burst stimulation (a-cTBS) over the left primary motor cortex (M1) in autistic children.

Methods:

The a-cTBS intervention consisted of 10 sessions per day for 5 consecutive days. We estimated the average treatment effect by comparing 1-month changes in Social Responsiveness Scale (SRS) scores between the single-arm trial (N=25) and historic controls (N=24) using mixed-effect models, with potential confounders handled using inverse probability of treatment weighting (IPTW). Electroencephalogram (EEG) data were collected before and immediately after treatment to estimate power spectral density (PSD) of each channel. Single-word comprehension was measured by the Peabody Picture Vocabulary Test (PPVT) before the treatment and at 1-month follow-up.

Results:

All participants completed the full course of the intervention and adhered to the 1-month follow-up. The a-cTBS treatment was associated with a reduction of 17.4 points (IPTW-weighted β , 95% CI, -20.1 to -15.0; $P<.001$) in SRS total scores within one month compared to historic controls. An increase in alpha PSD of the right parieto-occipital region immediately after the intervention was associated with changes in SRS scores within the same period and predictive of changes in SRS scores at the 1-month follow-up ($P=0.041$). A greater responsiveness in 1-month changes in SRS showed a trend toward the increase in single-word comprehension scores (adjusted β for PPVT IQ, -0.23, 95% CI, -0.52 to 0.06, $P=0.110$). Thirty-three percent of participants reported mild adverse events that resolved spontaneously.

Conclusions:

The proposed a-cTBS protocol was feasible, safe, and showed promise in treating social communication impairment in autistic children. Further randomized trials are needed to validate its clinical efficacy.

415.316 Evaluating the Impact of Toastmasters® for Autistic Adults: A Mixed-Methods Approach and Pilot Study

Y. Bolourian¹ and **S. M. Zeedyk²**, (1)UCLA Tarjan Center, University Center for Excellence in Developmental Disabilities, Los Angeles, CA, (2)Child and Adolescent Development, California State University, Fullerton, Fullerton, CA

Background: Autistic adults often experience social and communication challenges that can hinder their personal and professional development. Programs are needed to build upon the strengths of autistic people and limit the pressure to camouflage their true selves. Community-based programs like Toastmasters®, a widely recognized and respected global public speaking and leadership development program, may provide structured environments for improving these skills, but little research has been done on their specific outcomes for autistic individuals. This two-phase study investigated the meaningfulness of Toastmasters® for autistic adults, with stakeholder insights from phase 1 and a pilot study in phase 2.

Objectives: In phase 1, we aimed to identify contextual factors that influence outcomes for autistic participants in Toastmasters® and assessed the program's feasibility, including participant satisfaction, perceived benefits, and the acceptability of procedures. In phase 2, the pilot study aimed to evaluate the program's effectiveness in improving communication skills, self-confidence, and social functioning.

Methods: In phase 1, semi-structured interviews were conducted with 22 autistic Toastmasters® participants and 11 caregivers or Toastmasters® mentors. The majority of autistic participants identified as White (59%), male (68%), and between the ages of 25 and 44. Caregivers and mentors were predominantly White (91%), female (81%) and over the age of 55. Thematic content analysis identified key themes regarding the program's impact. Quantitative data were also collected on participants' involvement, including the number of clubs attended, duration of participation, and time commitment. Phase 2 involved a waitlist-controlled pilot trial with 18 new autistic participants completing a 10-week Toastmasters® program and 14 mentors. Autistic participants predominantly identified as White (44%) or Asian (28%), male (56%), and between the ages of 18 and 34. Mentors largely identified as White (50%) or Asian (29%), female (64%), and between the ages of 45 and 74. Pre-post measures were collected on comfort with public speaking, leadership skills, peer relationships, and camouflaging behaviors. Social validity of the program was also assessed from autistic participants' and mentors' perspectives.

Results: From phase 1, key themes included perceived improvements in public speaking and communication, self-confidence, leadership, and sense of community. Unexpected benefits, such as improvements in daily living skills, mental health, and social connections, were also reported. Challenges related to program logistics and feedback processes were noted, indicating a need for further exploration of autism-specific accommodations within Toastmasters®. Pilot data from phase 2 are currently undergoing scoring and analysis, which will be completed by the end of 2024.

Conclusions: Findings from phase 1 of the study suggest that Toastmasters® may be a valuable, community-based program for enhancing social, communication, and personal development among autistic adults. While the program offers significant benefits, adjustments such as tailored feedback and increased mentorship, could enhance its effectiveness. Phase 2 of the study, a pilot trial of autistic adults new to Toastmasters®, further explores these findings, focusing on measurable improvements in key areas and program adaptations.

415.317 Examining Mental Health and Non-Mental Health School Providers' Training in and Use of Cognitive Behavior Therapy Programs for Autistic Students

S. Valladares Ortiz¹, **N. Islam²**, **R. E. Boles³**, **J. Reaven⁴**, **L. G. Klinger⁵** and **K. Pickard⁶**, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (3)University of Colorado Anschutz Medical Campus, Aurora, CO, (4)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (6)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

Background: Cognitive Behavioral Therapy (CBT) has been shown to be effective when delivered to anxious autistic students within public schools (Perihan et al., 2020; 2022; Reaven et al., 2023). When provided resources, school providers with different training levels and experiences can identify students for CBT (Choi et al., 2022) and deliver CBT effectively. However, it remains unclear whether school providers' discipline and experience shapes their use of CBT for autistic students. This study addresses this gap by examining differences in use of CBT-based manualized programs for autistic students across interdisciplinary school providers (ISPs) from mental health (MH), including school psychologists, social workers, and school counselors, and non-mental health (NMH) backgrounds, including special educators, speech-language pathologists, and occupational therapists.

Objectives: This study aims to: 1) examine ISPs baseline experience with various manualized programs for anxiety and emotion regulation (e.g., Coping Cat, BrainWise, Facing Your Fears, Zones of Regulation); and 2) explore differences in training and use of these programs for autistic children between MH and NMH school providers.

Methods: This study was conducted as part of an ongoing comparative effectiveness trial of two school-based programs for autistic students. Baseline data was collected from 147 ISPs from MH and NMH backgrounds. Information regarding age, race, ethnicity, and gender was obtained as well as ISP work experience and professional background. Manualized program use was measured via a survey where ISPs indicated previous training in programs based on CBT principles for anxiety and emotion regulation and reported how frequently they used each of these programs. Independent t-tests were used to analyze program use, training, and frequency by ISP discipline. Pearson's correlation analyses were used to assess the relationship between ISP professional experience and their experience working with autistic youth in schools.

Results: There were significant differences found between MH and NMH ISPs in their experience with manualized programs. MH ISPs reported greater use of these programs ($M = 2.63$, $SD = 1.87$) than NMH ISPs, ($M = 1.27$, $SD = .98$) : $t(102) = 5.39$, $p < .001$, and more training in manualized programs ($M = 1.16$, $SD = 1.35$) compared to NMH ISPs, ($M = .63$, $SD = 1.24$) $t(137) = 2.42$, $p = .017$. Furthermore, MH ISPs reported using manualized programs more frequently ($M = 8.28$, $SD = 2.92$) than NMH ISPs, ($M = 7.1$, $SD = 1.95$) : $t(115) = 2.63$, $p = .010$. ISP's years of experience addressing emotional regulation or anxiety in general or special education was highly correlated with the number of years they reported working with autistic youth in schools, $r(136) = .93$, $p < .001$.

Conclusions: Overall, baseline data reveals that ISPs from MH backgrounds have greater experience with programs rooted in CBT principles than ISPs from NMH backgrounds. Given the known effectiveness of CBT programs for autistic students, this study emphasizes the need to bridge the gap between MH and NMH ISP's manualized school-based program use and training in schools. Future work can be done to ensure that NMH staff are provided with training in school-based manualized programs for anxiety to support anxious autistic students.

415.318 Examining the Relationship between Parenting Practices and Child Adaptive Behaviors

N. Bahri¹, L. L. McIntyre² and C. L. Neece³, (1)Loma Linda University, Loma Linda, CA, (2)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (3)Psychology, Loma Linda University, Loma Linda, CA

Background:

Research indicates that autistic individuals typically exhibit lower adaptive skills than both their typically developing and developmentally delayed peers (Klin et al., 2007; Franchini et al., 2018). Adaptive skills, defined as learned behaviors, are positively influenced by parenting practices such as sustained maternal responsiveness and authoritative approaches (Ghotbzadeh & Shakerinia, 2015; Warren et al., 2017; Balboni et al., 2020). Conversely, permissive and authoritarian styles are negatively associated with adaptive skills (Ghotbzadeh & Shakerinia, 2015). Given that early adaptive skills predict later outcomes (Bal et al., 2015), understanding the role of parenting behaviors is crucial for guiding interventions for autistic individuals.

Objectives:

We seek to determine whether 1) positive parenting behaviors improve pre- to post- participation in behavioral parent training (BPT) and 2) positive parenting behaviors are associated with adaptive behaviors.

Methods:

Participants included 88 children (61.7% male, M age = 4.48 years, SD = 1.01; 53.4% Hispanic/Latino) and their parents. Adaptive skills and parenting behaviors were collected prior to intervention (Time 1; T1). Between these two time points, parents participated in a BPT intervention. Parenting behaviors were assessed immediately after the intervention (Time 2; T2), while adaptive skills were collected at a follow-up point that varied across participants. Adaptive skills (daily living skills, socialization and communication) were assessed using the Vineland Adaptive Behavior Scales – Third Edition (VABS-III; Sparrow, Cicchetti, & Saulnier, 2016). Parenting behaviors were measured through the Parent-Child Behavior Observation System (PC-BOS; Phaneuf & McIntyre, 2007), which records behaviors during free-play, clean-up, and structured tasks in 30-second intervals. Behaviors coded included intrusion, inappropriate commands, lack of follow-through, and praise, with codes across tasks combined to create composite variables.

Results:

Paired samples t-test indicated significant improvements from T1 to T2 in positive parenting behaviors, daily living skills, and socialization, but not in communication (see Table 1). Correlational analyses were conducted to assess the relationships between baseline parenting behaviors and adaptive behaviors at T1 and T2 (see Table 2). Results revealed that baseline parent intrusive behaviors were negatively correlated with child communication and daily living skills at T1 and T2. Lack of follow-through was negatively correlated with T1 and T2 communication and daily living skills. Parent inappropriate commands also showed negative correlations with child communication and daily living skills at T1 only. Parent praise showed no significant correlations with child adaptive skills at T1 or T2. Future analyses will employ structural equation modeling (SEM) to investigate the relationships influencing T2 adaptive skills, accounting for time, T1 and T2 parenting behaviors, participation in BPT, child IQ, and diagnosis group. SEM will allow for the simultaneous examination of both direct and indirect effects, capturing the complex interplay between these variables over time.

Conclusions:

Our findings highlight significant improvements in positive parenting practices and daily living skills and socialization following BPT. Given that adaptive skills are learned behaviors, these results emphasize the need for further research to explore the specific mechanisms through which parental practices influence the development of these skills. Understanding how certain parenting behaviors directly support skill acquisition is crucial.

415.319 Exploring the Influence of Provider-Reported Adaptations on Parent Participation Engagement in Part C Early Intervention
A. Pomaes-Ramos¹, H. Tokish², S. R. Edmunds³, K. M. Frost² and B. R. Ingersoll¹, (1)Psychology, Michigan State University, East Lansing, MI, (2)Psychology, University of South Carolina, Columbia, SC, (3)Pediatrics, University of Massachusetts Chan Medical School, Worcester, MA

Background: Community-based clinicians delivering autism parent-mediated interventions report a need to adapt intervention protocols to address issues related to engagement and cultural relevance (Barnett et al., 2019). This is especially relevant when working with families from minoritized communities who encounter increased structural inequities and attitudinal barriers that have been shown to impact their engagement (Smith et al., 2020). While these adaptations are inherent in usual practice, limited research has examined how they relate to parent participation engagement (PPE; active, independent, and responsive engagement) and how demographic factors moderate this relationship.

Objectives: The current study aims to explore how provider-reported adaptations for Caregiver-Implemented Reciprocal Imitation Teaching (CI-RIT) are related to parent engagement and determine whether these effects are moderated by parent minoritized status.

Methods: EI providers in Part C systems implemented CI-RIT, an evidence-based social communication intervention, as part of an effectiveness-implementation trial. Parents ($n=54$) participated in weekly EI sessions with their provider ($n=30$) over four months. Up to three session recordings ($n=114$) for each parent-provider dyad were behaviorally coded with the *Parent Participation Engagement Observational Coding Scheme* to assess PPE. Providers rated the extent to which they adapted CI-RIT (e.g., content, coaching, pacing, and logistical adaptations) within three months of implementation for each family using a 5-point Likert scale. A 3-level multilevel model was conducted to examine the impact of overall adaptations on PPE given the repeated and nested nature of the PPE data. The model assessed the influence of adaptations and parents' minoritized status (i.e., families indicating Latine ethnicity and/or non-white race; $n=30$ minoritized families) on average PPE, controlling for marital status, household income, and session modality.

Results: Preliminary findings suggest a statistically significant interaction between adaptations and parent minoritized status, indicating that the effect of adaptations on PPE varied based on the parent's minoritized status (Table 1). A simple slopes analysis suggested that minoritized parents working with providers who reported higher adaptations demonstrated greater engagement, whereas non-Latine White parents working with providers who reported higher adaptations demonstrated lower engagement.

Conclusions: Findings highlight the significant role of adaptations in influencing parent engagement for minoritized families, particularly in the context of a parent-mediated intervention (CI-RIT). The interaction between adaptations and minoritized status revealed that higher adaptations were associated with greater engagement among minoritized parents, indicating that minoritized families may benefit more from flexible, culturally responsive approaches for active engagement. Given the different effects by minoritized status, further research is warranted to explore the specific types of adaptations that are most effective for different groups and to better understand the mechanisms underlying these differential effects.

415.320 Exploring the Relationship between Emotional Control and Ritualistic Behaviors in Youth with and without Autism Spectrum Disorder

S. Bansal¹, **H. Iyer¹**, **M. Santhosh²**, **H. Rea³** and **S. J. Webb⁴**, (1)SCRI, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Center for Human Development and Disability, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition that affects an individual's ability to communicate and interact with others (Orsmond 2004). It is characterized by restricted repetitive behaviors and interests (RRBs). Studies have alluded to the fact that a relationship exists between RRBs and difficulties with emotional regulation in individuals with ASD (Martínez-González et al. 2022). However, a better understanding of this relationship and a more targeted approach is not only critical for improving therapeutic approaches for individuals with ASD, but also to understand the underlying mechanisms of disorder.

Objectives: This study aimed to understand the relationship between emotional control and compulsive and ritualistic behaviors in youth aged 8-17 years with and without ASD. We hypothesize that participant groups with ritualistic and compulsive behaviors specifically will have lower emotional control.

Methods: Data were collected from the GENDAAR study, which assessed biological sex differences in autism. Final analyses included 177 autistic youth (44% female) and 168 typically developing (TD) youth (49% female). ASD diagnosis was confirmed via ADOS and ADI and all participants had an IQ $\geq$ 70. Emotional control was measured using Behavioral Rating Inventory Executive Functioning (BRIEF) T-scores from the Emotional Control scale, Compulsive (CompB) and Ritualistic Behaviors (RitB) were assessed as present (score>0) or absent (=0) from the Repetitive Behavior Scale-Revised (RBS-R) subdomains. We examined group differences between emotional control for individuals with and without compulsive and ritualistic behaviors by using Welch Two Sample T-Tests. We then examined the role of age with Emotional Control.

Results: In the autistic youth, 72% reported compulsive behaviors and participants with CompB showed significantly worse Emotional Control than those without ($t(89.2)=-4.54$, $p<0.05$). Similarly, 83% reported ritualistic behaviors and had worse Emotional Control than those without RitB ($t(43)=-4.83$, $p<0.05$). This relationship was also seen in the TD youth, where individuals with CompB (18%) and RitB (11%) compared to those who did not have lower Emotional Control ($t(36.20)=-3.87$, $p<0.05$; $t(20.25)=-2.20$, $p<0.05$, respectively). We also found Emotional Control was not related to Age in the ASD group ($r=0.001$) and TD group ($r=0.01$).

Conclusions: Results suggest that individuals who have compulsive and/or ritualistic behaviors struggle with emotional control. While our primary focus was to evaluate this in autistic youth, our comparison group of typically developing youth also showed these same relationships. Thus, it is important to consider that interventions targeting emotional control may have bi-directional influences on each other in childhood. Further exploration of additional factors, such as gender and sex, will help to better understand these relationships. Longitudinal data will also be necessary to understand predictive relationships.

415.321 Facing Your Fears for Autistic Youth: Individual Factors Related to Improved Mental Health Outcomes in a CBT-Based Anxiety Intervention

N. Eddy¹, **S. J. Howe²** and **C. McMorris³**, (1)Psychology, University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Calgary, AB, Canada, (3)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

Background: Autistic youth experience higher rates of anxiety than their non-autistic peers (e.g., Hennessy et al., 2023). Updated prevalence rates suggest that approximately 33% of autistic youth experience clinically elevated anxiety levels (Thiele-Swift & Dorstyn, 2024). Adapted cognitive behavioural therapy (CBT)-based interventions, such as *Facing Your Fears* (FYF; Reaven et al., 2011), have been effective in reducing anxiety symptoms of this group (e.g., McMorris et al., 2024; Reaven et al., 2012; Solish et al., 2020). However, few studies have identified which autistic youth (based on individual characteristics) are most likely to benefit from FYF for treating anxiety.

Objectives: To determine the individual demographic and clinical factors of autistic youth that are related to improved anxiety and mental health outcomes following participation in FYF.

Methods: Thirty-four 8- to 14-year-old ($M = 10.79$, $SD = 1.92$) autistic youth ($n_{cis-male} = 25$) completed 14 weekly sessions of the FYF program for reducing anxiety. Outcome measures (child and parent versions) of anxiety (Anxiety Scale for Children- Autism Spectrum Disorder; ASC-ASD), mental health symptoms (Behaviour Assessment System for Children, Third Edition; BASC-3), and quality of life (Pediatric Quality of Life Inventory; PedsQL) were completed at pre- and post-program. Individual demographic factors included youth's age, sex, age at autism diagnosis, formal anxiety diagnosis, and whether youth had previously or were presently being treated for mental health issues. Paired samples t -tests were conducted to evaluate post-program improvements in outcomes. For those improvements that were significant, change scores were calculated. Change scores of those youth who experienced post-program improvements were correlated (Pearson's r) with the individual factors listed to determine which characteristics were associated with greater program success (i.e., largest magnitude of improvement).

Results: On average, results indicated significant improvements in youth's overall (and specific) anxiety at post-program ($p_s \leq .031$, Cohen's $d_s = .242 - .485$), along with parent-reported internalizing ($p = .006$, $d = .435$), behavioural symptoms ($p = .009$, $d = .439$), and overall quality of life ($p = .001$, $d = .424$). Specifically, upwards of three-fourths of the sample (71-76%) reported reductions in anxiety. Improvements in anxious arousal (as reported by youth) were greatest for those who had no previous mental health treatments ($r = -.664$, $p = .010$). No other significant associations were found, though several approached significance (e.g., $p = .061$).

Conclusions: The findings of this study support previous research establishing FYF as an effective intervention for reducing anxiety in autistic youth. Only one association among program outcomes and individual factors was demonstrated by the results, which suggests that within the sample, no youth in particular (aside from those who had not experienced any mental health interventions prior to FYF) were more likely than others to experience program success. Results are preliminary and based on a limited sample; further data collection is needed to develop an understanding of which youth characteristics (and/or additional factors, e.g., parent or family-level factors) are related to successful program outcomes.

415.322 Families Forward: Development and Proof-of-Concept Trial of a New Program for Transition-Aged Autistic Youth and Their Families

K. Long¹, S. Suswaram², Y. Kim³, S. Krishnan³, A. Paredes Molina⁴, J. S. Eilenberg⁴, J. S. Wilson⁴, S. Visoso⁴, M. de Lemos⁴, A. Chu⁵, K. M. Guthrie⁶ and G. I. Orsmond³; (1)Boston University, Boston, MA, (2)Carolina Institute for Developmental Disability, University of North Carolina at Chapel Hill, Carrboro, NC, (3)Department of Occupational Therapy, Boston University, Boston, MA, (4)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (5)Brown University School of Public Health, Providence, RI, (6)Brown University, Providence, RI

Background: The transition to adulthood is characterized by insufficient adult autism services, particularly for racially- and ethnically-minoritized youth and families. Families' supportive roles often extend into adulthood, but the lack of support leads families to feel overwhelmed and ineffective. There are surprisingly few evidence-based, family-focused transition programs. No existing programs simultaneously emphasize skills to navigate transition, serve youth across the full autism spectrum, and center cultural considerations by individualizing program content. In response, the current community-partnered project developed a transition planning program that accounts for flexibility across autism presentation and co-occurring conditions, cultural values, family preferences, and readiness to engage in planning. **Families FORWARD (Focusing On Relationships, Well-being, And Responsibility ahead)** is an individually-delivered program that hones families' skills to promote successful transition while centering the autistic youth's vision for the future. Aligned with community feedback, Families FORWARD is geared toward parents, with optional youth participation.

Objectives: Refine Families FORWARD based on community input (Phase 1); test acceptability, feasibility, and clinical promise in a proof-of-concept trial (Phase 2).

Methods: **Phase 1:** a racially-, ethnically-, and linguistically-diverse sample of 20 parents, 6 autistic youth (ages 14-21), and 5 community providers completed qualitative interviews regarding their impressions of the Families FORWARD concept and suggestions for improvement. Feedback was iteratively incorporated into the program description; interviews continued until a final version of the program was reached. **Phase 2:** 14 families participated in a proof-of-concept trial. Families FORWARD was delivered remotely by community coaches. Families completed pre/post measures of mechanistic targets (self-efficacy, knowledge, readiness for change) and outcome (transition preparedness activities) and completed exit interviews. Quantitative data are presented descriptively. Qualitative data were analyzed using directed content analysis. A community advisory board (CAB) of racially-, ethnically-, and linguistically-diverse autistic young adults, parents, and providers guided the research.

Results: **Phase 1:** All participants expressed strong enthusiasm for Families FORWARD, particularly individualized planning goals, flexible youth participation, combined focus on knowledge and skills, and remote delivery via community-based organizations. Based on qualitative data and CAB input, individual culturally-tailored sessions include skill-building (goal-setting, communication, problem-solving, systems navigation) and education about transition-related and adult services (Table 1). **Phase 2:** Findings support the feasibility, acceptability, and clinical promise of Families FORWARD (Table 2). Parents and youth described benefits (e.g., better family communication about the future) and explained how the program facilitated their progress toward future planning goals. One recommendation was to increase youths' (optional) involvement across sessions.

Conclusions: Across racial and ethnic backgrounds and autism characteristics, families were enthusiastic about Families FORWARD, noting that it filled a need currently unaddressed by existing services. The individualized approach increases relevance for all families, aligned with eventual implementation within community settings serving youth with a range of autism presentations and cultural backgrounds. Participation in Families FORWARD may increase youth-centered planning and access to services and launch more positive trajectories of adult functioning, thereby addressing the well-documented difficulties faced by autistic adults. Next steps include incorporating recommendations for increased youth involvement; evaluating the revised program's feasibility, acceptability, and efficacy; and identifying implementation considerations.

**415.323 Feasibility Study of a Novel App-Based Anxiety Intervention for Autistic People**

B. Oakley¹, C. Boatman², R. Kent³, A. Ozsivadjian⁴, S. Doswell⁵, A. Dittner⁶, A. Roestorf⁶, D. Rawal⁶, B. Carter⁶ and M. M. A. G. .⁷; (1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, London, United Kingdom, (3)South London and the Maudsley NHS, London, United Kingdom, (4)St. Thomas Hospital, Evelina Children's Hospital Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (5)South London and Maudsley NHS Foundation Trust, London, London, United Kingdom, (6)South London and Maudsley NHS Foundation Trust, London, United Kingdom, (7)Autism Research Group, Department of Psychology, Autistica, London, United Kingdom, (8)Autistica, London, London, United Kingdom, (9)King's College London, London, London, United Kingdom

Background: At least 50% of autistic people experience clinically relevant anxiety symptoms. However, reasons for elevated rates of anxiety in autism remain poorly understood and there is a high unmet need for novel and adapted therapies for anxiety that are accessible to autistic people.

Objectives: This study aimed to establish the feasibility of a novel app-based anxiety management tool ('Molehill Mountain') that has been developed with, and adapted for, autistic people.

Methods: A non-randomised (single-arm) pilot trial design was employed, whereby autistic people (≥16-years) with mild-to-severe symptoms of anxiety were recruited over a 15-month period at one lead site (King's College London, UK; clinicaltrials.gov identifier NCT05302167).

Results: Of 123 prospective participants screened, 100 (81%) participants aged 16-74-years (n=69 female) were enrolled, meeting the original recruitment target. Retention of participants from screening (Week 0) to endpoint (Week 15 +/- 2) was 75%, based on completion of the primary outcome measure (Generalised Anxiety Disorder – 7 Item Scale; GAD-7). 66% (n=50) participants self-reported using the app for the full 13-weeks duration (recommended). 16% (n=12) of participants self-reported using the app daily (recommended), with most other respondents (58%, n=44) using the app weekly (from 1-6-days per week). A significant reduction in self-reported anxiety symptom severity pre- vs. post-intervention was identified on the GAD-7 (t(74)=5.63, p<0.001, 95% CI [1.80, 3.77]; d=0.43, 95% CI [0.13, 0.73]).

Conclusions: We have provided the first evidence that an autism adapted app-based anxiety management tool is acceptable to the community and can reduce anxiety symptom severity in autistic adults. Following optimisation to further enhance useability, the efficacy of the Molehill Mountain app for reducing anxiety must now be tested under randomised controlled conditions in a full-scale clinical trial.

415.324 Feasibility of an Ecological Momentary Assessment Intervention for Improving Social Cognition in Autistic and Non-Autistic Adults

C. I. Parenteau¹, A. Gerber², K. M. Hauschild³, K. Merritt-Gawe⁴, K. M. Hricak⁴, J. K. Richards⁵ and M. D. Lerner⁶, (1)Psychiatry and Behavioral Sciences, Center for ASD and NDDs, UCSF Dept of Psychiatry, San Francisco, CA, (2)Yale University, New Haven, CT, (3)Department of Psychology, Farmingdale State College, Stony Brook, NY, (4)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (5)Department of Psychology, Rowan University, Glassboro, NJ, (6)Department of Psychology, Drexel University, Stony Brook, NY

Background:

Low intensity interventions (LII's) for autistic individuals represent a valuable opportunity to increase access to care (Libsack et al., 2022). LII's have targeted a variety of outcomes, from adaptive behavior to language and social skills improvements (i.e. Marro et al., 2019; Popovic, et al., 2020; Shrestha et al., 2013). One potential form of LII posits that ecological momentary assessment (EMA) – participant *in vivo* responding via a smartphone – can be leveraged to improve key outcomes without the use of formalized clinical intervention. However, no work to date has yet examined the feasibility or acceptability of such an intervention approach for autistic individuals.

Objectives:

To assess the feasibility and acceptability of an EMA intervention to improve social cognition in autistic adults.

Methods:

Ninety adults were recruited for a study designed to utilize EMA as an intervention to improve social cognition (Table 1). All participants completed two in person lab visits. During the first lab visit, participants were trained to track social interactions– defined as exchanges lasting longer than 5 seconds. Participants were split into three conditions: Social Emotional Attention (SEA; log the primary emotion of their interlocutor(s)), Social Attention (AA; log the interlocutor(s) hair color), and the passive control (simply log their interactions). Over the course of the seven-day intervention period, participants also received text reminders to complete the form at 9 a.m., 9 p.m., and 10 additional randomized times between the 9 a.m. – 9 p.m. window.

To examine feasibility of the EMA intervention protocol, we calculated utilization (number of interactions logged within 9 a.m. to 9 p.m.); compliance (self-reported percentage of interactions logged *prompted* (with reminders) and *unprompted* (spontaneous); and acceptability (two independent coders reliably coded free responses of participants regarding the number of things they liked and disliked about the study). We conducted three 2 (autism status) x 3 (condition) ANOVAs to examine differences in feasibility as measured by utilization and acceptability (positive and negative). A Repeated Measures ANOVA was then used to investigate group differences of prompted and unprompted compliance.

Results:

Utilization, unprompted compliance, and acceptability of the EMA intervention were high, and were similar across all participants regardless of autism status or condition (see Table 1). However, autism status showed a significant effect on prompted compliance ($F(1, 75) = 4.39, p = 0.04$). While both the autistic and non-autistic groups provided more responses when prompted, the increase in compliance from the unprompted to the prompted condition was greater for the non-autistic group ($F = 4.51, p = .04$; see Figure 1).

Conclusions:

The LII EMA intervention protocol showed strong feasibility for autistic and non-autistic adults, and across conditions. However, the non-autistic group reported a larger increase in compliance when receiving intermittent prompts, suggesting these reminders may provide less benefit to autistic participants. Future researchers should explore alternative approaches beyond prompted reminders at random intervals to increase EMA compliance amongst autistic participants. As this EMA LII protocol appears feasible, the next steps are to examine its impact on key social cognition outcomes.

**415.325** Fostering Reciprocal Friendships for Neurodiverse Youth through Participation in the Summer Treatment Program

E. Allen¹, R. Chatterjee¹, A. Sipowicz², B. Aaronson³, W. McCloud⁴ and H. Bolotin¹, (1)University of Washington, Seattle, WA, (2)University of Cincinnati, Cincinnati, OH, (3)Pediatrics, University of Washington, Seattle, WA, (4)Advance Autism ADHD and Neurodevelopment for Youth, Seattle, WA

Background:

The Summer Treatment Program (STP) was designed to treat children with Attention-Deficit/Hyperactivity Disorder (ADHD) in a summer camp-like setting, with the overall program goals of improving children's relationships with peers, positive interactions with adults, self-efficacy, and ability to perform well academically in school settings (Pelham et al., 2010). While originally developed to treat children with ADHD, STPs have since been used to treat children with other developmental disabilities as well, including autism spectrum disorders. The STP model incorporates evidence-based intervention components including a comprehensive token economy system, daily report cards (DRCs), and explicit social skills instruction (Chronis et al., 2004). Children with autism spectrum disorders often manifest challenges with social reciprocity, and therefore building and maintaining friendships is an explicit goal of intervention (Chamberlain et al., 2007). Summer camps are a naturalistic setting for children to build social skills and friendships.

Objectives:

The objective of this study is to evaluate the effectiveness of the STP model in supporting the development of robust social networks and friendships for children ages 6-12 with neurodevelopmental disabilities, including autism spectrum disorders, ADHD.

Children as measured by their self-reports of friends, best friends, and non-preferred peers. Additionally, the team aims to examine the extent to which reciprocal friendships may be fostered by participation in the STP intervention.

Methods:

Using child self-report of friendships (Kasari et al., 2007), children (N = 126) were interviewed weekly during their participation a 5-week STP and asked to identify "who they like to hang out with" (friendships), their top three friends, their best friend, and "who they don't like to hang out with" (rejections). Using the reported endorsements, a peer social preference score is developed by considering the number of received friendship nominations and rejections (Coie et al., 1983). Peer social preference scores are then analyzed using R to create graphic representations of reciprocal (and non-reciprocal) relationships. Linear modeling is utilized to examine social network development over time.

Results:

Preliminary results indicate an increase in total outward nominations and inward nominations over time participating in the STP. Additionally, the number of reciprocal friendships (a bidirectional, mutual report of friendship) between participants was positively correlated with time participating in the STP.

Conclusions:

These results suggest that the STP provides neurodiverse children with a unique opportunity to practice social skills and build meaningful peer connections. It is important to note the limitations of the current study. In particular, the present study did not account for gender, race, socioeconomic status, or identifiers other than age and diagnoses when analyzing peer relationships. Additionally, the present study leaves room to further examine other factors and how these may relate to an individual's social network at baseline and over time.

415.326 A Novel Dance Intervention Program for Adults with Developmental Disabilities: A Pilot Randomized Control Trial

R. M. Amin¹, M. R. Pepper², D. X. Hu^{3,4}, F. Zollars⁵, J. Wennberg⁶ and G. Stobbe^{7,8}, (1)Department of Neurology, University of Washington, Seattle, WA, (2)Alyssa Burnett Adult Life Center, Seattle Children's Alyssa Burnett Adult Life Center, Bothell, WA, (3)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Alyssa Burnett Center, Seattle Children's Hospital, Seattle, WA, (5)The University of Washington, Seattle, WA, (6)Alyssa Burnett Adult Life Center, Seattle Children's Hospital, Seattle, WA, (7)Seattle Children's Autism Center, Seattle, WA, (8)Neurology, University of Washington, Seattle, WA

Background:

Physical activity has been shown to provide wide benefits to people of diverse backgrounds and health conditions (1). However, there are relatively few studies examining the impact of physical activity on individuals with intellectual or developmental disabilities. A recent study at UCLA assessing the impact of a dance intervention in children with developmental disabilities showed significant improvement on their motor abilities and positive trends in their social skills (2).

Objectives:

The objective of this study was to determine if a dance intervention is accessible and feasible for adults with intellectual and/or developmental disabilities (IDD) and understand if a dance intervention (Intervention group) leads to improvements in social or quality of life measures when compared to adults in an open recreation service (control group).

Methods:

The study design was a pilot study in which participants were randomized to active and control groups. Eligible participants included male and female adults older than 18 years old, who self-identified as having an intellectual or developmental disability and were registered participants at a community center for adults with neurodevelopmental disabilities. Pre and post intervention data on quality of life were gathered using the Adult Hope Scale, the Lifespan Self-Esteem Scale, the WHOQOL-BREF-ID & DISABILITIES MODULE, and the Perceived Stress Scale. Motor skills were assessed using the Motor Skills Scale, and intellectual and functional abilities were assessed using the Raven's Progressive Matrices and Vineland Interview, respectively. After gathering baseline data, the active group completed 1-hour of dance classes per week for 10 weeks, while the control group participated in a concurrent 1-hour recreational class each week for 10 weeks. All participants then returned to complete the same surveys above. Pre- and post-intervention data were analyzed using R Studio (Version 2023.06.2).

Results:

We recruited and randomized 24 adult participants with intellectual or developmental disabilities (mean age = 31.05, SD = 10.90), who were enrolled in a lifelong learning center for neurodiverse adults, of which 11 individuals participated in the dance intervention class and 9 participated in the control group's recreation class. The average attendance rate was 92.7 % for the active group and 87.8 % for the control group. The active group showed a significant improvement in social skills, as indicated by the Vineland Socialization domain ($\beta = 18.11$, $p = .02$). Additionally, we observed positive trends in the Agency domain (i.e., goal-directed energy) of the Adult Hope Scale (AHS) and in overall satisfaction with health, although these effects did not reach statistical significance.

Conclusions:

Our results indicate that it is feasible to develop and implement a dance intervention program for adults with intellectual or developmental disabilities. Further, we find increase in social skills can be detected after participation in Dance intervention. However, a lack of significant change in other areas (e.g., motor skills, quality of life) coupled with limitations in study implementation suggests further research is needed to determine the full impact of this dance program.

415.327 Help Our Autistic Children to be More Empathic: Comparing the Effectiveness of Human- and Robot-Based Intervention
 X. Li¹, M. Lui² and W. C. So³, (1)Chinese University of Hong Kong, Hong Kong, Hong Kong, China, (2)Psychology, University of Roehampton, London, NA, United Kingdom, (3)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, NA, Hong Kong (China)

Background: Prior studies have shown that autistic individuals lack empathy (e.g. Baron-Cohen & Wheelwright, 2004), which is an ability to understand and share others' feelings (Singer, 2006). Recently, RCT studies demonstrated that Theory of Mind (ToM) training, Early Start Denver Model, and JASPER model improved empathic responsiveness (e.g., Dawson et al., 2010; Goods et al., 2013; Holopainen et al., 2018). However, these intervention studies did not cover different kinds of emotional situations and all components of empathy (cognitive empathy (CE), affective empathy (AE), prosocial behaviours (PB), Watson & Bird, 2020). Besides, prior interventions are mainly conducted by human therapists. However, autistic individuals show deficits in initiating and engaging with humans and maintaining social relations with them (social motivation theory of autism; Chevallier et al., 2012). Additionally, given a particular form of brain hypertrophy, they may be overreactive to the intensive and unpredictable visual, auditory, and/or tactile stimulations when interacting with humans (Intense World Theory; Markram & Markram, 2010). Unlike humans, robots are operated in a predictable manner (Empathising-Systemising Theory, Baron-Cohen, 2009), which may provide autistic individuals with a favourable learning environment.

Objectives: This study aimed to compare the effectiveness of robot-based intervention for all empathy components (CE, AE, and PB) and emotional situations (happy, sad, fear, angry) to human-based intervention and wait-list control. We hypothesized that both robot-(RBI) and human-based (HBI) interventions could improve all empathy components in all kinds of emotional situations, in comparison to wait-list control (WC) (H1), and RBI is as effective as HBI in improving empathic responses (H2).

Methods: 54 Chinese-speaking autistic children (44 males) aged 5-8 (mean=6.56) with verbal IQ above 85 (mean=95.23) were recruited via online advertisement. Figure 1 shows the procedures.

Results: The effectiveness of intervention for each empathy component across different kinds of emotional situations was compared among the three conditions. For CE, there was a significant improvement between pretest and post-tests (time effect), $F(2,98)=4.35$, $p<.015$, $\eta^2=.08$, but the time*condition interaction was not statistically significant, $F(4,98)=.72$, $p<.58$, $\eta^2=.03$, suggesting that the improvement in CE was not significantly different among all conditions. Nonetheless, the exploration into the different emotional situations revealed that children in HBI and RBI improved more than those in WC in the angry situation, $F(6,147)=4.13$, $p<.001$, $\eta^2=.14$. Same as CE, the time effect of AE was significant, $F(2,98)=3.82$, $p<.025$, $\eta^2=.07$. But different from CE, the time*condition interaction of AE was significant, $F(4,98)=2.66$, $p<.037$, $\eta^2=.098$. Children in both HBI and RBI scored higher than those in WC, $ps<.05$, but no significant difference was found between HBI and RBI. Similar to AE, the time effect ($F(2,98)=9.93$, $p<.001$, $\eta^2=.17$) and the time*condition interaction ($F(4,98)=2.67$, $p<.037$, $\eta^2=.098$) of PB were significant. Children in HBI but not RBI scored higher than those WC, $p<.04$.

Conclusions: H1 was partially supported. There was an improvement in CE in all three conditions. RBI and HBI improved AE. HBI but not RBI improved PB. H2 was also partially supported. RBI was as effective as HBI in improving AE but not as effective as HBI in PB.

415.328 A Systematic Review of Implementation Processes and Outcomes of Evidence-Based Interventions for Autistic Students in Schools

Q. Xiong¹, E. Nsiah², B. Garman-McClaine³, B. Dale² and L. A. Ruble⁴, (1)Department of Counseling Psychology, Social Psychology, and Counseling, Ball State University, Muncie, IN, (2)Ball State University, Muncie, IN, (3)Indiana University, Bloomington, IN, (4)Department of Special Education, Ball State University, Muncie, IN

Background: Hume and colleagues (2021) conducted a comprehensive review of studies spanning nearly three decades (1990–2017), identifying 28 evidence-based practices with positive effects for skills such as social skills, communication, behavior, and academic achievement with autistic youth. However, there is a significant gap in research regarding the implementation of these interventions in school settings. Implementation strategy is defined as the methods used to improve on adopting, implementing, and sustaining a practice (Proctor et al., 2013). Building on the previous work, we conducted a systematic review of the articles from Hume et al. (2021) with specific attention to implementation processes of EBPs for autistic children and youth in U.S. public schools.

Objectives: To describe the implementation processes and strategies used by researchers of EBPs in public school settings.

Methods: An initial screening was conducted in studies synthesized by Hume et al. (2021) with the inclusion criteria of taking place in a U.S. public school and within the age range from 6 to 21 years old aligning with the Individuals with Disabilities Education Act (IDEA), Part B. A second round of screening was conducted to exclude studies where the intervention(s) was implemented by researchers rather than school personnel. A final full-text screening was conducted to extract details of implementation strategies.

Results: Of the 933 articles that were identified and reviewed, only 278 (29.8%) were conducted in U.S. public schools. Of those, just 98 (10.5%) involved implementation of EBPs by classroom teachers, peers, or other school personnel. Additionally, many of these studies lacked crucial details about the implementation process, such as the pre-intervention training provided to teachers or staff, who exactly implemented the interventions, how interventions were monitored, and whether the EBPs were maintained or sustained in the school environment. In other words, despite the development of numerous EBPs, very few are being tested in real-world school settings and conditions, and the lack of documented implementation process and strategies makes it difficult to ensure their effective and sustainable use as well as feasibility, appropriateness, and acceptability.

Conclusions: While extensive research has resulted in numerous EBPs for supporting autistic children and youth, their application in U.S. public schools remains limited. The results of our study suggest that school staff are often not the ones delivering the interventions; a small percentage of studies were delivered in school settings; and even fewer detailed the implementation outcomes and the necessary strategies for replicability and sustained success. There is a clear need for more focused research on how to effectively integrate and report these practices into everyday classroom environments - out of clinical or research settings. Without addressing these gaps, the potential benefit of EBPs may not reach the individuals who can benefit from them most.

415.329 Impact of a Co-Designed Solar Science Curriculum on Students' STEM Identity, Confidence, and Career Interest

A. R. Arista¹, W. Martin², A. Grillo-Hill³, J. Valcarcel³, R. Elsayed⁴, K. Melchior⁵, K. Nguyen³, B. Mendez⁴, L. Peticolas³ and L. Cominsky⁵, (1)Center for Children and Technology, Education Development Center, New York, NY, (2)Education Development Center, New York, NY, (3)WestEd, Redwood City, CA, (4)Space Sciences Laboratory, University of California, Berkeley, Berkeley, CA, (5)EdEon STEM Learning, Sonoma State University, Rohnert Park, CA

Background: [Program blinded], a multi-institution collaboration between [blinded], was designed as a pathway to STEM employment for neurodivergent learners. [Program] provides authentic experiences to neurodivergent youth, including co-design of STEM curricula in partnership with high schools serving neurodivergent youth across the US. In preparation for the total solar eclipse across the US on April 8th, 2024, a solar science curriculum was co-designed with partner schools in California in 2023 to include accessible visual guides, slideshows, teaching tips to improve engagement, and hands-on activities to provide multiple pathways for participation. In early 2024, three schools in the path of the total eclipse (two schools in Texas and one in Ohio) implemented a revised version of the curriculum.

Objectives: Evaluation was conducted to assess the accessibility of our solar science curriculum for neurodivergent students and collect feedback on curriculum content and design from students and instructors. Impact of lesson participation on student STEM identity was also evaluated.

Methods: Online surveys were administered to secondary school students whose teachers implemented some or all of the solar science curriculum. A total of 167 complete responses were recorded (171 total). STEM Identity was retrospectively assessed using the Professional Identity Overlap Single Item Measure (PIO-1, Figure 1).

Observations were also conducted at the two schools in Texas. Research team members observed classroom sessions and interviewed students and instructors.

Results: Analysis of student responses to the PIO-1 revealed that students' STEM identity after the lessons ($M = 3.5$, $SD = 1.7$) was significantly greater than before ($M = 2.6$, $SD = 1.6$) the lessons, $t(166) = 9.47$, $p < .01$ with a Cohen's d effect size of 0.55.

Students were asked how the solar science lessons impacted their confidence and interest in solving science mysteries. Most students said that the lessons made them more interested (66%) and more confident (69%). Only 5% said the lesson made them less interested in solving scientific mysteries, and only 3% said it made them less confident.

Students were asked whether the solar science lessons made them more or less interested in STEM-related careers. Just under half (48%) said the lessons made them a little (34%) or a lot more (14%) interested in NASA-related careers. Only 8% said the lessons made them less interested in NASA-related careers.

In interviews, students and instructors highlighted the importance of visual supports and activities included in the curriculum guide and suggested ways to increase engagement even further by including more videos and adding synchronous worksheets for students to complete during lectures.

Conclusions: These findings suggest that [program]'s solar science lessons had a positive impact on students' STEM identity and helped build students' interest and confidence in STEM. Evidence from this evaluation demonstrates the value of investing in the participatory curriculum co-design process with autistic students and their instructors to produce curriculum materials that are engaging, hands-on, and relevant to diverse learners.

Poster Session**416 - Combined Topics II**

May 1st, 2025, 5:30 PM - 6:30 PM - Hall 4A

416.330 Associations between Co-Occurring Psychiatric Conditions, Sensory Processing, and Challenging Eating Behaviors in Autistic Children

A. Dea¹, E. Peters¹, D. Akinsooto¹, A. C. Henley¹, H. L. Morgan¹, R. E. Aiello¹, N. O. Davis¹, C. M. Kerns², E. Ng-Cordell³, S. W. Nowell³, K. Rho², J. Schechter⁴, C. Stone⁴, E. Tenenbaum¹, A. Wallisch⁵, N. Zucker¹ and K. L. Carpenter¹, (1)Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC, (2)Department of Psychology, University of British Columbia, Vancouver, BC, Canada, (3)Health Sciences, Division of Speech and Hearing Sciences, UNC Chapel Hill, Chapel Hill, NC, (4)Department of Psychiatry and Behavioral Sciences, University of North Carolina Greensboro, Durham, NC, (5)Department of Pediatrics, University of Kansas Medical Center, Kansas City, KS

Background: Co-occurring psychiatric conditions, challenging eating behaviors (CEBs), and sensory processing differences are highly prevalent among autistic children (Baraskewich et al., 2021). However, few studies have investigated the interrelationship between these traits within autism. Previous findings have identified correlations between sensory differences and CEBs in autistic children (Page et al., 2021). Independently, the effect of one psychiatric condition on CEB outcomes has been investigated, but the effect of two or more co-occurring psychiatric conditions is not well understood, particularly in autism, attention-deficit hyperactivity disorder (ADHD), and anxiety. Furthermore, the presence of co-occurring psychiatric conditions could affect sensory preferences which may also influence the presentation or severity of CEBs. Ultimately, it remains unknown if different psychiatric profiles of co-occurring conditions, specifically in autistic children, are related to distinct CEBs.

Objectives: (1) Examine associations between co-occurring conditions and caregiver-reported CEBs. Specifically, the overall effect of the diagnostic group on CEB subdomains, as well as the differences between groups for different CEB subdomains. (2) Examine associations between sensory processing profiles and CEB subdomains. (3) Explore how the findings of Objectives 1 and 2 are interrelated by analyzing the joint effect of diagnostic group (from Objective 1) and sensory profiles (from Objective 2) on CEB subdomains by using an interaction term between diagnostic group overall and each sensory subdomain.

Methods: Participants include 97 children aged 4 to 8 years ($M_{age}=71.03$ months, $SD_{age}=14.13$ months; 69.07% male; 77.32% white) from four diagnostic groups: autism only ($n=24$), autism+ADHD ($n=23$), autism+anxiety ($n=19$), and autism+ADHD+anxiety ($n=31$). Eating behaviors and sensory profiles (hyper-responsivity [HYPER] and hypo-responsivity [HYPO]) were measured via caregiver report using selected subdomains from the Children's Eating Behavior Questionnaire (CEBQ; subdomains in Table 1) and Sensory Experiences Questionnaire 3.0 (SEQ-3) respectively. Analyses were run in SAS version 9.4 (SAS Institute Inc.) using general linear models. Covariates included sex, age, and developmental quotient.

Results: Diagnostic group, HYPER and HYPO sensory profiles, and the interaction between diagnostic group and HYPER/HYPO profiles significantly predicted various eating behaviors (Table 1). Marginal associations were found between diagnostic group and emotional overeating ($p=.09$), enjoyment of food ($p=.07$), and emotional undereating ($p=.06$); therefore, group differences were subsequently explored. Pairwise t-tests revealed that, compared to the autism only group: the autism+ADHD group showed heightened food responsiveness ($p=.004$), enjoyment of food ($p=.02$), and emotional undereating ($p=.02$); the autism+anxiety group showed increased emotional undereating ($p=.04$); the autism+ADHD+anxiety group showed higher food responsiveness ($p=.01$), emotional overeating ($p=.02$), enjoyment of food ($p=.04$), and slowness in eating ($p=.03$). No significant results were identified for satiety responsiveness.

Conclusions: These findings highlight the significant role of co-occurring conditions and sensory processing in CEBs among autistic children. Autistic children who have co-occurring conditions, especially ADHD, experience more severe CEBs than those with autism only. Sensory sensitivities influence CEBs in this population as well. Understanding the interaction between sensory processing, CEBs, and co-occurring conditions can help clinicians develop tailored interventions that can significantly improve long-term outcomes for autistic children with challenging eating behaviors.

**Panel Session****- Genetics of Autism Spectrum Disorders: Update**

May 2nd, 2025, 10:30 AM - 12:30 PM - 611-614

Panel Chair: Craig Powell, *Neurobiology, UAB School of Medicine, Birmingham, AL*

This invited panel will provide updates on the role of genetic variants in risk for autism spectrum disorders. Selected experts will speak about identification of rare causal variants as well as increased risk due to common genetic variants or single-nucleotide polymorphisms (SNPs). In addition, attendees will learn about phenotypes and potential therapeutic strategies for select genetic forms of autism spectrum disorders. Learners will come away with a clearer understanding of the genetic architecture of autism spectrum disorders, of gene discovery efforts, and of how such genetic variants can be used to study autism at the individual disorder and molecular pathway levels.

Targeting Genetic Mutations Associated with Profound Autism

J. D. Buxbaum, *Mount Sinai School of Medicine, New York, NY*

Background: Profound autism has been recently introduced as a category within the autism spectrum, recognizing that a significant fraction of individuals with autism will have significant functional needs, including, “24 h access to an adult who can care for them if concerns arise, being unable to be left completely alone in a residence, and not being able to take care of basic daily adaptive needs.” Addressing the needs of individuals with profound autism will need to consider modalities beyond behavioral interventions and adaptive or life skills training, including approaches that address the underlying biology of profound autism.

Over the past 15 years, there have been remarkable breakthroughs in understanding genetic causes of autism, including in individuals with profound autism. These genetic findings highlight the profound heterogeneity in autism and underscore the need for precision medicine to address disabling features of profound autism. Ongoing efforts to use genetic discoveries to identify shared pathways leading to autism have had limited success to date. However, many of the genetic discoveries, particularly those driven by mutations of large effect, present opportunities for gene-targeted therapeutics for these emerging rare genetic disorders.

Objectives: Recent advancements in treating pediatric genetic disorders through gene therapy, antisense oligonucleotides (ASOs), and small molecules provide a roadmap for applying similar approaches to genetically defined autism.

Methods: The Seaver Autism Center and its collaborators have conducted both clinical and preclinical studies on multiple key autism-related genes, including ADNP, DDX3X, FOXP1, and SHANK2/3. Clinical studies help define the phenotypic characteristics associated with mutations in these genes and begin to identify biomarkers that may be useful in assessing disease progression and treatment efficacy. In parallel, preclinical research using cellular and animal models aims to better understand the relationships between genetic mutations, cell biology, systems biology, and behavior. Having developed these foundational tools and clinical insights, we are now exploring multiple paths toward drug discovery and development for rare genetic disorders associated with a high risk of profound autism.

Results: This presentation will include examples of in-depth phenotypic studies, translational research including comparing biomarkers in animal models and human participants, and cellular studies focused on developing screening platforms and validation assays for therapeutic discovery. In addition, this presentation will provide updates on three approaches to gene-targeted therapeutics that are being explored by the Seaver Autism Center and its collaborators, including organoid phenotype-based screens, translational readthrough of premature termination codons, and small molecule targeting of mRNA.

Conclusions: In-depth phenotypic studies of genetic forms of autism along with cellular studies for therapeutic discovery will lead to future gene-targeted therapeutics.

Using Gene-First Approach to the Study of Autism Groups

W. Chung, *Department of Pediatrics, Boston Children's Hospital, Boston, MA*

Background: Autism is heterogeneous. One dimension to increase homogeneity and better understand the biology of the brain and behavior is to genetically stratify individuals and study genetic conditions that manifest autism in some individuals.

Objectives: To study a large number of individuals across a large number of genetic conditions associated with autism to better understand similarities and differences over the life course.

Methods: We began Simons Searchlight 14 years ago and collect data online on 180 genetic conditions associated with autism.

Results: We have studied ~8,000 individuals from around the world and have observed many similarities of delays in development, expressive language challenges, seizures, and autism across conditions. Some medical conditions including gastrointestinal complaints of reflux, diarrhea, and constipation are also common across conditions. Some conditions have unique features that are important to recognize including neurodegenerative aspects or association with cancer. Family meetings of these groups provide opportunities for educating families about research findings and for participants to help educate researchers.

Conclusions: Genetic stratification of autism provides important insights and is now preparing the path for future clinical trials.

Common Variant Discovery in Autism

A. D. Borglum, *Department of Biomedicine-Human Genetics, Aarhus University, Aarhus, Denmark*

Background:

Autism is highly heritable with most of the genetic predisposition residing in common variants. However, while gene discovery efforts in the *de novo* and rare variant space have succeeded in identifying hundreds of risk genes, only a handful of common variants have been identified so far. Major reasons for this are the need for very large GWAS sample sizes to robustly detect the weak risk effects conferred by common variants individually and the extensive clinical and genetic heterogeneity seen across the autism spectrum.

Objectives:

I will present an update on the ongoing autism GWAS meta-analysis by the Autism Workgroup of the Psychiatric Genomics Consortium, including identification of novel loci, tissues and cell-types enriched for common variant risk, and genetic overlap with other phenotypes. I will also present results on dissection of the polygenic architecture across autism subgroups and genetically informed risk prediction of developing cooccurring conditions.

Methods:

GWAS was performed using standard tools for quality control and analysis, primarily applying the RICOPILI pipeline. Functional annotation, genetic correlation, and dissection of common variant architecture across autism subgroups applied standard methods, including e.g. FUMA, LDSC, MiXeR, and multivariate PGS analyses. Prediction of absolute risk for developing cooccurring conditions was done using Cox regression.

Results:

GWAS meta-analysis included twice the number of autistic persons compared to the previous PGC autism GWAS and found 12 significantly associated loci. Early-phase functional annotation of the identified common variant risk found enrichment exclusively in brain, widespread across brain regions, only in neuronal cells, both excitatory and inhibitory neurons.

Univariate Gaussian mixture modelling found that around 10,000 common variants can explain 90% of the SNP-heritability and bivariate analyses quantifying the polygenic overlap irrespective of allelic directional effects revealed extensive sharing of variants with other mental health phenotypes. For instance, >95% of ADHD and schizophrenia risk variants were found to also influence autism predisposition.

Dissection of the polygenic architecture showed distinct profiles for ICD10 diagnostic subgroups as well as for autism with or without cooccurring intellectual disability (ID). Autism without ID showed higher SNP-heritability than autism with ID, and the two subgroups showed different genetic correlations with cognitive traits.

Leveraging longitudinal data on the iPSYCH Danish nationwide population cohort for risk prediction, we found clear separation of risk trajectories for developing co-occurring diagnoses such as ADHD and schizophrenia, depending on the polygenic load of ADHD and schizophrenia common variant risk, respectively. For instance, almost half of autistic individuals with high polygenic scores for ADHD (upper PGS decile) developed ADHD over time, while only 20% of those in the lower PGS decile did.

Conclusions:

Our GWAS with increased sample size revealed novel risk loci, implicating novel candidate genes and informing on the involved biological mechanisms. Significant variation in polygenic architecture was observed across autism subgroups, advancing our understanding of the genetic heterogeneity of autism. Autism subgroups partitioned on their common variant risk load showed distinct risk trajectories for developing co-occurring diagnoses. The latter may inform precision medicine approaches for early diagnosis and treatment of co-occurring conditions in autism.

A Research Agenda for Fulfilling the Promise of Gene Discovery in Profound ASD

M. W. State, University of California San Francisco, San Francisco, CA

Background: Nearly every contemporary review of the genetics and biology of autism spectrum disorders (ASD) begins with some version of a lament that despite more than a decade of remarkable progress, advances at the bench have not yet had a measurable impact in the clinic. In fact, despite now being able to identify specific genes, mutations, cell types, brain regions, biological themes, and developmental time points relevant to ASD, the promise of clinical translational progress based on advances in genetics and neurobiology has not yet been fulfilled, including for the group of individuals now referred to as having “profound autism”. This proposed diagnostic category is provisionally characterized by core features of autism, concurrent moderate or more severe intellectual disability, minimal or absent language, and the need for 24-hour care. While the precise clinical characteristics and diagnostic boundaries of this subset of individuals with ASD continues to be debated and refined, the terminology is useful in helping differentiate this group from the large number of people who do not experience the core symptoms of ASD as a disability.

Presently, approximately a quarter of all those diagnosed with ASD would meet the proposed criteria and, relevant to this presentation, this group is more likely to carry large effect, rare and *de novo* coding mutations and suffer from a range of severe neurodevelopmental phenotypes, including developmental encephalopathy and epilepsy.

Objectives: To make progress in mechanistic treatment via open science, new initiatives, and harnessing basic science advanced to positively impact the lives of those most severely affected by core features of ASD.

Methods: Various multidisciplinary approaches

Results: This presentation will provide a high-level overview of more than a decade of progress in the genomics, transcriptomics, and proteomics of ASD, as well as recent advances in genetic medicine and human neuroscience, and describe how this research across biological scales is coming together to offer new opportunities for the development of mechanism-driven treatments. A related research roadmap will be described for ARIA (Aligning Research to Impact Autism), a philanthropic initiative which aims to create, via collaboration, a dedicated open science ecosystem that will complement existing research efforts, support new initiatives, and harness the full range of promising basic science advances to positively impact the lives of those most severely affected by the core features of ASD as well as by frequently-occurring co-morbid conditions.

Conclusions: This new research initiative is poised to discover novel therapeutics for those challenged with profound ASD.

Panel Session

207 - Prioritizing Autistic Lived Experiences and Co-Development to Enhance Research Outputs

May 2nd, 2025, 10:30 AM - 12:30 PM - 6B

Panel Chair: Brittany St John, *University of Washington, Seattle, WA*

Discussant: Karla Ausderau, *University of Wisconsin-Madison, Madison, WI*

This panel focused on how the inclusion of stakeholder input and/or co-development with the lived experience community benefits both the research process and product. This panel brings together a diverse set of international investigators who all prioritize community engagement in their research. Each presentation provides insight into community engagement across multiple stages of the research process. Presenters will reflect on the contributions of the lived experience community and how engagement impacted research outcomes include programming and interventions.

Introduction

B. M. St John, *University of Washington, Madison, WI*

207.001 Enhancing Research through Community Engagement: The Power of Inclusion of Researchers with Lived Experience of Intellectual and Developmental Disabilities

H. J. Laufenberg^a, L. Hladik^a, K. K. Ausderau^a, M. Garner^a, E. Kastern^a, A. Caudill^b and J. Capelle^c, (1)University of Wisconsin-Madison, Madison, WI, (2)Masaryk University, Brno, Czechia, Czech Republic, (3)University of Wisconsin - Madison, Madison, WI

Background:

People with intellectual and developmental disabilities (IDD), including autistic adults, are often excluded from the research process even though their inclusion increases the validity of the research and likelihood their priorities are addressed and findings implemented in practice. Studies have found that engagement of individuals with lived experience of disability in all research phases improves data comprehensiveness and interpretation (Bigby et al., 2013; Di Lorito et al., 2017; Hladik, 2024; Kramer et al., 2019). Using community-based participatory research methods such as photovoice provides opportunities to meaningfully include people with IDD as research team members and as engaged participants. This inclusive approach demonstrates the importance of community engagement in producing robust, impactful research outcomes that address community-led priorities (Beighton et al., 2017; Hladik, 2024).

Objectives:

The purpose of this talk is to 1) describe the engagement of community researchers with intellectual and developmental disabilities as integral team members in the research process, and 2) how community-based participatory research methods, specifically photovoice, promote co-creation of equitable research dissemination.

Methods:

Adults with intellectual and developmental disabilities (n=18) participated in photovoice, a participatory action methodology adapted to support the inclusion of adults with intellectual and developmental disabilities. Participants took photos, captioned the images, and participated in focus groups to answer the primary question: What changed in your daily life during the COVID-19 pandemic? Throughout the research process, two co-researchers with lived experience assisted in data collection, analysis, and dissemination. In addition, community members and research participants actively engaged in interpreting results and co-creating materials for inclusive dissemination.

Results:

Researchers with lived experience of IDD were instrumental in shaping the data collection process to meet participant needs to increase opportunity for capturing the depth of participant experiences. They assisted in identifying important context for photos and facilitating member checking. Additionally, they worked with community partners and research participants to determine alternative forms of dissemination such as a photobook to document the breadth of experience of all participants with IDD and policy briefs to support advocacy topics that emerged through the results. The iterative process of engaging community researchers with IDD in multiple phases of the research process ensured that the findings were both accurate and reflective of the participants' lived experiences.

Conclusions:

The results highlight the transformative potential of community engagement and including co-researchers with IDD throughout the research process. This study contributes to the literature that photovoice is an exceptional methodology for the inclusion of people with IDD in research to elevate and share their lived experiences from a first-hand perspective. Reflections from community members and participants revealed that community engagement significantly strengthened the study, leading to more robust and meaningful outcomes. Their contributions were invaluable, offering perspectives that expanded and deepened the research outcomes and dissemination. This engagement highlights the value of involving community members at all stages of the research process, from idea generation to dissemination. The insights and interpretations provided by the community members were critical in shaping the study's findings and ensuring their relevance and impact.

207.002 Engaging in Community-Partnered Research with Autistic Community College Students: A Path Toward Increasing Instructors' Autism Knowledge

S. C. LaPoint¹, G. M. Osborne², K. Massey³, F. Rasnake⁴, M. Fraser⁵ and L. G. Klinger⁶, (1)University of North Carolina-Chapel Hill, TEACCH Autism Program, Carrboro, NC, (2)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (3)TEACCH Autism Program, The University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program, The University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)School of Teacher Education, Florida State University, Tallahassee, FL, (6)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC

Background:

Autistic students are increasingly enrolling in institutions of higher education (IHE). Community colleges are witnessing the greatest shift, as 85% of autistic students in IHE attend a 2-year college exclusively or as a bridge to a 4-year university (Roux et al., 2015). Once enrolled, many autistic adults experience challenges (e.g., executive functioning and mental health) related to navigating a new environment (Gurbuz et al., 2019). Furthermore, faculty and staff members in IHE report a lack of knowledge and being ill-equipped to support autistic students within this context (Hu & Chandrasekhar, 2021). Such experiences within IHE can have negative impacts on the academic success of autistic students. To our knowledge, this is the first community-partnered study that asks autistic community college students about their experiences and prioritizes these perspectives to advance instructors' understanding of how to support autistic students.

Objectives:

This study aims to (1) examine recommendations that autistic students have for community college instructors and (2) discuss the process of engaging with autistic community college students as partners throughout the research study.

Methods:

Eleven autistic adults (aged 18-39 years, $M = 22.64$, $SD = 5.80$) who were enrolled in a North Carolina community college participated in the current study (see Table 1 for additional participant characteristics). The research team conducted a 1-hour semi-structured interview over Zoom that included questions about participants' community college experiences and recommendations for instructors to improve the support they provide autistic students. Interviews were audio-recorded and transcribed verbatim. Participant responses were analyzed using Braun and Clarke's (2006) framework for inductive thematic analysis.

Two autistic community college students partnered with our team throughout the study. They supported the development of interview guides, reviewed autistic students' interview responses, and reflected on their own lived experiences to contextualize participant responses.

Results:

Recommendations described by participants revealed the following themes:

Setting expectations and being transparent. Participants described the importance of instructors providing students with clear directions and structure throughout the course to minimize confusion. For example, participants noted that course syllabi should specify weekly topics, assignments, due dates, and grading rubrics.

Bi-directional interactions. Participants highlighted a desire for approachable instructors with whom they felt comfortable initiating accommodation requests and asking for help on assignments. Additionally, some participants noted that instructors should initiate check-ins with students, particularly when they notice concerning changes in the student's behavior (e.g., no longer coming to class).

Familiarization with student needs. Several participants emphasized the need for instructors to review accommodation requests and seek clarification as needed. Further, participants reflected on their experiences with instructors 'forgetting' to provide accommodations that students were legally entitled to. Such experiences resulted in the student having to take exams multiple times and mental health concerns.

Conclusions:

Our preliminary analysis addresses a pressing need for training designed for community college instructors to increase autism knowledge and improve self-efficacy in supporting autistic students. Furthermore, this study demonstrates the importance of partnering with autistic students throughout the research project to ensure that data collection procedures and findings are meaningful to the community.

207.003 The Community Engaged Development of a Highly Acceptable Sensory Modified Hybrid-Protein Nugget to Target Microbiome in Autistic Individuals

B. M. St John¹, C. Mosca², A. Shindler³, S. Smilevska⁴, C. M. Brown⁵, G. Moschonis⁶, R. Belski⁶, A. Franks⁶, M. Doblin⁷ and A. E. Lane⁸,

(1)University of Washington, Seattle, WA, (2)CSIRO, Werribe, VIC, Australia, (3)Department of Microbiology, Anatomy, Physiology, & Pharmacology, La Trobe University, Melbourne, VIC, Australia, (4)Department Sport, Exercise and Nutrition Sciences, La Trobe University, Melbourne, VIC, Australia, (5)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, VIC, AUSTRALIA, (6)La Trobe University, Melbourne, VIC, Australia, (7)La Trobe University, Melbourne, VIC, Australia, (8)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia

Background:

Up to 85% of autistic children have significant feeding challenges impacting their diet variety, health, and development (Leader et al, 2020). Food selectivity based on the sensory properties of the food is the most reported feeding challenge among this population (St. John & Ausderau, 2024; Sharp et al., 2013). Due to their highly selective diets, many autistic children have significant nutrient deficiencies (Hyman et al., 2012; Sharp et al., 2012). In addition, autistic children have disrupted gut microbiome that has been associated with autism characteristics and development (Iglesias-Vázquez et al., 2020). Food innovators have an opportunity to create products that cover known nutritional gaps, enhances the diversity of the gut microbiome, and are aligned with the preferences and desires of the autism community. Newly developed sensory acceptable food products may offer autistic individuals with selective eating an enjoyable food source to fulfill nutritional deficits in their diet. Evaluation of the community acceptability of any developed product is an essential outcome to consider in the product development process.

Objectives:

The purpose of this pilot project was to develop and evaluate the consumer acceptability of a new nutritious food (hybrid-protein nugget) specifically designed for sensory acceptability by individuals with autistic feeding challenges.

Methods:**Nugget development:**

A collaborative research project was developed between the Olga Tennison Autism Research Centre and members of the La Trobe Institute for Sustainable Agriculture and Food (LISAF) and Commonwealth Scientific and Industrial Research Organisation (CSIRO)'s Agriculture and Food unit. Previous work from La Trobe's research team had captured the perceptions of the lived experience community related to the sensory underpinnings of feeding challenges and the acceptability of sensory modifications of foods. Building on the findings from the lived experiences community study, a new frozen nugget with a hybrid protein (texture variable protein and chicken) composition was developed. Sensory properties of the nugget were modified to align with the communicated preferences from the lived experience community. The nugget was specifically formulated to target microbiome composition when consumed regularly.

Consumer acceptability

Autistic individuals with feeding challenges (n=10) and families of autistic children with feeding challenges (n=5) were invited to trial the developed nugget in their homes and provide ratings of acceptability.

Results:

The developed nugget was highly acceptable with a mean enjoyment rating of 8.25/10 among autistic individuals and 9/10 among families. Families of autistic children with feeding challenges reported the nugget was accepted by 80% of the children. Acceptance of a novel food when first offered is rare among children with feeding challenges. Qualitative reactions and comments included complimentary comments on the nugget texture, smell, and flavor. 80% of families and individuals endorsed that they would purchase the nugget if available in the grocery store. Price was listed as an important factor in deciding to purchase.

Conclusions:

The developed nugget was highly acceptable and enjoyable to both families and autistic individuals. Lived experience community input was essential in the development of the product and evaluating the acceptability of the product.

207.004 Refinement and Feasibility of a Pilot Volunteer Program for Autistic Adults

M. L. Cook¹, H. Loeb², E. M. Lamarche³ and L. G. Klinger³, (1)TEACCH Autism Program, UNC Chapel Hill, Carrboro, NC, (2)Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (3)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC

Background:

Volunteering is positively associated with mental and physical health (Yeung et al., 2017), social support, employment skills (Proulx et al., 2018), and quality of life (Willigen, 2000) in the general population and may provide meaningful benefits for autistic adults as well. Stakeholder feedback is necessary to confirm the perceived value of a pilot volunteer program and provide feedback on accessibility and feasibility.

Objectives:

To develop and pilot a structured volunteer program for autistic adults (TEACCH Autism Gives, TAG) by 1) refining development with stakeholder feedback, 2) assessing feasibility, and 3) using a mixed methods approach to examine the impact of participation on autistic adults' experience of community participation, self-determination, and social engagement.

Methods:

Phase 1: Semi-structured stakeholder interviews were conducted with autistic adults to gauge value, feasibility, and feedback on draft program materials (n=15, ages 19-56, 53% male). Interviews were recorded, transcribed, and analyzed in Dedoose utilizing Braun and Clarke's reflexive thematic analysis approach. Resulting themes were used to refine materials and pilot design.

Phase 2: Autistic adults (n=12, ages 19-55, 75% male, mean FSIQ=103.2) were matched with a local volunteer site (n=4) and volunteered for 3-5 hours per week for 9 weeks. Site supervisors (n=6) completed a brief training with the study team on best practices for supporting autistic volunteers and all participants received the TAG handbook (a compilation of visual supports adapted from the TEACCH School Transition to Employment and Post Secondary Education Program). Autistic adults completed pre and post GPS tracking using Optimus 3.0 devices as well as self-report measures of community participation, self-determination, and social engagement. Site supervisors completed post measures of feasibility, acceptability, and appropriateness (see Table 1). ArcGIS software was utilized to calculate activity space and map GPS data (Figure 1), while self-report data is currently presented as descriptive means given the small sample size.

Results:

Stakeholder interviews revealed themes across three primary domains: barriers to volunteering (e.g., anxiety, logistical burden, competing demands, lack of access, unpleasant sensory experiences, wariness of negative social experiences), benefits of volunteering (e.g., community connection, engagement with interests, getting out of the house, sense of empowerment, feeling good when helping others, skill acquisition), and facilitators of successful volunteering (e.g., clear visual expectations, accommodations, supportive supervisors, and social support). Outcome data is currently available for 78% of the sample (n=10 autistic adults, n=4 supervisors) with additional data continuing to be collected. Initial analyses suggest high feasibility ratings amongst site supervisors, high satisfaction amongst participants, and improvements in the domains of community participation and self-determination (decision-making) for the majority of the sample (see Table 1).

Conclusions:

The inclusion of stakeholder feedback prior to the launch of the pilot was essential in tailoring materials to better meet the needs of the autistic community. Preliminary pilot data suggests that 1) participation in TAG provided both a meaningful and feasible opportunity for community participation and 2) a larger scale implementation is warranted to explore efficacy.

**Panel Session****208 - Not Autism. Not Yet. Characterizing the Diagnostic Experiences and Profiles of Late, Missed and Mis-Diagnosed Individuals.**

May 2nd, 2025, 10:30 AM - 12:30 PM - 6C

Panel Chair: Clare Harrop, *Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC*

Discussant: Somer Bishop, *Psychiatry and Behavioral Sciences, University of California, San Francisco, San Francisco, CA*

For many years, the field of autism research has focused on early identification and diagnosis (Gordon-Lipkin et al., 2016). Earlier diagnosis and access to interventions are associated with positive outcomes in cognitive functioning, daily living, and other areas of development (e.g. Gabbay-Dizdar et al., 2022). Further, a timely diagnosis is associated with self-identity and belonging (e.g. Oredipe et al., 2023). However, there has been an unprecedented rise in people diagnosed with autism outside of early childhood, including a disproportionate number of people assigned female at birth and gender diverse individuals. The overarching goal of this panel is to showcase diverse research spanning childhood through adulthood to capture the diagnostic experiences and profiles of autistic people diagnosed late or initially diagnosed with a condition other than autism. Talks will span diagnostic stability, methods developed to capture those diagnosed in adolescence and adulthood, and the profiles of children entering studies without a formal autism diagnosis, covering the complexity and breadth of late-, missed- or mis-diagnoses. Our panel includes multiple levels of analysis (qualitative, mixed methods, quantitative), diverse samples (over-represented for assigned sex, gender diversity, and racial and ethnicity minorities), and speakers across career stages (post-bac, postdoc, early career faculty, and tenured faculty).

Introduction

C. Harrop, *Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC*

208.001 Why the Wait?: Phenotypic Differences in 4- to 8-Year-Old Children with Suspected Vs. Confirmed Autism

A. L. Lee¹, **M. Lyons²**, **T. McFayden³**, **S. Schillinger⁴**, **L. J. Fulop⁵**, **J. S. Miller⁶**, **C. Faulk¹**, **R. Grzadzinski²**, **H. Hazlett¹**, **J. F. Strang³**, **C. Harrop⁶** and **J. Parish-Morris¹**, *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of North Carolina at Chapel Hill- Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (3)Carolina Institute for Developmental Disabilities, Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (4)University of North Carolina, Chapel Hill, NC, (5)Gender and Autism Program, Children's National Health System, Washington, DC, (6)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC*

Background: Autistic children and families face multiple barriers to participating in scientific research (Lee et al., 2024). One significant barrier includes the common requirement that children have a confirmed autism diagnosis prior to study enrollment (Shaia et al., 2019), which excludes many autistic children who receive a delayed diagnosis (considered after the age of 4; Zuckerman et al., 2017). Prior research suggests that people with complex psychiatric and/or neurodevelopmental profiles tend to receive later diagnoses (Wodka et al., 2022), as do females and individuals who are gender diverse (McQuaid et al., 2024). To replicate and extend these findings in a younger cohort followed longitudinally, we examined phenotypic differences in 4- to 8-year-old participants who entered a multi-site study as potentially autistic (TBD group, i.e., caregivers and other informants expressed concerns about the child having autism, but they had not yet received a formal diagnosis) vs. children who enrolled in the study with an established autism diagnosis (Dx group). Based on prior research, we hypothesized that children in the TBD group would be characterized by greater gender diversity than the established Dx group (McQuaid et al., 2024) and that TBD females would have more complex psychiatric/neurodevelopmental profiles than Dx females (Wodka et al., 2022).

Objectives: (1) Compare rates of gender diversity and (2) examine sex differences in psychiatric and neurodevelopmental profiles in children who came into the study with an autism diagnosis (Dx group), vs. children who received their diagnosis as part of study participation (TBD group).

Methods: 132 autistic 4- to 8-year-olds were grouped based on whether they entered the study with an autism diagnosis (Dx;n=106) or received a diagnosis as part of study participation (TBD;n=26). Rates of parent-reported child gender diversity were compared using Fisher's exact test. To assess psychiatric/neurodevelopmental characteristics in Dx and TBD children, Child Behavior Checklist (CBCL; Achenbach 1999) scores were compared in a smaller subsample matched on age, IQ, and assigned sex at birth (n=44;26F). Data normality was assessed using Shapiro-Wilk tests, followed by either two-sample t-tests or Wilcoxon signed-rank tests to compare CBCL scores between groups.

Results: TBD children were significantly more likely to be gender diverse than Dx children ($p=0.017$, odds ratio=0.176, 95% CI [0.032,0.888]). Parents of TBD females reported elevated symptoms of anxiety ($p=0.030$, Cohen's $d=2.20$), attention deficit hyperactivity disorder (ADHD; $p=0.044$, Cohen's $d=2.11$) and oppositional defiant disorder (ODD; $p=0.032$, Cohen's $d=2.23$) compared with Dx females. ODD symptoms were significantly greater for TBD females compared to TBD males ($p=0.035$, Cohen's $d=2.28$). There were no observed differences in CBCL scores between TBD and Dx male groups (all $p=ns$).

Conclusions: Children with complex behavioral profiles, specifically females and gender diverse individuals, may be at elevated risk of delayed diagnosis. This could lead to missed opportunities for specialized intervention and care, and potentially contributes to poorer long-term mental health outcomes. The current study is among the first to examine early developmental differences in autistic children longitudinally and will continue to explore outcomes during this critical developmental window to better inform diagnostic and treatment strategies.

208.002 Clinician Confidence over Time in a Sample of Children at High-Familial Likelihood for ASD

C. A. Burrows¹, R. Grzadzinski², K. E. Caravella³, T. St. John⁴, J. Pandey⁵, N. Marrus⁶, C. M. Lee⁷, C. Lasch⁸, M. Mosner⁹, A. Jones¹⁰, K. Mata¹¹, J. R. Pruett¹², A. M. Estes¹³, S. R. Dager¹⁴, R. T. Schultz¹⁵, L. Zwaigenbaum¹⁶, J. Piven¹⁷ and H. Hazlett¹⁷, (1)Department of Pediatrics, University of Minnesota, Minneapolis, MN, (2)Carolina Institute for Developmental Disabilities, Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (3)Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC, (4)University of Washington, Seattle, WA, (5)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (6)Washington University in St. Louis, St. Louis, MO, (7)Department of Pediatrics, University of Minnesota - Twin Cities, Minneapolis, MN, (8)Institute of Child Development, University of Minnesota, Minneapolis, MN, (9)Children's Hospital of Philadelphia, Philadelphia, PA, (10)University of Minnesota, Minneapolis, MN, (11)UNC Carolina Institute for Developmental Disabilities, Carrboro, NC, (12)Washington University School of Medicine, St. Louis, MO, (13)Speech and Hearing Sciences, UW Autism Center, Seattle, WA, (14)Radiology, University of Washington, Seattle, WA, (15)The Center for Autism Research/CHOP, Philadelphia, PA, (16)University of Alberta, Edmonton, AB, Canada, (17)University of North Carolina, Chapel Hill, NC

Background: Autism spectrum disorder (ASD) is historically considered to be a lifelong, pervasive neurodevelopmental disorder. Recent work highlights variability in diagnoses over time (Harstad et al., 2023) and varying clinician confidence in diagnoses (Klaiman et al., 2022; McDonnell et al., 2019). Siblings of autistic children are at higher likelihood for ASD, though their presentations may be milder (Micheletti et al., 2019), and they hover near the diagnostic boundary (Tunc et al., 2021). No studies to date have examined clinician confidence over time in a sample of children at high-familial likelihood for ASD (HL).

Objectives: To examine rates of clinician confidence in diagnosis over time and whether the sex of the child moderates clinician confidence.

Methods: HL participants with an older autistic sibling enrolled in the Infant Brain Imaging Study (IBIS; N=422, 39% female, 84% White, 93% Non-Hispanic) received clinical best estimate (CBE) diagnoses of ASD or non-spectrum (NO ASD) at 24 months, 36 months, and school-age (7-11 years) by clinicians expert in autism diagnosis. Clinicians also rated their confidence in their diagnostic impression on a scale of 1 (not at all confident) to 3 (very confident), which was dichotomized to high or low confidence.

Results: Clinicians had low confidence in their CBE determinations for 32.4% of 24-month visits, 23.4% of 36-month visits, and 20.5% of school-age visits (Table 1). In cases of diagnostic uncertainty, there were sex differences in the diagnosis assigned at 24 months, chi-square=4.01, $p=.045$, where females were more likely to receive a CBE of NO ASD (72.5% of girls), whereas boys had a more even split (53.8% of boys received a CBE of NO ASD). There were no sex differences in diagnosis assigned in cases of uncertainty at 36 months or school-age ($p>.05$). When examining clinician confidence in CBE's over time (Figure 1), 57.0% of participants were rated as NO ASD with high confidence at 2 or more visits, and 6.7% of participants were rated as ASD with high confidence at 2 or more visits. Conversely, there were 15.8% of participants where clinicians had low confidence in their CBE's at 2 or more visits. Reasons listed for diagnostic uncertainty include variability in mood or behavior on the day of testing, discrepancy between parent report and clinician observation, and clinician reports of both strengths and weaknesses in symptom domains of ASD.

Conclusions: Results highlight the high proportion of both high and low confidence in CBE over time in HL samples. Clinician confidence increased as children aged, but clinicians had low confidence in a substantial portion of the school-age HL children. For young children, when clinicians had low confidence in their CBE, they were more likely to rate females as NO ASD compared to males. This difference was not present as children aged. There is a variety of reasons why clinicians may have low confidence in their CBE impressions, which may change as children age. Implications for understanding the etiology of ASD will be discussed, as well as implications for repeated assessments of ASD over time and interventions.

208.003 Pathways to an Autism Diagnosis: Insights from Parents of Females

T. McFayden¹, A. S. Russell¹, M. McAllister² and C. Harrop³, (1)University of North Carolina at Chapel Hill- Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (2)University of North Carolina Chapel Hill, Durham, NC, (3)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC

Background: Females receive autism diagnoses significantly later than males, contributing to delayed access to supports (Kavanaugh et al., 2021). Reasons for diagnostic delays include child-level characteristics, including difficult differential diagnoses (Belcher et al., 2023), masking/camouflaging (Hull et al., 2020), or social strengths/atypical autistic phenotypes (Ratto et al., 2018), in addition to provider characteristics, including lack of knowledge about the female autism phenotype (Hiller et al., 2016). Person- and society-level characteristics intersect with racial/ethnic status, which can further delay access to a timely autism diagnosis (Fombonne & Zuckerman, 2022). Understanding barriers to, and pathways towards, an autism diagnosis is crucial to lowering the average age of diagnosis for females, particularly those from minoritized backgrounds.

Objectives: This study sought to quantitatively and qualitatively characterize the diagnostic pathway from parental first concern to an autism diagnosis for autistic females.

Methods: Caregivers enrolled in SPARK Research Match were contacted to complete a survey about their child's diagnostic pathway. The sample was over-recruited for caregivers of racial/ethnic minorities and females. The final sample comprised N=158 caregivers (n=90 with female children). Caregivers were largely college-educated (70%). Child average age was 9.48 years ($SD=4.86$, range=2.6-17.8 years). Youth were 78% not Hispanic and 36% White, 32% Multiracial, 16% Black, 8% Asian, and 5% another or an unspecified race. Parents reported an average age of diagnosis of 3.86 years ($SD=2.6$). Males and females did not differ on relevant demographic variables.

Results: Largely, quantitative results did not indicate many sex differences in diagnostic pathways. Males and females did not significantly differ on age of first concerns, $p=.667$ or age of diagnosis, $p=.969$. Males and females were equally likely to receive a diagnosis prior to autism, $\chi^2=3.609$, $p=.057$; no significant differences emerged in the type of prior diagnosis. Females received significantly more prior diagnoses than males ($M_{females}=2.11$, $M_{males}=1.69$), $t(65.817)=1.673$, $p=.05$. When bringing their concerns to their primary care physicians, parents of White females were more likely than parents of White males to be told that their child will "grow out of" their autistic behaviors, $\chi^2=3.745$, $p=.05$. Lastly, parents of females reported receiving autism diagnoses primarily from clinical psychologists (46%), whereas parents of males reported receiving diagnoses from a wider range of providers, and primarily from pediatricians (36%). Qualitatively, although age of diagnosis of males and females were not significantly different, parents of females reported many more inflection points and barriers on their diagnostic journey, including requiring consistent advocacy efforts. Parents of females also reported greater frustration, dissatisfaction, and perseverance required to arrive at an autism diagnosis compared to parents of males.

Conclusions: On the surface, autistic males and females reached equivalent diagnostic milestones. However, results from qualitative data revealed significant sex differences in diagnostic pathways, with parents of autistic females reporting more previous diagnoses, seeing more professionals, dismissive professional responses, and themes related to frustration, perseverance, and barriers that were notably absent for parents of autistic males. These results highlight the importance of mixed methods research, with implications for understanding how autistic females are missed or later-diagnosed.

208.004 Centering the Inner Experience of Autism: Preliminary Psychometrics and Validation of the Self-Assessment of Autistic Traits

L. Kenworthy¹, S. daVanport², J. Bascom³, A. B. Ratto⁴, L. Anthony⁵, A. Khuu⁴, E. Carel¹, J. F. Strang⁶, A. Verbalis⁷, J. Shen⁸, K. A. Pelphey⁹, J. S. Yang⁸ and A. Jack¹⁰, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Autistic Women & Nonbinary Network, Lincoln, NE, (3)Self, Washington, DC, (4)Center for Autism Spectrum Disorders, Children's National, Washington, DC, (5)University of Colorado, Denver, Aurora, CO, (6)Gender and Autism Program, Children's National Health System, Washington, DC, (7)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC, (8)University of Maryland, College Park, MD, (9)Department of Neurology, University of Virginia School of Medicine, Charlottesville, VA, (10)George Mason University, Fairfax, VA

Background:

Current tools for identifying autistic traits may lack sensitivity and specificity, especially in autistic people who are older, use compensatory strategies, are cis-gender girls or women, or are gender-diverse. Helping address this gap is the Self-Assessment of Autistic Traits (SAAT; Ratto et al., 2022), the first comprehensive self-report tool of autism traits for teens and adults written under the leadership of autistic people. SAAT items are designed to represent the internal experience of autism using strength-based, accessible language.

Objectives:

Evaluate preliminary psychometrics of the SAAT item pool; use pilot MRI data gathered from a subset of autistic survey respondents to explore the biological underpinnings of a novel factor (Brain-Body Disconnect) identified in the SAAT.

Methods:

We administered the SAAT item pool (58 items) to autistic ($N=500$; 48% female, 36% male, 5% nonbinary gender), and non-autistic ($n=80$) people ≥ 16 y from two samples (online community-based, autistic $N=440$; ACE-GENDER Network; autistic $N=60$, non-autistic $n=80$). 197 autistic people and 52 non-autistic people also completed the Social Responsiveness Scale-2 (SRS-2).

MRI methods. We analyzed resting-state fMRI data from $N=17$ autistic respondents who completed the SAAT during Wave 2 of ACE-GENDER Network project. Based on item content (e.g., "I can't always do what I need to do, because it feels like my mind and my body are disconnected"), we hypothesized striatal/basal ganglia involvement, as this system is associated with action selection and motor function. Using ICA + dual regression (Kohn et al., 2017), we identified group-level independent components (ICs) in the resting-state data, then selected the IC most highly correlated with a reference executive/striatal network (Smith et al., 2009). Dual regression was then used to test for associations between Brain-Body Disconnect factor scores and individual network parameter estimates (10,000 permutations; threshold-free cluster enhancement; corrected $p < .05$).

Results:

Exploratory factor analysis followed by a unidimensional confirmatory factor analysis revealed four factors: Modulation/Social Communication, Strengths/Passions, Brain-Body Disconnect, and Negative Community Context. Three of these factors are sensitive to autism across age, gender identity, assigned sex at birth, and gender diversity status, and moderately to strongly correlated with the SRS-2 Total score.

MRI results. The group-level IC most strongly correlated with the reference network was largely comprised of bilateral dorsolateral prefrontal cortex. Brain-body Disconnect scores were positively associated with subject-level parameter estimates in right globus pallidus ($x=25, y=-15, z=-5$; $p=.014$); Figure 1.

Conclusions:

The SAAT item-set has promise as a multi-dimensional self-report tool that is reliable and valid with respect to the samples examined, which included female gender, gender-diverse, adult, and nonspeaking individuals. It captures novel aspects of the inner experience of autism, enhancing its promise as a sensitive screening measure and revealing possible new autism phenotypes. The globus pallidus is a component of the basal ganglia that inhibits motor system action. Disrupted signaling between prefrontal cortex and basal ganglia is known to interfere with task switching in other conditions involving action initiation difficulties, such as Parkinson's. Our finding of increased pallidum involvement in a prefrontal network among individuals reporting greater Brain-Body Disconnect suggests a potential biological mechanism for reported difficulties.

**Panel Session****209 - Does Wiring Matter? Dynamic Connectivity and Excitation/Inhibition Imbalance in Autism Neuronal Network**

May 2nd, 2025, 10:30 AM - 12:30 PM - 6A

Panel Chair: Yeni Kim, Dongguk University, School of Medicine, Goyang, Gyeonggi, Korea, Republic of (South)

Recent advancements in dynamic connectivity, show that the human brain is a complex nonlinear system comprising multiple interacting components. Autism spectrum disorder (ASD) encompass a wide range of heterogeneous conditions, however the atypical balance between cortical excitation and inhibition (E/I) is a hallmark proposed as the etiology of ASD. However, mechanisms contributing to dynamic connectivity aberration and cortical E/I imbalance in ASD brain is still under investigation. This panel brings together four talks aimed at exploring dynamic connectivity and excitation/inhibition imbalance in neuronal network of Autism individuals. First talk explores conflicting findings in the field and support a developmental reconceptualization of the E/I imbalance theory of autism. The second presentation examines dynamical complexity in ASD neurons during differentiation, using the electrical recordings of stem cell-derived neurons. The third presentation uses aperiodic exponent of the EEG power spectrum as an indicator of E/I balance highlighting significant neurophysiological differences between autistic and NT children. Finally, the fourth presentation performs dynamic connectivity analyses in a unique transdiagnostic sample of school-age children assessed for both ADHD and ASD. These presentations advance our field by exploring abnormality in neuronal network specifically dynamic connectivity and excitation/inhibition imbalance, establishing new endophenotypic target for ASD.

Introduction

Papaleo⁸, G. Iurilli⁹, Y. Bozzi¹⁰, L. Cancedda², M. V. Lombardo¹¹ and A. Gozzi¹, (1)Functional Neuroimaging Lab, Italian Institute of Technology, Rovereto, Trento, Italy, (2)Brain Development and Disease Laboratory, Italian Institute of Technology, Genova, Genova, Italy, (3)Cellular, Computational and Integrative Biology Department, University of Trento, Povo, Trento, Italy, (4)CI-MeC - Center for Mind/Brain Sciences, University of Trento, Rovereto, Trento, Italy, (5)Fondazione Bruno Kessler, Trento, Trento, Italy, (6)Analytical Chemistry Facility, Italian Institute of Technology, Genova, Genova, Italy, (7)Central RNA Laboratory, Italian Institute of Technology, Genova, Genova, Italy, (8)Genetics of Cognition Laboratory, Italian Institute of Technology, Genova, Genova, Italy, (9)Laboratory of Systems Neurobiology and Behavior, Italian Institute of Technology, Rovereto, Trento, Italy, (10)CI-MeC - Center for Mind/Brain Sciences, University of Trento, Trento, Trento, Italy, (11)Laboratory for Autism and Neurodevelopmental Disorders, Italian Institute of Technology, Rovereto, Trento, Italy

Background:

Autism and related developmental disorders encompass a wide range of heterogeneous conditions with an overall prevalence of 1 % in the human population. Although autism varies in symptomatology and severity, its two main core symptom domains (i.e. social and communicative impairment, as well as restricted and repetitive behaviors) appear to be consistently affected across the spectrum. However, how diverse etiological mechanisms converge to produce the relatively narrow set of behavioral and etiopathological manifestations that characterize autism remains unclear. A popular theory posits that an imbalance between excitatory and inhibitory (E/I) activity might contribute to the etiology of autism. However, controversy exists about whether E/I imbalances observed in animal models and clinical populations causally contribute to autism pathology or are instead a compensatory or epiphenomenal phenotype.

Objectives:

To reconcile these views, here we test the hypothesis that transient E/I imbalance during early development is sufficient to alter the developmental trajectory of the brain, leading to lasting autism-relevant phenotypes.

Methods:

Cell-type specific increase of neuronal excitability was obtained with the use of intersectional genetics to express excitatory DREADD receptors in Vglut1-cre mice and the following chronic CNO treatment during the first two postnatal weeks. Longitudinal behavioral tests, RNA sequencing, electrophysiological measurements and resting state fMRI were performed at multiple developmental stages (late infancy, adolescence and adulthood).

Results:

We find that chemogenetically-induced E/I imbalance in the mouse neocortex during early development leads to permanently impaired sociability but largely preserved cognitive and motor-sensory functions. Corroborating the developmental specificity of these results, control studies in which the same manipulation was applied to adolescent mice did not result in any behavioral alteration. Social alterations are associated with transcriptional dysregulation of autism-risk ion channels and synaptic genes, thus putatively implicating activity-dependent transcriptional mechanisms in the generation of the observed phenotypes. Transcriptomic dysregulation furthermore resulted in enduringly altered electrical properties of pyramidal neurons, suggesting altered maturation of principal neurons. Circuit level investigations in adult mice using resting state fMRI show that developmental E/I imbalance profoundly disrupts functional connectivity in limbic fronto-hippocampal components of the social brain but preserved coupling in sensory regions. Notably, hypoconnectivity of prefrontal regions with dopaminergic nuclei is also highly predictive of social disruption in manipulated animals.

Conclusions:

Our results, reconcile conflicting findings in the field and support a developmental reconceptualization of the E/I imbalance theory of autism whereby developmental changes in E/I are sufficient to produce autism-related phenotypes via epigenetic dysregulation of autism-relevant synaptic genes.

209.002 Attention Entropy Measures Dynamic Complexity during Differentiation in iPSC-Derived Neurons from Autism Individuals

Y. Kim¹, Y. Choi¹, K. T. Park², S. H. Yi² and R. Santos³, (1)Dongguk University, School of Medicine, Goyang, Gyeonggi, Korea, Republic of (South), (2)Inje University, Gimhae, South Gyeongsang, Korea, Republic of (South), (3)Université Paris Cité, Institute of Psychiatry and Neuroscience of Paris, Paris, Paris, France

Background: The human brain is a complex nonlinear system comprising multiple interacting components at a variety of spatiotemporal scales. Neuronal activity can be modeled as a nonlinear dynamical system to yield measures of neuronal state and dysfunction. Previously, we reported a significant reduction in dynamical complexity in autism spectrum disorder (ASD) neurons during differentiation, using the electrical recordings of stem cell-derived neurons from individuals with ASD and controls (Amatya et al., 2019). In this study, Attention Entropy (AttnEn), initially proposed for assessing heart rate variability through the distribution of positional differences between extrema in interbeat intervals (IBIs), was adapted to analyze interspike intervals (ISIs) allowing real-time computation of AttnEn with linear time complexity.

Objectives: Our study aimed to investigate whether (1) AttnEn successfully differentiated the neural activity of ASD-derived neurons from that of controls and (2) dynamical analysis as a paradigm can be used to distinguish cellular electrophysiological and transcriptional signatures in disease-associated drug response.

Methods: Eight iPSC lines derived from ASD patients with an early brain overgrowth phenotype and seven age-matched neurotypical control lines from Marchetto et al. (2017) were analyzed. We performed RNA sequencing on iPSC derived neuronal progenitor cells at 15 days post differentiation. Gene ontology (GO) analysis was performed to determine which biological pathways were associated with differentially expressed genes. Raw signals recorded from microelectrode arrays (MEAs) were used to compute AttnEn for evaluation of neural activity between neurons derived from ASD patients and healthy controls.

Results: AttnEn successfully differentiated the neural activity of ASD-derived neurons from that of control, with ASD neurons exhibiting significantly lower entropy. This reduction in AttnEn suggests a diminished complexity in the neural firing patterns of ASD-derived neurons, reflecting potential deficits in neuronal communication and network maturation associated with the disorder. Furthermore, upon administration of risperidone, a drug frequently used to control behavioral symptoms in ASD, the AttnEn values in ASD neurons showed a notable increase, approaching those observed in the control group. Next, the gene expression signature of the AttnEn was examined in relation to Risperidone treatment. RNA sequencing data showed that the genes regulating synaptic vesicle cycle, postsynapse, transmission across chemical synapses, axon development, synaptic signaling, microtubule, and BDNF signaling pathway showed correlation with AttnEn changes observed with Risperidone treatment, suggesting that Risperidone contributed to restoring the complexity of neural activity and strengthening of the neural network. These findings implicate that dynamic electrical complexity of neural network measured using AttnEn is sensitive not only in detecting underlying differences in neural activity but also in monitoring the efficacy of pharmacological interventions.

Conclusions: AttnEn, a marker for dynamic neuronal complexity, is sensitive to drug treatment underscoring its potential as an endophenotypic target for evaluation of therapeutic agents. We present further evidence supporting dynamical analysis as a paradigm that can be used to distinguish disease-associated cellular electrophysiological and transcriptional signatures in neuropsychiatric disorders.

209.003 Aperiodic Activity EEG Measures Predict Executive Function in Kindergarteners with and without Autism

S. Jeong¹, A. B. Choi², Y. Braverman³, S. Faja⁴ and S. H. Kim¹, (1)School of Psychology, Korea University, Seoul, Seoul, Korea, Republic of (South), (2)Korea University, Seoul, Korea, Republic of (South), (3)Neurology, Boston Children's Hospital, Brookline, MA, (4)Boston Children's Hospital, Harvard, Boston, MA

Background: Executive function (EF) skills vary widely among autistic individuals, yet the underlying mechanisms of these differences, especially in early childhood, remain poorly understood. One key factor may be the atypical balance between cortical excitation and inhibition (E/I balance), a hallmark proposed in autism spectrum disorder (ASD). EEG spectral power, which is often altered in autistic children, has been linked to EF, but traditional EEG methods do not fully capture the complexity of E/I balance. Recent advancements, such as the aperiodic exponent of the EEG power, offer a more refined approach by serving as a proxy for E/I balance (Gao et al., 2017; Leno et al., 2022; Ostlund et al., 2022). This method allows researchers to better understand how shifts in cortical dynamics may influence cognitive processes like EF in young autistic children, providing new insights into their neurodevelopment.

Objectives: Our study aimed to (1) investigate whether autistic children show differences in aperiodic slopes when compared to neurotypical (NT) peers, and (2) examine whether the aperiodic slopes are associated with EF skills across both autistic and NT children.

Methods: A total of 52 kindergarteners (n=29 ASD, n=23 NT cases) completed a 5-minute baseline, resting-state EEG task. Both groups had fluent speech (i.e., complex sentences) and were cognitively-able (NVIQ scores above 80). The aperiodic exponent of the EEG power spectrum, calculated using SpecParam (Donoghue et al., 2020), was used as an indicator of E/I balance (e.g., with a steeper slope reflecting greater cortical inhibition relative to excitation). EF skills were measured using the EF Touch (Willoughby et al., 2010), a computerized task administered on a touch-screen tablet, which assesses multiple EF domains including attention shifting, working memory, and inhibitory control. Using multiple linear regressions, we examined whether children's diagnostic group (ASD vs. NT) predicted aperiodic exponents and explored the associations between aperiodic exponent and EF. All analyses accounted for age, sex, and cognitive ability.

Results: (1) Children's diagnostic group (ASD vs. NT) was significantly associated with the aperiodic slopes in both the frontal cluster, $B=-.09$, $SE=.04$, $p=.04$, and the midfrontal cluster, $B=-0.11$, $SE=.04$, $p=.02$. Specifically, autistic children had significantly flatter aperiodic exponents than NT children, indicating relatively less cortical inhibition in autistic children. (2) Aperiodic slopes the frontal cluster, $B=0.29$, $SE=0.12$, $p=.02$ and midfrontal cluster, $B=0.35$, $SE=0.12$, $p<.01$, were significantly associated with children's performance on the attention shifting task of EF Touch for the combined sample of ASD and NT cases. This indicates that flatter aperiodic exponents (reflective of less cortical inhibition relative to excitation) were related to weaker performance on attention-shifting, regardless of diagnosis.

Conclusions: These findings highlight significant neurophysiological differences between autistic and NT children, particularly in baseline, resting-state neural activity levels reflecting cortical E/I balance. Understanding these differences can inform the development of targeted interventions and support strategies for autistic children to enhance their executive function, a foundational skill to maximize functional outcomes during school transition. Further analyses with a larger sample collected across varied cultural backgrounds are currently underway and will be discussed.

209.004 What Can Brain State Dynamics and Transdiagnostic Samples Tell Us about Autism?

P. Thomson¹, P. Segura¹, S. Park², M. P. Milham³, T. Xu¹ and A. Di Martino¹, (1)Child Mind Institute, New York, NY, (2)Autism Center, Child Mind Institute, New York, NY, (3)Nathan S. Kline Institute for Psychiatric Research, Orangeburg, NY

Background: Research converges onto brain dysconnectivity models of autism largely characterized by a mosaic of hyper- and hypo-connectivity across large-scale networks. However, the networks involved have varied across studies, leaving an incomplete picture of connectivity patterns in autism. Most prior work has focused on time-averaged measures that only capture a static representation of brain connectivity, thus ignoring dynamic shifts in brain networks and between-network interactions over time. Additionally, most studies have focused on ‘case-control’ group mean comparisons, limiting the ability to assess inter-individual variability across continuous ranges of clinically-relevant measures. This presentation represents a departure from prior research by introducing results from a novel application of dynamic connectivity analyses in resting-state functional MRI data from children on the autism spectrum and/or with attention-deficit/hyperactivity disorder (ADHD), two frequently co-occurring neurodevelopmental conditions.

Objectives: The aim of this presentation is to illustrate the potential of studying dynamic functional connectivity in transdiagnostic neuroimaging samples to inform neural models of autism and their clinical relevance. Specifically, this presentation will: 1) introduce the coactivation pattern (CAP) approach, selected as a validated, robust method to assess dynamic changes in functional connectivity; 2) share results of CAP analyses aimed to identify prominent brain states across a sample of children with autism and/or ADHD; 3) provide initial findings on the links between dynamic properties of brain states and symptoms of autism and ADHD transdiagnostically.

Methods: Analyses were conducted on high quality resting-state functional MRI data from $n=166$ children (75% male, 8.9 ± 1.7 years old) with rigorously confirmed autism and/or ADHD. Eight CAPs (brain states) were derived across the sample using k-means clustering. Properties of these CAPs were computed for each person, including: dwell time —mean continuous time spent in a given brain state; occurrence rate —proportion of total time spent per state; incidence rate —number of times entering each state. Spearman partial correlations tested dimensional associations between CAP properties, and autism and ADHD symptoms (covariates: age, sex and in-scanner motion). Based on prior literature, a priori analyses focused on CAPs showing coactivation involving the default network (DN). Further analyses explored behavior associations with other identified CAPs.

Results: Analyses identified eight brain states organized into pairs of states with opposing network activation. Analyses focusing on the two state pairs prominently involving the DN revealed that dwell time in one of these states (CAP 6) was positively correlated with autism symptoms ($r=.19$, $p=.016$), and negatively correlated with ADHD symptoms ($r=-.20$, $p=.010$). Notably, CAP 6 is characterized by simultaneous deactivation of the DN and frontoparietal network, accompanied by activation of the somatomotor network. Exploratory analyses on other CAPs revealed that lower incidence rate of the visually dominant state (CAP 3) was also associated with higher autism symptoms ($r=-.27$, $p_{FDR}=.019$).

Conclusions: Findings revealed a double dissociation by symptom domain for time spent in the brain state involving networks previously reported to show connectivity differences in studies of autism or ADHD, thus clarifying their role across conditions. Results suggest that dynamic connectivity approaches are sensitive in identifying brain-behavior associations in clinically heterogeneous samples.

Panel Session

211 - Novel Transdiagnostic and Personalised Approaches for the Assessment and Support of Autism and Neurodevelopmental Conditions

May 2nd, 2025, 10:30 AM - 12:30 PM - 608-609

Panel Chair: Adam Guastella, *Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia*

Discussant: Adam Guastella, *Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia*

The presentations in this panel showcase the latest innovative and cross-disciplinary research that is being conducted internationally to ensure that novel and personalised approaches to care can be rapidly translated into clinical practice for children with neurodevelopmental concerns. The panel has a strong focus on priority populations, those experiencing significant social disadvantage, and a translational focus. Speakers will discuss different approaches to transdiagnostic science and assessment relevant to autism, including developing genetic clinics for very young children before neurodevelopmental vulnerabilities are detected, using digital research registries in public health services to advance a transdiagnostic science that can better meet needs of a largely culturally diverse, priority populations, to developing data driven approaches to establish models of autism, ADHD and neurodevelopment, to reporting on how well established neurocognitive tests perform in differentiating and identifying needs and profiles.

Introduction

A. J. Guastella, *University of Sydney, Sydney, NSW, Australia*

211.001 How Integrating Genetics in Clinical Care Can Address a Growing Unmet Need and Facilitate Research Discovery

N. Hoang, J. Vorstman, J. Summers and A. Deshwar, *The Hospital for Sick Children, Toronto, ON, Canada*

Background: An increasing number of genetic variants are being associated with neurodevelopmental and psychiatric disorders (NPDs), including intellectual disability (ID) and autism spectrum disorder (ASD). A significant consequence of integrating genetic testing into pediatric practice is the rapid identification of genetically mediated vulnerabilities in very young children, even before NPD symptoms manifest. This emerging scenario presents new and largely unaddressed clinical challenges, as well as unique research opportunities.

Objectives: To address the needs of the growing population of parents whose newborns are identified as being at increased risk for neurodevelopmental and/or psychiatric outcomes based on genetic testing results, we have established the DAGSY (Developmental Assessment of Genetically Susceptible Youth) clinic. This presentation describes the rationale for and design of the DAGSY clinic, as well as its potential for clinically relevant research.

Methods: DAGSY is an interdisciplinary service offering integrated clinical genetic, psychiatric, and psychological expertise in a single patient visit. Several aspects contribute to DAGSY's innovative potential: 1) children are referred based on genetic risk alone, providing an opportunity to explore preventative interventions; 2) the DAGSY team is interdisciplinary, combining genetic counseling, child psychiatry, and psychology in a single visit; and 3) while DAGSY is primarily a clinical service, it also serves as a research platform. To exemplify the latter, we evaluated two young patients with variations affecting the same gene. Prompted by the similarity in their NPD profiles, we subsequently collected extensive phenotypic data from a cohort of 11 international patients, all of whom harbored predicted deleterious variants in the *DENND2B* gene. We investigated the functional effects of these *DENND2B* variants using zebrafish models.

Results: We will present diagnostic findings and clinical recommendations for the 250 children evaluated at the DAGSY clinic to date. We will also report our observations in 11 patients with *DENND2B* variants, two of whom were identified through DAGSY, including their neuropsychiatric profiles, which show an increased prevalence of episodic behavioral changes. Our zebrafish experiments demonstrated that the *DENND2B* variants found in these patients lead to a loss of protein function, affecting cilia formation.

Conclusions: The early identification of genetically mediated neuropsychiatric risk at an increasingly young age introduces a new, largely unmet clinical need in child psychiatry. The DAGSY clinic addresses this need while also serving as a research platform. As an illustration of the latter, our case series unveils the potential role of *DENND2B* in the etiology of NPDs. Our findings suggest that monoallelic loss-of-function variants in this gene influence cilia growth and are associated with a novel autosomal dominant neurodevelopmental disorder with an increased risk for psychosis.

211.002 Transdiagnostic Approaches within an Autism Science in the Australian Child Neurodevelopment Research Registry

K. A. Boulton¹, A. Hodge², N. Ong³, N. Silove⁴ and A. J. Guastella⁵, (1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)Sydney Children's Hospital Network, Sydney, NSW, Australia, (3)The Children's Hospital at Westmead, Sydney, NSW, Australia, (4)Sydney Children's Hospital Network, Sydney, Australia, (5)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia

Background: Neurodevelopmental conditions, such as Autism Spectrum Disorder, affect 10% of the population, with most children receiving more than one diagnosis. Despite shared needs and high comorbidity, research and clinical practice has historically been diagnostically siloed, hampering advancements in knowledge and treatments to support these children. Adopting a transdiagnostic approach to neurodevelopment, where stable and shared markers of neurodevelopmental delay are identified, has potential to advance the science and practice of how we detect, assess, and support neurodevelopmental conditions.

Objectives: This presentation provides an overview of findings from a program of clinically integrated research using the Australian Child Neurodevelopment Research Registry. The registry is a digital platform integrated in public autism and developmental assessment settings in Australia. This talk focuses describing the body of work that has disseminated from the registry to enable identification of family focused transdiagnostic needs, strengths based approaches, and the transformation of assessment pathways to better meet the needs of families.

Methods: The data presented (N=2500) in the Australian Child Neurodevelopment Research Registry used mixed methods to: (1) collect information on large, priority cohorts of children and their families, with 50% representation from culturally diverse communities, 7% representation from indigenous communities and the majority of the populations reporting financial disadvantage; (2) detect diagnosis specific and transdiagnostic needs in this underserved population; (3) modify clinical service pathways based on these needs to personalise responses for each individual child to promote support and inclusion.

Results: Findings are presented across the entire cohort of 2500 children who presented to public health services for assessment, 76% of whom met criteria for Autism Spectrum Disorder. We describe the needs, strengths and barriers to supports identified by families across this cohort. We additionally report on the development and implementation of transdiagnostic assessment measures so that services can better capture this information. We then provide data to show how transdiagnostic and symptom profiles in this population predict function and disability. We present data to describe how the clinical service has modified pathways in response to this data.

Conclusions: Results highlight the significant unmet transdiagnostic needs shared across children with neurodevelopmental conditions. Findings support transdiagnostic models of neurodevelopment to further a developmentally sensitive science that can reveal how broad developmental delays contribute to profiles and functioning. We also discuss current responses and approaches initiated by our team to provide swift responses to unmet transdiagnostic needs, such as the use of digital tools to improve access to tailored supports and facilitate clinical monitoring and tracking of needs over time.

211.003 The Monash Autism-ADHD Genetics and Neurodevelopment (MAGNET) Project: A Transdiagnostic Exploration of Neurodevelopment and Mental Health in Children and Adolescents

B. Johnson¹, T. Chau², R. Knott¹, E. J. Forbes³, J. Langmead⁴, A. Finlay⁵, N. Johnston², K. Cappel¹, J. Tiego⁴, K. Williams³ and M. A. Bellgrove¹, (1)Monash University, Notting Hill, VIC, Australia, (2)Department of Paediatrics, Monash University, Clayton, VIC, Australia, (3)School of Psychological Sciences, Monash University, Melbourne, VIC, Australia, (4)Turner Institute for Brain and Mental Health, Monash University, Clayton, VIC, Australia, (5)Paediatrics, Monash University & Monash Health, Melbourne, VIC, Australia

Background: Neurodevelopmental conditions, such as autism and attention deficit hyperactivity disorder (ADHD), emerge in childhood and are associated with co-occurring mental health conditions, such as anxiety and depression, and increased risk of suicide. The categorical diagnoses (e.g. DSM-5, ICD-11) for autism and ADHD have broadened over time to capture a wider range of clinical presentations. However this has increased the variability in how symptoms present among individuals with the same diagnosis, and alongside the high prevalence of co-occurring conditions, contributes to diagnostic delays and creates challenges for clinicians in formulating treatment and support recommendations. To address this, the Monash Autism and ADHD Genetics and Neurodevelopment (MAGNET) Project was established in 2019 to better understand the overlap between autism, ADHD, broader neurodevelopmental traits, and their overlap with mental health traits. This landmark cohort is currently comprised of 600 children and >850 parents, who have been trans-diagnostically and deeply phenotyped across behavioural, neurocognitive, brain imaging and genetic measures.

Objectives: To create data-driven hierarchical and dimensional models of neurodevelopment and mental health traits that applies to children and adolescents, organised at varying levels of granularity, from clinical traits through to neurocognitive and motor biomarkers (e.g. oculomotor and vocal acoustic biomarkers).

Methods: Families (i.e. probands, siblings and parents) were recruited from across Victoria, Australia, from the community and from paediatrician referral, with diagnosis

for all participants confirmed by a paediatrician or psychologist, and speech pathologist. All participants undertook all assessments at a single site (Monash University), regardless of diagnostic status. Here we present data from autistic (n = 83), ADHD (n = 80), autism+ADHD (n = 170) and neurotypical children (n = 158) who have been phenotyped using parent-rated measures of neurodevelopment, mental health, quality of life and adaptive functioning, alongside standardised clinician-administered cognitive (e.g. WISC), speech and language (e.g. CELF-5) and semi-structured assessments (i.e. ADOS), and direct child measures, including eye tracking and neurocognitive tasks.

Results: Hierarchical dimensional models of parent-rated neurodevelopmental and mental health traits autism and ADHD share a common higher-level factor called Neurodevelopment and a middle-level factor called Emotional or Behavioral Dysregulation. Internalizing (e.g., anxiety, depression) and externalizing (e.g., aggressive behavior) issues were mostly separate from autistic and ADHD traits, with a unique role for pragmatic and structural language. Preliminary results from linear mixed effects models of more granular transdiagnostic features such as vocal acoustic markers have revealed significant associations between inattentive traits and pauses during speech, while autistic traits (SRS-2) were associated with variability or perturbation (jitter) and articulation rate. Linear mixed effect models of oculomotor markers revealed transdiagnostic patterns in responses to motor error (i.e. variability final eye position following saccadic adjustments, frequency of catch-up saccades).

Conclusions: Understanding autism, ADHD and mental health dimensionally, rather than as categories, suggests there might be overlapping sources of emotional and behavioural traits.

211.004 A Systematic Review and Meta-Analysis of the Transdiagnostic Associations between Cognition and Neurodevelopmental and Mental Health Disorders.

D. C. Coghill, *University of Melbourne, Melbourne, VIC, Australia*

Background: While cognitive impairments are reported across all mental disorders and neurodevelopmental conditions it is often difficult to make comparisons both within and between disorders due to the methodological variations between studies. One major limitation in interpreting the findings of these studies is the use of very different cognitive tasks to measure similar cognitive functions. The Cambridge Neuropsychological Test Automated Battery (CANTAB) is a well validated battery of tasks that has been used for over 30 years to study cognition across a wide range of neurodevelopmental and mental health conditions.

Objectives: To address the issue of between study task variation, we aimed to investigate the similarities and differences in cognitive functioning profiles on tasks from CANTAB across autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder (ADHD) and a range of mental health disorders using systematic review and meta-analysis.

Methods: We systematically searched: MEDLINE, PsycINFO, EMBASE, PubMed, Cambridge Cognition (from database inception to 16 January 2024) with no language restrictions. Included studies compared cognitive outcomes, on tasks from the CANTAB battery, in individuals with a mental health disorder (including ASD, ADHD, anxiety, depression, bipolar, obsessive-compulsive disorders, psychosis, and posttraumatic stress disorder) to a comparison group without a neurodevelopmental or mental health disorder. All studies diagnoses were confirmed using a validated diagnostic method (i.e., diagnostic interview). We excluded participants taking psychiatric medication. Random effects meta-analyses were performed to calculate standardised mean differences (Hedges' g) between individuals with a mental health disorder and controls. This study was pre-registered in PROSPERO (CRD4202295849).

Results: 140 studies were included for data extraction, and meta-analyses were conducted across 13 CANTAB tasks yielding 19 different outcome measures, comprising 9903 participants across clinical groups and 7244 controls. Participants with ASD, ADHD and all included mental health disorders had poorer performance than controls across all the reported CANTAB cognitive outcome measures. There was no unique cognitive profile for any of the included conditions. However, while small to medium effect sizes were reported across most disorders, large effect sizes were reported for some outcomes in both psychosis and ASD.

Conclusions: These results strongly support cognitive differences as a transdiagnostic feature of neurodevelopmental disorders. They also provide compelling evidence that, while cognitive differences may be more pronounced in ASD and psychosis, there are no unique cognitive profiles for any of the included neurodevelopmental and mental health disorders. On the basis of these findings, we conclude that cognitive profiles should not be used to define particular mental health disorders or to differentiate between them in either research or clinical practice settings. While not useful in making a diagnosis they may however help to define an individual's strengths and weaknesses and inform clinical recommendations.

Panel Session

212 - Discursions on Discourse: How Autistic Traits Contribute to Language Processing and Expression in Various Discourse Contexts

May 2nd, 2025, 10:30 AM - 12:30 PM - 606-607

Panel Chair: Emily Zane, *Communication Sciences and Disorders, James Madison University, Harrisonburg, VA*

Moderator: Molly Losh, *Communication Sciences and Disorders, Neurodevelopmental Disabilities Lab, Northwestern University, Evanston, IL*

Discussant: Molly Losh, *Communication Sciences and Disorders, Neurodevelopmental Disabilities Lab, Northwestern University, Evanston, IL*

Discourse involves language that is “bigger than a sentence,” where word/phrase meaning often depends on extrasentential information, including discourse context. Perhaps due to the demands involved in incorporating contextual information, extensive evidence finds that autistic people diverge from non-autistic people in their interpretation and expression of various forms of discourse. The current panel represents a deep dive into factors that may contribute to such differences, by exploring how diagnosis, autistic traits, and/or underlying subskills, like executive function, correlate with subtle differences in discourse expression, comprehension, and processing for adolescents and adults. Included projects use differing data-collection, coding, and analysis techniques to examine features of three discourse types: conversation, narrative, and persuasion. Projects involve creative manipulations of discourse context, by, for example, changing who participants interact with and switching discourse modality from words to pictures. The panel’s audience will learn about how such manipulations affect autistic participants’ performance and which underlying subskills may explain differences. Together, findings suggest that while some notable differences in autistic discourse depend on context and cognitive subskills separable from autism (e.g., language ability), others are context independent and directly correlative with autistic traits.

Introduction

E. Zane, *FACE Lab, James Madison University, Boston, MA*

212.001 Autistic Adults Display Different Verbal Behavior Only in Mixed-Neurotype Conversations: Evidence from a Referential Communication Task

P. Geelhand¹, **F. Papastamou²**, **S. Jaspard³** and **M. Kissine⁴**, *(1)ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium, (2)Université libre de Bruxelles, Bruxelles, Belgium, (3)Belgian American Chamber of the South (BACoS), Duluth, GA, GA, (4)ACTE — Center of research in Linguistics — ULB Neuroscience, Université libre de Bruxelles, Brussels, Belgium*

Background: Recent accounts of social difficulties in autism suggest that autistic and non-autistic individuals mutually misunderstand each other (Davis & Crompton, 2021). This assumption aligns with findings that mixed-neurotype interactions are less efficient than same-neurotype interactions (Crompton et al., 2020). However, in studies finding a ‘same-neurotype communicative advantage,’ interaction partners knew about each other’s neurotype. Therefore, it remains unclear whether different outcomes between mixed- and same-neurotype interactions are due to contact with a different neurotype or to inherently different communication styles, specific to each neurotype. Moreover, neurotype matching has been primarily investigated in verbal interactions. However, autistic adults often prefer written over oral communication (Howard & Sedgewick, 2021), possibly due to the lower social pressure associated with non-face-to-face interactions. As such, it remains unexplored whether the communication challenges of mixed-neurotype pairs experienced during verbal interactions also transpire in written interactions.

Objectives: This study investigates: (1) how neurotype (mis)match influences communication style when participants are unaware of their partner’s neurotype, and (2) how this manifests in both oral and written interactions.

Methods: 134 adult participants were divided into three same-sex dyad types: 23 autistic dyads, 23 non-autistic dyads, and 21 mixed-neurotype dyads. Participants were unaware of their partner’s neurotype. Dyads completed an online referential communication task where a ‘Director’ guides a ‘Matcher’ to rearrange abstract images, using both written (chat) and oral (microphone, no video) communication modes. Interaction outcome measures were task duration and verbosity of the Director. Task duration was the time (in seconds) dyads took to complete the task. Verbosity was the number of words produced by the Director during the task and were categorized as either “image description” or “small talk”.

Results: Across both oral and written communication modes, we found that non-autistic dyads were overall faster than autistic and mixed dyads. There was no difference in task duration between autistic and mixed dyads. For verbosity, across both oral and written communication modes, there was no difference regarding image description between same-neurotype dyads. Within mixed dyads, however, autistic directors used more words to describe images than non-autistic directors. Likewise, for small talk, there were no significant differences in verbosity between same-neurotype dyads. Within mixed dyads, autistic directors were more verbose than non-autistic directors. Furthermore, autistic directors from mixed dyads were more verbose than autistic directors from autistic dyads and non-autistic directors from non-autistic dyads. Non-autistic directors from mixed dyads were not more verbose than non-autistic directors from non-autistic dyads and autistic directors from autistic dyads.

Conclusions: Across both communication modes, non-autistic dyads completed the task faster than autistic and mixed dyads, indicating that dyads with at least one autistic partner were generally slower. Notably, in mixed dyads, autistic Directors were more verbose than non-autistic Directors across both communication modes. These results suggest that neurotype mismatch triggers different verbal behavior in autistic adults, even without awareness of the partner’s neurotype and in the absence of non-verbal cues. This suggests inherent differences in communication styles between autistic and non-autistic individuals, persisting across both oral and written communication modes.

212.002 Linguistic Alignment in Individuals with and without a History of Autism: The Role of Discourse Context, Theory of Mind, and Verbal Ability

M. J. Stabile, **A. Paxton** and **I. M. Eigsti**, *Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Conversational partners frequently converge on similar linguistic structures when engaged in discourse. This “linguistic alignment” enhances communicative clarity and promotes social affiliation. Studies using structured tasks report comparable alignment in autistic (AUT) and neurotypical (NT) participants; however, studies of *extended spontaneous discourse* suggest reduced alignment in autism. The current study extends past work to include individuals diagnosed with autism in childhood who no longer meet criteria later in life (loss of autism diagnosis; LAD).

Objectives: This study probed group differences in alignment overall, and as a function of task-internal discourse contexts. Associations with language, theory of mind, and executive functioning to inform theories of linguistic alignment.

Methods: The ADOS-2 was administered by trained graduate clinicians to 89 autistic, LAD, and NT adolescents and adults (Table 1) as part of a larger study of LAD outcomes. Sessions were recorded and transcribed, and three forms of alignment (lexical, semantic, and syntactic) were measured across four subtests of the ADOS using an open-source computational tool (Duran, Paxton, & Fusaroli, 2019). Participants completed measures of verbal, nonverbal, executive skills, and a theory of mind (ToM) task. Mixed-effects models examined fixed effects and interactions of group and task for each form of alignment, controlling for age, and compared actual alignment with chance alignment from a control set of response pairs. Analyses examined associations with age, verbal ability, ToM, and executive function.

Results: Groups did not differ in verbal, nonverbal, executive or ToM abilities, and generally engaged in comparable levels of each form of alignment. However, on a task that involved explicit discussion of social content (“social difficulties”), the LAD group showed more lexical alignment than both the AUT ($p = .03$) and NT ($p = .03$) groups; Fig 1. A similar pattern was observed for syntactic alignment, though analyses did not survive correction for multiple comparisons (LAD vs NT, $p = .08$; LAD vs. AUT, $p = .05$). The social difficulties task elicited more semantic alignment across groups than each of the other three tasks (Tuesday story, description of a picture, and school/work interview questions; $p < .001$). Each form of alignment was positively associated with age for the NT ($ps \leq .03$) but not LAD and AUT groups ($ps \geq .20$). Similarly, ToM performance was positively associated with lexical ($r = .36$, $p = .04$) and syntactic ($r = .48$, $p = .01$) alignment for the NT group alone.

Conclusions: Results revealed no differences in autistic participants in aligning their word choices, subject matter, or sentence structures, relative to neurotypical peers. Further, LAD individuals who display few or no current symptoms of autism were more aligned with partners, suggesting an increase in affiliative behavior, particularly in contexts in which social content is explicitly invoked as a topic of discussion. This, and the limited role of ToM and verbal abilities, point to the potentially greater impact of experience with intervention and with similar kinds of interactions in discourse alignment.

212.003 I'm Convinced! the Role of Content and Manner of Delivery in Convincing Peers in Autistic and Non-Autistic Adolescents' Persuasive Discourse

J. H. L. Wong¹, M. L. Beauchamp¹, G. Luk², E. A. Smith³, K. H. Onishi⁴ and A. Nadig⁵, (1)McGill University, Montreal, QC, Canada, (2)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (3)Linguistique, Université du Québec à Montréal, Montreal, QC, Canada, (4)Department of Psychology, McGill University, Montreal, QC, Canada, (5)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada

Background: Persuasive discourse involves using language to change others' thoughts or behaviours. (Rocklage et al., 2018). As it is a complex skill that becomes refined in adolescence (Heilmann et al., 2020), its development may be difficult for autistic individuals who experience social communication challenges (Kelly et al., 2018). Indeed, during persuasive discourse, autistic adolescents generate fewer supporting arguments and counterarguments than neurotypical peers (To et al., 2016), demonstrating that *content* (or macrostructure) of persuasive discourse may be affected by autism. It is also important to consider *manner of delivery*, because for the same persuasive discourse, content and manner of delivery may lead to different impressions: neurotypical raters had negative first impressions of autistic speakers based on audiovisual clips, but not based on transcripts alone (Sasson et al., 2017).

Objectives: We examined whether *content* and *manner of delivery* play a role in how convinced a listener was to make a proposed change (*convincingness*) in the persuasive discourse of both autistic and non-autistic adolescents.

Methods: Data collection, transcription, and coding/analyses are on-going. Of the forty-two French-speaking adolescents who have participated so far, we report on 27 whose data have been transcribed and coded (11 autistic; 16 non-autistic; ages 14-19). Groups did not statistically differ with respect to age, receptive vocabulary, grammatical ability, or nonverbal IQ. Participants were asked to persuade a peer (enacted by a research assistant) to do something (e.g., switch shifts with them at a part-time job). To assess content, transcripts of the persuasive language samples were analyzed using the Persuasive Scoring Scheme (Heilmann et al., 2020), which evaluates the presence and complexity of macrostructure elements such as supporting arguments, counterarguments, and compromises, resulting in a composite score. To assess manner of delivery, an independent listener viewed the persuasive sample by video and rated the speaker's confidence, body language, and tone of voice. A second independent listener rated how convinced they were to make the proposed change. Study staff were neurotypical, naïve to diagnostic group, and 18 – 22 years old.

Results: The two groups did not differ significantly on content, manner of delivery, or convincingness scores. In our preliminary analysis, across all participants, manner of delivery (but not content) positively and significantly predicted convincingness. As shown in Figure 1, the relationship between manner of delivery and convincingness differed significantly between the two groups: for the non-autistic group, higher manner of delivery scores resulted in the listener being more convinced, possibly due to their following neurotypical or ‘standard’ ways of speaking. However, for the autistic group, manner of delivery scores were unrelated to how convinced the listener was.

Conclusions: This study informs us about the discourse factors that may ultimately determine whether an adolescent can achieve their goals when interacting with neurotypical partners.

212.004 Visual Attention to the Climax of Pictorial and Verbal Narratives Decreases with Increasing Autistic Traits

E. Zane¹, E. Booth¹, R. Bunner¹, H. Chappell¹, C. Soong¹, N. Cohn² and E. L. Coderre³, (1)Communication Sciences and Disorders, James Madison University, Harrisonburg, VA, (2)Tilburg University, Tilburg, Netherlands, (3)University of Vermont, Burlington, VT

Background: Narrative comprehension can be difficult for autistic individuals, at least when narratives are presented in words (McIntire et al., 2017). Some research has suggested autistic people focus on story elements that are irrelevant to the “main idea,” thereby prohibiting global story understanding (Nuske & Bavin, 2011). Building on this, we test whether attention to non-central story-elements corresponds with autistic traits, and importantly, whether these differences transcend the verbal modality, affecting even the processing of stories presented in pictures (e.g., comic strips).

Objectives: We seek to determine whether/how autistic traits relate to a person’s attention to important story elements, irrespective of whether stories are presented in words or pictures, and even when taking into account other factors related to comprehension (e.g., single-sentence comprehension).

Methods: Fifty-two (52) adults (m age = 24:3, 34 cisgender female, 6 cisgender male, 11 nonbinary and/or trans male, 1 gender queer) responded to a recruitment effort seeking autistic and non-autistic adults to participate in a comprehension study. Participants completed multiple assessments measuring cognition, language, and autistic traits. For current analyses, we focus on scores from three: The Sentence Comprehension subtest of the Wide Range Achievement Test-5th Edition (WRAT-SC; m = 111.37, range = 92-133) (Wilkinson & Robertson, 2017); the Visual Language Fluency Index (VLFI), which measures experience and expertise engaging with comics (m = 9.37, range = 2.12-32.63 [scores between 12 and 20 of represent average experience/expertise]) (Cohn, 2014); and the AQ (m = 22.74) (Baron-Cohen, 2001).

Each participant viewed 96 novel narratives: 48 wordless *Peanuts* comics and 48 written stories. For each narrative, a single panel/sentence was identified, *a priori*, as representing the peak/climax event. Participants viewed/read each narrative and then “segmented” the narrative into two constituent sections (Figure 1). Eye-tracking was recorded throughout.

To analyze data, we used a backwards, stepwise procedure to determine the best-fitting mixed-effects linear regression model for predicting proportion dwell time to each sentence/panel for each story with the following variables included as possible fixed effects and interactions: VLFI, WRAT-SC, AQ, narrative modality (linguistic vs. pictorial), and panel/sentence type (climax vs. not).

Results: In the identified best-fitting model, no main effects significantly predicted proportion dwell to sentences/panels, but several interactions did: panel/sentence type by AQ ($p < .001$), panel/sentence type by modality ($p < .001$), panel/sentence type by WRAT-SC ($p = .03$), and modality by VLFI ($p < .001$). Focusing on results that speak to study objectives, the significant AQ-by-panel/sentence-type interaction reflected decreased relative looking to climax panels/sentences as AQ scores increased. Figure 2.

Conclusions: As autism traits increase, participants’ relative visual attention to a story’s climax decreases, even when stories are presented in pictures, and even when accounting for variance related to other abilities likely related to comprehension, like sentence comprehension and comic-strip experience. Results importantly implicate that autistic differences in story processing are independent of presentation modality (i.e., words or pictures), suggesting that well-documented struggles with reading comprehension, at least for written stories, may depend on differences in story-parsing and attentional constructs that underlie the comprehension of narratives no matter their form (Coderre et al., 2018).

Panel Session

213 - Gender Diversity and Autism: Gender Trajectories and Gender Outcomes in Complex Socio-Political Contexts

May 2nd, 2025, 2:00 PM - 4:00 PM - 6B

Panel Chair: John Strang, *Gender and Autism Program, Children's National Health System, Washington, DC*

Discussant: Meng-Chuan Lai, *Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada*

Increased public awareness of the common autism and gender diversity intersection has spurred research interest and advocacy. Being in the public eye has also increased efforts to restrict care access. Some legislative initiatives to limit transgender youth rights have employed as justification the common autism co-occurrence, based on apparent ableist assumptions that autistic youth should not be trusted to make decisions about their lives and bodies. These assumptions and legal initiatives have advanced with little research available to evaluate or comment on them. This panel will present the first long-term outcome findings of autistic transgender youth followed into adulthood. Patterns of continuity as well as shift in both gender and gender-related medical care will be examined, with consideration of whether the diagnosis of autism changes the likelihood for detransition and regret. A cross-national approach is employed in three of the talks, including report on how autistic transgender youth are faring in locations which restrict care and broader rights. Equity and accuracy in autism-related neuroscience are discussed in the context of capturing and modeling gender beyond assigned sex at birth. Preliminary brain findings demonstrate that gender diversity measured in adolescence retrospectively predicts greater variations in early childhood brain structure.

Introduction

J. F. Strang, *Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC*

213.001 Gender and Gender-Related Care Outcomes of Autistic Transgender Youth Followed into Adulthood

J. F. Strang¹, **L. Baczewski**², **A. L. Fischbach**³, **L. Campos**⁴, **J. K. Lee**⁵, **C. W. Nordahl**⁶ and **A. I. van der Miesen**⁶, (1)Gender and Autism Program, Children's National Health System, Washington, DC, (2)Center for Autism, Center for Autism Spectrum Disorders, Children's National, Washington, D.C., DC, (3)Department of Psychology, University of Cincinnati, Cincinnati, OH, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Rockville, MD, (5)Department of Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (6)Department of Child and Adolescent Psychiatry, Center of Expertise on Gender Dysphoria, Amsterdam University Medical Centers, Location Vrije Universiteit, Amsterdam, Netherlands

Background: The common intersection of autism and gender diversity has been reported across the age span and in multiple countries (Kallitsounaki & Williams, 2023). No studies have investigated gender and gender-related care outcomes of autistic transgender youth followed into adulthood. Yet, increasing rhetoric and related legislative initiatives have been advanced to limit autistic transgender youth access to care and broader liberties.

Objectives: This study aims to begin to fill the profound gap in research on autistic transgender youth gender trajectories. We present the findings of two cohorts of autistic transgender children/adolescents followed into adulthood: one from the U.S. ($n=27$ at baseline) and one from the Netherlands (Dutch; $n=23$ at baseline). Both cohorts received care according to the international standards of care for gender-diverse people.

Methods: U.S. cohort: 66 U.S. transgender adolescents were assessed through comprehensive developmental, in vivo diagnostic, and multiple informant evaluation to provide high-confidence diagnostics of autism (Strang et al., 2023). Of the 66 youth, 27 met criteria for autism (M_{age} at $T1=17.37$; $SD=2.08$). U.S. participants provided follow-up report on their gender, gender-related medical care, and anxiety ~4 years later in young adulthood (M_{age} at $T2=21.09$; $SD=1.88$). Dutch cohort: As Dutch participants were first diagnosed in the 2000s, the autism diagnostic protocol differed from contemporary approaches. Twenty-three of 115 gender-diverse children and adolescents were diagnosed autistic with the DISCO and expert clinician child interview (M_{age} at $T1=10.8$, $SD=3.58$). Long-term outcome assessments were conducted ~15 years following baseline (M_{age} at $T2=29.42$, $SD=4.90$). Participants reported on gender and gender-related care outcomes.

Results: Retention rate for the U.S. cohort (at ~4 years) was 96.3%. Retention rate for the Dutch cohort (at ~15 years) was 60.1%. Continuity of gender-diverse identities was high in both cohorts (see Figures 1 and 2). Among U.S. adults, 92.3% were gender-diverse at T2; among Dutch adults, 85.7% were gender-diverse at T2. No medical gender reversals were reported among either cohort, though one Dutch participant reported mixed feelings about their gender-affirming surgery and one U.S. participant stopped their hormone treatment once the desired effects were achieved. Those who shifted to cisgender identities ($n=4$ across both cohorts) never received gender-related medical care. In the U.S. cohort, for those who wanted gender-related medical care ($n=25$), earlier receipt of such care (by T1) was associated with significant reductions in anxiety across time ($b=-4.55$, $SD=1.73$, $t=-2.63$, $p=.016$). Comparing gender trajectories across both samples, 50% of U.S. participants had moved to or added a nonbinary identity by T2, while only one Dutch participant was nonbinary.

Conclusions: Two separate studies in two countries found generally high rates of gender diversity continuity for autistic transgender youth receiving standard-of-care healthcare followed into adulthood. Four of 40 moved to cisgender identities in adulthood and there were no documented medical gender reversals. Study findings do not support current rhetoric suggesting that autistic transgender youth are highly likely to shift away from gender diversity and reverse medical gender transitions. Findings should be interpreted in the context of a notable loss to follow-up in the Dutch 15-year study.

213.002 The Impact of Transgender-Limiting Legislation on Autistic Vs. Not-Autistic Transgender Youth

A. Hindenach¹, A. L. Fischbach², J. Feng³, A. I. van der Miesen⁴ and J. F. Strang⁵, (1)Children's National Hospital, Washington, DC, (2)Department of Psychology, University of Cincinnati, Cincinnati, OH, (3)Graduate School of Education, University of Pennsylvania, Philadelphia, PA, (4)Department of Child and Adolescent Psychiatry, Center of Expertise on Gender Dysphoria, Amsterdam University Medical Centers, Location Vrije Universiteit, Amsterdam, Netherlands, (5)Gender and Autism Program, Children's National Health System, Washington, DC

Background: Over the last four years, more than half of states in the United States (US) have restricted transgender youth healthcare and/or broader civil rights. Legislation in Arkansas and Ohio specifically limits autistic minors from accessing gender care, and Georgia defends their ban of several forms of care for all transgender youth based in part on the common co-occurrence of autism and gender diversity. In contrast to the US, the Netherlands is a country in which transgender youth are broadly accepted and affirmed, and by adulthood transgender youth in the Netherlands show mental health outcomes equivalent to their cisgender peers. Our team has, through an international Delphi study, identified the Netherlands as a gold standard comparator for research in the US to understand the impacts of varying policy on transgender youth wellbeing (van der Miesen et al., under review).

Objectives: This transnational study of transgender youth ages 11-16 sought to understand relationships between autism, legislative context, gender minority stress, perceptions of safety, and mental health. Three legislative and societal contexts are compared: the Netherlands ($n=73$), US states not restricting transgender youth civil rights ($n=51$), and US states restricting transgender youth civil rights ($n=52$), ranked in order of increasing legislative/societal restriction.

Methods: The recruitment of autistic youth was proportionally balanced between the US and NL ($n=50$ autistic, $N=175$ total). Each participant completed a face-to-face 1.5-hour virtual study visit. The protocol included measures validated and calibrated in both countries and in English and Dutch. Measures were: the Transgender Youth Perceptions of Environmental Support self-report interview (TYPES), which captures a young person's sense of safety as a transgender person; the Gender Minority Stress and Resilience Scale-Adolescent (GMSR-A) assessing non-affirmation and internalized transphobia; and the ASEBA Youth Self-Report (YSR total problems subscale) capturing overall mental and behavioral health. Autism diagnostic status and ratings on the Social Communication Questionnaire (SCQ) were collected from parents/caregivers.

Results: Perceptions of feeling safe as a transgender young person (TYPES) were lower among the autistic subgroup. More restrictive location was also related to lower perceptions of safety, suggesting an additive risk for autistic transgender youth in restrictive locations (Table 1, Row 1). Autistic transgender young people reported more experiences of not being affirmed in their gender, with a similar additive risk for those in restrictive contexts (Row 2). They also experienced a greater sense of internalized transphobia than those not-autistic (Row 3). Autistic transgender young people experienced more mental health problems than not-autistic transgender youth (rows 4-9). Lower sense of safety (Rows 4-5) and greater internalized transphobia (Rows 8-9) were each associated with exacerbated mental health problems in addition to autism, but autism did not predict mental health when included in the model with non-affirmation (Rows 6-7).

Conclusions: Results suggest that youth at the intersection of autism and gender diversity face particular risks for feeling unsafe and experiencing gender minority stress and related mental health challenges in the context of civil rights restrictions. Our ongoing longitudinal study seeks to understand how these stressors will affect autistic youth development over time.

213.003 Gender Diversity in Adolescence Linked to Early Childhood Brain Structure in Autistic and Not-Autistic Youth

J. K. Lee¹, B. Heath¹, D. S. Andrews², A. Marquand³, J. F. Strang⁴, M. Solomon¹ and C. W. Nordahl¹. (1)Department of Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, MIND Institute, UC Davis Medical Center, Sacramento, CA, (3)Centre for Neuroimaging Sciences, King's College London, London, United Kingdom, (4)Gender and Autism Program, Children's National Health System, Washington, DC

Background: Substantial heterogeneity exists in the neurophenotypes of autism, hindering scientific progress in understanding the neural basis of autism. Gender diversity encompasses the range of differences between an individual's internal, subjective experience of their gender identity and the sex assigned to them at birth. Gender diversity is proportionally overrepresented in autism, with 8-20% of autistic individuals identifying as gender diverse. Neuroimaging research has reported differences in brain structure and function associated with gender diversity, yet the autism neuroimaging literature has virtually ignored how gender diversity may impact our models of autistic neurophenotypes. Until we parse the neural heterogeneity of gender diversity in the brains of autistic youth, the field will lack explanatory power beyond that of sex assigned at birth. This study leverages a longitudinal brain imaging study, the Autism Phenome Project (APP) to investigate how gender diversity reported during adolescence is retrospectively associated with individual differences in brain structure from when they were 2- to 4-years-of-age.

Objectives: Retrospectively assess brain differences in early childhood in association with self-reported gender diversity in adolescence.

Methods: As part of ongoing longitudinal data collection in the APP during adolescence (age 15-18) 41 participants (18 autistic, 23 TD) provided self-report data related to their gender diversity, which includes felt femininity and masculinity over two 7-point Likert scales. These scores were reverse coded by assigned sex and then averaged to create a distance scale from 0 to 6 of increasing gender diversity. Retrospective analysis of cortical thickness and subcortical volumes at age 2- to 4-years of age was assessed from MRI acquired during natural sleep from T1w images in 30 of these participants (15 autistic). A reference sample from the general population, comprising ~60,000 MRI scans was utilized to model lifespan trajectories of cortical thickness and subcortical regions of interest (ROIs) using Bayesian Linear Regression with likelihood warping. We leverage this normative model to derive Z scores for each ROI for each participant which indicates the degree to which the ROI differs from the age- and sex- normed means. We counted the number of ROIs within each individual with Z-scores at the extreme tails of the normal distribution, defined as exceeding an absolute Z-threshold > 2, regressed onto a model including gender diversity scores, autism diagnosis, and developmental quotients from the Mullen Scales of Early Learning.

Results: Autistic participants on average reported greater diversity ($M=1.88$) than did non-autistic participants ($M=0.7$) ($b=1.18$, $SE=0.50$, $t=2.38$, $p=.023$), and scores exhibited overall greater variability in autism (Levene-Test, $p=0.011$). Poisson regression revealed a significant effect of self-rated gender diversity in adolescence, ($\beta=1.06$, $SE=0.05$, $z=5.2$, $p<.0001$), such that for each one-unit increase in gender diversity on its Likert scale, the expected count of extreme deviations increased by 1.3. Autism diagnosis and developmental quotients did not reach statistical significance ($ps<.05$).

Conclusions: Gender diversity in adolescence is linked to early childhood brain structure differences in both autistic and non-autistic individuals, underscoring the need to account for gender diversity when examining neurophenotypic variability in autism.

213.004 Profiles of Detransition in Autistic Gender Diverse Individuals

K. R. MacKinnon, York University, Toronto, ON, Canada

Background: Detransition, defined as stopping, shifting, or reversing a gender transition, is a heterogeneous phenomenon reported by some gender-diverse people. Detransition can be prompted by various social, medical, and mental-health-related factors. These factors can include lack of support or discrimination, shifts in gender identity, medical complications, among other reasons. Many individuals who detransition affirm a sexual or gender minority identity (e.g., LGBTQ+). While decisional regret can overlap with detransition, some people also report positive or ambivalent feelings about their journey.

From an exploratory mixed-methods study completed in the United States and Canada, this study investigates profiles of detransition as they relate to autism as well as other socio-demographic characteristics and life experiences.

Objectives: Employing survey and qualitative interview data from the Detransition Analysis, Representation, and Exploration (DARE) study, we: (1) examined discrete profiles of detransition, their respective rates of autism, and whether autistic individuals were likelier to report certain pathways/reasons to detransition; (2) investigated whether experiences of regret were similar or different among autistic as compared to non-autistic individuals who detransition, and (3) sought to qualitatively understand the care experiences of autistic participants who underwent detransition.

Methods: The DARE Study included 957 individuals ages 16-74 in the U.S. and Canada who self-reported a lifetime experience of gender detransition. To understand autism and detransition, proportional descriptives of autistic vs. non-autistic participants were presented and compared to current estimates of the rates of autism within gender diverse communities, generally. Prevalence of regret relating to pathway to detransition, as well as autism status were explored. Finally, qualitative themes of the intersection of autism and detransition were identified ($N=40$ from the surveyed sample).

Results: The sample had a mean age of 26 and 79% were assigned female at birth (AFAB). 25% of the DARE sample reported a formal autism diagnosis and 42% reported self-diagnosing or identifying as autistic. Latent class analysis identified four sub-groups of detransition profiles characterized by the following self-reported reasons to detransition: Class A ($n=315$; 90% AFAB): identity shift/reconceptualizing gender norms, worsening mental health, and decisional regret; Class B ($n=186$; 88% AFAB): identity shift/reconceptualizing gender norms, and overall satisfaction with treatments; Class C ($n=182$; 75% AFAB): discrimination/lack of support, worsening mental health, and decisional regret; and Class D ($n=271$; 62% AFAB): discrimination/lack of support, with overall treatment satisfaction. Rates of diagnosis of autism or autistic self-identity did not differ across these four sub-groups. Finally, qualitative analyses revealed a pattern of participants who were AFAB, mainly from Class A, receiving a late autism diagnosis, with some indicating they would have preferred to have been aware of being autistic prior to making gender-related care decisions.

Conclusions: These results suggest that detransition is a heterogeneous and complex experience requiring further research, particularly as it intersects with autism, sex/gender, and mental health care. Our results suggest that while some individuals who report experiences of detransition are also autistic, prevalence of decisional regret does not appear to be higher among autistic people when compared to non-autistic people who also report detransition.

214 - Translational Cross Species Neuroimaging Studies of Sensory Processing in Fragile X Syndrome and Autism

May 2nd, 2025, 2:00 PM - 4:00 PM - 6C

Panel Chair: Carol Wilkinson, *Department of Developmental Medicine, Boston Children's Hospital / Harvard Medical, Boston, MA*

Discussant: Carol Wilkinson, *Department of Developmental Medicine, Boston Children's Hospital / Harvard Medical, Boston, MA*

This panel brings together cross-species research on sensory processing in Fragile X syndrome (FXS) and autism. Featuring four talks, it integrates complementary neuroimaging findings from both rodent and human studies to describe potential neural mechanisms underlying alterations in sensory processing in these populations. The speakers will also address key benefits and limitations in studying sensory processing across species, including highlighting differences in recording techniques and presented stimuli, as well as developmental considerations in data collection and interpretation of sensory responses across the age range. The panel discussion will emphasize the clinical implications of these studies, and future steps for improving diagnostic and therapeutic strategies for individuals. Attendees will gain a deeper understanding of how diverse methodological approaches converge to uncover the complexities of sensory processing in autism-related disorders, and how these insights can advance the development of targeted interventions.

Introduction

C. L. Wilkinson, *Developmental Medicine, Boston Children's Hospital / Harvard Medical, Boston, MA*

214.001 How EEG Markers in FXS Relate to Behaviors

S. Lippe¹, **I. S. Knott²** and **M. Proteau-Lemieux³**, *(1)Neurosciences of Early Development Lab, CHU Sainte-Justine University of Montreal, Montreal, QC, Canada, (2)CHU Sainte-Justine Research Center, Neuroscience of Early Development lab, Montreal, QC, Canada*

Background:

Individuals with neurodevelopmental disorders exhibit atypical brain dynamics. Electroencephalographic (EEG) markers have been linked to autism spectrum disorders and intellectual disabilities and are believed to be useful for better understanding the underlying mechanisms of these conditions, as well as for assessing disorder severity and treatment-related recovery. In the case of Fragile X Syndrome, there is some consensus on which EEG markers are altered. However, the extent to which these markers correlate with behavior remains unclear.

Objectives:

The objective is to test whether the EEG markers altered in Fragile X Syndrome (FXS) are associated with the core behavioral symptoms observed in this population. The implication is that this will help identify which EEG markers should be targeted for modification through treatment.

Methods:

Forty-seven participants with FXS aged between 5-20, 49 participants with ASD, and 52 neurotypical controls with similar age distribution took part in the study. EEG features from resting-state and the auditory oddball paradigm using tones were extracted. Power spectrums, multiscale entropy, alpha peak frequency, component peaks amplitude and latencies (including the MMN) for each repetition of the oddball paradigm were compared between groups (MANCOVAS). Then, correlation and regression analyses were performed to assess whether they were associated with NVIQ, adaptive behavior, socialization, irritability, lethargy, inappropriate speech, repetitive behaviors, inattention, impulsivity, anxiety and depression.

Results:

Group comparisons confirmed signal complexity, alpha peak frequency, alpha band power, low gamma band power and habituation alterations, particularly in the FXS group. Increased N100 amplitude and reduced N100 habituation were associated with social affects and restricted and repetitive behaviors. Reduced N100 habituation and augmented MMN latencies were associated with reduced adaptive behaviors. EEG markers from the resting-state condition were also associated with the core symptomatology. Complexity measures were associated with NVIQ, while reduced alpha power and augmented gamma power were respectively associated with social avoidance, and lethargy and irritability.

Conclusions:

Alterations in EEG features in individuals with Fragile X Syndrome (FXS) reflect the severity of their behavioral impairments, making these features strong candidate markers for investigation in clinical trials. Whether these markers change in response to treatment-induced behavioral improvements remains an open question.

214.002 Characterization of Habituation to Tones in FXS, Autism, and Down Syndrome

W. An¹, **M. Khela²**, **M. Tsou³**, **K. Pawlowski⁴**, **N. Baumer⁵** and **C. L. Wilkinson⁶**, *(1)Pediatrics, Division of Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Tufts University, Medford, MA, (3)Boston Children's Hospital, Boston, MA, (4)Boston Children's Hospital, Boston, MA, (5)University of Colorado, Aurora, CO, (6)Department of Developmental Medicine, Boston Children's Hospital / Harvard Medical, Boston, MA*

Background: Fragile X syndrome (FXS) is a rare genetic disorder and is commonly associated with autism spectrum disorder (ASD) and intellectual disability. Previous studies have focused on FMR1 KO mice and adults with FXS and observed reduced neural habituation to repeated sounds, as evidenced by their electroencephalography (EEG) signals. However, little is known about the habituation phenotype in children with FXS and how it compares to children with idiopathic ASD and other neurogenetic disorders like Down syndrome (DS).

Objectives: To characterize neural habituation to repeated tones in children with typical development (TD), ASD, FXS, and DS.

Methods: We designed an auditory habituation paradigm with pure tones. Each trial contained *three* identical, 1000-Hz tones separated by 500 ms. These tones were analyzed as three conditions, namely First, Second, and Third. 20 children with FXS (27 – 78 months; 3 females; all with documented full mutation of FMR1), 28 children with ASD (32 – 83 months; 1 female), 26 children with DS (24 – 68 months; 11 females), and 46 typically-developing (TD) children (23 – 76 months; 9 females) contributed usable high-density EEG (≥ 40 trials per condition post-processing) while they were passively listening to these tones. Time windows for P2 (44 – 188 ms) and N2 (216 – 384 ms) components were determined via a cluster-based permutation test (Figure 1). The amplitude of P2 and N2 components were extracted from the event-related potential as the peak value within their respective window. Habituation was calculated as the amplitude difference between First and Third conditions (First – Third in P2 and Third – First in N2) and was compared to zero within each group using a one-sample t-test.

Results: We observed significant P2 habituation in the TD ($p=0.009$) and ASD ($p<0.001$) groups, but not in children with FXS ($p=0.194$) or with DS ($p=0.434$). The TD ($p=0.022$) and DS ($p=0.012$) groups also showed significant habituation in N2, but not the other two groups.

Conclusions: Typically developing children habituate to repeated tones in both P2 and N2 components in their auditory evoked response. Children with FXS showed no significant habituation in both components, while children with ASD or DS showed significant habituation in only one component. Future analyses will investigate whether degree of habituation is associated with clinical measures including language and cognitive development.

214.003 A Human Electrophysiological Biomarker of Fragile X Syndrome Is Shared in V1 of *Fmr1* KO Mice and Caused By Loss of FMRP in Cortical Excitatory Neurons

S. S. Kornfeld-Sylla¹, C. Gelegen Van Eijl², J. E. Norris³, F. A. Chaloner⁴, M. Y. Lee⁵, M. Khela⁶, M. J. Heinrich⁷, P. S. Finnie⁸, L. E. Ethridge⁹, L. M. Schmitt⁹, S. F. Cooke⁹, C. L. Wilkinson¹⁰ and M. F. Bear¹, (1)Picower Institute for Learning and Memory, Massachusetts Institute of Technology, Cambridge, MA, (2)Department of Basic and Clinical Neuroscience, Institute of Psychology, Psychiatry and Neuroscience, King's College London, London, United Kingdom, (3)Department of Psychology, University of Oklahoma, Norman, OK, (4)Centre for Developmental Neurobiology, Institute of Psychology, Psychiatry and Neuroscience, King's College London, London, United Kingdom, (5)Tufts University, Medford, MA, (6)University of Toronto, Toronto, ON, Canada, (7)Pediatrics, University of Oklahoma Health Science Center, Oklahoma City, OK, (8)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (9)Wolfson Sensory, Pain, and Regeneration Centre, King's College London, London, United Kingdom, (10)Department of Developmental Medicine, Boston Children's Hospital / Harvard Medical, Boston, MA

Background: One prominent feature of electroencephalogram (EEG) recordings measured in typically developing (TD) adults is a narrow-band oscillatory peak centered around 10.5 Hz. In Fragile X Syndrome (FXS), the leading inherited cause of intellectual disability and autism spectrum disorder, this “alpha rhythm” is altered, but the lack of an apparent correlate in *Fmr1* KO mice has limited study of the neurobiological basis for this biomarker.

Objectives: We seek to identify a comparable phenotype in the mouse model and investigate its mechanistic basis.

Methods: We use field potential recordings to compare altered physiology of occipital cortex across species. This included high-density (128 channel) EEG recordings from TD and FXS male adults (19-44 years, 20 per group) and children (2-7 years, 17 per group), skull-screw EEG electrodes in adult male wild-type (WT) and *Fmr1* KO mice (10-16 weeks, 11 per group), and local field potential (LFP) recordings from layer (L)4 of male WT and *Fmr1* KO mice (4-20 weeks, 67 per group). Custom spectral analysis code permitted unified analyses of these varied methodologies.

Results: Replicating previous reports, we find the center frequency of the narrow-band peak is shifted from ~10.5 Hz to ~7.5 Hz in EEG recordings of adults with FXS. A comparable narrow-band peak centered around 6 Hz is identifiable in skull-screw EEG resting state data of freely moving adult WT mice, and is shifted to ~4.5 Hz in *Fmr1* KO mice specifically in primary visual cortex (V1). Next, we recorded the LFP in L4 of V1 in awake, head-fixed mice viewing a dark or illuminated gray screen. This revealed: 1) a two sub-peak structure to these oscillations and 2) altered power and temporal dynamics of these oscillations in *Fmr1* KO mice. The addition of luminance enhanced power differences, especially in juvenile (4-6 week) mice. We observe a weakening of periodic alpha power in children, but not adults, with FXS.

Since inhibitory interneurons coordinate cortical oscillations and there is a deficiency of Parvalbumin (PV+) interneuron activity in FXS, we inhibited PV+ interneuron activity in WT mice while measuring the LFP in L4. We observed reduced power in the second, but not the first sub-peak of the low-frequency oscillation. Inhibition of Somatostatin (SOM+) interneurons reduced power in the first sub-peak. However, loss of FMRP solely in excitatory neurons and astroglia in cortex reproduced the L4 LFP phenotype.

Conclusions: The robust “alpha” biomarker of FXS patients is shared in V1 of *Fmr1* KO mice. Surface recordings in *Fmr1* KO mice reveal the shift in center frequency of the comparable oscillation, and intracortical LFP recordings further reveal power differences between genotypes that are enhanced by luminance and dependent on age. We also observe developmental differences in this biomarker in humans. While inactivation of different classes of interneurons in WT mice parallel the *Fmr1* KO mice phenotypes, loss of FMRP from cortical excitatory neurons alone is sufficient to reproduce the phenotype. This implicates altered inputs from excitatory neurons rather than the loss of FMRP in inhibitory neurons as the mechanistic basis, informing future therapeutic strategies.

214.004 Development of Abnormal Temporal Processing in the *Fmr1* Knock out Mice

K. A. Razak, University of California, Riverside, Riverside, CA

Background: Sensory sensitivity differences and delayed language functions are consistently seen in children with autism spectrum disorders (ASD). Auditory temporal processing is crucial for speech perception and language development. Abnormal development of temporal processing observed in children with ASD may lead to language impairments. To understand the cellular and circuit mechanisms underlying temporal processing differences requires an animal model, but Very little is known about the development of temporal processing in any animal model of ASD.

Objectives: The major objectives of this study were to quantify development, sex differences and hemispheric asymmetries in temporal processing in a mouse model of Fragile X Syndrome (FXS), a leading known genetic cause of ASD.

Methods: Epidural screw electrode electroencephalogram (EEG) recordings were obtained from awake and freely moving WT and Fmr1 KO mice. Recordings were obtained at postnatal day (P)21, 30 and in young adults of both sexes. For hemispheric differences analysis, skull 30 channel multielectrode array recordings were obtained from male adult mice. Spectrotemporally dynamic chirps, 40 Hz auditory state responses (ASSR) and 40 Hz gap-in-noise ASSR were recorded. Intertrial phase coherence (ITPC) was quantified to determine trial to trial consistency of phase locking to stimulus temporal aspects.

Results: In P21 and adult WT mice, MEA recordings show higher ITPC in the left hemisphere compared to the right at gamma frequencies (40-80 Hz) in both ASSR and chirp responses. Such hemispheric differences were not seen in Fmr1 KO mice. In the KO mice, ITPC was lower compared to WT mice for all stimuli. Epidural EEG recordings show sex differences in ITPC for gap-in-noise ASSR, with male KO mice showing reduced ITPC at P21 and P30, but female KO mice only showing deficits at P21. No sex differences were seen in WT mice at any age.

Conclusions: These analyses reveal reduced fidelity of responses across trials to both gap-in-noise stimuli and spectrotemporally dynamic chirps. Increased trial-to-trial variability of responses is present from early development in mice (~P21), but female KO mice temporal processing matures faster than in males. The lack of sex differences in WT mice indicates that the observed sex differences in the Fmr1 KO mice is specific to the genotype. Hemispheric differences in fast temporal processing in humans is related to speech processing, with a strong link between gamma band oscillations and parsing of speech input in the phoneme range. Therefore, our observed differences in gamma band ITPC suggests a bridge between animal work and language development in ASD. Future studies should examine hemispheric differences in ASSR and chirp stimuli in children with FXS to identify potential correlations with language function.

Panel Session

215 - Cultural Adaptation for Improving Equity in Autism Screening and Service Access across Systems and Settings

May 2nd, 2025, 2:00 PM - 4:00 PM - 6A

Panel Chair: Shana Attar, *Psychology, University of Washington, Seattle, WA*

Discussant: Alice Carter, *Department of Psychology, University of Massachusetts Boston, Boston, MA*

Culturally and linguistically diverse (CLD) families often experience greater challenges accessing timely, autism-specialized care relative to non-CLD families, and as a result, experience less optimal health outcomes. Factors contributing to these health disparities include a dearth of both culturally and linguistically adapted measures suitable for autism-specific developmental surveillance and educational materials appropriate for service navigation. This panel presents four independent research studies that employ culturally-adapted measures or educational materials and examine their effectiveness and/or feasibility. Taken together, these studies represent considerable efforts to improve the cultural sensitivity of early autism identification and service navigation processes across systems (e.g., educational, medical) and settings (e.g., community-based organizations and primary care), and serve as important models for moving forward.

Introduction

S. M. Attar, *University of Washington, Boston, MA*

215.001 Development and Evaluation of a Culturally-Adapted Autism Diagnosis Model for Young Children in Western Kenya

K. Fauntleroy-Love¹, **C. Saina**^{2,3}, **E. Oyungu**^{2,3}, **A. Nafiseh**¹, **M. McHenry**¹ and **R. McNally Keehn**¹, (1)*Pediatrics, Indiana University School of Medicine, Indianapolis, IN*, (2)*Moi Teaching and Referral Hospital, Eldoret, Kenya*, (3)*Moi University, Eldoret, Kenya*, (4)*University of California San Francisco, San Francisco, CA*

Background: Ninety-five percent of the world's autistic children live in low and middle-income countries (LMIC), yet there is virtually no data on autism in these settings. This is due in large part to a lack of neurodevelopmental expertise and resources including available diagnostic tools. Easy-to-administer, culturally-appropriate, open-source assessment approaches are key to improving autism detection and diagnosis in LMIC.

Objectives: To develop and conduct a pilot implementation of an evaluation model for the diagnosis of young children at increased likelihood for autism in a public hospital in western Kenya. Specifically, we sought to: 1) culturally adapt the ASD-PEDS, an observational assessment tool, 2) field test use of the adapted ASD-PEDS, and 3) implement the ASD-PEDS within a diagnostic evaluation model.

Methods: This study was conducted at Moi Teaching and Referral Hospital (MTRH) in Eldoret, Kenya in partnership with the Academic Model Providing Access to Healthcare (AMPATH) program. The ASD-PEDS is an open-source tool developed for the observation of autism characteristics in young children. Following forward and backward (English-Kiswahili) translation of the ASD-PEDS, cognitive interviews were conducted with Kenyan clinicians (n=5) and caregivers of young children (n=5) by trained Kenyan facilitators. Interviews assessed culturally normative social communication and play behaviors and cultural relevance of ASD-PEDS tasks, materials, and administration instructions. Interviews were translated, transcribed, and analyzed for key qualitative themes and data-driven adaptations were made to the ASD-PEDS. The ASD-PEDS was then field tested with 20 children ages 2-7 years (mean age: 46 months; 65% with a previous clinical diagnosis of autism) by trained research personnel (with live supervision by RMK) during which iterative refinements to enhance cultural relevance were made. Finally, two physicians were trained in best-practice autism evaluation, including use of the ASD-PEDS to inform overall clinical diagnosis of 48 children (mean age: 51 months; 81% with autism diagnosis outcome) in MTRH pediatrics and psychiatry clinics.

Results: Results of cognitive interviews suggested that early emerging social communication skills such as joint attention, requesting, and use of non-verbal communication strategies are culturally normative in Kenya. Considerations for adaptation of ASD-PEDS included offering culturally appropriate snacks, inclusion of culturally familiar play routines, and adapting the clinical environment to support the comfort of children and caregivers. In field testing, ASD-PEDS categorical risk matched the child's diagnosis in 100% of cases (n=13 autism; n=7 non-autism). When the ASD-PEDS was used as part of the MTRH clinical evaluation model, ASD-PEDS categorical risk matched child clinical diagnosis determined by physician clinical judgment in 100% of cases (autism: n=39, ASD-PEDS total score mean: 19, clinician high diagnostic certainty: 95%; non-autism: n=8; ASD-PEDS total score mean: 9, clinician high diagnostic certainty: 12%).

Conclusions: The ASD-PEDS is a promising tool for use in resource-constrained and LMIC settings. The ASD-PEDS assays early emerging social communication and play behaviors, requires minimal adaptation, can be used by non-specialist clinicians to inform diagnosis, and fits well within a standard autism evaluation protocol. Adaptation and validation of diagnostic assessment tools has the significant potential to advance autism clinical care and research in LMIC.

215.002 Leveraging Community-Based Organizations to Connect Culturally and Linguistically Diverse Families to Autism Identification and Support Services: A Pilot Feasibility Trial of a Novel Co-Designed Navigation Program

S. M. Attar, H. Benavidez and W. L. Stone, Psychology, University of Washington, Seattle, WA

Background: Healthcare and early educational systems are usual entry points for autism diagnostic and specialized services, yet culturally and linguistically diverse (CLD) families are less likely to have timely or consistent interactions with these two systems. Alternative pathways to autism-specialized care are urgently needed to increase access to evidence-based autism-specialized care and to improve health equity for CLD families. Community-based organizations (CBOs) frequently serve as an entry point for many underserved populations to access housing, vocational, educational, and health information more easily and comfortably than governmental or traditional medical facilities, yet they are underutilized in autism service provision. As such, the features of an alternative pathway to access autism services within the setting of a CBO that would best serve CLD families remain unclear.

Objectives: (1) To co-design a CBO-based pathway to access autism services in partnership with CLD families and CBO staff; (2) To examine the implementation outcomes of using non-specialist providers to administer the novel, co-designed program.

Methods: First, we initiated a co-design process within a CBO that supports refugees and immigrants to the US. Participants included seven non-specialist providers, two program supervisors, two organization leaders, eight caregivers of children aged 16 months - 5 years old, and four autism specialists. Eight, two-hour co-design sessions were conducted over six months. Second, six multilingual non-specialist providers completed a self-paced, web-based training tutorial on the novel program and delivered the curriculum across four sessions to 35 culturally and linguistically matched families with children aged 0-5 at increased autism likelihood. Seven language groups were represented across both the co-design and pilot: Somali Mai Mai, Swahili, Arabic, Dari/Pashto, French (African dialects), Amharic, and Tigrinya. The non-specialist providers and caregivers completed surveys and participated in a feedback session at the conclusion of the pilot.

Results: The co-design sessions revealed five key design features of an effective pathway for increasing access to autism identification and services for CLD families; see **Table 1**. These considerations informed the co-production of a modular and flexible workbook ("The Family Care Project"; FCP) and an associated self-paced, web-based tutorial for use by CLD non-specialist providers with caregivers. All non-specialist providers who participated in the feasibility pilot strongly agreed that the FCP aligned with their role as a service provider and was easy to use; 100% of caregivers strongly agreed that the FCP was relevant for their families. Six months after the pilot concluded, all non-specialist providers report continued use of the FCP, with an additional 24 families having participated in the FCP to date.

Conclusions: The five design features identified by co-design members highlight the key importance of adapting both the content and the delivery of psychoeducational materials and services for CLD families. Pilot results suggest that a low-resource and culturally-sensitive curriculum administered by culturally-matched non-specialist providers in non-profit community organizations is appropriate, feasible, and sustainable. This pilot lays the foundation for programmatic changes in the services and settings available to support CLD communities during autistic children's early years and thereby improve child and caregiver outcomes and health equity.

215.003 Cognitive Pretesting: An Approach to Address Autism Research Disparities Among Families with Limited English Proficiency

D. J. Abate¹, A. W. Lu², L. Rivas Vazquez³, H. Tran⁴, X. Yang⁵, C. Tran⁴, N. Julceus Fabien⁵, O. J. Lindly⁶, K. E. Wallis⁷, K. Zuckerman⁸ and S. Broder-Finger⁹, (1)E. K. Shriver Center, E. K. Shriver Center, University of Massachusetts Medical School, Worcester, MA, (2)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (3)Department of Pediatrics (Division of General Pediatrics), Oregon Health & Science University, Portland, OR, (4)Department of Pediatrics, Oregon Health and Science University, Portland, OR, (5)UMASS Chan Medical School, Worcester, MA, (6)Health Sciences, Northern Arizona University, Health Sciences Department, Flagstaff, AZ, (7)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (8)Division of General Pediatrics, Oregon Health & Science University, Portland, OR, (9)UMASS Medical School, Boston, MA

Background: Families who are dually impacted by autism spectrum disorder (ASD) and limited English proficiency (LEP) face substantial barriers to care yet have been systematically excluded from disparities research^{1,3}. Very few parent-reported measures of ASD treatment mediators or outcomes have been validated in languages other than English or Spanish, with research illustrating that healthcare disparities may be greater for LEP families who do not speak either language^{4,6}. To overcome these challenges in understanding the relationship between LEP status and service use disparities, we developed the Limited English Proficiency and Family Experiences with Autism Project (LEAP) Survey to validate measures of autism service utilization in five languages.

Objectives: The purpose of this study was to conduct cognitive pretesting of a preliminary draft of the LEAP Survey. Cognitive pretesting will identify elements of the LEAP Survey that impact its acceptability, accessibility, and understandability with English-speaking and LEP caregivers of autistic children.

Methods: 15 caregivers of autistic children aged 5-12 years were recruited from community organizations in Massachusetts and Oregon to complete cognitive pretesting in their primary language (Chinese ($N = 3$), English ($N = 10$), Haitian Kreyol, Spanish ($N = 1$), Vietnamese ($N = 1$)) via Zoom. Caregivers viewed each section of the LEAP survey and were instructed to utilize a think-aloud method⁷, where they read each survey item and were asked to both answer the question and to provide section-specific critiques. Caregiver feedback was documented and categorized according to whether they addressed survey phrasing, section-specific probing questions, or survey design.

Results: Caregivers reported the following limitations with the preliminary LEAP Survey draft: (1) Comprehension difficulties due to the use of improper phrasing, tone, or sentence complexity in specific survey questions; (2) Cultural and linguistic influence on familiarity with autism services, medications, and providers; and (3) Design issues including repetitive response options for validated survey measures and a visually taxing layout. Table 1 depicts examples of caregiver feedback.

Conclusions: English-speaking and LEP caregivers of autistic children identified limitations of the initial LEAP Survey that impacted their ability to answer questions about their autism service utilization. Cognitive pretesting of the internet-based and telephone modalities of the LEAP Survey will be conducted to further revise the survey before it is piloted.

**215.004 A Framework for Developing Culturally-Sensitive Caregiver-Report Autism Screening Measures**

M. Chiu¹, S. M. Attar², A. S. Carter³ and W. L. Stone², (1)University of Washington, Maple Valley, WA, (2)Psychology, University of Washington, Seattle, WA, (3)Department of Psychology, University of Massachusetts Boston, Boston, MA

Background: Universal autism screening is intended to serve as an early opportunity to identify children with autism characteristics and promote access to timely autism-specialized services. Indeed, children with a positive autism screen receive a diagnosis and access to specialized services seven-months to two-years earlier than children with a false negative or missed screen. However, autistic children from culturally and linguistically diverse (CLD) families are more than twice as likely to be incorrectly identified on autism screening measures in comparison to non-CLD children, delaying access to critical autism-specialized care. One factor contributing to inequitable autism identification is that current screening tools have been validated primarily on White families and may not be sensitive to how CLD caregivers interpret screening questions or what their expectations are for normative social behavior of their children. While there has been previous work developing culturally-sensitive measures, there has been limited research that describes a systematic process for generating autism measures that are intended to be culturally-sensitive from their inception.

Objectives: To develop and assess a framework for generating a culturally-sensitive caregiver-report autism screening measure that is highly predictive of autism likelihood.

Methods: We developed a pilot pictorial screening tool to identify toddlers at increased likelihood for autism. In this pilot tool, eleven social communication behaviors associated with autism (e.g., reciprocal play, use of facial expression, imitation) are presented along with photos and brief text illustrating each behavior; **see Figure 1** for an example item. We employed two Plan-Do-Study-Act (PDSA) cycles to solicit feedback from CLD communities and allow us to adjust the behaviors, photographs, and item wording as needed. PDSA employs an iterative process that focuses on the translation of ideas into appropriate action by repeatedly soliciting feedback from end-users throughout development. Two nonprofit community-based organizations that serve African and Middle Eastern immigrants and refugees and Black Americans assisted with recruitment. During the two PDSA cycles, we conducted focus groups with different CLD caregivers of children aged 16-35 months. Additionally, caregivers completed the pilot version of the initial items and a Likert-scale survey assessing the usability and acceptability of the items. Nonprofit providers (i.e., program staff working directly with CLD families) also completed a survey about the items.

Results: 115 caregivers completed surveys and participated in one of 12 focus groups. Eight focus groups were facilitated through an interpreter who spoke either Arabic, Somali Mai-Mai, Dari, French, or Swahili. Five providers completed surveys. Mixed-methods analyses revealed that aspects of six of the 11 social communication behaviors required adjustment. Thematic analysis of the focus group transcripts resulted in three themes; **see Table 1**. Frequencies of the specific social communication behaviors that caregivers most commonly expect within their communities were tallied; **see Table 2** for an example.

Conclusions: PDSA cycles paired with mixed-methods analyses to systematically assess the cultural sensitivity of screening items from multiple end-users (i.e., providers and caregivers) results in rich feedback that informs essential revisions to the development of screening items. This process may provide a model for the future development of culturally sensitive measures.

Panel Session**216 - Using Digital Phenotyping Techniques to Assess Autism Severity**

May 2nd, 2025, 2:00 PM - 4:00 PM - 611-614

Panel Chair: Ilan Dinstein, *Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel*

Digital phenotyping techniques utilizing computer vision, speech analysis, and wearable devices are now enabling researchers to study the behavior of autistic children in novel ways in every day locations including the clinic, classroom, and at home. These techniques offer exciting opportunities for measuring the severity of core autism symptoms and co-occurring symptoms in direct and objective ways. The panel will present a tour-de-force of multiple research approaches and initial findings.

Introduction**I. Dinstein**, *Psychology Department, Ben Gurion University, Beer Sheva, Israel***216.001** Differences in Infant-Caregiver Interaction Are Present in Autism from the First Postnatal Months

A. L. Ford¹, L. Lang², G. Berman³ and **S. Shultz⁴**, (1)Marcus Autism Center, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Neuroscience, Emory University, Atlanta, GA, (3)Department of Biology, Emory University, Atlanta, GA, (4)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA

Background:

From birth, newborns and caregivers exhibit species-typical behaviors—that is, repeated patterns of behavior that are highly uniform across infant-caregiver dyads—that create critical opportunities for social interaction and newborn learning. These behaviors are mutually-adapted and mutually-reinforcing, progressively advancing cycles of learning. Despite the critical role of infant-caregiver interaction in guiding social development, few studies have examined how autism may alter this early-emerging and foundational learning process.

Objectives:

Here we: 1) leverage advances in computer vision and machine learning to detect—in an automated, data-driven approach—the repertoire of species-typical behaviors produced during infant-caregiver interactions from birth to 6 months, and 2) quantify differences in behaviors produced by infants and caregivers in dyads with an infant later diagnosed with autism (AUT) compared to dyads with a neurotypically-developing (NT) infant.

Methods:

Video recordings of screen-mediated infant-caregiver interaction were collected longitudinally from birth to 6 months. Infant outcome (NT or AUT) was ascertained by clinical assessment at 24-36 months. The sample consisted of 88 NT dyads (44 female, 179 sessions) and 38 AUT dyads (15 female, 80 sessions).

Behaviors of infants and caregivers were identified using markerless tracking of facial features via DeepLabCut and nonlinear mapping of behaviors via MotionMapper (Figure 1), allowing for high-throughput and reliable identification of species-typical behaviors with minimal *a priori* assumptions. Identified behaviors were reviewed to confirm ecological validity with canonical dyadic behaviors and developmental trends in behavior change. Change in infant and caregiver behavior was examined across four age groups: 0-1.5, 1.6-3, 3.1-4.5, and 4.6-7 months (Figure 2.1) and NT versus AUT differences in frequency of behaviors were identified using hierarchical bootstrapping (Figure 2.2).

Results:

Age-effects: Behavior density maps showed clear age-related shifts in the species-typical behaviors performed by infants and caregivers (Figure 2.1). Visualization of behavior maps showed that younger infants displayed more head turning and tilting behaviors, with more stable head positioning and mouth movements observed as infants aged. Interestingly, these infant behavior changes mirrored some of the changes among caregivers (caregivers displayed more side-to-side head movements when their infants were younger and more stationary head positioning and mouth movements as their infants aged).

NT versus AUT differences: 6 (out of 37) caregiver behaviors were significantly different between NT and AUT dyads ($p < 0.05$), and 25 behaviors showed large effects sizes (Cohen's $d > 0.8$). No infant behaviors were significantly different, but 8 (out of 34) had large effects sizes (Cohen's $d > 0.8$). Visualization of behavior maps showed that infants and caregivers in AUT dyads had a higher representation of behaviors more common amongst younger (0-1.5 month) dyads and less representation of behaviors more common amongst older (4.6-7 month) dyads, suggesting possible delays or disruptions in the emergence and/or refinement of social interactive behaviors over infants' first 6 postnatal months.

Conclusions:

Data-driven identification and quantification of interactive behavior shows that robust differences in infant-caregiver interaction are present in dyads with an infant later diagnosed with autism from the earliest postnatal months, altering this most critical platform for infant social learning.

**216.002** Objectively Measured Speech and Movement Characteristics in the Classroom Distinguish Preschoolers with Autism Spectrum Disorder

M. Drye¹, L. Angeles^{1,2}, S. Fazal^{1,2,3}, L. Estrada¹, A. Viggiano¹, L. Vitale¹, L. K. Perry¹, V. Aguiar-Pulido² and D. S. Messinger^{1,4,5,6}, (1)Department of Psychology, University of Miami, Coral Gables, FL, (2)Department of Computer Science, University of Miami, Coral Gables, FL, (3)Miller School of Medicine, University of Miami, Coral Gables, FL, (4)Department of Electrical and Computer Engineering, University of Miami, Coral Gables, FL, (5)Department of Pediatrics, University of Miami, Coral Gables, FL, (6)Department of Music Engineering, University of Miami, Coral Gables, FL

Background: Autism spectrum disorder (ASD) is characterized by social communication differences, including atypical patterns of interpersonal movement and vocalization. Inclusion classrooms, where autistic and neurotypical children are educated together, are an understudied naturalistic context for examining potential differences in such behaviors. We use a data-driven approach to identify and quantify behavioral markers of ASD by analyzing social movement and vocalization patterns in real-world environments.

Objectives: Leverage high-density, longitudinal datasets to explore objective features of preschoolers' classroom movements and vocalizations that may distinguish autistic (ASD) children from neurotypical (TD) children.

Methods: We observed 56 preschoolers (26 ASD, 30 TD) from eight inclusion classes. Children's real-time vocalizations and classroom movements were tracked using LENA DPL recorders and Ubisense Ultra-Wideband Radio-Frequency Identification (RFID) tags (respectively) worn in vests. Overall, 390 observations ($M=103$ minutes) were collected (135 ASD, 255 TD). Child speech and social movement features were first entered into a set of machine learning models. The optimally performing model identified variables that best distinguished ASD and TD observations. The top performing variables were then individually analyzed with mixed-effects models (observations nested in children nested in classrooms) to test for ASD and TD differences.

Results: The best performing model utilized a Light Gradient-Boosting Machine (LightGBM) framework, which builds decision trees iteratively to minimize prediction error. The model correctly identified 24 ASD (true positives) and 22 TD (true negatives) cases while incorrectly identifying 8 ASD (false positives) and 2 TD cases (false negatives), achieving 82.1% agreement; Kappa=0.65, 95% CI: 0.45 – 0.84. The most frequent prediction across a child's observations yielded the child's final predicted classification (i.e., ASD or TD). The five variables that best distinguished observations in order of importance were average peak loudness (dB) of a child's vocalizations; the proportion of a child's proximal contact (≤ 1 m interpersonal distance) spent with teachers; the average loudness (dB) of a child's vocalizations; the proportion of a child's proximal contact spent with neurotypical peers; and a child's mean velocity toward a partner in the 2.5 seconds preceding social contact. Compared to children with TD, autistic children exhibited lower average peak vocalization loudness ($p<.001$) and quieter average vocalization loudness ($p=.001$); they spent a larger proportion of proximal time with teachers ($p<.001$) and a smaller proportion of proximal time with neurotypical peers ($p=.024$); and they approached social partners significantly faster ($p<.001$; **Table 1 & Figure 1**).

Conclusions: Speech characteristics and social movement behaviors in everyday inclusion preschools distinguished children with ASD from children with TD, with some tendency to over-identify ASD. Follow-up models accounting for nesting indicated that children with ASD showed lower peaks of vocalization loudness and were quieter on average than neurotypical peers. Autistic children approached social partners more quickly and spent more time in proximal contact with teachers—but not with neurotypical peers—compared to children with TD. These findings illustrate the potential of combining interpretable machine learning models with statistical modeling to better understand the ASD phenotype in natural environments in which children with and without ASD spend large quantities of time.

216.003 Fully Automated AI Measurement Demonstrates Reduced Nonverbal Interpersonal Coordination in Autism

L. D. Yankowitz¹, E. Sariyanidi¹, C. J. Zampella¹, J. Pandey¹, J. D. Herrington¹, B. Tunc¹ and R. T. Schultz², (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA

Background: Interpersonal coordination contributes to social communication success, and reductions in autism have been demonstrated across domains (e.g., rhythmic tapping, body movements, facial expressions). There is no universally-accepted operationalized definition or method for quantifying interpersonal coordination. Most existing statistical methods are correlation-based and assume correlations between signals are linear, restricting the patterns that can be explored and preventing quantification of coordination within multidimensional crossmodal data (e.g., head movements with facial expressions). Artificial intelligence (AI) offers promising solutions, but has been under-utilized because of the need for gold-standard training labels. We developed a new AI approach – concurrence-based coordination – that overcomes these limitations by using a self-supervised deep learning architecture to automatically expose statistical dependences between multi-dimensional time series. Furthermore, while prior machine learning work has focused on diagnostic classification, our method provides individual coordination scores that can be analyzed with traditional statistics for group differences and dimensional properties.

Objectives: 1) Quantify and compare nonverbal interpersonal coordination in individuals with neurotypical development (NT), autism (AUT), or (an)other psychiatric condition(s) (e.g., ADHD, anxiety, depression; PSY); 2) Explore robustness of our method to conversational and recording context; 3) Test coordination's associations with two hypothesized developmental building blocks: mutual gaze and imitation ability.

Methods: 430 individuals participated in a brief video-recorded conversation with a research partner, either in a lagless (not over internet) Zoom-like video set-up ("room-to-room", main sample), or in-person face-to-face (replication sample). Time series data from 3 head movement parameters and 79 facial expression signals were generated via computer vision for both participant and partner. Time series were segmented into overlapping 4-second windows. A deep-learning algorithm was trained to separate participant and partner segments that are concurrent (temporally aligned) vs. non-concurrent (temporally misaligned between participant and partner), defining coordination as any statistical dependence between signals. The output was a single coordination score (higher score=more coordinated), which was the dependent variable in linear mixed models controlling for age, sex, and cognitive ability among 12–18-year-olds (Table 1).

Results: AUT demonstrated significantly lower coordination compared to both NT (*unadjusted Cohen's d*=0.95, $p<0.0001$) and PSY ($d=0.48$, $p<0.05$) in the room-to-room sample (Figure 1). The AUT<NT effect was replicated in the face-to-face sample ($d=0.7$, $p<0.05$). When face-to-face and room-to-room samples were matched on age, sex, and IQ and combined in a single linear model, there was no group-by-context interaction ($p=0.13$), suggesting group differences are robust to recording context; though, there was a significant main effect of context, with greater coordination in room-to-room ($d=0.49$, $p<0.05$). Within a subset of the face-to-face sample, coordination was positively associated with mutual social gaze between partners during the conversation ($r(102)=0.43$, $p<0.0001$) and gross motor imitation ability assessed in a separate task ($r(31)=-0.44$, $p<0.05$).

Conclusions: Nonverbal interpersonal coordination reductions in autism were quantified using a fully automated method and were robust to recording context. Interpersonal coordination was associated with two hypothesized preconditions of coordination: mutual gaze and motor imitation ability. Future work should explore the clinical utility of this automated coordination score in establishing autism diagnoses and tracking treatment effects.

216.004 Quantifying Behavior with Automated Computer Vision Analyses of ADOS-2 Video Recordings

Background: Current techniques for estimating the severity of core autism symptoms in children are based on subjective reports from clinicians, teachers, and parents who often do not agree. Variability across reporters with no clear ground truth hinders research into the underlying mechanisms of autism and impedes clinical trials searching for effective interventions. The growing availability of video recordings of autistic children offers an opportunity to develop new computer vision techniques for identifying and quantifying behaviors such as stereotypical movements and facial expressions that are expected to differ in autistic children. Here we present data from several recently developed algorithms that quantify such behaviors in ADOS-2 video recordings from the Azrieli National Centre for Autism and Neurodevelopment Research (ANCAN). **Objectives:** To assess the accuracy and reliability of computer vision algorithms in identifying and quantifying stereotypical movements and facial expressions of children, while comparing findings across children with and without autism.

Methods: Since 2015, ANCAN has been collecting longitudinal data from children with autism diagnosed in nine clinical sites throughout Israel. As part of this effort, over 2000 children with autism, 1-8-years-old, have completed Autism Diagnostic Observation Schedule, 2nd edition (ADOS-2) assessments that were recorded with 2-5 video cameras. In **project 1** we manually annotated >7300 exemplars of stereotypical movements from video recordings of 241 autistic children, enabling us to train a CNN deep learning algorithm (ASDMotion) to identify and quantify stereotypical movements. We demonstrate the accuracy of the algorithm using precision and recall metrics. In **project 2** we report results from 3 existing algorithms designed to identify facial expressions (FaceReader, iMotions, and PyFeat). So far videos of 100 children (72 with autism) were analyzed. We assessed the agreement across algorithms in identifying 6 facial expressions while comparing their quantities across autism and control participants with ANCOVA analyses, controlling for age and sex.

Results: The ASDMotion algorithm accurately detected >92% of manually annotated stereotypical movements with a precision of >66%. When assessing the total number of stereotypical movements per child in an independent dataset there was a highly significant correlation between the number of movements estimated by ASDMotion and manual annotation ($r=0.8$, $p<0.001$). Identification of facial expressions by the three facial analysis algorithms differed significantly across algorithms ($F(2, 294) = 64.09$, $p < 0.001$). Despite differences across algorithms, there were no significant differences across autism and control groups in the quantity of facial expressions during ADOS-2 assessments.

Conclusions: Initial analyses reveal promising results and challenges in the development of algorithms that quantify behaviors relevant to the severity of core social and RRB symptoms of autism. While stereotypical movements seem to be accurately quantified by the ASDMotion algorithm, facial expressions seem difficult to quantify reliably with existing algorithms. Moreover, quantifying relevant differences in facial expressions across autism and control participants may require development of algorithms that quantify the quality of facial expressions (e.g., flatness) in addition to their number/frequency. Further development of these and additional algorithms are highly warranted for establishing new techniques for quantifying behavior objectively and directly from autistic children.

Panel Session**217 - Physiological Indicators and Neural Mechanisms of Dysregulated Emotional Profiles in Autistic Youth**

May 2nd, 2025, 2:00 PM - 4:00 PM - 608-609

Panel Chair: Rachel McDonald, Department of Psychology, Montclair State University, Montclair, NJ

Discussant: Matthew Siegel, Boston Childrens Hospital, Boston, MA

This session will focus on examining physiological indicators and neural mechanisms associated with dysregulated emotional profiles in autistic youth across broad age ranges. The panel will present a range of distinct objective measurement approaches (e.g., EEG, heart rate variability, MRI, or RSA), and demonstrate their links to behaviorally expressed dysregulation. Specifically, talks will span topics such as, delta-beta coupling (e.g., brain wave coherence) predicting emotion dysregulation, how depressive and anxious profiles related to structural differences in the brain, and how respiratory sinus arrhythmia-reactivity relates to emotion and behavioral dysregulation. In addition, the panel will also feature findings on the use of physiological data to inform treatment approaches, including the use of heart-rate variability to predict treatment effectiveness. In sum, these presentations seek to inform clinicians and scientists about neuroscientific and physiological approaches that can be used to inform clinical presentations of emotion dysregulation, and thereby informing relevant treatment approaches for mental health conditions in autistic people.

Introduction

R. G. McDonald, Center for Autism and Related Disorders, Montclair State University, Baltimore, MD

217.001 Toward a Biopsychosocial Model of Emotion Dysregulation and Behavior Problems in Autism

J. K. Baker¹, R. M. Fenning², S. A. Erath³ and D. S. Messinger⁴, (1)Center for Autism; Dept. of Child & Adolescent Studies, California State University, Fullerton, Fullerton, CA, (2)Psychological Science, Claremont McKenna College, Claremont, CA, (3)Human Development and Family Studies, Auburn University, Auburn, AL, (4)Department of Psychology, University of Miami, Coral Gables, FL

Background: Behavioral challenges represent a key obstacle to functioning and well-being for children with autism, interfering with learning opportunities and social relationships, and increasing distress for the children and those who support them. Emotion dysregulation has been proposed as an underlying mechanism for behavioral disruption in this population, but little is known about its development in autistic children or contributors to related processes. The current examination takes a biopsychosocial approach to testing competing models involving interactions between child and family factors in the emergence of regulatory competence and behavioral functioning in autistic children. A recent examination (Baker et al., 2020) predicted externalizing problems in children with autism from an interaction between negative parenting and higher child respiratory sinus arrhythmia reactivity (RSA-R), or withdrawal of parasympathetic influence in response to challenge. A likely mechanism by which this process might unfold would be through child emotion dysregulation and, indeed, some concordance has been established between higher RSA-R and more concurrent observed emotion dysregulation in this population (Baker et al., 2022). It is possible that RSA-R may underlie or contribute to greater emotion dysregulation, which in turn may eventuate in more difficulties with behavioral functioning. Given this conceptualization, a central remaining question is where moderation by parenting might occur in the causal chain.

Objectives: We compared contrasting models in which: 1) child RSA-R and negative parenting interact to predict observed child emotion dysregulation, and 2) child observed emotion dysregulation and negative parenting interact to predict child externalizing problems.

Methods: A sample of 61 children (74% male) with ASD aged 6 to 10 years participated in laboratory activities to examine physiological baseline and to assess independent child emotion dysregulation and physiology in response to challenge. Children were diverse with regard to ethnicity (33% Caucasian, non-Hispanic), socioeconomic status, ASD symptom levels, and cognitive functioning (IQ range 47-121). RSA was collected with a wired MindWare system and RSA-R represented decreases in respiratory sinus arrhythmia from baseline to the challenge task. Negative parenting was an average of scores coded from a speech sample (total number of critical comments) and from parent report of harsh discipline. Emotion dysregulation was coded from videotape and included global dimensions outlined by Cole et al. (1994; ICC = .91). Primary caregivers reported on their children's symptoms of oppositional defiant disorder and broad externalizing problems.

Results: Regressions controlling for child age, autism symptom levels (ADOS-2), and family income (no other covariates were necessary) revealed a significant interaction between RSA-R and negative parenting in the prediction of independent child dysregulation, $\beta=.37$, $t=2.77$, $p=.008$. Higher RSA-R was related to more observed dysregulation in the context of high, $t=3.59$, $p<.001$, and moderate, $t=2.05$, $p=.04$, but not low negative parenting, $t=-0.92$, $p=.36$. The interaction between observed emotion dysregulation and negative parenting in the prediction of children's externalizing symptoms was not significant, $\beta=.15$, $t=0.63$, $p=.53$.

Conclusions: Findings suggest that critical or harsh parenting may amplify the risk for emotion dysregulation in autistic children with higher physiological reactivity. Implications for successful parent-child co-regulation will be discussed.

217.002 Emotion Dysregulation: Examining the Predictive Utility of Delta Beta Correlations in Autistic Youth

R. G. McDonald¹, E. Lynch¹, N. Cifuentes², H. Garcia², R. Ahmad², A. C. Castillo² and E. Kang¹, (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Montclair State University, Montclair, NJ

Background: Emotion dysregulation (ED) occurs when there is a mismatch between felt/expressed emotions, choice of regulation strategy, and the environmental context (Gross et al., 2002). Autistic youth experience more severe ED as compared to both neurotypical youth and youth with other psychiatric conditions (McDonald et al., 2024). Research in non-autistic youth has explored how disrupted relationships between slow (delta) and fast (beta) brain waves indexed by electroencephalogram (EEG) are related to greater ED, where different patterns of coherence between delta/beta reflect dysregulation (Myruski et al., 2022). However, no research to-date has examined this relationship in autistic youth, despite higher rates of dysregulation, including behaviorally expressed (e.g., emotional reactivity), negative mood states (e.g., emotional dysphoria), and general lability (e.g., emotional control). Understanding relationships between neural mechanisms and behaviorally expressed emotions can assist in clarifying constructs, which in turn may strengthen their validity and lead to better treatment specificity.

Objectives: The current project examined the relationships between delta-beta couplings (DBC) and emotion dysregulation profiles (e.g., reactivity, control, and dysphoria) in autistic and non-autistic youth.

Methods: Seventy-four youth (43 autistic; Range-IQ: 57-140) participated in a study in a metropolitan area in northeastern US ($M_{age}=9.9$, $SD_{age}=3.0$; 55.1% male, 6.1% Black/African American, 6% Asian, 1.5% Native American, 6.1% MENA, 24.2, Multiracial, 50% White, & 6.1% Other). Youth completed an 8-minute resting-state EEG paradigm alternating between eyes open or closed. Delta and beta waves were recorded in the frontal (Fz, F3, F4), central (Cz, C3, C4), and parietal (Pz, P3, P4) regions. DBCs closer to zero, after calculating residuals (delta predicting beta), indicate better coherence (Myruski et al., 2022). Emotional dysphoria, reactivity, and control were examined via parent report (Emotion Dysregulation Index; Mazefsky et al., 2018; BRIEF-2; Gioia et al., 2015).

Results: Regional DBC were associated with one another ($ps <.05$). Linear regressions suggest that DBC did not predict ED in non-autistic youth. In autistic youth, less central ($b<-.75$, $p<.04$) and greater parietal ($b>.54$, $p<.04$), but not frontal, DBC coherence predicted more reactivity and dysphoria. Lower central ($b=-1.08$, $p=.002$), but greater parietal ($b=.72$, $p=.008$) and frontal ($b=.53$, $p=.03$) DBC coherence predicted more difficulty with emotional control.

Conclusions: Results suggest that in community samples of autistic youth, but not non-autistic youth, disruptions in DBC may relate broadly to ED. Specifically, lower central greater parietal DBC coherence may relate to reactivity, dysphoria, and control. These findings provide some evidence that greater neural resources may be dedicated to parietal regions, and thus regulating emotions, even at rest in autistic youth. Lower DBC coherence in central regions relates to more ED, which could in part reflect the impact of dysregulated sensory centers have on emotions (Simon et al., 2017). Lastly, greater frontal DBC coherence was related to more emotional control only, reflecting increased resources needed to choose/deploy appropriate regulation strategies to control emotional lability in autistic youth. Future work should continue to explore how DBC relates to ED presentations and downstream impacts on mental health in autistic youth.

217.003 White Matter Microstructural Organization Associated with Depressive Symptoms in Autistic Children in the ABCD Study
P. D. Radoeva¹, **C. Elizardo**¹, **R. G. McDonald**², **J. I. Hunt**³, **S. Deoni**⁴, **S. J. Sheinkopf**⁵, **C. A. Mazefsky**⁶, **D. P. Dickstein**⁷ and **N. S. Philip**³, (1)Bradley Hospital, East Providence, RI, (2)Department of Psychology, Montclair State University, Montclair, NJ, (3)Warren Alpert Medical School of Brown University, Providence, RI, (4)King's College London, London, United Kingdom, (5)Thompson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO, (6)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (7)Harvard Medical School, Boston, MA

Background: Mood problems, including depression, occur more frequently in autistic children as compared to neurotypical peers. Altered white matter microstructure has been reported in non-autistic youth with depression. No prior studies have reported on the white matter microstructural correlates of depressive symptoms in autistic children, and only one prior study has explored this association in autistic adults (Mohajer et al, 2019).

Objectives: The goal of our data analysis was to investigate the white matter microstructural organization associated with depressive symptoms in autistic children in the ABCD study. We hypothesized that decreased microstructural organization in limbic and fronto-frontal and fronto-thalamic circuits may be associated with more severe depressive symptoms in autistic youth.

Methods: We analyzed de-identified data from the ABCD study (a large longitudinal multi-site study), focusing on data from the initial study visit. Data was accessed through the NIMH Data Archive after completion of a Data Use Certification agreement. Our analysis included data from 176 children (age: 9-11 years; mean(SD): 10.0(0.63); female: 15.3%) who met the following criteria at the initial study visit: (1) parent-reported diagnosis of autism spectrum disorder; (2) available diffusion tensor imaging data, and (3) available Child Behavior Checklist (CBCL) data. Our variables of interest included: fractional anisotropy (FA) of white matter tracts derived through probabilistic tractography (full-shell AtlasTrack data; 41 white matter tracts as well as FA average across all white matter tracts) and CBCL Anxious/Depressed and CBCL Depressed/Withdrawn t-scores. After assessing the distributions of the variables of interest using Shapiro-Wilk tests of normality, we conducted Spearman correlations between FA of each white matter region and each of the two CBCL subscale t-scores, and then applied FDR correction for multiple comparisons.

Results: We found negative correlations between CBCL Depressed/Withdrawn t-scores and FA in the following white matter tracts/regions: limbic white matter tracts: right uncinate ($\rho=-0.229$, $pFDR<0.05$), right fornix ($\rho=-0.212$, $pFDR<0.05$), left and right parahippocampal cingulum ($\rho=-0.204$, $pFDR<0.05$ and $\rho=-0.236$, $pFDR<0.05$, respectively); white matter tracts to/from frontal cortical regions: right inferior fronto-occipital fasciculus ($\rho=-0.240$, $pFDR<0.05$), left superior corticostriate-frontal cortex ($\rho=-0.181$, $pFDR<0.05$), left and right corticospinal/pyramidal tract ($\rho=-0.270$, $p<0.01$ and $\rho=-0.265$, $p<0.01$, respectively), forceps minor ($\rho=-0.198$, $pFDR<0.05$); the corpus callosum ($\rho=-0.181$, $pFDR<0.05$); left and right inferior longitudinal fasciculus ($\rho=-0.206$, $pFDR<0.05$ and $\rho=-0.183$, $pFDR<0.05$, respectively), and broader regions: right hemisphere DTI atlas tract fibers ($\rho=-0.185$, $pFDR<0.05$), right hemisphere DTI atlas tract fibers without corpus callosum ($\rho=-0.204$, $pFDR<0.05$) as well as the average FA across all DTI atlas tract fibers ($\rho=-0.179$, $pFDR<0.05$). The correlations between FA and CBCL Anxious/Depressed t-score did not reach statistical significance.

Conclusions: In summary, we found that aberrant white matter microstructural organization in limbic-cortical-striatal circuits, the corpus callosum and on average- across all white matter tracts in the atlas was associated with depressive symptoms in autistic children. Future analyses could focus on the longitudinal aspect of the ABCD study data as related to depressive symptoms and disorders in autistic youth. Better characterization of the neural mechanisms underlying mood problems and disorders in autistic individuals is a vital step in the development of targeted treatments.

217.004 Using Heart Rate and Behaviors to Predict Effective Intervention Strategies for Children on the Autism Spectrum: Validation of a Technology-Based Intervention

A. Emezie¹, **R. Kamel**², **M. Dunphy**¹, **A. Young**³ and **H. J. Nuske**², (1)University of Pennsylvania, Philadelphia, PA, (2)Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA, (3)Mayo Clinic, Rochester, MN

Background: Many children on the autism spectrum engage in challenging behaviors, like aggression, due to difficulties communicating and regulating their stress. Identifying effective intervention strategies is often subjective and time-consuming. Utilizing unobservable internal physiological data to predict strategy effectiveness may help simplify this process for teachers, therapists and parents.

Objectives: This study examined whether physiological data (heart rate) could be a predictor of intervention strategy effectiveness for strategies addressing challenging behaviors in elementary school-aged students on the autism spectrum. We also explored heart rate reduction by intervention strategy type (proactive vs. reactive based on the onset of the challenging behavior).

Methods: In this proof-of-concept study, five educational teams were recruited in this study (five students and their parents, teachers and therapists). Teachers and coders from the research team recorded behavioral and heart rate data over three months for each participating student on the autism spectrum using the KeepCalm app, a platform that provides in-the-moment strategy suggestions based on heart rate and past behavioral data. A total of 226 instances of strategy interventions were recorded. A binary logistic regression was performed to assess whether heart rate reduction, time to return to heart rate baseline, and documented skills and challenging behaviors predicted strategy effectiveness. To explore the impact of strategy type, we ran *t*-tests on heart rate reduction by strategy type.

Results: The main logistic regression model was statistically significant, $\chi^2(4)=27.11$, $p<.0005$ and explained 23% (Nagelkerke R²) of the variance in strategy effectiveness (see Table 1). Heart rate reduction ($p<.05$), subsequent behaviors ($p<.01$), and subsequent skills ($p<.01$) were all found to be statistically significant in explaining strategy effectiveness, but minutes to return to green heart rate zone was not. According to these results, a 1% increase in heart rate reduction increases the likelihood of intervention strategy effectiveness by 6%.

Overall, 82% of observations recorded included a proactive strategy ($n=211$), while 18% included a reactive strategy ($n=45$) (reactive strategy included both). Proactive vs. reactive strategies were rated effective 84% vs. 56% of the time, respectively. An independent samples *t*-test indicated that proactive strategies ($M=18\%$, $SD=11\%$) had significantly higher heart rate reduction than reactive strategies ($M=14\%$, $SD=10\%$), $t(228)=2.14$, $p=.03$. We then looked at the magnitude of heart rate reduction by each intervention strategy under strategy type to see which strategies were driving these trends (see Figure 1). Self-management, prompting time delay and emotion regulation training (used proactively) were the most effective strategies, each leading to >25% reduction in heart rate.

Conclusions: Findings suggest that when educators perceive their intervention strategies as effective, there is corresponding physiological regulation in children, as evidenced by a reduction in heart rate. They also support the existing practice of using behavioral patterns as proxies for strategy effectiveness. Additional analyses indicated proactive strategies are more effective and are associated with greater reduction in heart rate (particularly strategies supporting autonomy and self-regulation), relative to reactive strategies. Further exploration of how internal physiological data can complement observable behaviors in assessing intervention strategy effectiveness is warranted given the novelty of our findings.

Panel Session

218 - Supporting Autistic Students in Schools: Development and Implementation of Evidence-Based Practices to Improve Teacher Attrition, Knowledge, and Student Outcomes

May 2nd, 2025, 2:00 PM - 4:00 PM - 606-607

Panel Chair: Kelly Beck, *Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Discussant: David Mandell, *Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA*

Autistic children experience many learning barriers, bullying from peers, and have worse mental health and educational outcomes than their non-autistic peers. Most educators are not well trained in how to support autistic children's learning and behavioral needs, and teacher attrition is alarmingly high, which creates challenges in maintaining an effective school workforce. This panel presents four community-engaged studies that draw attention to different aspects of the school experience for autistic students and those who work with them. Our presentations cover factors associated with teacher attrition, implementation supports to increase the reach of an evidence-based executive functioning intervention, a randomized controlled trial of an evidence-based program to reduce challenging behaviors in the classroom, and the development of a school-wide inclusivity program that trains educators how to reduce learning barriers for neurodivergent students. These projects attempt to understand and address complex school systems by measuring outcomes for autistic students and a broad range of school personnel, including special education and general education teachers, paraprofessionals, and administrators. Our findings emphasize the importance of implementation science in school research for retaining and training educators, and we detail three promising evidence-based programs with potential to improve the school workforce and learning experience for autistic children.

218.001 School Characteristics and EBP Fidelity Predict Attrition Among Autism Support Teachers in Urban Economically Disadvantaged Schools

A. M. Hernandez¹, **K. Zhang²**, **A. Kahn³**, **Z. Piotrowski⁴**, **D. Cooney⁵**, **N. Sabatino⁶**, **D. S. Mandell³** and **J. Worley⁶**, (1)*Psychology, University of Pennsylvania, Philadelphia, PA*, (2)*Wharton Business School, University of Pennsylvania, Philadelphia, PA*, (3)*Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA*, (4)*University of Pennsylvania, Philadelphia, PA*, (5)*Philadelphia School District, Philadelphia, PA*, (6)*Penn Center for Mental Health, Philadelphia, PA*

Background: Schools across the United States are experiencing many vacancies and high attrition rates for special education teachers. Studies demonstrate attrition rates are higher for special education teachers than general education teachers. Among general education teachers, lack of professional development, poor administrative support, and limited school and district resources contribute to attrition. These issues have not been examined among autism support (AS) teachers, who comprise a critical component of the special education workforce.

Objectives: To estimate AS teachers' attrition rate, defined as the rate at which AS teachers leave the AS teacher position; and examine teacher (e.g., years teaching, grades), school (e.g., student-teacher ratio, school climate), and implementation (i.e., fidelity to evidenced-based practices; EBP) characteristics associated with retention.

Methods: We leveraged data from our 15-year community academic partnership between the University of Pennsylvania and the School District of Philadelphia to examine attrition among autism support teachers, and teacher and school characteristics associated with teacher retention from school years 2011-12 to 2022-23. We calculated attrition rates, probability of retention at 5 years, and median years of retention. We used a Kaplan-Meier plot to graph retention. We used Cox regression to examine teacher and school factors associated with attrition. We measured hazard ratios (HR) associated with different characteristics & added a cluster parameter for cohort year.

Results: Our sample included 571 kindergarten-through-fifth-grade AS teachers. The average rate of attrition per year was 20.3%, which ranged from 9.7% in 2020-21 to 26.1% in 2016-17. The retention probability at 5 years was 35%, 95% CI [31%, 40%]. Median retention time was 3 years, 95% CI [3, 4]. Figure 1 displays the Kaplan Meier plot. In the first model, the HR decreased with increased percentage of students with 95% yearly attendance ($p = 0.047$). The HR increased with increased student-teacher ratio ($p = 0.028$). In the second model, the HR decreased with improved EBP fidelity ($p < 0.001$). HR decreased with increased percentage of students with 95% yearly attendance ($p = 0.007$). Cohort differences were large and statistically significant (Chi-square = 39.3, $df = 8$, $p < 0.001$). Table 1 displays results from Cox regression models. AS teachers stayed more during pandemic. Data analysis is ongoing and will be updated to include school and leadership climate and teachers' salary.

Conclusions: The high rate of attrition is concerning, as it likely negatively impacts both students and schools, and is costly for the district. Reducing the student-teacher ratio and enhancing support for teachers to improve their implementation of evidence-based practices may offer effective strategies to mitigate attrition. Previous research has shown that greater EBP fidelity is linked to lower end-of-year emotional exhaustion. Our ongoing analysis will examine additional mechanisms of action and points of intervention to improve teacher retention in districts like Philadelphia. Through our academic-community partnership, we can translate these findings into policies and actions that address teacher attrition.

218.002 A Pilot Randomized Trial of Rubi in Educational Settings (RUBIES) with Paraeducators Supporting Autistic Students with Co-Occurring Challenging Behaviors

K. Bearss^{1,2}, **D. M. Tagavi**³, **W. I. Shih**⁴ and **J. Locke**³, (1)Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Catalight, Walnut Creek, CA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California - Los Angeles, Los Angeles, CA

Background: Approximately 50% of autistic youth experience behaviors such as meltdowns, aggression, and transition difficulties. The Research Unit on Behavioral Interventions (RUBI) Network developed a low-intensity, manualized parenting intervention designed to support families of autistic children in successfully navigating their child's behaviors. With 20+ research studies, RUBI is acceptable to parents and effective in reducing quality of life impacting behaviors. Schools are the most accessed service system for autistic youth, and challenging behaviors may also impact meaningful engagement in academic tasks and with peers, resulting in placement in more restrictive settings. There is limited evidence on the feasibility and effectiveness of training paraeducators to utilize behavioral techniques designed to support autistic students and improve behavioral outcomes. Using the Discover, Design, Build, and Test Framework, which combines human-centered design and implementation science, RUBI content was iteratively redesigned (and renamed RUBI in Educational Settings or RUBIES), in collaboration with elementary school partners, to tailor RUBI content to be more practical, usable, and accessible in schools.

Objectives: This pilot randomized trial examined the feasibility (session engagement, intervention fidelity) and acceptability (attrition, satisfaction) of the redesigned RUBIES intervention compared to Psychoeducation when delivered by paraeducators supporting autistic youth with challenging behaviors in elementary school. Using the Aberrant Behavior Checklist-Irritability (ABC-I) and Hyperactivity (ABC-H) subscales, exploratory analyses also were conducted to examine the effectiveness of RUBIES compared to Psychoeducation in reducing challenging behaviors.

Methods: Paraeducator-student dyads were randomized to the trainer-led 8-module RUBIES intervention or an 8-module self-guided Psychoeducation course on autism, with 16 weeks allotted to complete the assigned program. Students were stratified by grade band (K-2; 3-5) and time in inclusion (<50%; ≥50% in their least restrictive environment). Data collection occurred at Baseline, Week 16 (Endpoint), and Week 24 (follow-up).

Results: Sixty-seven paraeducators (mean age 41 years, 87% female, 70% White, 13% Hispanic) and their 65 autistic students (57% in K-2; 62% White, 15% Hispanic) from 39 elementary schools across 12 states were randomized to RUBIES (N=34) or Psychoeducation (N=33) over 3 years. RUBIES was feasible in schools (average session length was 60 minutes; implementation fidelity ranged from 58-100%) and acceptable to paraeducators (attrition=7%). Ninety-six percent of RUBIES paraeducators rated having more confidence in managing future student behaviors at week 24 compared to 54% of paraeducators in Psychoeducation. Generalized linear mixed models showed no treatment effect for irritability (ABC-I; both groups improved) or hyperactivity/noncompliance (ABC-H; both groups improved).

Conclusions: While feasibility and acceptability benchmarks suggest RUBIES may be a promising intervention for paraeducators supporting autistic students with co-occurring challenging behaviors, these findings did not translate to robust differences in change scores on student-level outcome measures. The lack of findings may be better understood when considering: (1) difficulties in promoting change with one educator-student dyad, in a complex system of care; (2) measurement issues; (3) variability in baseline rates of behavior due to inclusionary criteria, (4) small sample size, (5) psychoeducation promotes a different pathway to the same endpoint, and/or (6) perhaps the intervention is ultimately not impactful enough to promote measurable behavioral change.

218.003 Extending the Reach of an Elementary School Executive Function Intervention through the Development and Evaluation of Online Implementation Supports

L. Kenworthy¹, A. Verbalis², J. V. Smith³, L. Campos⁴, T. Dahlman⁵, J. Holmes⁶, L. Cannon⁷, M. A. Werner⁸, K. C. Alexander⁹, M. Gunn¹⁰, K. Decker¹¹, J. Safer-Lichtenstein¹², D. Brown¹¹, J. Whiteford¹¹, C. Studts⁶ and L. Anthony¹³, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC, (3)Children's National Hospital, Rockville, MD, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Rockville, MD, (5)Department of Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (6)University of Colorado Anschutz Medical Campus, Aurora, CO, (7)Ivymount School, Rockville, MD, (8)Monica Werner Counseling, Chevy Chase, MD, (9)The Occupational Therapy Institute, La Mesa, CA, (10)Innovations Institute, University of Connecticut School of Social Work, Hartford, CT, (11)Innovations Institute, University of Connecticut School of Social Work, Hartford, CT, (12)University of Colorado School of Medicine, Aurora, CO, (13)University of Colorado, Denver, Aurora, CO

Background:

Childhood executive function (EF) abilities are adversely affected by poverty and drive academic, mental and physical health outcomes. In a comparative effectiveness trial, we found that the *Unstuck and On Target* intervention improved classroom EF behaviors in elementary school students with autism or ADHD. It was effectively delivered with good fidelity by school staff in low-income community schools. Outcomes did not significantly differ by family factors (race/ethnicity, income), suggesting that *Unstuck* works for all kinds of students and may be an accessible and equitable alternative to clinic-based care. Educator trainings were provided by research staff, however, limiting the scalability of the intervention.

Objectives:

We report on a dissemination and implementation project to convert the educator training from in-person delivery to asynchronous, online delivery with continuing education credits to increase the reach, adoption, implementation, and maintenance of *Unstuck*.

Methods:

With guidance from an advisory board (educators, caregivers of children with autism or ADHD, autistic parent/self-advocate, cultural competence expert), we created an on-line asynchronous educator training. Educators (n=293; 94% female, 90% white, M age=40±11 years) from elementary schools in Colorado and Virginia were asked to complete the training and deliver the *Unstuck* intervention. We also disseminated the training worldwide through the UnstuckandOnTarget.com website, conference presentations, listservs and media outreach.

Results:

Evaluation of the Reach, Effectiveness, Adoption, Implementation and Maintenance (RE-AIM outcomes) of *Unstuck* supported by the new online training indicated an exponential increase in its reach, with at least 5,024 students exposed to *Unstuck*, 33 times the number of students reached in the original effectiveness trial. Reach was extended beyond this implementation trial, as over 3,000 educators from across the US have now accessed the free online training and some are presumably delivering *Unstuck* to students as a result. Educators rated the training as effective with high scores for acceptability, feasibility and appropriateness. Parents (n=36) of a subsample of students who received *Unstuck* reported improvements in their child's EF. Of those educators who completed end point surveys (n=165), 73% reported delivering *Unstuck* lessons that school year, and 96% planned to run a group the following year. The training was an effective implementation support, as indicated by significantly improved educator knowledge of *Unstuck* ($t(170) = -6.26, p < 0.001$), and educator delivery of *Unstuck* with good fidelity (M fidelity = 4.7; 1-5 point scale; n=46). An implementation challenge for the *Unstuck* intervention was identified, in that only 9.3% educators reported completing all 21 *Unstuck* lessons, and 36% completed 10 or more lessons during the school year.

Conclusions:

Unstuck & On Target is evidence-supported and can be implemented with fidelity by educators who receive online, asynchronous training, distributed through a website with substantial national and international traffic. Wide dissemination of this implementation tool enhances the scalability of *Unstuck*, so that it can reach children in their community schools across the nation. Implementation challenges for the school-based delivery of *Unstuck* persist, however, including difficulty completing all 21 *Unstuck* lessons in a school year. Modularization of the curriculum may be an important next step.

218.004 The Schools Unified in Neurodiversity (SUN) Collaborative: Co-Designing and Testing a Program to Foster Inclusive Schools for Neurodivergent Children

K. B. Beck¹, A. Ionadi¹, T. Wagner², D. Beck³, R. Harris⁴, S. Edwards⁵, D. Westbrook-Martin⁴, J. Upshaw⁵, A. Rhone⁶, T. Kesich⁷, A. Kleinschmidt⁸ and C. A. Mazefsky⁴, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Upper St. Clair School District, Pittsburgh, PA, (3)Fox Chapel School District, Pittsburgh, PA, (4)ACLD Tillotson School, Pittsburgh, PA, (5)Autism Urban Connections, Inc., Pittsburgh, PA, (6)Community College of Allegheny County, Pittsburgh, PA, (7)Pittsburgh Public School District, Pittsburgh, PA, (8)Penn Trafford School District, Pittsburgh, PA

Background: Neurodivergent children face social, sensory, and environmental challenges at school that negatively impact learning and wellbeing. Many neurodivergent youth are bullied,^{11,12} feel less connected to school personnel, and report less membership with their school compared to their neurotypical peers.¹³⁻¹⁵ Aside from special education teachers, most educators are not trained in neurodevelopmental disabilities, leaving them with outdated knowledge and limited confidence about how to support neurodivergent children.^{15,23} Ultimately, this leaves educators unprepared and without necessary skills to create an affirming school climate for neurodivergent children. The Schools Unified in Neurodiversity (SUN) Collaborative project aimed to address these challenges by providing educators with the knowledge and tools to create a safe and inclusive school environment for neurodivergent children.

Objectives: This research project was ranked as a top priority by our established group of autistic community partners, who proposed that addressing challenges at school will improve lifetime experiences of poor mental health and suicidality. In a two-phase project, we sought to (1) co-design the SUN Program for school educators and (2) pilot test this program in one public school district.

Methods: First, we used community-based participatory research (CBPR) methods to form an interdisciplinary team of neurodivergent educators and community members. The team is comprised of general and special education teachers, school counselors, building- and district-level administrators, neurodivergent people, and parents of neurodivergent children across 6 public school districts. We then used human centered design (HCD) methods to iteratively design the SUN program (Figure 1). In Phase 2, one public school district implemented the SUN program with 192 educators, grades K-12 (Table 1). Attendees completed a SUN knowledge survey ($\alpha=.965$), the AASPIRE Autism Healthcare Provider Self-efficacy Scale adapted for educators ($\alpha=.958$), and three established implementation scales: Acceptability of Intervention Measure (AIM), Intervention Appropriateness Measure (IAM), Feasibility of Intervention Measure (FIM). We hypothesized that educator's knowledge and self-efficacy would increase and that the SUN Program would have strong feasibility, acceptability, and appropriateness for implementation.

Results: The resulting SUN Program is a 6-hour program with 4 content modules: (1) neuroscience of neurodiversity, (2) supporting safe relationships, (3) creating inclusive environments, and (4) preventing and responding to emotional distress. The SUN Program is designed to be implemented across an entire school with all school personnel (e.g. general and special education teachers, paraprofessionals, principals, district administrators). Both educator knowledge ($t(191) = -27.7, p < 0.001; d = 9.54$) and self-efficacy ($t(191) = -20.7, p < 0.001; d = 7.02$) significantly improved with large effect sizes. Educators found the SUN tools to be acceptable ($M = 4.2; SD = .71$; 86% agreed or strongly agreed), appropriate ($M = 4.35; SD = .63$; 92% agreed or strongly agreed) and feasible ($M = 4.29; SD = .59$; 93% agreed or strongly agreed) to implement in their classrooms and school.

Conclusions: Together, CBPR and HCD provided an innovative and community-driven approach to intervention development, resulting in a program that was well-received, effective, and conducive to implementation. Future work will test the effects of the SUN program on child outcomes and explore the role of professional learning communities to support implementation and sustain change.

Oral Session -

315 - Pathways to Mental Health: Exploring Interventions, School Environments, and Emotional Burden for Autistic and other Neurodivergent Youth

May 2nd, 2025, 4:30 PM - 5:30 PM - 6B

Moderator: Steven Kapp, School of Psychology, Sport and Health Sciences, University of Portsmouth, Portsmouth, Hampshire, United Kingdom

315.001 The Association between Mental Health Hospitalizations and Applied Behavior Analysis Receipt Among Autistic Youth
N. G. Aguirre Mtanous¹, J. Koenig¹, M. Nikahd², J. M. Hyer³, B. N. Hand³ and L. Bishop⁴, (1)University of Wisconsin-Madison, Madison, WI, (2)The Ohio State University, Columbus, OH, (3)General Internal Medicine, The Ohio State University, Columbus, OH, (4)University of Wisconsin - Madison, Madison, WI

Background: Applied Behavioral Analysis (ABA) is a widely used intervention for autistic children. While intended to improve autistic children's social functioning and reduce problem behaviors, in recent years, autistic self-advocates have critiqued the use of ABA as contributing to adverse mental health outcomes in adulthood. There has, however, been limited quantitative research on the association between childhood ABA receipt and mental health outcomes.

Objectives: This study aimed to investigate the association between ABA receipt and mental health outcomes.

Methods: We used de-identified, individual-level healthcare records from the 2012-2020 IBM MarketScan Commercial Claims and Encounters Database. Autistic youth who had at least one outpatient ABA encounter (N=18103) were propensity score matched to autistic youth (N=18103) who never received ABA on the basis of sex, age, US region of residence, super-rurality, amount of follow-up time, intellectual disability, mood disorder, anxiety disorder, and psychotic disorder. We used ICD-9 and ICD-10 diagnostic codes to identify mental health diagnoses and hospitalizations. Demographic variables included sex, age, US region of residence, and super-rurality. We calculated descriptive statistics and used negative binomial regression with a log link and log(person years) offset to assess average rates of mental health inpatient hospitalization and length of hospital stay. We then used logistic regression with log(person years) offset to assess odds of suicidality and PTSD diagnoses for ABA compared to non-ABA groups.

Results: Both the ABA and non-ABA groups were 79.6% male and relatively evenly distributed across the US. Clinically, 5% had intellectual disability, 10.3% had a mood disorder, 25.2% had an anxiety disorder, and 3.6% had a psychotic disorder. Adjusting for sex, region, super-rurality, baseline age, intellectual disability, anxiety disorders, mood disorders, and psychotic disorders, those in the ABA group were 1.39 (95% CI: 1.19-1.63) times more likely to experience a mental health hospitalization ($p<0.001$). Those in the ABA group had 46% (95% CI: 1.25-1.71, $p<0.001$) higher rates of mental health hospitalizations and 32% (95% CI: 1.07-1.64, $p<0.05$) longer lengths of stay across inpatient stays compared with the non-ABA group. There were no differences detected between the ABA and non-ABA groups on the likelihood of PTSD diagnoses or suicidality.

Conclusions: This study found significantly higher odds of experiencing a mental health hospitalization and a significantly longer length of stay for mental health hospitalizations among autistic youth who received ABA. Of note, our sample of autistic youth were matched on demographic factors including mood, anxiety, and psychotic disorders, suggesting similar baseline levels of mental health needs. Findings warrant future examination of the potential unintended consequences of ABA. Future research should seek to leverage longitudinal data that tracks mental health outcomes in autistic youth over a longer follow-up period to better understand the association between ABA dosage and mental health outcomes, particularly in young and middle adulthood.

315.003 “My Emotions in School Inventory” (MESI): Emotional Burden Experienced By Mainstream Secondary Students with Neurodivergence As Measured By a Novel Self-Report Measure

S. Lukito¹, S. Chandler², M. Kakoulidou³, K. Griffiths⁴, A. Wyatt⁵, E. Funnell⁶, G. Pavlopoulou^{6,7}, S. Baker⁸, D. Stahl¹ and E. Sonuga-Barke⁹,
(1)Department of Child and Adolescent Psychiatry, King's College London, London, UNITED KINGDOM, (2)King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (3)King's College London, London, United Kingdom, (4)King's College London, London, London, United Kingdom, (5)University of Bath, Bath, Bath, United Kingdom, (6)Department of Psychology and Human Development, Institute of Education, Group for Research in Relationships in Neurodiversity, London, UNITED KINGDOM, (7)Anna Freud Centre/UCL Brain Sciences, London, United Kingdom, (8)Royal Central School of speech and drama, LONDON, United Kingdom, (9)KCL, LONDON, United Kingdom

Background: Emotion dysregulation (ED) has been shown to mediate the risk for developing mental health problems in neurodivergent youths with ADHD and/or autism. However, mainstream literature almost exclusively defines emotion dysregulation as deficits of emotion processing and control (DEPAC) within the person. The RE-STAR (Regulating Emotions Strengthening Adolescent Resilience) research programme puts forward an alternative mediator between neurodivergence and mental health, i.e., emotional burden (EB), extrinsically driven by frequency and intensity commonly upsetting events (CUEs), for example, at school.

Objectives: Using the “My Emotions in School Inventory” (MESI), a novel self-report measure of emotional burden, co-produced with neurodivergent RE-STAR youth researchers, we investigated in a cross-sectional design:

- The construct of the EB index, a measure of emotional burden produced by the MESI.
- The frequency and intensity of CUEs at school, and the EB experienced by neurodivergent secondary school students (with autism and/or ADHD) compared to their neurotypical peers.
- The association between EB and DEPAC and mental health problems among students.
- Whether burden was influenced by distinct sets of CUEs for autistic students compared to those with ADHD.

Methods: The MESI consists of 25 school-based CUE and assesses: (a) how frequently the CUE occurs, and (b) how upsetting it is. The EB index was created from a latent construct indicated by the multiplication of the CUE frequency and intensity. We conducted exploratory factor analysis (EFA) to construct a psychometrically robust EB-index. We also conducted group comparisons, linear discriminant analyses (LDA), and multiple regression, using data collected from 735 young people (ADHD, n=100; autism, n=104; ADHD+autism, n=79; and neurotypical [NT], n=452).

Results: EFA showed that the EB-index, based on 24 or 25 MESI items, was a robust psychometric construct. The neurodivergent groups (i.e., autism and/or ADHD) experienced higher frequency and intensity of CUE and demonstrated higher EB than their neurotypical peers. EB strongly predicted depression/anxiety, and both EB and DEPAC independently predicted depression/anxiety, controlling for ADHD and autistic traits. LDA showed distinctive CUE items which contributed to a strong burden in ADHD compared with in autism.

Conclusions: Our initial cross-sectional findings illustrate the potential value of the *EB index*, as measured by the MESI, as a contributory factor in mental health risk in neurodivergent adolescents alongside DEPAC. This is being further investigated through a longitudinal study. The findings also identify both EB and DEPAC as potential targets for school-based interventions which aim to support the mental health of neurodivergent young people.

315.004 Supporting Autistic Children Who Have Experienced Interpersonal Trauma - a Delphi Study

A. Nielsen¹, A. Tan², L. Kalisch³, A. Quinton⁴, K. Williams⁵ and A. Ure⁶, (1)Monash University, Melbourne, VIC, Australia, (2)Paediatrics, Monash University, Clayton, VIC, Australia, (3)Turner Institute for Brain and Mental Health, Monash University, Melbourne, VIC, Australia, (4)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Paediatrics, Monash University & Monash Health, Melbourne, VIC, Australia, (6)Paediatrics, Monash University Department of Paediatrics, Clayton, VIC, Australia

Background: Autistic children are more vulnerable to experiencing and being impacted by interpersonal trauma. Despite this enhanced risk, research proposing therapeutic support recommendations is outdated, limited and methodologically inconsistent. It is currently unclear how clinicians are supporting these children. Without evidence to guide practice, support is inconsistent at best, while at worst, it is inadequate and potentially exacerbating mental ill health. In the absence of evidence, it is valuable to look to clinical expertise as a complementary source of knowledge that can offer guidance.

Objectives: This study aimed to establish expert consensus for what constitutes optimal therapeutic support for autistic children who have experienced interpersonal trauma, with the intention of facilitating the development of preliminary best practice guidelines. Specifically, we sought to identify therapeutic recommendations and modalities clinicians consider 'helpful' or 'unhelpful' when supporting these children.

Methods: We recruited 29 experts in autism and interpersonal trauma in childhood. Via a 2-round Delphi survey, experts commented on and rated the helpfulness of recommendations drawn from a recently published scoping review. A revised list of recommendations including new recommendations suggested by experts in the first round was submitted to a second round (n = 20; 69% retention) of expert review and rating. Data was analysed thematically and consensus was achieved when agreement was greater than or equal to 80%. Two researchers independently analysed the data via thematic analysis, compared their findings and revised discrepancies to enhance the credibility of the findings.

Results: Eighty-seven (60.0%) recommendations achieved a 'helpful' consensus, and three (2.1%) reached an 'unhelpful' consensus. Generally, participants endorsed therapeutic recommendations that align with guidelines for supporting similar populations of children, such as neurotypical children who have experienced interpersonal trauma. Three key themes emerged: prioritising child and family safety, involving parents/caregivers in therapy and individualising supports to the child's characteristics. The effectiveness of therapeutic recommendations was considered dependent on child and family safety and whether therapy was individualised according to the child's traits. Where possible, participants encouraged parent/caregiver involvement in therapy.

Conclusions: These findings provide valuable insights into current clinical practice and may be used to facilitate the development of preliminary best practice guidelines to direct therapeutic support in the absence of empirical evidence. This study also identified therapeutic recommendations for this population that should be validated in future research.

316.001 Testing the E/I Imbalance Theory of Autism By Combining Genetic Scores, Concentrations of Glutamate and GABA, and Behavioral Characteristics of Autism

V. Hollestein¹, A. R. Thomson², E. Loth³, D. Murphy⁴, J. K. Buitelaar⁵ and N. A. Puts³, (1)Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behavior, Nijmegen, Netherlands, (2)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (3)Department of Forensic and Neurodevelopmental Sciences, Flat 2, 116, South Hill Park, London, London, United Kingdom, (4)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (5)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Center, Nijmegen, NETHERLANDS

Background:

The excitatory/inhibitory (E/I) imbalance theory suggests that an imbalance between excitatory and inhibitory mechanisms in the brain underlies autism traits. However, we do not know how this E/I imbalance manifests and whether it differentially affects autism traits. To date, studies have mainly focused on either excitation or inhibition in isolation, and in a unimodal fashion, failing to take their potential interactions into account and leading to inconsistent results.

Objectives:

To bridge this gap, genetic measures were combined with the in vivo 1H-MRS measures of *both* glutamate (excitation) and GABA (inhibition), and their ratios, in the anterior cingulate cortex (ACC) and thalamus. We explored how these genetic and neurochemical markers may be interconnected, and how their potential interactions could influence behavioral characteristics associated with autism.

Methods:

Participants were part of the third wave of the AIMS-2-TRIALS Longitudinal European Autism Project (LEAP) cohort (166 participants (autistic = 103, male/female = 79/24; neurotypical = 63, male/female = 42/21) aged between 13-36 years. Behavioral characteristics of autism were measured using interviews and questionnaires; social communicative behaviors (Social Responsiveness Scale-Revised (SRS-2), repetitive behaviors (Repetitive Behavior Scale-Revised (RBS-R), and sensory processing (Short Sensory Profile (SSP). For the autistic participants scores on the Autism Diagnostic Observation Schedule (ADOS-2) were also available.

Associations between aggregated genetic variations of the glutamate and GABA gene-sets and glutamate and GABA concentrations were estimated using MAGMA (multi-marker Analysis of GenoMic Annotation). MAGMA tests whether the aggregated association of the genes in the gene-set with the phenotype (1H-MRS measured glutamate or GABA) is stronger than all other genes in the genome.

Linear models were used to assess interactions between glutamate and GABA genes with glutamate and GABA concentrations on behavioral autism characteristics. Gene-set autism polygenic scores (PGS), glutamate and GABA concentrations and their ratios in each region (ACC, thalamus) were the predictors, with behavioral measures as outcome measures. Each combination of polygenic score x MRS measure resulted in 48 models.

Results:

Genetic variation of glutamate genes were associated with GABA concentrations in thalamus, and GABA genes with glutamate concentrations in thalamus (Table 1). Interactions were observed between ACC glutamate and glutamate PGS on social-communicative, sensory behaviors, and core clinical autism traits captured by ADOS-2. Glutamate/GABA ratios in the thalamus with gene-set PGS also had interaction effects on social-communicative behaviors and ADOS-2 scores.

Conclusions:

These findings demonstrate that a complex interaction between markers of glutamate and GABA play a critical role in shaping autism characteristics, with these associations being influenced by both genetic factors and metabolic processes. This underscores the importance of measuring glutamate and GABA concentrations together, and using multimodal markers of their functioning to more effectively unravel how excitation/inhibition (E/I) imbalances may contribute to autism in diverse ways. Particularly the interaction effects observed in the thalamus, a region crucial for sensory processing consolidation, show that sensory processing alterations in autism may have differing underlying factors than other core clinical characteristics.

316.002 Assessing the Impact of Open Data Sharing in Autism Neuroimaging Research of the Brain Connectome

P. Thomson¹, D. Perez¹, S. Park², T. George¹, M. P. Milham³ and A. Di Martino¹, (1)Child Mind Institute, New York, NY, (2)Autism Center, Child Mind Institute, New York, NY, (3)Nathan S. Kline Institute for Psychiatric Research, Orangeburg, NY

Background: The Autism Brain Imaging Data Exchange (ABIDE) provided the first open neuroimaging autism-related data resource aggregating over ~2100 MRI and related phenotypic information across 24 international research laboratories, with the goal to accelerate the pace of discovery and facilitate collaborations. Over 10 years have passed since its first release, offering a critical opportunity to evaluate ABIDE's impact on the scientific community.

Objectives: We aimed to systematically assess the impact of the open ABIDE dataset in autism neuroimaging research, specifically regarding its use and scope of research questions addressed.

Methods: A systematic literature review consistent with PRISMA guidelines identified peer-reviewed articles published between January 2013–June 2023. We then categorized articles into those using ABIDE MRI data and those not. Article data extracted from included articles were across three domains: 1) analysis/approach, 2) publication information, 3) sample characteristics. Summary statistics within, and statistical comparisons between, ABIDE and non-ABIDE articles were conducted. During review, a complementary criteria set was developed to assess transparency of reporting in seven domains: research objectives/hypotheses, datasets, analysis variables, imaging preparation, analytical approach, participant description, imaging results. Criteria were applied to ABIDE resting-state functional MRI (R-fMRI) articles yielding a reporting transparency score from 0–10.

Results: We identified 718 peer-reviewed empirical neuroimaging articles published using ABIDE and 654 using non-ABIDE data (Fig.1). Most ABIDE articles considered R-fMRI data (75%), while non-ABIDE articles predominantly analyzed structural MRI (sMRI; 50%) (Fig.2A-B). Across ABIDE and non-ABIDE articles, group mean comparisons was the most common research purpose. There was, however, a wider range of research purposes in ABIDE than non-ABIDE articles and a significantly greater number of studies focusing on novel analytical approaches (Fig.2C). For example, significantly more ABIDE studies focused on diagnostic classification, neurosubtyping and development of new methods. There were no significant differences in journal impact factor ($p=.056$; Fig.2D). ABIDE articles examined significantly larger sample sizes than non-ABIDE ($p<.001$; Fig.2E) and older mean sample ages ($p=.002$; Fig.2F), though both focused predominantly on childhood and adolescence. The average reporting transparency score for ABIDE R-fMRI articles was 6.5; transparency was higher for basic sample characteristics and analytical design, but lower for participant selection rationale, detailed sample characteristics and MRI data quality reports.

Conclusions: Over 1300 autism studies in R-fMRI, sMRI and diffusion MRI modalities have been published in the last 10 years. ABIDE has facilitated an explosion of this research, providing greater statistical power for group mean comparisons, and facilitating approaches exploring heterogeneity (e.g., neurosubtyping) and inter-individual differences (e.g., classification). Along with clear benefits of open data resources, results from this review emphasize several needs. For example, the strong focus on child-adolescent collections highlights the need for including a wider age range in large cohorts. Adopting clear reporting standards will also clarify the representativeness of neuroimaging findings, bolstering robustness and replicability. Findings motivate and inform future open data efforts for autism and beyond.

316.003 Structural Determinants of Signal Speed: An Intermodal Investigation of Face Processing in Autism Spectrum Disorder

C. R. Coleman¹, M. G. Nance¹, K. A. Pelphrey¹, J. D. Van Horn^{2,3}, B. T. Newman² and M. H. Puglia¹, (1)Department of Neurology, University of Virginia School of Medicine, Charlottesville, VA, (2)Department of Psychology, University of Virginia, Charlottesville, VA, (3)School of Data Science, University of Virginia, Charlottesville, VA

Background:

The N170 is an event related potential (ERP) elicited in response to faces over posterior scalp electrodes. Previous studies demonstrated slower responses to faces in Autistic (Autism Spectrum Disorder, ASD) participants as compared to typically developing (TD) participants. Observed differences in latency may be due to variations in axonal morphology, which has been challenging to measure. However, a new MRI metric, aggregate conduction velocity (ACV), incorporates measurements of myelin and axonal diameter to estimate action potential speed. By relating axonal structure to function, we can investigate microstructural differences underlying heterogeneous behavioral phenotypes observed in ASD.

Objectives:

To elucidate the microstructural correlates of face processing across cohorts, this study tested the interaction between ACV and tract length with latency of the N170. We examined white matter pathways connecting the primary visual cortex (V1) and right fusiform cortex (rFFA) across cohorts. We hypothesized observing slower N170 latency to faces in ASD, and that this delay would be negatively associated with V1 to rFFA ACV.

Methods:

ASD ($n = 66$) and TD participants ($n = 66$) viewed faces and objects in a social reward task while undergoing electroencephalography (EEG) and later underwent diffusion MRI. An AIC stepwise regression analysis identified the best predictors of N170 latency based on phenotypic and imaging metrics along V1 to rFFA pathways, including ACV, tract length, age, sex, Social Communication Questionnaire (SCQ) score, pubescence, and IQ.

Results:

TD participants demonstrated significantly faster responses to both objects and faces ($p < 0.001$). ACV along the V1 to rFFA pathway did not differ as a result of diagnosis ($p = 0.188$), although ACV was higher across all pathways in TD participants relative to those with ASD ($p < 0.003$). While TD participants had faster responses to faces than ASD participants, this was not statistically significant ($p = 0.51$). The best fit model as determined by AIC was significant and explained 29.88% of the variance in N170 latency ($p < .001$). It showed that N170 latency in the right hemisphere was negatively associated with ACV ($p = 0.043$) and positively associated with tract length ($p = 0.007$). Also included in the final model was age ($p = .091$), SCQ score ($p = .186$), the interaction between ACV and SCQ score ($p = .128$), and the interaction between tract length and age ($p = .023$). This relationship was driven by participants below the median SCQ score, or those with less severe autistic traits.

Conclusions:

We demonstrated that ACV and tract length along the V1 to rFFA pathway are both significantly associated with N170 latency in response to faces. This study is the first time a biological explanation of N170 latency has been tested. We demonstrate the efficacy of ACV as a non-invasive, in-vivo metric of information transfer speed, sensitive to autism trait severity. Our method allows assessments of function in regions unable to be evaluated by EEG due to gyrification. Importantly, our results present a novel and robust bimodal methodology which successfully integrates structural markers to assess functional differences in neurodevelopmental disorders.

316.004 Functional Temporal Dynamics and Spatial Heterogeneity of the Fusiform Gyrus in Autism

D. L. Floris¹, L. F. Saccaro², F. Delavari³, D. Strzelczyk⁴, B. Hebling Vieira⁴, C. Elleaume⁴, L. G. EU-AIMS⁵ and N. Langer⁴, (1)Department of Psychology, University of Zurich & ETH Zurich, Zurich, Switzerland, (2)Psychiatry Department, Faculty of Medicine, Geneva, Switzerland, (3)Developmental Imaging and Psychopathology Lab Research Unit, Faculty of Medicine, University of Geneva, Geneva, Switzerland, (4)Department of Psychology, University of Zurich, Zurich, Switzerland, (5)EU-AIMS Organization, London, United Kingdom

Background:

Autism is primarily characterized by social difficulties. Differences in the way autistic individuals process faces have been examined at the neural level in core regions of the face processing network, such as the fusiform gyrus (FFG)^{1,2}. While functional magnetic resonance imaging (fMRI) studies report different patterns of activation and connectivity within the FFG in autism^{1,4}, prior research mainly addressed static functional properties across the whole FFG. How activity within the FFG and its functional subdivisions dynamically reconfigures with the rest of the brain in autistic compared to non-autistic individuals (NAI) remains unclear. Furthermore, typical sex differences in face processing exist with females outperforming males on emotional face recognition tasks⁵ and having a reduced right hemisphere dominance compared to males⁶. Also, in autism, sex differences have been implicated in regions and networks related to face processing^{7,8}. Whether these sex difference in autism also extend to dynamic functional connectivity (dFC) of the FFG with the rest of the brain remains to be established.

Objectives:

Using a recent extension of a dFC approach (micro-co-activation patterns [μ CAPs] analysis^{9,10}), we aimed to characterize both spatially and temporally the functional reconfigurations of the FFG with the rest of the brain in autistic compared to non-autistic males and females.

Methods:

We included 286 autistic individuals (208 males) and 228 NAI (146 males), aged 6–30 years from the large-scale EU-AIMS Longitudinal European Autism Project. We used resting-state fMRI data to derive data-driven, k-means-clustering based μ CAPs using the left and right FFG as one seed region. Unlike conventional methods, μ CAPs extract dynamic spatial patterns that reveal functional subdivisions of the seed region (i.e., FFG). Functional networks were characterized by overlapping them with the 17 Yeo networks. To assess the spatial overlap between the μ CAP subdivisions within the FFG between autistic and NAI, we computed Dice coefficients and evaluated statistical significance with 10,000 permutations. We further compared the occurrences of the different μ CAPs using linear mixed-effects models with diagnosis, sex, diagnosis-by-sex interaction, mean framewise displacement and age as fixed effects and acquisition site as random effect.

Results:

We derived six μ CAPs co-activating with the ventral attention/somatomotor, dorsal attention, visual central, visual peripheral, limbic, and default network (DN). All six μ CAPs showed large spatial overlap between autistic and NAI ($p > 0.05$). There was a significant sex-by-diagnosis interaction ($t = 2.61$, $p = 0.009$, $pFDR = 0.05$) with NAI females exhibiting fewer occurrences of the DN μ CAP than NAI males ($t = 3.79$, $p = 0.001$), whereas autistic individuals did not show such sex difference ($t = 0.17$, $p = 0.99$).

Conclusions:

Using a novel dFC approach, we examined the spatial and temporal reconfigurations of the FFG in autism. Our findings revealed that autistic individuals do not differ from NAI in the spatial extent of FFG subdivisions co-activating with various brain networks. However, autistic males and females did not show sex differences in co-activation patterns between the FFG and DN as observed in NAI. These findings suggest that the typical sex differences in the dFC of face processing networks are attenuated in autism, highlighting the importance of considering sex-related variability when examining brain dynamics in autism.

Oral Session -**317 - Addressing Self Injurious & Dangerous Behaviors in Individuals with Profound Autism**

May 2nd, 2025, 4:30 PM - 5:30 PM - 6A

317.001 ECT in Profound Autism and Incredibly Dangerous Self-Injurious Behavior

L. E. Wachtel, *Neurobehavioral Unit, Kennedy Krieger Institute, Baltimore, MD*

Background: Individuals with profound autism have a high risk of psychiatric comorbidities given that both autism spectrum disorders and intellectual disability independently increase the risk of additional psychiatric diagnoses which may be exquisitely responsive to electroconvulsive therapy (ECT).

Objectives: This presentation aims to review severe psychiatric and associated behavioral comorbidities of profound autism that may be safely, rapidly and efficaciously treated with ECT, often after lack of response to pharmacological interventions and accrual of significant clinical morbidity

Methods: A comprehensive literature review surrounding electroconvulsive therapy in autism and intellectual disability combined with multiple illustrative case examples.

Results: Eight decades after its inception in 1938, electroconvulsive therapy remains the most powerful agent in the psychiatric armamentarium, specifically for severe affective, psychotic, catatonic and combined psychopathology that has not proven responsive to first-line psychotropic interventions and has led to significant and often life-threatening clinical morbidity and potential mortality. Autism across the spectrum is associated with increased risk of multiple psychiatric comorbidities, including ADHD, anxiety, depression, psychosis and catatonia. Intellectual disability has been recognized since the 1970 Isle of Wight studies to confer an approximately three to four-fold increased risk of all psychiatric comorbidities. Given that profound autism by definition includes IQ below 50, it is not surprising that in recent years, a growing literature documents the utility, efficacy and safety of ECT not only for individuals with profound autism struggling with major affective and psychotic illness, but most prominently in catatonia, including both its psychomotor agitated and retarded forms, life-threatening malignant catatonia and intractable, highly dangerous repetitive self-injurious behavior devoid of social function and newly recognized along the catatonia spectrum. Although ECT often remains stigmatized and implemented as a last resort, its critical role in ASD, and particularly profound ASD is expanding given vast clinical need and astounding response, at times when all hope was otherwise lost.

Conclusions: ECT plays a growing role in the treatment of severe affective, psychotic, catatonic and combined pathology that occurs at elevated rates in profound autism. Although highly stigmatized and unequally available, ECT is a critical agent in the clinician's profound autism toolbox to optimize outcomes for individuals served and their families.

317.002 Treatment Outcomes for Behavioral Concerns in Profound Autism

M. Scheithauer¹, M. McMahon², C. Muething³, J. Lomas Mevers⁴, N. Call¹ and J. Herrod², (1)Pediatrics, Emory University School of Medicine, Atlanta, GA, (2)Emory University; Marcus Autism Center, Atlanta, GA, (3)Emory University, Atlanta, GA, (4)Marcus Autism Center, Atlanta, GA

Background: Externalizing behavioral concerns, such as aggression, self-injury, disruption, elopement, and pica, are prevalent among autistic individuals, and even more so in individuals with autism with high-support needs (e.g., profound autism). Behavioral treatments are empirically supported to help with these behaviors, but past research has often either focused on individuals with lower support needs (e.g., minimal or no intellectual disability) or has not provided sufficient description of the sample to determine if individuals with profound autism are included.

Objectives: The aim of the current project is to evaluate behavioral presentations and outcomes for individuals with profound autism from a) a clinical trial targeting elopement in autistic youth and b) outcomes from an intensive behavioral treatment program.

Methods: We previously conducted a randomized clinical trial of a caregiver-mediated function-based elopement treatment with 76 autistic youth (age 4 to 13). In this study, we compare outcomes from 27 youth with significant intellectual disability to the remaining sample on primary outcomes of the Clinical Global Impression Scale and caregiver-collected data on elopement frequency. Second, we evaluate 40 records from a consecutive retrospective case review (20 with profound autism and 20 without; age 6-19) from an intensive outpatient program treating behavioral concerns in autism. We compared these groups (individuals with and without profound autism) based on specific behavioral concerns targeted in treatment; behavioral assessment outcomes; treatment components included in final treatment packages; and success of intervention (defined as meeting caregiver-set goals and observed reductions in behavioral concerns). Multivariate analysis of variance (for continuous) and chi-squared analyses (for categorical) outcomes were conducted.

Results: In the randomized clinical trial, no significant differences were observed when separating the sample based on recent definitions of profound autism based on the primary outcomes ($p = .57$). In the intensive outpatient sample, self-injury was more common among individuals with profound autism and elopement was more common in those without profound autism, which aligns with previous research. No significant differences were observed in success of intervention, based on observed reductions in target behaviors ($p = .33$) or caregiver goals met ($p = .12$). However, more treatment components were in final treatment packages for individuals with profound autism ($p < .005$).

Conclusions: Retrospective analyses of data from a randomized clinical trial of a caregiver-mediated treatment for elopement suggested no differences in treatment efficacy for those with and without profound autism. In the intensive outpatient program, significant differences were not noted in overall success of intervention. However, more nuanced variables (e.g., number of treatment components included) suggest that behavior of youth with profound autism may be more resistant to change. The researchers and clinicians that designed the elopement manual and that serve as case managers in the intensive program specialize in treating behavioral concerns in youth with profound autism. Thus, results are discussed as they relate to this expertise, with an emphasis on the need for determining which factors in treatment contexts relate to positive outcomes for youth with profound autism.

317.003 A Multi-Phased Training Approach: Using Module, Video, and Simulation-Based Education to Teach Behavior Management Skills to Multidisciplinary Teams in a Pediatric Hospital Setting

E. Klinepeter^{1,2}, J. Reece¹, M. Cashin¹ and M. Costilla¹, (1)Texas Children's Hospital, Houston, TX, (2)Baylor College of Medicine, Houston, TX

Background: In the United States, there is recognition of a “mental health crisis” among children and adolescents with behavioral health needs, particularly those with autism spectrum disorder (ASD) and high support needs. Given limited access to specialized psychiatric care, children with ASD are likely to present to acute care hospital settings. While hospitalized, children are at increased risk of aggression and self-injury, exacerbated by the novel and overstimulating hospital environment and lack of adequate staff training on meeting patients’ needs. To address this, research on approaches to educate staff is warranted, particularly multidisciplinary staff that might respond to behavioral events. To date, some preliminary research exists on medical staff educational programs, particularly programs using lecture-based formats. However, research is needed on training packages that include skills-based practice and target multidisciplinary teams.

Objectives: The purpose of this study was to 1) describe a multi-phased medical staff training program on caring for patients with ASD and behavioral health needs, and 2) evaluate learning outcomes from the program.

Methods: A team of nursing leaders and educators, board certified behavior analysts, and simulation specialists designed a 3-part training series consisting of: 1) didactic instruction (modules and training tools), 2) modeling (training video), and 3) applied skills practice (simulation). A modified version of the Behavior Activity Rating Scale (BARS) was adopted to guide design of the simulation, in which a simulated, minimally verbal patient escalated from baseline (level 1) to severe aggression (level 5) and staff responded in line with pre-determined actions corresponding to their role. Pre- and post-survey questions were administered to measure staff knowledge and confidence in responding to behavioral events, a competency checklist was used to assess for skills demonstrated during the simulation, and staff provided ratings for each educational component. All staff who completed the training were offered the option to consent for data use as part of the study.

Results: A total of 122 staff members consented to data use. Staff members included nurses, personal care assistants, sitters, house supervisors, security guards, and social workers. The Wilcoxon signed rank test was used to compare participants’ pre and post-ratings. All scores increased significantly as a result of the training, staff rated the training highly overall, and staff rated the simulation portion of the training as most helpful. See Tables 1 and 2 for details. In addition, staff demonstrated skills with 83.6% accuracy, with 96% interobserver agreement achieved between raters. Long-term outcome data is also being collected.

Conclusions: This study describes a multi-phased educational approach that was designed and implemented to increase staff knowledge, confidence, and skills in providing care to patients with ASD and behavioral health needs. Our study suggests that multi-modal learning may increase staff knowledge and confidence, particularly by allowing staff to learn about and observe skills followed by practice of skills. In addition, staff likely benefit from debriefing and repeated practice that is offered for any skill gaps. Currently, we are working on educational strategies to address any educational gaps and to target maintenance of educational gains.

317.004 Characterizing Key Correlates of Challenging Behavior Domains in Profound Autism

E. F. Ferguson¹, T. W. Frazier², A. Y. Hardan³ and M. Uljarevic³, (1)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Psychology, John Carroll University, Cleveland, OH, (3)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA

Background: Challenging behaviors (CB) encompass clinically impactful, disruptive behaviors that commonly co-occur in a range of neurodevelopmental disorders (NDD), including autism spectrum disorder and neurogenetic developmental disabilities (NDG). Existing research in NDD samples broadly suggests associations between higher levels of CB and features such as lower speech level, elevated autism traits, and difficulties with regulating emotions. However, despite the prominence of these factors among individuals with NDD and severe intellectual disability (ID), their role in the emergence and maintenance of CB in this population remain poorly understood, especially when considering individuals with profound autism. Thus, more work is needed to identify potential risk markers for CB among individuals with profound autism characteristics, where these behaviors might be particularly prevalent and impactful.

Objectives: To characterize the relative contributions of developmental and clinical features in predicting the severity of CB subdomains in a sample that includes individuals with NDG, ASD, and significant ID and speech delays.

Methods: Parents/caregivers of 255 individuals with NDG (3-45 years old) participated in this study (51.0% male; 46.1% nonspeaking or single word speech). Parents/ caregiver informants completed questionnaires as part of the Neurobehavioral Evaluation Tool (NET), a set of 11 online-administered survey scales developed for people across the cognitive ability range. Hierarchical regression models were conducted to examine unique predictors of property destruction, aggression, elopement, conduct problems, and self-injury. For each model, age and speech production were entered in step 1, social communication in step 2, emotion dysregulation in step 3, physiological anxiety and worry in step 4, and sensory sensitivity in step 5.

Results: Speech production and social communication were negatively correlated with each of the CB subdomains ($r = -0.21$ - -0.54). Additionally, emotion dysregulation, physiological anxiety, and sensory sensitivity were positively associated with the five CB subdomains ($r = 0.16$ - 0.62). Worry was negatively correlated with elopement ($r = -.14$) and positively associated with aggression ($r = 0.14$). Unique profiles of predictors emerged for distinct CB. Specifically, lower speech production was associated with conduct problems ($t = -2.99, p = .003$) and elopement ($t = -2.46, p = .015$), while emotion dysregulation uniquely predicted self-injury ($t = 3.01, p = .003$), conduct problems ($t = 7.61, p < .001$), property destruction ($t = 5.894, p < .001$), aggression ($t = 6.05, p < .001$), and elopement ($t = 2.91, p = .003$). Physiological anxiety uniquely predicted aggression ($t = 2.31, p = .022$) and elopement ($t = 3.99, p < .001$).

Conclusions: These findings provide further evidence that clinical features associated with profound autism are associated with greater CB severity. These features include nonspeaking profiles, significant delays in social communication, and greater difficulties in emotion regulation due to significant ID. Emotion dysregulation emerged as a consistent, strong predictor of severity across distinct types of CB, suggesting that dysregulation is an important intervention target for CB in profound autism. Findings provide unique insights into nuanced associations between developmental and psychological correlates of CB to inform improved assessment and monitoring of CB in profound autism.

Oral Session -

318 - The Importance of Access to Public Health Care for Autistic Adults

May 2nd, 2025, 4:30 PM - 5:30 PM - 611-614

Moderator: Adam Guastella, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia

318.001 Perinatal Mental Health Among Autistic Individuals in an Integrated Healthcare Setting in California

J. L. Ames¹, M. Anderson¹, L. A. Avalos¹, E. Cronbach², D. L. Gassner³, C. Lee⁴, M. Giwa Onaiwu⁵ and L. A. Croen¹, (1)Division of Research, Kaiser Permanente Northern California, Oakland, CA, (2)Obstetrics and Gynecology, The Permanente Medical Group, Walnut Creek, CA, (3)Social Work, AJ Drexel Autism Institute, West Hempstead, PA, (4)Epidemiology & Biostatistics, University of California San Francisco, School of Medicine, San Francisco, CA, (5)Drexel University, Philadelphia, PA

Background: Autistic pregnant individuals commonly experience known risk factors for perinatal depression, including a history of psychiatric problems and trauma before pregnancy, intimate partner abuse, pregnancy complications, and low social support. Qualitative interviews and survey studies indicate a heightened risk of depression and anxiety during pregnancy for autistic people, though research in this area remains limited.

Objectives: To compare perinatal mental health outcomes between pregnant autistic people and non-autistic peers, both of whom received obstetric care and perinatal depression and anxiety screening in the same US healthcare system.

Methods: Our study took place at Kaiser Permanente Northern California (KPNC), a large, integrated healthcare delivery system. Among KPNC members with a clinician-documented diagnosis of autism, we identified individuals with pregnancies ending between January 2011 and July 2022 and matched them 100:1 on birth year to pregnancies among non-autistic peers. For this analysis, we then further restricted the sample to pregnancies ending in live births. From electronic health records, we extracted information on sociodemographic factors; mental health diagnoses in the 2 years preceding pregnancy, during pregnancy, and 12 months postpartum; severity of depressive symptoms during pregnancy and postpartum; and psychotherapeutic medication use during pregnancy. We defined mild, moderate, and severe depressive symptoms as scores of 5-9, 10-15, and 15-27, respectively, on the PHQ-9, a validated screener for depression that has been regularly administered throughout prenatal and postpartum care at KPNC since 2011.

Results: Our sample included 91 autistic and 11012 non-autistic pregnant people. Autistic people were significantly more likely than non-autistic peers to be diagnosed with depression during the two years before pregnancy (32% vs. 10%), during pregnancy (63% vs. 17%), and during the 12 months postpartum (29% vs. 12%). Most diagnoses of depression during pregnancy were new episodes (i.e., did not have a diagnosis in the two years preceding the pregnancy), though this proportion was smaller among the autistic group than in the non-autistic group (56% vs. 64%). Depressive symptom severity during pregnancy was similar between both groups, but severe postpartum depressive symptoms were more common in the autistic group than in non-autistic group (severe: 38% vs. 29%). Anxiety during pregnancy was also more frequent in autistic people than in non-autistic people (26% vs. 11%). Rates of antidepressant use among those with a depression or anxiety diagnosis during pregnancy were similar between the autistic and non-autistic groups (25%).

Conclusions: Our findings corroborate earlier reports that autistic individuals experience a more significant perinatal mental health burden than their non-autistic counterparts. In a setting with universal perinatal depression screening, prenatal depression was recognized in over half of autistic pregnant people. Despite comparable antidepressant use between groups, autistic individuals with diagnosed depression typically exhibited more severe depressive symptoms than non-autistic people. Inadequate mental health management during and after pregnancy can have lasting impacts on both parent and child. To better inform support and intervention services for autistic pregnant people, we will augment these results with analyses of sociodemographic predictors of perinatal mental health and the use of psychotherapy services following perinatal depression diagnosis.

318.002 Beyond the Numbers: Key Drivers of Emergency Room Use Among Autistic Adults Aged 18-80

N. Canter¹ and T. W. Benevides², (1)Department of Community & Behavioral Health Sciences, School of Public Health, Augusta University, Augusta, GA, (2)Institute of Public and Preventive Health, Augusta University, Augusta, GA

Background: Autistic individuals are significantly more likely to experience a variety of co-occurring health conditions. The best care environment for any person, but particularly autistic individuals, is routine care with known and trusted providers. Emergency departments (EDs) are not only overwhelming, but rarely have providers with training or resources to facilitate communication or accommodations needed for positive care outcomes. While many studies have identified high rates of ED visits among autistic children, adolescents, and young adults (e.g., Benevides et al., 2020; Giannouchos et al., 2023; Kalb et al., 2022; Ianuzzi et al., 2022), we need a more nuanced understanding the reasons for those visits, with few to no studies examining the top contributing reasons for high ED utilization. Further, the clinical and research community has called for more research with autistic people having greater functional need.

Objectives: The objective of this cross-sectional study of all-payer ED data was to identify the top reasons for visits among autistic adults aged 18-80y. A secondary objective was to quantify reasons by varying levels of physician-coded intellectual disability (ID).

Methods: We used the 2019 Healthcare Costs and Utilization Project State Emergency Department Dataset (H-CUP SEDD) from 21 U.S. states (total visit sample of 37,013,841). States were selected based on having a zipcode in purchased data. We selected visits by autistic individuals (ICD-10 F84, $n=25,170$) with or without varying co-occurring intellectual disability (mild ID-F70; moderate ID-F71; severe/profound ID-F72-73; other/unspecified ID-F78-79). Clinical Classification Software Refined (H-CUP, AHRQ) was used to categorize ICD-10 'reason for visit' diagnosis codes into meaningful groups. We present logistic models with incidence rate ratios and robust standard errors adjusting for covariates to examine differences in reasons for visit by group (not all data presented due to space).

Results: Selected sociodemographic characteristics are presented in Table 1. The top reasons for ED visit accounting for 43% of all visits included: epilepsy, suicide/self-inflicted injury, specific co-occurring mental health conditions (e.g., anxiety, ADHD), lower respiratory disease, restlessness and agitation, gastrointestinal dysfunction (e.g., abdominal pain, nausea/vomiting), injuries/wounds, lower respiratory disorders, and connective tissue disorders. Reasons differed by co-occurring ID (Figure 1). Among other findings, results indicate that those with autism+severe/profound ID were significantly more likely to visit the ED for epilepsy than those with autism+no ID (IRR=1.61, SE=0.17). Individuals with autism+mild ID had significantly higher incidence of suicide/self-inflicted injury visits (IRR=2.23, SE=0.2) compared to those with autism+no ID. The incidence of suicide/self-inflicted injury visits was significantly higher among adults aged 18-30y (compared to 60y+), IRR=7.38 (SE=1.94).

Conclusions: Consistent with calls to differentiate practice recommendations to assure individuals across the spectrum receive appropriate and needed care, we found differing reasons for ED visit for people by type of co-occurring ID and age. Our findings support a more nuanced approach to better understanding care gaps and healthcare needs across the lifecourse and within the autism spectrum. Additional county social determinants of health associated with greater risk for ED visit for various reasons will be presented (e.g., county provider supply, internet access, education, etc.).

318.003 Evaluation of Equity in Hospice Care Utilization Among Medicare-Enrolled Autistic Older Adults

L. Bishop¹, M. Nikahd², B. J. Wolf³, B. W. Patterson⁴, A. Longo⁵, D. Radford², E. Krantz², J. M. Hyer² and B. N. Hand², (1)University of Wisconsin - Madison, Madison, WI, (2)The Ohio State University, Columbus, OH, (3)Medical University of South Carolina, Charleston, SC, (4)University of Wisconsin-Madison, Madison, WI, (5)General Internal Medicine, The Ohio State University, Columbus, OH

Background: Better identification of autistic people and increased life expectancy for people with intellectual and developmental disabilities have given rise to an urgent need to better understand end-of-life care in autistic people. Although research suggests significant and pervasive disparities in the prevalence of co-occurring physical and mental health conditions in adulthood among autistic people, a more limited body of research assesses disparities in healthcare access and utilization among autistic adults, particularly at the end of life.

Objectives: Our primary objective was to compare hospice care utilization of autistic older adults to that of non-autistic older adults. The secondary objective was to determine if race, sex assigned at birth, region, and rurality altered rates of utilization in autistic older adults compared to non-autistic older adults.

Methods: We analyzed hospice claims from Medicare, which insures Americans over 65 years and covers hospice costs. We used data on a 100% sample of Medicare beneficiaries from Medicare's Standard Analytical Files (SAF) Limited Dataset. Our sample included 5,468 autistic older adults and 10,934 matched population comparison older adults who died during 2013-2021. We used variable ratio propensity score matching to match two population comparison beneficiaries to one autistic older adult; beneficiaries were matched exactly on sex, race, region, and rurality, while age and year of death were matched with a caliper of 0.2. We used multivariable logistic regression to compare these groups on the odds of any, early, intermediate, and late hospice utilization. We defined early hospice utilization as at least 28 days before death, intermediate as 4-27 days before death, and late as within 3 days of death. Interaction terms assessed whether effects were modified by beneficiary's sex, race, or rurality. In a sensitivity analysis, we repeated our analyses in unmatched samples.

Results: Overall, our autistic older adult and matched population comparison groups had similar odds of any hospice utilization (OR: 1.05; 95% CI: 0.98-1.13). Our autistic older adult and population comparison groups had similar odds of utilizing early hospice (OR: 1.01; 95% CI: 0.91-1.11), intermediate hospice (OR: 1.03; 95% CI: 0.95-1.13), and late hospice (OR: 1.07; 95% CI: 0.96-1.19). In our multivariable models evaluating the impact of other known inequities (Table 2), we did not find significant interactions between autism diagnostic status and sex, race, or rurality. Results were similar in the unmatched samples.

Conclusions: We found that autistic older adults and older adults in our population comparison group had similar odds of hospice utilization and experienced similar timing of hospice utilization. Further, we found that hospice utilization differences between autistic and population comparison beneficiaries were not moderated by sex, race, or rurality, though known disparities related to sex, race, and rurality were present in both groups. Given the body of literature documenting health disparities in autistic people, our findings are heartening, suggesting autistic older adults experience similar receipt and timing of hospice as non-autistic peers. Our findings highlight the potential power of health policies that provide zero cost, universal benefits in reducing healthcare utilization disparities among autistic people.

318.004 Falls and Injuries in Autistic Older Adults: A Critical Public Health Issue

L. Bishop¹, M. Blake², M. Nikahd², J. M. Hyer², B. Wolf³, B. W. Patterson⁴ and B. N. Hand², (1)University of Wisconsin - Madison, Madison, WI, (2)The Ohio State University, Columbus, OH, (3)Medical University of South Carolina, Charleston, SC, (4)University of Wisconsin-Madison, Madison, WI, (5)General Internal Medicine, The Ohio State University, Columbus, OH

Background: Falls-related injuries are a major public health issue for older adults. Falls significantly contribute to mortality and morbidity, leading to decreased functional ability, loss of independence, and increased healthcare costs. Autistic older adults may be at greater risk for falls compared to non-autistic older adults due to increased rates of motor coordination difficulties including ataxia, antipsychotic medication use, and epilepsy, all known correlates of falls in the general population. Yet, no research conducted to date characterizes fall prevalence among autistic older adults. Better understanding fall prevalence among autistic older adults is the necessary first step towards developing fall prevention strategies that have the potential to decrease morbidity and mortality.

Objectives: The goals of this study were to compare: (1) the odds of experiencing a fall; and (2) the rate of falls-related injuries between autistic and non-autistic older adults.

Methods: We analyzed data from Medicare Standard Analytical Files from 2013-2021 for autistic and non-autistic older adults aged 65+. We selected age 65 as the cutoff because of Medicare eligibility criteria for older adults. The sample included 10,677 autistic older adults and 21,351 non-autistic older adults who were propensity score matched on sex, race, region, rurality, and Medicare enrollment year. We identified falls based on a well-defined set of ICD-9 and ICD-10 diagnostic codes in inpatient or outpatient encounters. We then employed an established algorithm to identify unique falls-related injuries based on clusterings of ICD-9 and ICD-10 diagnostic and procedure codes. Descriptive statistics summarized the characteristics of the beneficiaries and prevalence of falls. Multivariable logistic regression was used to compare the odds of falling between autistic and non-autistic older adults, controlling for the beneficiary's sex, race, rurality, age, year, region, and Charlson Comorbidity Index score. Finally, we used negative binomial regression to compare the rate of falls-related injuries between autistic and non-autistic older adults.

Results: Overall 47.7% (N=5098) of autistic older adults compared to 21.5% (N=4581) of non-autistic older adults had at least one fall. In total, 40.6% (N=4339) of autistic older adults compared to 18.1% (N=3866) of non-autistic older adults had at least one falls-related injury, while 33.8% (N=3605) of autistic older adults and 13.8% (N=2956) of non-autistic older adults had two or more falls-related injuries. Compared to non-autistic older adults, autistic older adults had 3.55 times higher odds of falling (95% CI: 3.36, 3.74, $p<0.0001$). Finally, the incidence rate of falls-related injuries per year was 3.07 times higher (95% CI: 2.91, 3.25, $p<0.0001$) for autistic older adults compared to non-autistic older adults.

Conclusions: We found that autistic older adults had significantly higher odds of falling and had a higher rate of falls-related injuries compared to non-autistic older adults, with nearly half of autistic older adults having at least one fall. These findings underscore the urgent need for targeted fall prevention strategies developed for autistic older adults. Implementing tailored fall prevention strategies has the potential to reduce morbidity and mortality among autistic older adults.

319.001 Genetic and Environmental Influences on the Recognition of Mental States and the Fusiform Gyrus

N. R. Raman¹, **L. C. Lazzeroni**², **J. M. Phillips**¹, **J. F. Hallmayer**¹, **A. Y. Hardan**¹ and **J. P. Hegarty**³, (1)*Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*, (2)*Biomedical Data Science, Stanford University, Stanford, CA*, (3)*Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Palo Alto, CA*

Background:

Our research suggests genetic and environmental factors influence neurological structures and their relationships with cognition and behavior in autistic twins compared to non-autistic control twins. However, we do not know how these factors affect the relationship between mental state recognition and the fusiform gyrus, the primary brain region that processes facial expressions supporting social cognition.

Objectives:

The primary objective of this investigation is to examine the impact of genetic and environmental factors on mental state recognition, morphometric properties of the fusiform gyrus, and their relationship in autistic compared to control twins.

Methods:

Same-sex monozygotic (MZ) and dizygotic (DZ) twin pairs where at least one twin was diagnosed with autism, or both were non-autistic controls (aged 6-15 years) were recruited to participate, and we obtained T1-weighted MRI scans. MRI images ($n=164$) were processed with FreeSurfer to examine brain volume. The Eyes Mental State Task assessed the ability to recognize mental states. Groups were compared using independent samples t tests. The relationships between the fusiform gyrus and Eyes Task were evaluated with Pearson's correlations. Intra-class correlations (ICC) were also computed within twin pairs and ACE modeling for broad sense heritability (a^2 =additive genetics) and environmental influences (c^2 =shared family environment, e^2 =unique environment), providing estimates for the proportion of variation associated with genetic versus environmental factors. ACE, AE, or CE models were generated based on which were the most parsimonious and appropriate.

Results:

108 twins were diagnosed with autism (88 autistic; 18 non-autistic co-twins of autistic twins; 2 with subthreshold symptoms). 70 were controls. Autistic twins (mean=16.55 $\pm$ 5.13) exhibited lower emotion recognition ($t(110)=-2.69$, $p=0.008$) compared to control twins (mean=18.82 $\pm$ 3.77). However, neither the right ($t(110)=0.32$, $p=0.748$) or left ($t(110)=0.35$, $p=0.727$) fusiform differed between autistic (mean=11641.26 $\pm$ 1471.28; mean=11787.81 $\pm$ 1425.42) and non-autistic groups (mean=11557.69 $\pm$ 1268.41; mean=11690.54 $\pm$ 1469.82), respectively. The right fusiform gyrus ($r=-0.21$, $p=0.030$) correlated with the Eyes Task across all participants but the left fusiform gyrus ($r=-0.12$, $p=0.226$) did not. Within the autistic twins, scores on the Eyes task correlated with both the right ($r=-0.36$, $p=0.013$) and left ($r=-0.34$, $p=0.021$) fusiform. However, the fusiform gyri were not correlated with scores on the Eyes Task in controls, $p>0.05$. ACE modeling revealed performance on the Eyes Task was primarily genetically mediated in both autistic ($a^2=0.62$, $e^2=0.38$) and control twins ($a^2=0.63$, $e^2=0.37$). The size of the fusiform gyrus was associated with almost equal impacts from genetic and environmental influences on both the right ($a^2=0.51$, $e^2=0.49$) and left ($a^2=0.59$, $e^2=0.41$) fusiform in non-autistic controls. Autistic twins exhibited potential genetic dominance on the size of the fusiform gyrus, but limitations in the current modeling approaches require further investigation to generate appropriate estimates.

Conclusions:

Our findings support the existing literature that individuals with autism experience challenges recognizing mental states from facial expressions, with the fusiform aiding this interpretation. More importantly, we show genetic variation affects mental state recognition similarly in autistic and non-autistic youth, although genetic factors could have a higher impact on the fusiform specifically in autistic youth. These findings warrant further investigation to determine the impact of genetic and environmental factors on these brain-behavior relationships.

319.002 Polygenic Architecture of Co-Occurring Neuropsychiatric Diagnoses in Autistic Children

T. R. Thomas¹ and **E. B. Robinson²**, (1)Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, (2)Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA

Background:

The autistic community has higher prevalences of neuropsychiatric diagnoses compared to non-autistic samples. A key question is whether these co-occurring neuropsychiatric diagnoses stem primarily from the core presentation of autism itself or from an over-representation of common neuropsychiatric genetic risk. If the latter explanation holds, we expect autistic individuals with co-occurring diagnoses to carry additional, diagnosis-specific genetic risk.

Objectives:

The objective was to describe how polygenic variation explained differences in 20 co-occurring neuropsychiatric diagnoses in a large sample of autistic children.

Methods:

We investigated the common genetic architecture of 20 neuropsychiatric diagnoses in a sample of $N=13,359$ unrelated autistic children ages 6 to 17 in the Simons Foundation Powering Autism Research for Knowledge (SPARK) cohort. Genetic methods included SNP-based heritabilities (h^2), polygenic score (PGS) associations, and polygenic transmission disequilibrium tests for over-transmission of PGS from parents to child in a subset of the sample that also had parental genotypes ($N=4,818$ complete trios).

Results:

90% of the autistic children in our sample had at least one co-occurring neuropsychiatric diagnosis, with the average number of diagnoses being four. Increasing number of co-occurring diagnoses was positively associated with PGS for ADHD, anxiety, depression, schizophrenia, and neuroticism and negatively associated with PGS for cognitive performance, educational attainment, and openness.

Overall, co-occurring learning and developmental disabilities had lower SNP heritabilities ($h^2_{\text{liability}} < 0.07$) and were not significantly over-transmitted PGS from their parents. Anxiety and obsessive-compulsive disorders also had lower SNP heritabilities ($h^2_{\text{liability}} < 0.03$). In contrast, externalizing conditions and mood disorders had higher SNP heritabilities (ADHD $h^2_{\text{liability}} = 0.17$, oppositional defiant disorder $h^2_{\text{liability}} = 0.33$, major depressive disorder $h^2_{\text{liability}} = 0.13$, disruptive mood dysregulation disorder $h^2_{\text{liability}} = 0.21$). The most frequent co-occurring diagnosis was ADHD (54%), which was associated with higher PGS for ADHD, anxiety, and depression. Autistic children with ADHD were significantly over-transmitted ADHD PGS from their parents (compared to autistic children without ADHD). The second most frequent co-occurring diagnosis was language disorder (45%), which had no SNP heritability ($h^2_{\text{liability}} = 0$). Autistic children with language disorder were not significantly over-transmitted any of the 15 PGS investigated.

Conclusions:

Our results provide evidence that common genetic variation explains a significant proportion of liability for autistic children to have co-occurring externalizing and mood disorders, including ADHD, oppositional defiant disorder, major depressive disorder, and disruptive mood dysregulation disorder. The lack of SNP heritability in learning and developmental disabilities and anxiety and obsessive-compulsive disorders indicates that common genetic variants likely play a lesser role in the manifestation of these co-occurring diagnoses *in autism* and that alternative explanations for their co-occurrence should be investigated (i.e., rare genetic variants and co-occurring diagnostic unreliability *in autism*).

319.003 Integrating Clinical and Transcriptomic Data Via Similarity Network Fusion to Identify Subtypes of Autism Spectrum Disorder in Toddlers

J. Zahiri¹, K. Pierce², E. Courchesne³, N. E. Lewis⁴, C. Andreason⁵, S. Arias⁶ and C. Carter⁶, (1)Autism Center of Excellence, UCSD, San Diego, CA, (2)Autism Center of Excellence, Department of Neurosciences, University of California San Diego, San Diego, CA, (3)Neuroscience, Eric Courchesne, San Diego, CA, (4)Pediatrics and Bioengineering, University of California San Diego, La Jolla, CA, (5)Neurosciences, Autism Center of Excellence, UCSD, La Jolla, CA, (6)UCSD Autism Center of Excellence, La Jolla, CA

Background:

Autism spectrum disorder (ASD) encompasses a wide range of symptoms, from mild social difficulties to profound impairments in cognition, language, and social abilities. Profound autism, characterized by severe symptoms, presents the highest risk for poor outcomes. While studies suggest that dysregulation of processes like embryonic neurogenesis and cell proliferation play roles, the molecular biology driving subtype-specific differences, particularly in profound autism, remains unclear. This study integrates clinical data—such as diagnostic, cognitive, and language scores—with transcriptomics to explore the biology underlying different ASD subtypes.

Objectives:

- **Identify ASD Subtypes:** Integrate clinical and molecular data using similarity network fusion (SNF) to uncover distinct clusters.
- **Characterize Subtype-Specific Molecular Dysregulation:** Analyze MSigDB Hallmark pathways and gene expression.
- **Compare Subtype-Common and Specific Pathways:** Identify both shared and unique molecular mechanisms behind mild, moderate, and profound autism.

Methods:

We used SNF to classify toddlers with ASD into clinically meaningful subtypes. We applied SNF on clinical and transcriptomic data from 363 male toddlers aged 1-4 years. Blood samples were collected, RNA extracted, and RNA sequencing performed to analyze the transcriptome. Data preprocessing involved quality control, alignment, and expression quantification. Twelve patient similarity networks (PSNs) were created using eight clinical and four transcriptomic measures. PSNs were fused using SNF to identify ASD subtypes, with spectral clustering applied for optimal subtype determination. Clustering robustness and significance were validated through statistical tests, linking subtypes to ASD symptom severity, eye-tracking measures, and differential gene expression analysis. The study also investigated mutations in ASD risk genes and examined brain activation using fMRI in a subset of subjects. Outcomes were tracked longitudinally, and clinical measure progression was modeled using linear mixed models.

Results:

SNF analysis identified four clinical-gene expression clusters with distinct profiles, including a profound autism cluster (Cluster 4) with severe symptoms and 100% diagnostic stability over time. Robust statistical validation confirmed the reliability of these clusters. Clinical scores showed significant differences between clusters, particularly for social, language, and cognitive abilities, with profound autism exhibiting the lowest scores. Pathway analysis revealed dysregulation in 17 Hallmark pathways for ASD, with seven being subtype-specific to profound autism. Notably, SFARI gene mutations did not differ significantly between ASD and non-ASD groups, while fMRI data indicated reduced temporal lobe activation in severe clusters. Profound autism trajectories indicated worsening outcomes, particularly in social and adaptive behavior, compared to moderate ASD subtypes.

Conclusions:

We identified subtype-specific dysregulated Hallmark pathways vital for embryonic brain development, providing insights into the biological basis of profound autism. Dysregulation in pathways and processes like glycolysis, oxidative phosphorylation, Wnt/ β -catenin signaling, and DNA repair mechanisms play crucial roles in cellular proliferation and neuronal growth. Interestingly, mutations in SFARI Level 1 and 2 ASD risk genes did not correlate with symptom severity or dysregulations, indicating that genetic risk alone cannot explain ASD heterogeneity. This work highlights the need for a multi-modal approach integrating transcriptomics, molecular, brain imaging, and clinical data to better understand ASD subtypes and develop targeted interventions. Future ASD treatment strategies should address the specific needs of each subtype to optimize outcomes.

**319.004 Calibrating Behavioral and Cognitive Instruments for Genetic Validity**

M. Elsadany, T. Sanderson, C. Strathearn and J. J. Michaelson, Psychiatry, University of Iowa, Iowa City, IA

Background: Psychologists are familiar with the need to demonstrate multiple forms of validity in behavioral and cognitive instruments, for instance face validity (i.e., superficial thematic relevance) and construct validity (i.e., items adequately capture the theoretical construct they are meant to characterize), among others. As genetic data continues to become more available in neurocognitive research, it is vital to recognize the need for “genetic validity” as a new addition to the psychometrist’s toolbox. Here, we define “genetic validity” as the degree to which weighted combinations of instrument items correlate with polygenic scores (PGS) relevant to the purpose of the instrument.

Objectives: N/A

Methods: To demonstrate the potential of genetic validity as a performance target, we present a general framework of regularized regression of tests (e.g., survey items or cognitive subtests) to predict a polygenic score calculated for each participant. We applied this framework in two experiments involving the ABCD study (N=9752) as a training set, and a local neuroimaging sample of gifted and twice-exceptional individuals (N=39) as a test set to gauge the real-world utility of genetic validity. First, we used Child Behavior Checklist (CBCL) items as predictors of the polygenic score for autism. Second, we used NIH Toolbox subtest scores as predictors of the polygenic score for cognitive performance. These experiments resulted in weights (betas), that, when applied to the results of the CBCL or NIH Toolbox cognitive battery, yield quantitative estimates of genetic propensity for autism and cognitive performance, respectively.

Results: In our test set sample, both the autism propensity score (APS) and cognitive performance propensity score (CPS) were positively and significantly correlated with diagnosis and full-scale IQ (FSIQ), respectively (p-values: 1.9×10^{-4} and 1.8×10^{-7}). When compared to neuroimaging features, the APS showed a significant positive correlation with fractional anisotropy (FA) in the corpus callosum (p-value: 0.0085) and a negative correlation with the mean diffusivity (MD) in the inferior longitudinal fasciculus in both left and right hemispheres (p-values: 0.002 and 0.004, respectively). Additionally, a principal components analysis (PCA) on both APS and CPS and found a strong correlation between PC1 and both FA and MD of the same tracts. This suggests that the link between APS and diffusion metrics might also involve cognitive functions and how they are represented in ASD.

Conclusions: Together, these findings suggest that genetic validity can be a powerful indicator of construct validity, i.e., that an instrument captures individual variation that is meaningful on a fundamental, biological level. Ongoing work is investigating the relationship between the APS and CPS with neuroimaging features.

320.001 Health Inequities among Autistic Transgender Individuals

L. Shea¹, S. Valtire², H. R. Steinberg³, K. Chvasta⁴, W. L. Lee⁵, K. Ardeleanu⁶, C. B. Klein⁷, J. Ventimiglia⁸ and T. W. Benevides⁹, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)AJ Drexel Autism Institute, Philadelphia, PA, (4)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (5)TEACCH Autism Program; Psychology & Neuroscience, TEACCH Autism Program, UNC Chapel Hill, Chapel Hill, NC, (6)Institute of Public and Preventive Health, Augusta University, Augusta, GA

Background: Examining population-level outcomes among autistic transgender individuals can inform understanding of their service needs. Previous research has used health data to identify and describe outcomes among transgender populations (Proctor et al., Jasuja et al), relative to cisgender individuals (gender identity corresponding with sex assigned at birth). Identifying transgender individuals can support priorities to address identified needs.

Objectives: Identify chronic conditions and service needs of transgender autistic adults to advance the understanding of their healthcare needs.

Results: More than 2,100 transgender autistic individuals (16.6% with co-occurring ID), 680 transgender individuals with ID, and 593 transgender individuals without autism or ID were identified. Comparison cisgender groups of 432,584 autistic individuals (52% with co-occurring ID), 825,552 individuals with ID, and 536,902 individuals without autism or ID were identified. Across groups, most individuals were ages 18-29, including 77.4% of transgender autistic individuals (with or without ID). Among autistic transgender individuals, 9.3% were Black, 9.4% were other race/ethnicity, and 71.6% were white.

Among transgender individuals, 20% of autism only, 19.2% of autism + ID, 17.8% of ID only, and 14.7% of no autism or ID had 4-5 chronic conditions compared to cisgender groups (8.1% of autism only, 11.1% of autism + ID, 14.2% of ID only, and 8.7% of no autism or ID). Among transgender individuals with autism or ID, more than half had depression, bipolar, or other depressive mood disorder or anxiety disorder (averages: 61.6% and 56.9% respectively).

Conclusions: This study identified autistic transgender individuals chronic conditions and other service needs. In particular, depressive/mood and anxiety disorders and service access were priorities. Improved data collection to understand their service and support needs is urgently needed.

320.003 Facilitators to Mental Healthcare for Autistic LGBTQ+ Young Adults: Insights from a Community-Partnered Phenomenological Study

L. Baczewski¹, D. Gohari², R. Caplan³, B. R. Nachman⁴, M. McDonald⁵, K. Rodriguez⁶, R. Taylor⁷, K. E. Sharp⁸ and M. L. Massolo⁹, (1)Center for Autism, Children's National Hospital, Washington D.C., DC, (2)Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)Autistic LGBTQ+ Advisory Group, Los Angeles, CA, (4)University of Pittsburgh, Pittsburgh, PA, (5)Center for Autism Spectrum Disorders, Children's National Hospital, College Park, MD, (6)Division of Research, Kaiser Permanente Division of Research, Oakland, CA

Background: Autistic young adults are at an increased risk for mental health challenges compared to their non-autistic age-mates (Crane et al., 2019). Autistic LGBTQ+ people are at a compounded risk for mental health problems due to multiple minority stressors (e.g., discrimination; Botha & Frost, 2020). Compared to autistic cisgender heterosexual adults, autistic LGBTQ+ people are twice as likely to have a psychiatric diagnosis and are more likely to report being denied care by a medical provider (Hall et al., 2020). Despite these evident risks, few studies have examined the first-hand experiences of autistic LGBTQ+ in the mental healthcare context, and what factors facilitate their access to care.

Objectives: This study is part of a larger investigation of the first-hand experiences of autistic LGBTQ+ young adults (18-28 years old) with regard to their mental health and interactions with the U.S. mental healthcare system. Here, we present themes related to facilitators to mental healthcare for autistic LGBTQ+ young adults.

Methods: This study utilized a community-partnered, phenomenological approach. Each aspect of the study was conducted in collaboration with five autistic LGBTQ+ adults who became the Autistic LGBTQ+ Advisory Group. Twenty autistic LGBTQ+ participants ($M_{Age} = 23.3$ years) completed oral or text-based interviews about their mental health and mental healthcare experiences. Interviews were coded inductively by two members of the study team who achieved substantial interrater reliability (Cohen's Kappa = .69). Thematic analysis (Braun & Clarke, 2006) of the interviews generated themes related to barriers and facilitators to mental healthcare for autistic LGBTQ+ young adults. Here we present themes related to facilitators to care.

Results: Almost half of interviewees (9/20) identified as gender fluid, nonbinary, or gender expansive, and more than half reported having anxiety, depression and/or ADHD. The majority of participants faced identity-specific barriers to mental healthcare, which are described in a forthcoming paper from our group. Some participants successfully accessed care (e.g., therapy) and were satisfied with the supports they received. In the face of numerous barriers to adequate care, participants described finding alternative coping and self-care practices that were promotive of their mental health. Facilitators to accessing the traditional mental healthcare system included the following themes: 1) finding 'safe' providers who are equipped to support diverse autistic people and 2) connecting to care through a system I am a part of. Facilitators of improved mental health outside of traditional care included: 1) individual practices (e.g., using special interests to self-regulate) and 2) community-based care (i.e., connecting with other autistic LGBTQ+ people and using those connections to find vetted providers).

Conclusions: We identified several factors that increase access to mental healthcare for autistic LGBTQ+ young adults, from their own perspectives. Accessing care was easier for those who were already embedded in a healthcare system with wrap-around care (e.g., university health center). Community care and individual coping practices were critical to participants' mental health. Mental health providers working with this population may benefit from including these individualized practices into their care plan (e.g., using special interests as tools for emotion regulation).

320.004 Psychiatric Emergency Visits of Autistic Adults with or without a Coexisting Borderline Personality Disorder Label in Their Health Record

C. H. J. Lee^{1,2}, L. Man³, A. Morra², C. Castelino³, V. Courchesne⁴, J. Zaheer⁵, S. H. Ameis⁶, H. Y. Lin², Y. Lunskey⁷ and M. C. Lai⁸, (1)Ministry of Health and Welfare Tsao-Tun Psychiatric Center, Tsao-Tun, Nan-Tou County, Taiwan, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Centre for Addiction and Mental Health (CAMH), Toronto, ON, Canada, (4)University of Montreal, Montréal, QC, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, Canada, (6)Child and Youth Mental Health, The Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (8)Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada

Background:

Autistic individuals who have been given a borderline personality disorder (BPD) diagnosis often present with complex mental health needs, leading to frequent use of psychiatric emergency department (ED) services. Sex-assigned-at-birth may also affect whether a BPD label is given to an autistic individual. Limited research has explored psychiatric ED presentations in autistic people with versus without a BPD label. This large-scale chart-review study at an urban tertiary psychiatric ED aims to address this significant knowledge gap.

Objectives:

(1) To compare the primary reasons for ED visits between autistic individuals (aged ≥ 16 years) with and without a BPD diagnosis noted in their ED visit records. (2) To examine whether sex-assigned-at-birth, BPD diagnosis, and whether autism is noted in the ED visit documentation influence restraint use and disposition plans.

Methods:

Data were extracted from electronic medical records (EMR) for ED visits for autistic patients at an urban tertiary psychiatric hospital in Toronto, Canada, from January 1, 2018, to December 31, 2020. Autism was identified based on a formally recorded DSM-5 Autism Spectrum Disorder diagnosis in the EMR, either before, at or after the ED visit. Demographic data were compared between individuals with and without a BPD diagnosis recorded during the ED visit. The primary reasons for ED visits, restraint use (chemical and/or mechanical), and disposition outcomes (discharge or admission) were compared using chi-square tests across all visits, and mixed-effect logistic regression models across unique autistic individuals. The impact of BPD diagnosis alongside autism diagnosis mentions in the chart (implying that the BPD and/or autism diagnosis was known to the clinician at the visit) and sex-assigned-at-birth were specifically assessed for associations with restraint use and disposition outcomes.

Results:

In 2018-2020, 345 unique autistic individuals (aged 16-63 years) made 1027 ED visits. Of all visits, when autism was recorded in chart, 33.5% had BPD recorded as well. When autism was not noted in the ED record, BPD appeared more frequently (12.7%, p -value < 0.001). Autistic individuals assigned-female-at-birth (AFAB; 20.6%) and those with intellectual disabilities (16.8%) were more likely to have a BPD label noted (Figure 1). Visits of autistic individuals with BPD noted were more likely to be primarily due to suicidality (24.3%) and less likely due to homicide/aggression (4.9%), self-harm (4.7%), anxiety (1.5%), substance withdrawal (0.4%), or medication adjustment (1.8%) (Table 1). Analyzing unique autistic individuals, BPD was only significantly associated with suicidality as the reason for ED visits (odds ratio, OR 4.366, 95% confidence interval, CI [2.659, 7.169], $p < 0.001$). Neither sex-assigned-at-birth, BPD, nor autism mention during the visits significantly correlated with discharge or admission plans. Amongst autistic individuals with BPD noted, those who were assigned-male-at-birth (AMAB) were less likely to be restrained than AFAB individuals (OR 0.350, 95% CI [0.139, 0.881], $p = 0.026$).

Conclusions:

Autistic adults with autism mentioned in their ED charts had a lower rate being concurrently labeled BPD during those visits. BPD labels were most associated with suicidality as the primary reason for ED visits. Further investigations should understand how care is provided to autistic individuals in ED settings.

**Oral Session -****321 - Therapeutic Biomarkers in Autism**

321.001 Epl/ASD013 As a Dual-Target Therapeutic for Autism Spectrum Disorders: Modulating Glutamate Excitotoxicity and Neurobehavioral Symptoms

A. Raja¹, H. Singh², H. Kaur³, S. Charan⁴, P. k Prabha⁵, A. Jain³, D. A. Prakash³ and B. Medhi³, (1)Pharmacogy, University of Pittsburgh, Chandigarh, (2)Post Graduation Institute of Medical Education and Research, Chandigarh, India, (3)Post Graduation Institute of Medical Education and Research, Chandigarh, Chandigarh, India, (4)Post Graduate institute of Medical Education & Research (PGIMER) Chandigarh, Chandigarh, Chandigarh, India, (5)Pharmacology, Post Graduate institute of Medical Education & Research (PGIMER) Chandigarh, Chandigarh, India

Background:

Current treatment strategies for Autism Spectrum Disorders (ASD) predominantly focus on managing co-morbid symptoms through pharmacotherapies. However, there is a lack of pharmacological interventions targeting core symptoms of ASD. Growing recognition of novel therapeutic targets, particularly those modulating neurobiological pathways linked to ASD, has led to the exploration of dual-active molecules.

Objectives:

In this study, we evaluate the potential of EPL/ASD013, a dual-target molecule screened based upon pharmacophore modelling to inhibit both Histone Deacetylase 2 (HDAC2) and Histamine H3 Receptor (H3R) from our previous study. This dual inhibition aims to address two crucial facets of ASD pathology: glutamate excitotoxicity and behavioral disturbances, including anxiety, sleep disorders, and cognitive impairments.

Methods:

In-vitro studies using primary astrocytic cultures evaluated EPL/ASD013's impact on gene and protein expression, as well as glutamate clearance. In-vivo efficacy was tested using a Valproic Acid (VPA)-induced rodent model of ASD, with significant improvements observed in anxiety, social interaction, curiosity, strength, coordination, and cognition through various behavioral tests. Morphological changes were assessed via hematoxylin and eosin staining, and expression levels of EAAT2, HDAC2, and H3R were analyzed using RT-PCR, immunohistochemistry, and western blotting. Intraperitoneal kinetic profiling and high-dose toxicity assessments confirmed the compound's safety.

Results:

Our in vitro studies revealed significant insights into EPL/ASD013's effects on astrocytic cells, particularly focusing on HDAC2, Excitatory Amino Acid Transporter 2 (EAAT2) gene expression, and glutamate regulation. Treatment with EPL/ASD013 resulted in dose-dependent upregulation of EAAT2 mRNA and protein expression, as well as downregulation of HDAC2. Notably, high-dose EPL/ASD013 treatment enhanced intracellular glutamate uptake, suggesting improved glutamate homeostasis. In vivo, using a well-established animal model of ASD induced by valproic acid (VPA), EPL/ASD013 demonstrated significant improvements in neurobehavioral outcomes. Behavioral assays such as the Open Field Test and Marble Burying Test indicated a reduction in anxiety and anxiety-related repetitive behaviors in high-dose treated groups. Furthermore, the Sociability Index and Novelty Preference Tests showed improvements in social interactions, while the Morris Water Maze test demonstrated enhanced spatial learning and memory retention. These findings suggest that EPL/ASD013 can reverse cognitive impairments commonly seen in ASD. At the molecular level, EPL/ASD013's dual-target mechanism of action was further validated by the observed dose-dependent upregulation of EAAT2 and the downregulation of HDAC2 and H3R. Pharmacokinetic analysis of EPL/ASD013 in both plasma and brain tissue highlighted its favorable profile, with a sustained half-life and significant drug exposure in the central nervous system.

The safety profile of EPL/ASD013 was confirmed through clinical panel blood tests and histopathological evaluations, which showed no signs of toxicity or adverse effects, even at the highest therapeutic dose of 30 mg/kg. This, coupled with its neuroprotective effects in the hippocampus and improvements in neurobehavioral symptoms, suggests that EPL/ASD013 could be a promising therapeutic candidate for ASD.

Conclusions:

In conclusion, EPL/ASD013 demonstrates potential as a dual-targeted therapeutic for ASD, addressing both glutamate excitotoxicity and behavioral symptoms. Further studies are warranted to investigate its long-term efficacy and safety in other ASD models, as well as its potential application in clinical settings.

321.002 Distinct Protein Expression in Umbilical Cord Blood of Individuals with Autism Spectrum Disorder

L. Kalich¹, B. E. Biri², C. Yoffe³, P. Baryakh⁴, M. Mayorov⁵, E. Glick Saar⁶ and O. Bar Yosef⁷, (1)Weinberg Child Development Center, Sheba Medical Center, Tel HaShomer, Israel, Ramat Gan, Israel, (2)Pediatric Neurology, Safra Children Hospital, Tel Hashomer, Ramat Gan, Israel, (3)Weinberg Child Development Center, Sheba Medical Center, Tel HaShomer, Ramat Gan, Israel, (4)National Cord Blood Center, Sheba Medical Center, Ramat Gan, Israel, (5)National Cord Blood Center, Sheba Medical Center, Tel HaShomer, Israel, Ramat Gan, Israel, (6)Cancer Research Center and Wohl Centre for Translational, Medicine, Sheba Medical Center, Tel HaShomer, Israel, Ramat Gan, Israel, (7)Weinberg Child Development Center, Pediatric Neurology, Safra Children Hospital, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel

Background:

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition with high heritability. Genetic factors are associated with the autistic phenotype in 30–40% of children diagnosed with ASD. Despite substantial advances in genetic research, the precise cause of ASD remains unclear, suggesting that environmental factors may also play a crucial role. Stressors such as ischemia, maternal immune activation (MIA), and toxins have been linked to the development of ASD, either through direct effects on the brain or by inducing mitochondrial dysfunction and endoplasmic reticulum (ER) stress. These processes, in turn, are associated with perturbations in neuronal differentiation, potentially disrupting synaptic protein function and impairing neural circuit formation.

Extracellular vesicles (EVs) are membrane-surrounded nanovesicles routinely excreted by cells, containing proteins, lipids, nucleic acids, and metabolites, and play a role in cell-to-cell communication. EVs mainly originate from the Golgi system, ER, or, to a lesser extent, direct exocytosis from cellular or mitochondrial membranes. The content of EVs extracted from plasma reflects physiological processes occurring in body tissues, including the brain. Thus, disrupted processes, in the brain, characteristic of ASD may be evident in their protein profiles.

Objectives:

The aim of this study was to investigate the protein composition in children with ASD at birth and compare it to that of neurotypical (NT) children. We hypothesized that the protein profile in idiopathic ASD would reveal differences associated with MIA, mitochondrial dysfunction, and ER stress.

Methods:

The study was conducted on 30 children with idiopathic ASD and 30 NT children. EVs were extracted from plasma collected from their cord blood, and mass spectrometry-based proteomic analysis was used to identify the protein content. Only proteins found in more than 21 children in each group were included in the analysis. Statistical analysis was performed using Python statistical packages.

Results:

Mass spectrometry identified 2,924 proteins, with 565 proteins showing differential mean expression levels between the groups. A striking finding was the exceptionally lower variance in protein expression within the ASD group. STRING analysis classified the differing proteins into three major clusters: mitochondrial (aerobic respiration, ATP synthesis, and uncoupling proteins), ER stress, and neutrophil secretory proteins. Cytoscape analysis indicated that a substantial portion of the proteins (140/565) potentially originated from the brain. Based on the Human Protein Atlas, 13 proteins representing each cluster were predominantly expressed in the brain. Using machine learning algorithms, we identified 11 significant proteins capable of differentiating samples originating from ASD. These proteins, along with the most dominant brain proteins, are associated with mitochondrial and ER stress.

Conclusions:

The findings suggest that mitochondrial dysfunction and ER stress are present in children with ASD at birth, processes that are associated with abnormal brain development, specifically synaptogenesis and myelination. Post-mortem studies of children diagnosed with ASD have found similar pathophysiological patterns. The distinct protein profile of children diagnosed with ASD and the homogeneity within the group raise the hypothesis that mitochondrial dysfunction and ER stress represent a common and potentially necessary pathway leading to abnormal brain microstructure and an increased susceptibility to developing ASD.

321.003 Validation of Plasma microRNAs As Biomarkers for Early Diagnosis of Autism Spectrum Disorder

S. Salloum-Asfar, S. Ltaief, R. Taha, W. Nour-Eldine, S. Ali Abdulla and A. R. Al-Shammari, Neurological Disorders Research Center, Qatar Biomedical Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental disorder characterized by social communication challenges and repetitive behaviors. Early diagnosis is crucial for effective intervention and improved outcomes; however, there are currently no approved biomarkers for ASD diagnosis. MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression and have emerged as promising biomarkers for various neurological disorders, including ASD. In our previous discovery study, we identified dysregulated expression of several miRNAs in the plasma samples of children with ASD aged 5–12 years.

Objectives: In this study, we aimed to validate the altered expression of these plasma miRNAs in a younger cohort with ASD (ages 2–4 years) and explore their potential use as diagnostic biomarkers for early diagnosis of ASD.

Methods: A total of 108 young children aged 2–4 years were recruited, including children with ASD (n=66) and age- and sex-matched control subjects (n=42). Using next-generation sequencing and advanced bioinformatics, we validated the differential expression of 17 miRNAs in ASD that exhibited consistent dysregulation in our current and previous cohorts.

Results: We also observed significant correlations between several miRNAs and the age of the study participants, suggesting that age is a key factor influencing dynamic miRNA changes, particularly in the ASD group. Pathway analysis linked these miRNAs to critical regulatory networks involved in neurodevelopment and immune responses. Finally, we found that a combination of four miRNAs (miR-4433b-5p, miR-15a-5p, miR-335-5p, and miR-1180-3p) showed an area under the curve (ROC-AUC) of 0.936 (95% CI = 0.892, 0.980; $p < 0.001$), which demonstrated the diagnostic accuracy of the four-miRNA panel in ASD diagnosis.

Conclusions: This study findings reinforce the potential use of the four-miRNAs as robust biomarkers for ASD and lay the groundwork for future research into miRNA-based diagnostic tools and therapeutic strategies for ASD.

321.004 Linking Gut Microbiome to Cingulate Cortex Morphology and Clinical Symptoms in Autism Spectrum Disorder

J. C. Chang^{1,2}, H. T. Lin^{1,2} and S. S. F. Gau^{1,2}, (1)Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan

Background: Growing evidence suggests the influence of gut microbiota on autism spectrum disorder (ASD), yet the relationships between gut microbiome composition, brain structure, and clinical symptoms are not well-elucidated. The high prevalence of gastrointestinal issues in ASD individuals and documented differences in gut microbial composition compared to typically developing individuals suggest a potential gut-brain connection. Neuroimaging studies have identified structural alterations in the cingulate cortex of individuals with ASD, a region crucial for social-emotional processing and cognitive function. While previous studies have separately examined gut microbiota alterations and brain structural changes in ASD, no research has simultaneously investigated the associations among gut microbiome profiles, cingulate cortex morphology, and autistic symptoms.

Objectives: To elucidate the complex relationships among gut microbiome profiles, cingulate cortex morphology, and autistic symptoms in individuals with ASD.

Methods: We enrolled 231 participants, including 139 with ASD and 92 typically developing controls (TDC), aged 4-18 years. ASD The clinical diagnosis of ASD was made according to DSM-5 criteria, further confirmed by using the Autism Diagnostic Interview-Revised and Autism Diagnostic Observation Scale with parents and autistic participants, respectively. Full-length 16S rRNA gene sequencing was performed on fecal samples to characterize gut microbiota. Structural MRI assessed cortical thickness and surface area of cingulate subregions using FreeSurfer 7.2.0. Group differences in microbial diversity and abundance were analyzed using various indices, followed by correlation analyses between ASD-specific microbiota, cingulate cortex metrics, and symptom severity, controlling for age, sex, Full-scale IQ, body mass index, and food preference.

Results: Beta diversity analyses revealed distinct microbial community structures between ASD and TDC groups, while alpha diversity showed no significant differences. Linear discriminant analysis effect size identified an increased abundance of Enterococcaceae, Lachnospiraceae, and Coriobacteriaceae families in ASD. Notably, the abundance of family Enterococcaceae and genus Enterococcus was negatively correlated with cortical thickness in the left isthmus and posterior cingulate ($\rho = -0.19$, $p = 0.006$; $\rho = -0.17$, $p = 0.017$, respectively) while positively correlating with isthmus cingulate surface area (right: $\rho = 0.14$, $p = 0.049$; left: $\rho = 0.21$, $p = 0.003$). Higher Enterococcaceae abundance was associated with more severe autistic symptoms ($\rho = 0.098$, $p = 0.037$). Additionally, increased left isthmus cingulate surface area significantly correlated with greater symptom severity ($\rho = 0.25$, $p < 0.001$). Functional prediction analysis suggested alterations in pyrimidine metabolism pathways between groups.

Conclusions: This study provides novel evidence for gut-brain-behavior relationships in ASD, highlighting specific associations between Enterococcaceae abundance, cingulate cortex structure, and clinical symptoms. These findings suggest that the gut microbiota could impact brain development and the presentation of ASD through alterations in cingulate cortex morphology, particularly within the isthmus region. Our results support the potential role of the gut-brain axis in the pathophysiology of ASD and suggest new directions for biomarker development and therapeutic interventions targeting the gut microbiome. Future longitudinal studies are needed to establish causal relationships and further delineate the underlying mechanisms driving these associations.

322.001 Shaping Young Minds: How Autism Labels, Environment, and Developmental Factors Affect Preschoolers' Acceptance of Autistic Behaviors

X. Peng^{1,2}, **T. Li**³, **H. Zhao**⁴, **X. Su**⁵, **Y. Jiang**⁵, **Z. An**⁶, **T. Tang**⁶ and **L. Yi**^{7,8}, (1)Peking-Tsinghua Center for Life Sciences, Peking University, Beijing, China, (2)Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China, (3)Department of Psychology, School of Education Science, Qingdao University, Qingdao, Shandong, China, (4)Peking University Kindergarten, Beijing, China, (5)School of Psychological and Cognitive Sciences & Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (6)Yuanpei College, Peking University, Beijing, China, (7)School of Psychological and Cognitive Sciences & Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (8)PKU-IDG/McGovern Institute for Brain Research, Peking University, Beijing, China

Background:

In inclusive educational settings, it is crucial to understand how neurotypical (NT) children perceive and accept autistic behaviors. Previous studies have emphasized the importance of early exposure to autism in fostering acceptance and reducing stigma (Turnock et al., 2022). However, little is known about how NT preschoolers perceive autistic behaviors and how various environmental and developmental factors influence these perceptions.

Objectives:

This study aimed to investigate how NT preschoolers in inclusive classrooms evaluate autism-related behaviors and the individuals displaying them. We explored the role of autism labeling, along with environmental factors (e.g., socioeconomic status, parental attitudes, and knowledge about autism) and developmental factors (e.g., age, empathy, and theory of mind) in shaping these evaluations.

Methods:

Ninety-two NT children (age: 5.26 ± 0.30) from an inclusive kindergarten, where each class includes at least one autistic child, participated in a "flap hands task" (Sargent & Jaswal, 2022). They listened to six short stories featuring a character exhibiting autism-like behaviors, such as hand-flapping. The children were split into two groups: in one, the character was labeled as "autistic," while in the other no labels were given. Children then evaluated these behaviors regarding acceptability, punishment, willingness to befriend the character, and their likelihood of mimicking the behaviors.

Additionally, we measured children's empathy and theory of mind (ToM). We also assessed children's family socioeconomic status (SES), which included parents' education levels, family income, and subjective SES. We further explored parents' attitudes and knowledge about autism, as well as whether children had prior exposure to information about autism. Mann-Whitney U tests, generalized linear models (GLM), and natural language processing (NLP) techniques were employed to analyze the children's performance.

Results:

The findings revealed that when characters were labeled as autistic, children perceived their unconventional behaviors as more acceptable and less deserving of punishment, leading to a more positive attitude toward autistic peers (Figure 1). Notably, NLP analysis indicated a change in children's language: without the autism label, they described the characters' behaviors as "disturbing others," whereas with the label, they emphasized that the characters "had no choice." This shift was further supported by sentiment analysis, which showed a more favorable attitude toward autism-labeled characters. Additionally, our GLM analysis showed environmental factors, including parental attitudes toward inclusive education and children's exposure to autism information, positively predicted children's acceptance of autistic behaviors. In contrast, SES and parental knowledge of autism had no significant impact. Regarding developmental factors, children's ToM significantly predicted their acceptance of autistic behaviors, while age and empathy did not (Figure 2).

Conclusions:

Our findings underscore the importance of autism labeling and various environmental and developmental factors in shaping NT preschoolers' understanding and acceptance of autistic behaviors. These results have important implications for promoting inclusivity and reducing stigma in early childhood educational settings.

322.002 Shifting Views, Shaping Outcomes: Exploring the Relationship between Teacher Perceptions and Autistic Students' School Experiences

J. Y. Chou¹, E. G. Kilgallon¹, J. Blacher², N. Hamsho³ and A. Eisenhower¹, (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)School of Education, University of California, Riverside, CA, (3)School of Psychology and Counseling, Fairleigh Dickinson University, Teaneck, NJ

Background: The school context can be a challenging socioemotional setting for autistic children; they are often at risk for social exclusion, bullying, and internalizing symptoms (Lai et al., 2019; Wainscot et al., 2008). Autistic first-person accounts reflecting on early school experiences reported that teachers reinforced ableist stigma (Cohen et al., 2022; Mueller, 2021). As school environments frequently serve as a source of socialization but also stigma for autistic students (Aubé et al., 2021), teachers can be a crucial source of neuroaffirming views. Teachers' perceptions of students can also shape student-teacher relationship quality and students' emotional and behavioral adjustment (Murray & Zvoch, 2011). This study focuses on understanding how general education teachers perceive autistic students and how these perceptions shape students' school experiences.

Objectives:

- To investigate three dimensions of teacher perceptions (i.e., strengths/deficit-based, holistic/reductionist, and external/internal locus of control) of their autistic students through open-ended descriptions.
- To explore how these perceptions predict student-teacher relationship quality and student socioemotional well-being.
- To assess which dimensions of perceptions most strongly predict student-teacher relationship quality and student socioemotional well-being.

Methods: Participants included 47 K-2 general education teachers (92.9% female; 55.4% White; 80.4% with a graduate degree; 80.4% without professional autism training) with at least one autistic student in their classroom, all enrolled in an autism professional development (PD) program. To assess teachers' perceptions, we coded their written responses to the question: "...take a moment to think about your autistic student...add a few words or word phrases that describe your student..." Two independent raters coded the degree to which these responses reflected strengths/deficit-based perceptions, holistic/reductionist perceptions, and external/internal locus of control. Teachers rated student-teacher relationship quality using the Student Teacher Relationship Scale (STRS; Pianta, 2001) and students' socioemotional well-being using the Social, Academic, and Emotional Behavior Risk Screener (SAEBRS; Kilgus et al., 2014) and BASC-3 Behavioral and Emotional Screening System (BESS; Kamphaus & Reynolds, 2015).

Results: The plurality of teachers expressed perceptions that were deficit-based (44.7%) and expressed an internal locus of control (46.8%); however, most teachers (74.4%) expressed a holistic or partially holistic view of their student. Preliminary analyses revealed that all three dimensions of teacher perceptions predicted student-teacher conflict and externalizing problems ($p < .05$), but only strengths/deficit-based and holistic/reductionist perceptions predicted socioemotional behavior in the classroom ($p < .05$). None of the three dimensions of perceptions predicted student-teacher closeness or internalizing problems ($p > .05$). When all three dimensions of perceptions were considered together, teachers' external attributions of locus of control was the dimension that most strongly predicted lower student-teacher conflict ($B = -3.02$, $p = .071$), while strengths/deficit-based perceptions most strongly predicted more favorable levels of social behaviors ($B = 1.25$, $p < .001$), emotional behaviors ($B = 1.13$, $p = .004$), and externalizing problems ($B = -1.15$, $p = .028$).

Conclusions: Our analysis indicated that teachers generally held more deficit-based holistic perceptions, attributing an internal locus of control to autistic students. Teacher perceptions of autistic students may be a pivotal predictor of student-teacher relationships and students' socioemotional well-being. Adopting more autism-affirming teacher attitudes, including strengths-based, holistic perceptions that attribute an external locus of control, may foster enhanced relationships and well-being for autistic students.

322.003 What Do Autistic Parents Really Need? a Participatory Study Revealing Diverging Perspectives between Autistic Individuals and Professionals

A. Lacroix¹, G. Lio², D. Langlois³, M. Pignard⁴, M. Dubreucq^{5,6} and C. Demily^{2,7}, (1)Campbell Family Mental Health Research Institute, Toronto, ON, Canada, (2)CH Vinatier, GénoPsy | CNRS - UMR5229 - Center for Cognitive Neuroscience, Lyon, Rhone-Alpes, France, (3)Autisme France, Saint Etienne, Rhone-Alpes, France, (4)PAARI, Grenoble, Rhone-Alpes, France, (5)Centre référent de réhabilitation psychosociale REHALise, GCSMS REHACOOR 42, Saint Etienne, Rhone-Alpes, France, (6)Unité de recherche RESHAPE - INSERM 1290, École Doctorale EDISS, Université Lyon1, Lyon, Rhone-Alpes, France, (7)iMind Excellence center, Bron, Rhone-Alpes, France

Background:

While it is increasingly recognized that autistic individuals can be parents, there is still little research focused on parenthood in autism (McDonnell & DeLucia, 2021). Existing studies highlight the positive aspects of parenting for autistic individuals and their strong parenting skills (Pohl et al., 2020). However, challenges such as organizational difficulties, sensory overload, and communication barriers with healthcare professionals are also reported. Moreover, autistic parents often express fears regarding the involvement of child protective services (Donovan, 2020). Research shows that parents with developmental disabilities face a higher risk of having their children removed from their care (Theodore et al., 2018). We suggest that this may be partly due to professionals' lack of training, which can lead to a gap between how autistic individuals and professionals perceive autism and the needs of autistic parents, as well as reinforce prejudices. These can impair the support autistic parents receive, sometimes leading to negative outcomes for parents and their children.

Objectives:

This study aimed to investigate the differing perceptions that autistic individuals and professionals have regarding autistic parents and their needs. The ultimate goal is to inform professional training and guide policy development.

Methods:

This research objective and priority was identified by autistic parents through a participatory approach. A small research group was formed in 2020, including three autistic adults (two of whom were mothers, and one was a researcher) and two non-autistic researchers. Together, the team developed a clinical case describing an autistic mother in a hospital setting with her child, along with a questionnaire. These were distributed online in France. From May 2023 to May 2024, the study was completed by 122 individuals who had received an autism diagnosis and 988 professionals from various fields, including healthcare, psychology, paramedics, speech therapy, social work, education, and the legal system.

Results:

Both autistic parents and professionals agreed that the clinical case described atypical behavior in the mother, especially before knowing the diagnosis. However, professionals expressed greater concern than autistic individuals about the mother ($p < .001$) and were more likely to suggest child protective services involvement ($p < .001$). Notably, legal professionals were the most likely to indicate this. Regarding autistic parents' needs in general, while both autistic parents and professionals recognized the importance of workplace adaptations, household help, and administrative support, autistic parents were more likely to highlight these needs than professionals ($p < .001$). Conversely, professionals were more likely than autistic parents to emphasize the need for child protective services ($p < .001$).

Conclusions:

This participatory study confirms some of the fears expressed by autistic individuals and supports our hypotheses about discrepancies between their perspectives and those of professionals on autistic parenting and related needs. The findings underscore the need for enhanced autism training for professionals, particularly in the legal system. Additionally, the study reveals unmet needs voiced by autistic parents—needs that are sometimes recognized by professionals but remain unaddressed in France. Moving forward, we aim to present these findings at an institutional level to advocate for policy changes that will improve support for autistic parents.

322.004 Exploring Sex Differences in Caregiver Report of the Autism Diagnostic Journey Based on Results from the SPARK Events History Calendar Interview Questionnaire

G. Caprara¹, Z. Algaze², C. Klaiman³, L. Green Snyder⁴, J. A. Benson⁵, E. M. Butter⁶, P. Feliciano⁷, A. Gulsrud⁸, J. F. Harris⁹, R. P. Goin-Kochel¹⁰, A. S. Kolios¹¹, R. Landa¹², L. Shulman¹³, E. Wodka¹², J. Pandey¹ and S. Consortium¹, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (3)Emory University/Marcus Autism Center, Atlanta, GA, (4)Simons Foundation, New York, NY, (5)Marcus Autism Center, Emory University, Atlanta, GA, (6)Nationwide Children's Hospital/Ohio State University, Columbus, OH, (7)Department of Pediatrics, Boston Children's Hospital, Boston, MA, (8)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (9)Children's Specialized Hospital, Mountainside, NJ, (10)Baylor College of Medicine, Houston, TX, (11)Marcus Autism Center, Atlanta, GA, (12)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (13)546 Wilmerding Ave., Bronx, NY

Background: The autism diagnostic journey is described as one that presents significant challenges for families navigating medical systems, education planning, and intervention services. In the United States, diagnostic delays are prolonged by racial and sociodemographic factors (Lappé et al., 2016). Seeking to better understand how sex differences further impact the diagnostic journeys of autistic individuals within racial groups, this study examines responses to the Events History Calendar Interview (EHCI) Questionnaire utilizing a large online U.S. cohort, SPARK. The EHCI is an electronic adaptation of the Constantino et al. (2020) interview version, developed to allow for broader dissemination and collection of caregivers' perspectives at a national scale.

Objectives: To identify potential sex differences within the relationships between 1) age of caregiver's first concern, 2) age of diagnosis, and 3) initiation of ASD intervention services among 4 racial groups.

Methods: 871 participants with sex data from the EHCI Questionnaire were categorized into 4 racial groupings: White (n=583, 137 female), Black/African American (n=103, 19 female), Asian (n=36, 19 female), and Multiracial (n=149, 40 female) (see Table 1 for additional demographic data). Relationships between the ages of caregiver's first concern, diagnosis, and initiation of services were evaluated using bivariate correlations with a covariate of sex at birth within each group

Results: Bivariate correlations yielded significant differences in age of first concern, age of diagnosis, and initiation of services across racial groups and sex (See Table 2). Age of first concern was significantly correlated with age of diagnosis in Asian and White children, with no significant differences according to sex at birth. Asian females displayed a strong relationship between age of first concern and initiation of services ($r = 0.64$, $p < 0.001$), significantly higher than other racial groups, and higher than that seen in males. The same was true regarding initiation of services and age at diagnosis ($r = 0.34$, $p < 0.001$), although a weaker association. Overall, females across all racial groups expressed stronger positive correlations among all variables related to age of onset and services, as compared to their male counterparts.

Conclusions: This analysis highlights compelling disparities between different racial groups, and between males and females, in relationships between age of first concern and clinical attention. These results strongly support previous research findings of significant delays in parental concerns, diagnostic age, and intervention initiation for autistic females. Delayed identification and intervention results in overwhelming downstream implications related to functional outcome. Further analyses will look to examine additional data on diagnostic severity and cognitive ability with respect to implications for diagnostic and functional outcomes.

323.001 Neurobiological Underpinnings of Co-Occurring Mental Health Conditions in Autism

C. M. Pretzsch¹, **M. Arenella²**, **B. Oakley¹**, **T. Charman³**, **D. L. Floris⁴**, **D. Murphy⁵** and **C. Ecker⁶**, (1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (4)Department of Psychology, University of Zurich & ETH Zurich, Zurich, Switzerland, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (6)Department of Child and Adolescent Psychiatry, University Hospital, Goethe University, Frankfurt am Main, Germany

Background: Many autistic people (> 20-50%) experience co-occurring mental health conditions, including anxiety and depression. These conditions frequently persist across development, and their symptom severity can fluctuate over time. This can significantly affect psychological and physical wellbeing and reduce quality of life. Hence, a better understanding of the contributors to co-occurring conditions in autism may facilitate future mental health support for those who want or need it. Initial research has traced altered clinical profiles in autism to variation in neuroanatomy; but how anxiety and depression, as well as change in anxiety and depression across time, relate to neuroanatomy remains unclear. **Objectives:** Hence, we aimed to identify neuroanatomical patterns underpinning anxiety and depression, and change in anxiety and depression, in autistic and neurotypical individuals across age. We further aimed to examine how these patterns relate to variation in clinical and genomic profiles.

Methods: To examine this, we analysed cross-sectional and longitudinal behavioural (parent and self-reported clinical measures of anxiety and depression, Beck inventory) and neuroanatomical (structural magnetic resonance imaging) data from 639 individuals (360 autistic, 279 neurotypical, aged 6-31 years) collected at two time points (T1 and T2, separated by ~12-24 months). First, we identified spatial patterns in cortical thickness (CT) and surface area (SA) variation that best explained clinical profiles at T1, and change in profiles from T1 to T2, using partial least squares regression. Next, we tested how neuroanatomical profiles correlated with autism traits (measured using the Social Responsiveness Scale 2 [SRS-2], Repetitive Behaviors Scale [RBS], and Short Sensory Profile [SSP]); and genomic variation using the Allen Human Brain Atlas.

Results: We identified patterns in CT and SA that explained a significant amount of variance in anxiety (21-57%) and depression (17-49%); and in change in anxiety (29-64%) and depression (35-74%). Anxiety at T1 was underpinned by neuroanatomical variation in prefrontal, pre/postcentral, and occipital regions; while change in anxiety was linked to variation in precentral and occipital regions. Depression at T1 was related to neuroanatomical variation in precentral, temporal, and parietal areas; and change in depression related to variation in parietal and occipital regions. Neuroanatomical profiles underpinning cross-sectional, but not longitudinal, measures of anxiety and depression correlated with all three autism traits. Specifically, neuroanatomical profiles associated with greater mental health problems correlated with greater symptom scores (parent-rated; $|r| \geq 0.27$, $p \leq 0.0005$). Further, neuroanatomical profiles were transcriptomically enriched for genes linked to atypical neurodevelopment, including e.g., those regulating maturing excitatory neurons, endothelial cells, and excitatory deep layer neurons (enrichment odds ratio $OR \geq 2.7$, $p_{FDR} < .05$).

Conclusions: Our results suggest that co-occurring mental health conditions, and change in these conditions over time, may each have distinct neural substrates. These substrates, involving widespread cortical regions and multiple neuroanatomical features, may further vary across the autism spectrum, and be linked to various biological mechanisms. Once validated, our observations may support the development of tailored interventions, e.g., targeting mechanisms linked to relatively poorer outcomes.

323.002 Detecting Divergent Structural Connectivity in Autism Via Multisite Harmonization

R. S. Shen¹, W. Parker¹, A. A. Chen², T. Roberts³, B. Tunc⁴, R. T. Shinohara⁵, B. E. Yerys⁶ and **R. Verma⁶**, (1)University of Pennsylvania, Philadelphia, PA, (2)Department of Public Health Sciences, Medical University of South Carolina, Charleston, SC, (3)Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Penn Statistics in Imaging and Visualization Center, Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania, Philadelphia, PA, (6)Diffusion & Connectomics In Precision Healthcare Research, Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background:

Investigation of structural connectivity in autism using diffusion MRI (dMRI) based structural connectomes has not produced consistent findings, primarily due to small sample sizes of individual studies and high heterogeneity in autism. To maximize information gleaned from existing studies, it is essential to integrate data retrospectively while overcoming extensive site-related differences. Solving this need requires specialized harmonization paradigms to address statistical complexity of structural connectomes while preserving biological variability. We anticipate that harmonized data will facilitate robust detection of autism-related patterns by increasing pooled sample size.

Objectives:

To propose a harmonization paradigm for pooling structural connectomes from retrospective studies, and to investigate divergence in structural connectivity associated with autism in a large, pooled cohort.

Methods:

We analyzed dMRI of 1503 participants (1194 neurotypicals and 309 autism, aged 6-21 years) from 6 sites (Table1). Structural connectomes were created by parcellating the brain into 86 regions defined by Desikan-Killiany atlas and performing probabilistic tractography, with streamline counts used as connectivity weights, yielding 86x86 connectivity matrices. Since connectivity weights were non-gaussian distributed, we modeled edgewise weights using a gamma-distributed generalized linear model (gamma-GLM) with a log link, incorporating site, sex, age, and age² as covariates. Site-related coefficients were estimated edgewise from neurotypicals alone and applied to harmonize structural connectomes for autism and neurotypical groups. Removal of site effects was validated using ANOVA tests on harmonized edgewise weights and 6 graph topological measures, controlling for sex, age, and age². We assessed group-level differences and group-by-age interactions in graph measures in harmonized data between autistic and neurotypicals. Only males (n=890) were included in this analysis. We further tested Spearman correlations between graph measures and autism clinical assessments, controlling for age. We compared harmonized structural connectomes to unharmonized data where site covariate was regressed out at the level of graph measures.

Results:

Among 1480 edges after consistency-based thresholding, 1377 (93%) exhibited significant site effects pre-harmonization ($p < 0.05$). Site effects at all edges were non-significant following gamma-GLM harmonization (Fig.1A). Additionally, all derived graph measures showed significant site effects before harmonization ($p < 0.05$), while none were significant after harmonization (Fig.1B).

Unharmonized data revealed no group-level differences in graph measures. A weak group-by-age interaction in clustering coefficients (standardized $\beta = 0.16$, $p = 0.043$) and a marginally significant interaction for global efficiency (standardized $\beta = 0.16$, $p = 0.052$) were noted (Fig.1C top), but no measures were linked to clinical scores.

Post harmonization, males with autism showed significantly higher intra-hemispheric strength compared to neurotypicals (Cohen's $d = 0.37$, $p = 0.041$). Significant group-by-age interactions were observed for clustering coefficient (standardized $\beta = 0.27$, $p < 0.001$) and global efficiency (standardized $\beta = 0.26$, $p = 0.002$), with both measures increasing with age in autism but decreasing in neurotypicals (Fig.1C bottom). Intra-hemispheric strength positively correlated with SRS-2 t-score ($R = 0.12$, $p = 0.012$), while clustering coefficient ($R = 0.15$, $p = 0.006$) and global efficiency ($R = 0.14$, $p = 0.013$) correlated positively with VABS communication subscale.

Conclusions:

Our gamma-GLM harmonization can effectively remove site-related differences in structural connectomes for retrospective data integration. With gamma-GLM harmonized structural connectomes from 6 sites, we observed hyper intra-hemispheric connectivity and divergent age-related patterns in clustering coefficient and global efficiency in autistic children compared to neurotypicals.

323.003 Pubertal Timing Effects on Anterior Pituitary Volume and Symptomology in Autistic Adolescents from the ABCD Study
G. Picci^{1,2}, **C. Mills**³ and **H. F. Feser Stessman**², (1)Institute for Human Neuroscience, Boys Town National Research Hospital, Boys Town, NE,
 (2)Pharmacology & Neuroscience, Creighton University School of Medicine, Omaha, NE, (3)Creighton University School of Medicine, Omaha, NE

Background: Puberty is sorely understudied in autism spectrum disorders (ASD), yet studies suggest potential increases in symptom severity during adolescence for some autistic individuals. During normative development, puberty instigates massive reorganization of neural circuitry and behavior necessary for successfully transitioning into adulthood. Although this is a rapidly growing area of research in normative populations, research examining puberty in autistic individuals is in its nascence. Thus, this study will begin to address this novel topic by examining a brain region implicated in pubertal hormone production – the anterior pituitary gland (PG). Anterior PG volume increases with rising pubertal hormone levels and has established links with mental health during adolescence in non-autistic adolescents. Understanding how similar processes unfold in autistic adolescents could garner much-needed insights into pubertal effects on neurodevelopment and mental health in ASD.

Objectives: The current study sought to explore how pubertal timing affects anterior PG volume in autistic adolescents compared to controls and whether diagnostic status moderates relationships between anterior PG size, pubertal timing, and elevated autism symptomology (Figure 1).

Methods: The final sample will include 276 adolescents from the Adolescent Brain Cognitive Development (ABCD) study with T1-weighted MRI scans and pubertal timing data (i.e., Pubertal Development Scale regressed onto age) who are matched on age, sex, race, ethnicity, IQ, household income, and parent education. Anterior and posterior PG lobes were manually traced using preliminary data from a random sample from the final sample ($N = 100$; 50 ASD; 23 ASD girls, 27 ASD boys, $M_{\text{age}} = 10.01$ ($SD = 0.62$)). Tracing reliability was performed on 15% of the pilot sample with good reliability for the anterior and posterior PG tracings ($ICCs = .91, .84$, respectively). Analyses were conducted using ANCOVA models to examine group by pubertal timing interactions on anterior and posterior PG volumes, and group by pubertal timing by anterior PG volume interactions on autism symptom severity (age, sex, total intracranial volume as covariates).

Results: Preliminary results from the 100 matched participants revealed a group by pubertal timing interaction predicting anterior PG volume ($F_{(1,99)} = 5.06, p = .03$), but *not* posterior PG ($F_{(1,99)} = 1.61, p = .21$). Simple slopes analyses revealed that in later maturing adolescents in particular, TD adolescents exhibit *smaller* anterior PG volumes than ASD adolescents (Table 1). In addition, there was a significant group by pubertal timing by anterior PG volume interaction predicting social responsiveness scale (SRS) scores ($F_{(1,98)} = 4.64, p = .03$). Follow-up analyses revealed that in those with earlier pubertal timing, compared to TDs, ASD adolescents exhibited stronger associations between anterior PG volume and elevated SRS scores (all $p < .01$).

Conclusions: Results suggest that there are key group differences in how pubertal timing affects anterior PG (but not posterior PG) volume and autism symptom severity. This work highlights the utility of examining the anterior PG in populations who may have puberty-specific increases in symptomology. Moreover, findings here corroborate and extend work showing autistic adolescents experience a potential deterioration in functioning during puberty by providing a potential neural mechanism that may explain individual differences in ASD.

323.004 Linking Brain Microstructure to Behavioral Severity in ASD: Associations of G-Ratio and Conduction Velocity with Behavioral and Cognitive Metrics

H. Ressa¹, B. T. Newman¹, Z. Jacokes², J. McPartland³, N. Kleinhans⁴, M. Dapretto⁵, S. Y. Bookheimer⁶, T. J. Druzgal⁷, K. A. Pelphrey⁸ and J. D. Van Horn², (1)Department of Psychology, University of Virginia, Charlottesville, VA, (2)School of Data Science, University of Virginia, Charlottesville, VA, (3)Yale Child Study Center, Yale Child Study Center, New Haven, CT, (4)University of Washington, Seattle, WA, (5)Department of Psychiatry and Biobehavioral Sciences, University of California Los Angeles, Los Angeles, CA, (6)Dept of Psychiatry and Biobehavioral Sciences, David Geffen School of Medicine at UCLA, Los Angeles, CA, (7)University of Utah School of Medicine, Salt Lake City, UT, (8)Department of Neurology, University of Virginia School of Medicine, Charlottesville, VA

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder marked by impairments in social communication and the presence of restrictive, repetitive behaviors. While diagnosis is traditionally based on cognitive and behavioral assessments, identifying biomarkers that link these behaviors to neurobiological differences remains a challenge. Previous research from our lab suggests that ASD individuals exhibit reduced axonal conduction velocity and alterations in the g-ratio (the ratio of axon diameter to myelin thickness), implying structural differences in white matter pathways. This study expands upon previous findings by exploring associations between brain microstructure metrics and a range of behavioral assessments commonly used in the clinical evaluation of ASD.

Objectives: This study aims to identify behavioral metrics that are most strongly associated with neurobiological differences in individuals with ASD. In addition, it seeks to compare the relative associations of two neuroimaging-based metrics—conduction velocity and g-ratio—with cognitive and behavioral performance. Finally, the study aims to explore whether neuroimaging metrics can serve as early biomarkers for predicting both ASD diagnosis and symptom severity, providing insight into the neurobiological foundations of ASD.

Methods: **Participants:** 273 participants (148 with ASD and 125 neurotypical), aged 8 to 17 years, matched for age and sex, were recruited from the NIH Autism Centers of Excellence cohort. Each participant completed a battery of cognitive and behavioral assessments, including the Autism Diagnostic Observation Schedule (ADOS), Behavior Rating Inventory of Executive Function (BRIEF), and Social Responsiveness Scale (SRS-II). **Neuroimaging:** Diffusion MRI was employed to evaluate brain microstructure, focusing on g-ratio and conduction velocity. Image processing followed standard protocols, including FOD modeling and fixel-based analysis. Microstructural data were examined across 214 brain regions of interest (ROIs). **Statistical Analysis:** Linear models were used to assess correlations between neuroimaging metrics and behavioral subscales, adjusting for age, sex, and IQ. Multiple comparisons were corrected using the Benjamini-Hochberg method. Two machine learning clustering analyses were also conducted to uncover latent patterns in neuroimaging and behavioral data.

Results: Significant associations were identified between conduction velocity and multiple behavioral metrics, particularly in the BRIEF subscales measuring executive function and emotional regulation. Conversely, g-ratio exhibited stronger correlations with behavioral metrics in ASD-only analyses, particularly in the motor cortex and white matter regions. Within the ASD cohort, g-ratio correlated with severity scores on the ADOS and CBCL tests, while conduction velocity associations were weaker. Machine learning analyses revealed clusters of participants aligned with gradients in brain microstructural maturity. These clusters corresponded to distinct behavioral profiles, suggesting neurodevelopmental variability underlying behavioral differences in ASD.

Conclusions: This study demonstrates that brain microstructural metrics, particularly g-ratio, are significantly associated with behavioral severity in ASD. The results suggest that axonal diameter, rather than myelination alone, plays a crucial role in the neurobiology of ASD, with possible implications for identifying early biomarkers. These findings highlight the value of integrating neuroimaging and behavioral assessments to enhance the understanding and prediction of ASD severity, potentially enabling earlier and more accurate diagnoses.

Oral Session -

324 - Assessing Language & Communication Skills in Individuals with Profound Autism

May 2nd, 2025, 5:30 PM - 6:30 PM - 6A

Moderator: Alison Singer, Autism Science Foundation, New York, NY

na

324.001 Investigating the Relation between Fine Motor Skills and Expressive and Receptive Language Skills in Minimally Verbal Autistic Adults Using Structural Equation Modeling

M. Pecukonis¹, P. Hickey Townsend^{2,3}, L. Sarnie¹, C. Jafari¹, N. Kosmyna⁵, N. Protyasha⁵, J. Williamson⁴, S. C. Yuditskaya⁴, P. Maes⁵, T. Quatieri⁶, C. J. McDougle¹, M. Mody^{1,3} and L. Nowinski¹, (1)Lurie Center for Autism, Massachusetts General Hospital, Lexington, MA, (2)Psychiatry, Massachusetts General Hospital, Boston, MA, (3)Athinoula A. Martinos Center for Biomedical Imaging, Charlestown, MA, (4)Lincoln Laboratory, Massachusetts Institute of Technology, Lexington, MA, (5)Media Lab, Massachusetts Institute of Technology, Cambridge, MA, (6)Lincoln Laboratory, MIT Lincoln Laboratory, Lexington, MA

Background: Research suggests that the motor system plays an important role in spoken language development for individuals with autism (Mody & McDougle, 2019). In autistic children and adolescents, fine motor skills are positively associated with expressive and receptive language skills (Hwang & Lee, 2024). This positive relation between motor skills and language skills has also been found in samples of minimally verbal (MV) autistic children and adolescents (Butler & Tager-Flusberg, 2022; Chen et al., 2024; Pecukonis et al., 2019). However, no studies to date have examined this association in MV autistic adults.

Objectives: To investigate the relation between fine motor skills and expressive and receptive language skills in MV autistic adults. We predicted that higher fine motor skills would be associated with higher language skills.

Methods: The sample included 31 MV autistic adults (10F, 21M) 19 to 32 years old ($M=23.75$). MV status was determined using the following criteria: 1) entirely non-verbal/non-speaking; 2) ability to produce less than 30 words or word approximations spontaneously; and/or 3) Expressive Vocabulary Test (EVT-3) scores ≤ 1 st percentile. We used correlation analyses and structural equation modeling (SEM) to examine the association between fine motor skills and expressive and receptive language skills. SEM is a statistical method that allows for exploration of associations between observed variables and latent factors by combining principles of factor analysis with multiple regression analysis. Fine motor skills were measured using the Grooved Pegboard Test (GPT), the Beery-Buktenica Test of Visual-Motor Integration (VMI-6), and the caregiver-report Vineland Adaptive Behavior Scales (VABS-3) fine motor subscale. Expressive language skills were measured using the EVT-3 and the caregiver-report MacArthur-Bates Communicative Development Inventory-Words and Sentences (MCDI) vocabulary subscale. Receptive language skills were measured using the Peabody Picture Vocabulary Test (PPVT-5) and the Clinical Evaluation of Language Fundamentals (CELF-5) sentence comprehension subscale. Participant age and sex were included as covariates in the model.

Results: Zero-order correlations are reported in Table 1 and the model is summarized in Figure 1. The model included three factors (fine motor, expressive language, and receptive language skills) which were composed of raw scores from the measures listed above. Fine motor skills were significantly and positively associated with expressive ($\beta=.719/B=1.656$, $SE=.152$, $p<.001$) and receptive language skills ($\beta=.611/B=1.047$, $SE=.235$, $p=.010$). Participant sex was significantly associated with expressive ($\beta=.395/B=2.124$, $SE=.172$, $p=.022$) and receptive language skills ($\beta=.475/B=1.903$, $SE=.223$, $p=.034$), with female participants demonstrating higher language skills than male participants. The overall model indicated good fit ($\chi^2(18)=19.930$, $p=.337$; CFI=.978; TLI=.958; RMSEA=.059; SRMR=.087), and explained 84.2% and 71.5% of the variance in expressive and receptive language skills, respectively.

Conclusions: Fine motor skills were positively associated with expressive and receptive language skills in MV autistic adults, supporting the growing body of evidence that the motor system is involved in both the production and comprehension of spoken language. Future studies should explore whether targeting fine motor skills through intervention leads to improvements in language skills for MV autistic adults. Further research is needed to determine whether current findings replicate in a larger sample of MV autistic adults using longitudinal data.

324.002 Examining Adaptive Behavior and Communication in Non/Minimally-Speaking Individuals with Profound Autism

M. Kannisto¹, B. Booth² and K. T. Johnson³, (1)Northeastern University, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Northeastern University, Cambridge, MA

Background: Profoundly autistic individuals who are non- or minimally-speaking communicate through many modalities, including vocalizations, gestures, body movements, facial expressions, and augmentative technology. These individuals are often well understood by caregivers or those close to the individual; however, many language/communication assessments struggle to measure their communicative abilities and compare it to other measures of development, such as adaptive behavior. The Rapid Online Sample of Communication (ROSCO) is a new communication sampling protocol that is administered over Zoom and records naturalistic communication behaviors between a caregiver and non/minimally-speaking individual. Caregiver knowledge of the communication is captured during a structured interview after ROSCO.

Objectives: This research performs an exploratory analysis of the relationship between scores on an existing adaptive behavior assessment and the types of communicative interactions between caregivers and their non/minimally-speaking children.

Methods: N=19 non/minimally-speaking individuals (2-12years; 8M:11F) completed a 15-minute ROSCO session, which includes everyday interactive activities like mealtime, free play, and watching a video that buffers unexpectedly to elicit mild frustration and communication opportunities. During the structured post-ROSCO interview, the caregiver re-watches the recorded ROSCO session with an examiner and describes the action, directedness, and function associated with communication attempts during ROSCO. This analysis examines functions associated with behavior-regulating communication like requesting or rejecting something (REQ+REJ), as well as social interactions or commenting by the child (SOC+COM). Frequency of communicative acts was defined as the count of the function divided by session duration. Some individuals completed multiple sessions, for which their counts were averaged. Caregivers also completed the Vineland Adaptive Behavior Scales (VABS-3; Interview). Linear regression models were used to examine possible preliminary correlations between function frequencies and VABS-3 composite standard scores (SS), subdomain v-scale scores, and growth scale values (GSVs).

Results: SOC+COM frequencies and VABS-3 scores were positively correlated across all score categories, while REQ+REJ frequencies held no consistent relationship. Moderately high explained variances were observed between SOC+COM frequencies and Adaptive Behavior Composite SS ($R^2 = 0.4277$; see figure), Receptive Language V-scale (0.5817), Domestic Daily Living Skills GSV (0.5319) & V-scale (0.4923), Personal Daily Living Skills V-scale (0.5811), Interpersonal Relationships GSV (0.5442), and Play-Leisure GSV (0.4064). Less variance was explained between SOC+COM frequencies and Communication Composite SS (0.3325) and Expressive Language GSV (0.3141). Consistent trends were not observed between REQ+REJ and any VABS-3 scores.

Conclusions: The relationship between higher SOC+COM frequencies and VABS-3 Daily Living Skill (assessing skills like eating, dressing, chores, and safety) and Socialization subdomains (assessing eye contact, understanding of emotions, and ability to play with others) may reflect the ability to engage in and learn from a social environment as more social communicative skills emerge. The lack of relationship between early developmental communicative functions (e.g., requesting/rejecting) and VAB-3 scores may reflect a limitation of the VABS-3 in capturing sensitive or reliable measures for this population before more social behaviors have emerged. Future work will further examine communicative functions by continuing to explore function categories and analysis with a larger sample, as this study is ongoing. Analyses with other behavioral assessments will be done for comparison.

324.003 Assessing Communicative Capacity in Minimally Verbal Autistic Individuals: Validation of the Low-Verbal Investigatory Survey (LVIS)

E. Tenenbaum¹, I. M. Eigsti² and A. Naples³, (1)Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

Background: Approximately 30% of autistic individuals are minimally or low verbal (MLV), a condition that significantly impacts their quality of life and service use. Given the heterogeneity of communicative profiles in autism, it has been challenging to reliably predict which children without productive language in toddlerhood will develop language and which will remain MLV and could benefit from alternative and augmentative forms of communication. Current measures of communicative capacity are often time-intensive, expensive, and require significant training to administer. This has limited the use of these measures in clinic and research settings alike. Where brief screening tools do exist, they are often normed on neurotypical populations and fail to capture the multi-dimensional nature of language acquisition in autism. The Low-Verbal Investigatory Survey (LVIS) was developed to address this gap.

Objectives:

This study aims to:

1. Assess the convergent and divergent validity of the LVIS with gold-standard measures of language and autism symptoms in a large and diverse sample of autistic children.
2. Determine whether correlations between LVIS scores and established measures of communication differ by socioeconomic status, race, or ethnicity.
3. Identify data-driven cut points for clinical indications of MLV status.

Methods: Data were collected via an online survey from 764 participants (Table 1), recruited through the Simons Foundation Autism Research Initiative (SPARK) sample. Participants completed the LVIS and other established measures of communication and autism symptomatology. The survey included demographic questions to assess the influence of socioeconomic status, race, and ethnicity on LVIS scores.

Results: The LVIS demonstrated strong convergent validity with established language measures, and a three-factor structure of Verbal Communication, Non-Verbal Communication, and Atypical Communication (Figure 1). The LVIS scores correlated significantly with Vineland Communication domain scores, $R(543) = 0.76, p < .001$ and Age of First Words, $R(643) = -0.34, p < .001$. Weaker correlations with Vineland Daily Living, $R(545) = 0.59, p < .001$, and Motor Skills, $R(310) = 0.53, p < .001$, suggest divergent validity. Analysis of the effects of demographic factors suggest comparable LVIS scores as a function of race and ethnicity with two exceptions. Participants who identified as White had higher Verbal Communication Scores ($p = .016$) and participants who identified as African American had lower Verbal Communication Scores ($p = .042$). A cut point of 16 on the LVIS resulted in sensitivity of .74 and specificity of .81 relative to parent report of verbal status.

Conclusions: The LVIS is a valid and efficient tool for assessing communicative capacity in MLV autistic individuals. It requires minimal time, money, and training to administer, making it suitable for diverse research and clinical settings. This ease of administration and ready availability makes it more feasible for the LVIS to be administered in large and diverse groups. Information collected in larger samples can help us understand the heterogeneity of communicative profiles in autism and potential mechanisms that contribute to such a large proportion of autistic individuals remaining minimally verbal into adulthood.

**324.004** Remote, in-Home Assessment of Spoken Language in Low- and Minimally Verbal Autistic Children

K. V. Chenausky¹, M. F. Maffei², J. R. Green³, V. E. Sanchez⁴ and H. Tager-Flusberg⁵, (1)Communication Sciences and Disorders, MGH Institute of Health Professions, Boston, MA, (2)Infant Communication Lab, Boston University, Boston, MA, (3)Speech and Feeding Disorders Lab, MGH Institute of Health Professions, Boston, MA, (4)Speech and Hearing Bioscience and Technology, Harvard University, Boston, MA, (5)Psychological and Brain Sciences, Boston University, Boston, MA

Background:

Traditional research methods often fail to capture the communication behaviors of profoundly autistic or minimally verbal individuals. In this presentation, I will first describe a remote data collection protocol designed to meet autistic children where they are and show the kinds of information it can yield. To illustrate its ability to provide information about even profoundly autistic children's oromotor skills, I will present results of a preliminary kinematic analysis of speech production from 2D video. Finally, I will describe ongoing work employing advanced analytics that we hope will reveal much about speech and oromotor ability in this population.

Previous work has shown that a perceptually-judged measure of speech production in low- and minimally verbal autistic individuals (percent correct speech repetition) accounts for significant variance (46%) in a measure of expressive language (number of different words from a language sample)¹. Other work has shown that an acoustic measure of speech production in low- and minimally verbal individuals (normalized acoustic distance between the vowels in "bee" and "baa") accounts for significant variance (26%) in Vineland Expressive Language subtest raw scores².

Objectives:

Here, we tested whether a kinematic measure of speech production, cross-correlation of upper- and lower-lip velocity, would account for significant variance in a measure of expressive language. Cross-correlation between the velocity of the upper and lower lips is a measure of speech production skill that develops over time as children learn to use the upper lip in coordination with the lower lip and jaw during speech³.

Methods:

Parents completed the Vineland Adaptive Behavior Scales. Children participated in several short tasks by Zoom, lasting under an hour total: A 15' parent-child interaction, a speech repetition task, a feeding task, and a "resting face" task where children watched a video of their choice while their faces were videotaped.

Children's oral movements were analyzed from 2D Zoom video using a now-discontinued program (DynamiXyz Performer[®]). Specifically, movement of the upper and lower lips was tracked during production of the syllable "ba" in 19 autistic children (4 F) aged 4;6-7;10. A linear regression was run to determine whether upper- and lower-lip velocity cross-correlation contributed significant variance to Vineland expressive language scores.

Results:

The overall model was significant, $F(1,17) = 4.413$, $p = 0.05$. Cross-correlation between the velocity of the upper and lower lips accounted for 20.6% of the variance (R^2) in Vineland Expressive Language v-score.

Conclusions:

Results are consistent with previous findings that speech production significantly contributes to expressive language ability in low- and minimally verbal autistic children. Here, a kinematic measure of lip movement during syllable production, derived from 2D video, replicates this effect. The results show that remote assessment of spoken language can be carried out with profoundly autistic children non-invasively and from their homes and that even simple, non-stressful tasks can yield rich, valid data. Ongoing work includes validating remotely-collected data against the same data collected in person, and nonlinear dynamical analyses (using Google FaceMesh) of how head movement relates to autism core symptoms and mouth movement relates to expressive language.

**Oral Session -****325 - Social and Emotional Outcomes in Young-Mid Adulthood**

May 2nd, 2025, 5:30 PM - 6:30 PM - 611-614

325.001 Autism and Mental Health Outcomes from Childhood to Adulthood: Evidence from the Avon Longitudinal Study of Parents and Children (ALSPAC) Cohort

J. F. Underwood¹, P. Madley-Dowd², C. Dardani³, L. Hull⁴, A. Kwong⁵, R. Pearson⁶, J. Hall⁷ and D. Rai⁸, (1)Neuroscience and Mental Health Innovation Institute, Cardiff University, Cardiff, United Kingdom, (2)University of Bristol, Bristol, United Kingdom, (3)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (4)Population Health Sciences, University of Bristol, Bristol, UNITED KINGDOM, (5)University of Edinburgh, Edinburgh, Scotland, United Kingdom, (6)Manchester Metropolitan University, Manchester, Manchester, United Kingdom, (7)Division of Psychological Medicine and Clinical Neurosciences, School of Medicine, Cardiff University, Cardiff, United Kingdom, (8)Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom

Background:

Autistic children and adults are more likely to experience mental health problems. However, the mechanisms behind the increased risk of mental health problems in this population are less well known. Longitudinal studies following up children into adulthood with information on potential intermediate variables are crucial to the understanding of modifiable factors behind such associations.

Objectives:

- To describe the Avon Longitudinal Study of Parents and Children (ALSPAC) and its contributions as a longitudinal resource to understand the mental health outcomes of children with autism and autistic traits.
- To investigate the longitudinal association of autism/autistic traits with depression up to age 28 years, and the potential mediating role of traumatic experiences.

Methods:

ALSPAC is a population based birth cohort, which contains detailed prospectively-collected information on parents and children from pregnancy to adulthood. It recruited 14,541 pregnant women from Bristol and surroundings, UK, with expected dates of delivery 1st April 1991 to 31st December 1992 (further recruitment and enrolment after the age 7 increasing enrolled pregnancies to 15,447), with 14,901 children alive at one year of age. Children with an autism diagnosis have been identified by multisource case ascertainment. Four independent autistic trait measures have been identified as being the most predictive of 93 developmental measures predicting an autism diagnosis- including the social communication difficulties checklist (age 7), the coherence subscale of the Children's Communication Checklist (age 9); repetitive behaviours (age 5), and sociability temperament (age 3 years). Further, a measure of broad autism phenotype has been derived and polygenic risk scores for autism in the cohort have been estimated for those with genome-wide association (GWAS) data ($n > 6000$), based on the most recent autism GWAS. Mental health outcomes including depression, anxiety, self-harm and psychotic symptoms have been assessed at multiple time points throughout childhood into young adulthood. Extensive data on potential confounders is available. Mixed-effects growth-curve models were used to estimate the trajectories of depressive symptoms by autism/autistic traits from age 10 to 28, further stratified by presence/absence of trauma exposure. Confounder adjusted associations between autism/autistic traits and depression in adulthood were also estimated and the role of childhood trauma was investigated via mediation analysis.

Results:

All autism variables demonstrated increased depressive symptom trajectories between ages 10-28 years. In line with previous ALSPAC investigations on mental health outcomes of autism/traits (which will be summarised in this talk)- social communication difficulties were the trait most strongly associated with a depression diagnosis in adulthood (age 24 OR= 2.15; 95%CI:1.22-3.76). Trauma and autistic traits combined to further increase depression symptom scores. Mediation analyses provided evidence for direct pathways between autistic traits and increased risk of depression alongside indirect pathways through increased risk of trauma.

Conclusions:

Depressive symptom trajectories in autism/traits emerging in childhood persist into adulthood. Preventative efforts against adverse mental health outcomes in autistic adults may need to focus on earlier experiences such as trauma in the adolescence period.

325.002 Postsecondary Landscape for Autistic Young Adults

K. Hume¹, J. R. Steinbrenner², S. L. Odom³, L. E. Smith DaWalt⁴, L. J. Hall⁵ and B. Kraemer⁴, (1)School of Education, University of North Carolina, Chapel Hill, Chapel Hill, NC, (2)Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (4)University of Wisconsin-Madison Waisman Center, Madison, WI, (5)Special Education, San Diego State University, San Diego, CA

Background: The most used source of information about young adults transitioning into the community, the National Longitudinal Transition Study (NLTS2), is decades old, offering little knowledge about the contemporary generation of autistic young adults transitioning out of school and into employment, postsecondary education, and community-based activities at a time when their numbers are increasing. The purpose of this study is to describe the current status of a national sample of autistic young adults after they finished school and transitioned into postsecondary education, employment, and community.

Objectives: This study provides a contemporary snapshot of postsecondary life for 211 autistic young adults who participated in the Center on Secondary Education for Students with Autism (CSESA) study from 2015-2018. The young adults and their caregivers reported on their engagement in education, employment, and social interaction and completed standardized measures related to self-determination, adaptive behavior, and family functioning 1-5 years post high school.

Methods: CSESA team members re-recruited young adults and their caregivers from the original sample based on contact information obtained as part of the original study. Data collection was completed via online questionnaires, paper questionnaires, and interviews. The measures included a demographic form, three standardized assessments about young adult characteristics (Scales of Independent Behavior, Self-Determination Scale, Adolescent and Young Adult Activities Card Sort), two standardized measures about caregiver experiences (Family Empowerment Survey and Zarit Burden Interview), and three project-developed measures that gathered information about young adults' experiences and participation.

Results: The young adults ranged in age from 17-25 (mean = 20.2). 84% of the follow-up sample identified as male, 15% as female, and 1% as nonbinary. 34% identified as non-white, including 12% Black, 5% Asian, 3% Native American, and 6% multi-racial. 17% identified as Hispanic/Latino.

Approximately 66% of young adults reported being involved with each employment and education activities after high school. About 11% of young adults reported no involvement with either employment or educational activities. Young adult report of social engagement was higher, with over 85% reporting having friends and meeting new people and nearly 75% reporting calling or texting friends. Only 3% reported no engagement in social activities. Most lived at home (85%) with 10% living independently. Approximately 84% of caregivers reported at least some use of services since high school.

More detailed results from the standardized assessments and caregiver reports can be found in the attached tables.

Conclusions: The autistic young adult participants in the CSESA study differed from previous generations in that they were more likely to have been diagnosed earlier, participated in early intervention, experienced evidence-based practices, had a formal transition plan, and to some degree were prepared for transition out of school. The general finding is that autistic young adults have more employment experiences, more social engagement, and are engaging in more community activities. We still have far to go in terms of policies, services, and supports to ensure autistic young adults can access both an independent and interdependent life in the community.

325.003 Self-Reported Strengths and Difficulties of Autistic Young Adults

J. Ferraiolo¹, C. I. Parenteau², J. M. Khaw^{3,4}, G. A. Herbert⁵, R. Adams⁶, J. L. Taylor⁷, S. Bishop⁸ and S. Zheng⁹, (1)Center for ASD and NDDs, UCSF Dept of Psychiatry, University of California- San Francisco, San Francisco, CA, (2)Psychiatry and Behavioral Sciences, Center for ASD and NDDs, UCSF Dept of Psychiatry, San Francisco, CA, (3)UC Santa Barbara, Santa Barbara, CA, (4)UCSF, San Francisco, CA, (5)Vanderbilt University Medical Center, Nashville, TN, (6)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (7)Department of General Pediatrics, Vanderbilt University Medical Center, Nashville, TN, (8)Psychiatry and Behavioral Sciences, University of California, San Francisco, San Francisco, CA, (9)Psychiatry and Behavioral Sciences, The University of Texas at Austin, San Francisco, CA

Background: The neurodiversity movement has called for research to include autistic voices and focus on strengths within the autistic community (Huntley et al., 2019). However, the majority of existing research is still from non-autistic perspectives with a focus on impairments and challenges (DePape & Lindsay, 2016; Russel, 2019). Understanding strengths and difficulties can inform how to tailor strength-based clinical support in areas of need explicitly expressed by autistic individuals. Moreover, studies have shown that the ability to identify and utilize strengths helps improve overall well-being for autistic adults (Taylor et al., 2023). Therefore, the current study aims to understand strengths and difficulties reported by autistic adults.

Objectives: To identify the self-reported strengths and difficulties of autistic adults using qualitative data.

Methods: We took an inductive coding approach to analyze free-text responses provided by autistic adults to two questions, “*What are your strengths?*” and “*What are your primary difficulties at this time?*”. Data was drawn from a larger study of self-reporting independent adults (18 to 35 years old, 52% assigned male at birth) with a childhood diagnosis of autism recruited from the SPARK research match registry (Zheng et al., 2021). A subsample of 292 individuals responded to the strengths question, and 294 responded to the difficulties question. Four independent coders and a content expert carried out the iterative in-vivo coding process, and different pairs of team members coded each response. Any coding discrepancies were resolved through consensus discussion.

Results: The research team generated nine substantive themes, resulting in 55 codes associated with strengths and 47 associated with difficulties (see Table 1 for themes and descriptions, Figure 1 for code word cloud). Four major themes pertaining to self-reported **strengths** emerged: interpersonal skills (46%), mental/cognitive abilities (40%), specialized knowledge/interests/skills (32%), and overcoming adversity/grit (31%). The most frequently mentioned strengths were kind/caring, smart/intelligent, creative, and resilience/mental strength. Five major themes pertaining to self-reported **difficulties** emerged: everyday life challenges (38%), mental/cognitive challenges (32%), interpersonal skills challenges (30%), emotional wellbeing/mental health challenges (26%), and physical health challenges (17%). The most frequently reported difficulties included socializing, financial challenges, emotional challenges, and unemployment/finding a job.

Conclusions: Participants reported a wide array of strengths and challenges, highlighting the heterogeneity of autistic experiences. Interestingly, autistic adults most frequently reported interpersonal skills as a strength while it was the third most frequently reported difficulty. While many existing services focus on interpersonal deficits among autistic adults, participants often reported difficulties with mental health, finances, employment, and physical health. Our findings underscore the importance of working with autistic individuals collaboratively in research and clinical work to identify their personal experiences of strengths and challenges. Moreover, the reported difficulties emphasize the need for wraparound services to support autistic adults, as participants reported difficulties extending beyond those commonly associated with autism. Additional research is needed to understand the underlying causes of these difficulties and how to improve existing support services based on self-reported autistic strengths.

325.004 Emotion Regulation Strategies, Gender, Gender Diversity and Assigned Sex at Birth: Associations with Depressive and Anxious Symptomatology in Autistic Adults

G. A. McQuaid¹, M. J. Barrett¹, G. L. Wallace² and A. Jack¹, (1)George Mason University, Fairfax, VA, (2)The George Washington University, Washington D.C, DC

Background: Depression and anxiety are common co-occurring psychiatric conditions in autistic adults,^{1,2} and are present at elevated rates relative to general population estimates,^{1,3-5} although reasons for this enhanced risk are poorly understood. Emotion regulation [ER] challenges, prevalent in autism,^{6,7} are associated with depression and anxiety.⁷ While risks for depression and anxiety are particularly elevated in autistic gender-diverse people and those assigned female sex,⁸ extant research on ER has involved male-predominant-or-exclusive samples, and typically youth samples. To our knowledge, no study has examined assigned-sex and gender identity and ER, a critical gap in the literature.⁹

Objectives: In this preregistered study,¹⁰ we 1) characterized ER strategies (adaptive [cognitive reappraisal; CR] and maladaptive [expressive suppression; ES]) in autistic adults based on gender, gender-diversity and assigned-sex, separately; and 2) examined associations of ER strategies and gender, gender-diversity and assigned-sex, separately, with depressive and anxious symptomatology.

Methods: An intentional sampling strategy sought to recruit an ethno-racially representative sample of autistic adults aged 18-30y from SPARK's Research Match registry.¹¹ 225 autistic adults ($M=25.6y$, 42.2% White, non-Latina/o/e) reported their gender and assigned-sex, and completed the following measures of ER strategies, depressive symptoms and anxious symptoms, respectively: Emotion Regulation Questionnaire [ERQ],¹² Patient Health Questionnaire [PHQ-9],¹³ and Generalized Anxiety Disorder 7-item [GAD-7].¹⁴ Three (gender, gender-diversity, assigned-sex) multivariate analyses of variance [MANOVA] examined differences in ER strategy use, with the ERQ CR and ES subscales as dependent variables. Six hierarchical multiple linear regression models were conducted with depressive (or anxious) symptoms as the dependent variables.

The ERQ subscales were entered in the first step and, in separate models, gender (binary-male: $n=59$; binary-female: $n=88$; not binary male or female: $n=78$), gender-diversity (cisgender: $n=139$, gender-diverse: $n=86$) or assigned-sex (male: $n=66$, female: $n=159$) in the second step.

Interaction terms for ERQ subscales and gender, gender-diversity, and assigned-sex were examined.

Results: The MANCOVA revealed no significant differences in ERQ-ES or ERQ-CR based on gender, gender-diversity, or assigned-sex ($ps>.05$).

Regression modeling revealed that after accounting for the significant effects of the ERQ subscales (higher ES scores associated with more symptoms; higher CR scores with less symptoms), higher depressive and anxious symptomatology were each predicted by gender (PHQ-9: $\beta=0.188$, $t=2.922$, $\Delta p=.004$, $\Delta R^2=0.031$; GAD-7: $\beta=0.167$, $t=2.623$, $\Delta p=.009$, $\Delta R^2=0.024$); gender-diversity (PHQ-9: $\beta=0.172$, $t=2.674$, $\Delta p=.008$, $\Delta R^2=0.025$; GAD-7: $\beta=0.170$, $t=2.676$, $\Delta p=.008$, $\Delta R^2=0.025$); and assigned-sex (PHQ-9: $\beta=0.198$, $t=3.066$, $\Delta p=.002$, $\Delta R^2=0.035$; GAD-7: $\beta=0.171$, $t=2.669$, $\Delta p=.008$, $\Delta R^2=0.025$). A post-hoc ANCOVA with FDR-corrected pairwise comparisons revealed the following pattern of depressive and anxious symptoms: not binary male or female ($M_{PHQ-9}=13.1$, $M_{GAD-7}=11.8$) > binary-female ($M_{PHQ-9}=10.6$, $M_{GAD-7}=10.4$) > binary-male ($M_{PHQ-9}=9.5$, $M_{GAD-7}=8.9$), with the comparison between binary-male and those not binary male or female (PHQ-9: $p=.01$; GAD-7: $p=.03$) surviving correction for multiple-comparisons.

Conclusions: For the first time, we showed that ER strategies, while associated with depression and anxiety, do not differ in autistic adults based on gender, gender-diversity, or assigned-sex. Nevertheless, separate associations between depression/anxiety symptoms and gender, gender-diversity and assigned-sex after controlling for ER, a known risk factor in depression and anxiety, underscore the importance of considering gender and assigned-sex independently.

326.001 Multifactorial Behavioral Contributions to Autism-Related Differences in Imitation

S. McWeeny¹, *S. H. Mostofsky², E. Wodka³, B. Caffo⁴ and J. B. Ewen⁵*, (1)Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, (2)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (3)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (4)Department of Biostatistics, Johns Hopkins University, Baltimore, MD, (5)Ann & Robert H. Lurie Children's Hospital, Chicago, IL

Background: Imitation plays a critical role in enhancing social-communicative reciprocity and social skill learning. Accordingly, impaired imitation may have downstream implications on the acquisition of learned, skilled behaviors in autism. Numerous behavioral and cognitive processes (e.g., social motivation, executive function, action representation, and motor execution) are thought to contribute to imitation performance, but it is unknown the degree to which differences in these domains contribute to autism-related imitation differences.

Objectives: The goals of the present study were to understand the role of various behavioral and cognitive processes (social motivation, executive function, action representation, and motor execution) in imitation performance and differences in imitation in ASD.

Methods: We assessed 7–12-year-old children ($n = 711$) with $FSIQ \geq 80$ with and without ASD, using a wide battery of performance-based and parent-report tests. These tests measured novel-gesture-imitation performance (Florida Apraxia Battery), motor execution (Movement Assessment Battery for Children (mABC-2); Physical and Neurological Examination of Subtle Signs (PANESS)), action representation (Postural Knowledge Test), social motivation (Social Responsiveness Scale (SRS)), and executive function or attentional processes (Wechsler Intelligence Scale for Children (WISC), Behavior Rating Inventory of Executive Function (BRIEF-P)). Children with ADHD were included in both non-ASD and ASD samples to improve generalization. Bootstrapped mediation analyses and cross-validated regression were utilized to quantify the role of the various processes in imitation.

Results: Non-autistic children significantly outperformed autistic children on novel-gesture-imitation performance ($t(709) = 13.03, p < .001, d = 1.05$). Mediation analyses revealed that motor execution tests most strongly mediated novel-gesture-imitation differences in autism (56% [42.8–70.5]), though effects from social motivation (21% [1.6–41.1]), action representation (23% [14.0–33.3]) and executive function (22% [12.5–32.7]) also partially mediated the relationship between autism and imitation performance. 95% bootstrap intervals were all above 0, indicating significant mediation from each process. Executive processes did not explain unique variance once adjusting for motor execution, suggesting that the executive component may in part comprise motor execution. However, motor execution tasks still mediated a moderate percentage (41%) of imitation differences in ASD after adjusting for EF. Using cross-validated regression models, the domains tested here accounted for 39% of the variation in imitation performance.

Conclusions: Several cross-domain factors may account for autism-associated differences in novel-gesture-imitation, including motor execution, action representation, social motivation, and to a lesser extent, executive function. Though the data are cross sectional, we discuss the models as evaluating a range of potential causal paths that explain why autistic children may struggle to imitate. Future research with true causal inference will require longitudinal data, particularly from earlier stages of development. Nonetheless, this research synthesizes possible contributors to autism-related-imitation differences that are often tested in isolation, which allows us to compare several competing hypotheses. This observational study is complementary to ongoing experimental work on potential factors related to autism-related imitation differences.

326.002 Motor and Socio-Cognitive Mechanisms Explaining Peers' Synchronization of Joint Action across Development in Autistic and Non-Autistic Children

R. Poyas-Naharan¹, Y. Estrugo², S. Bar Yehuda³ and N. Bauminger-Zviely⁴, (1)Faculty of Education, Bar-Ilan University, Ramat-Gan, Israel, (2)Faculty of Education, Bar Ilan University, Ramat-Gan, Israel, (3)Faculty of Education, Bar Ilan University, Ramat - Gan, Israel, (4)Faculty of Education, Bar-Ilan University, Ramat Gan, NA, Israel

Background:

Partners coordinating their movement in time and space to reach a goal engage in joint action (JA), a fundamental component of everyday social interaction. This process relies on both motor skills and socio-cognitive abilities (e.g., Theory of Mind, ToM). Autistic children often exhibit difficulties in executing fine and gross motor tasks, inferring or predicting others' actions and intentions on the basis of their behavior (ToM), and mirroring and complementing others' movements (JA). Despite JA's importance for peer interaction, the shared contribution of motor and socio-cognitive mechanisms (ToM) to its formation is insufficiently explained.

Objectives:

The current study's aim was to explore motor skills and ToM abilities' joint contribution to JA performance with a peer partner. Mediation model assumes that the link between the dependent variable (JA) to the independent variable (Group) is better explained by indirect mechanisms that mediate this link and contribute to its more comprehensive understanding. Since theoretically motor and socio-cognitive mechanisms underlie JA constitution, we assumed that these mechanisms would jointly mediate autistic and non-autistic children's JA performance.

Methods:

This study included 84 autistic children ages 6–16 years, and 64 non-autistic children matched by age, sex, IQ, and mother education across three developmental-age groups (early childhood, 6–8.5 years, preadolescents, 8.5–12, adolescents, 12–16 years). Group differences on age and IQ were non-significant. The participants' composite score of gross and fine motor skills was assessed using the Individual Motoric Observation Scale (IMOS), while their early, basic, advanced and composite ToM scores, as rated by parents, were evaluated using the ToM Inventory (TOMI). Children also completed four-dyadic-JA tasks (side-by-side walking, face-to-face movement, imaginary-football, and crossing a narrow corridor), yielding a total JA-coordination score.

Results:

To examine possible mediation effects (indirect effects) of motor skills and ToM abilities, as parallel mediators between group and JA and to explore their joint contribution to JA performance, we used SPSS PROCESS mediation model 4. Our mediation analysis revealed a significant indirect effect of group (autism/ Non-autistic) on the total JA score through the IMOS total score, as well as a significant indirect effect of group on the total JA score through the TOMI composite score (see Figure 1).

Conclusions:

Together, motor and socio-cognitive underlying mechanisms significantly contributed to JA performance beyond the participant's diagnostic-group affiliation, elucidating the relationship between these three capabilities. This offers a novel theoretical and therapeutic perspective on autistic and non-autistic children's everyday social-motor interaction. Consequently, improving motor skills and ToM abilities can enhance JA performance, thereby positively influencing autistic children's social participation throughout their school years.

326.003 Sleep Mediates the Association between Emotion Dysregulation and Repetitive Behaviors in Autistic Children

S. Passarini^{1,2}, E. Fucà¹, S. Guerrera¹, F. Dentale², F. Costanzo¹, M. Parisi¹, L. Casula¹, S. Pirchio³, D. Menghini¹, G. Valeri¹ and S. Vicari^{1,3}, (1)Child and Adolescent Neuropsychiatry Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, RM, Italy, (2)Department of Dynamic and Clinical Psychology and Health Studies, Sapienza University of Rome, Rome, RM, Italy, (3)Life Sciences and Public Health Department, Catholic University, Rome, RM, Italy

Background: Restricted and Repetitive behaviors (RRBs) are a core feature of Autism Spectrum Disorder (ASD), often hindering social interaction and learning opportunities, which can lead to negative developmental outcomes. Additionally, RRBs may increase parenting stress and affect parenting styles. Interestingly, RRBs have been linked to Emotion Dysregulation – ED (Giuliani et al., 2008). ED appears to be a significant predictor of unusual interests and it is positively associated with the intensity of self-injurious behaviors and repetitive sensory-motor actions (Ferguson et al., 2024). Moreover, both ED (Fisher et al., 2022) and RRBs (Hundley et al., 2016) have been associated with sleep disturbances in ASD. However, the connection between ED and RRBs, along with the mediating role of sleep in this relationship, remains poorly understood.

Objectives: we aimed at testing the role of sleep as a mediator between ED and RRBs in a sample of school-age autistic children; if so, we aimed at understanding whether sleep mediates the association between ED and low- and high-order RRBs differently.

Methods: Data were retrospectively collected from patients who attended the Child and Adolescent Neuropsychiatry Unit of an Italian Children's Hospital between 2020 and 2023. The final sample consisted of 90 autistic children (Mean age=8.8±1.8; Mean IQ=79.9 ±21.2; IQ<70= 37%; IQ>70= 63%; 19 females and 71 males). Alongside routine assessments (e.g., neuropsychiatric, cognitive and ASD symptoms evaluations), parents completed a battery of parent-report questionnaires, including the Repetitive Behaviors Scale- Revised (RBS-R), the Child Behaviour Checklist (CBCL), and the Sleep Disturbance Scale for Children (SDSC). The ED profile was computed using the Attention, Aggression, and Anxious/Depressed subscales of the CBCL, resulting in the CBCL-AAA index (Keefer et al., 2020). Additionally, the total score of the RBS-R was calculated, along with low-order RRBs (e.g., motor stereotypes and self-harming actions) and high-order RRBs scores (e.g., strong preference for sameness and narrowly focused interests), see Turner (1999). A mediation analysis was conducted with the CBCL-AAA as the independent variable, RBS-R scores (total, high-order, and low-order scores) as the dependent variables, and the total SDSC score as the mediator.

Results: Results showed the total SDSC score mediated the relationship between the CBCL-AAA and the RBS-R total score ($\beta = .1048$; 95% CI = .0036 - .2315). This mediation effect remained significant even after controlling for IQ and sex. Additionally, the total SDSC score mediated the relation between the CBCL-AAA and the low-order RBS-R score ($\beta = .1441$; 95% CI = .0362 - .2709). However, the mediation pathway for the total SDSC score was not significant for the high-order RBS-R score ($\beta = .0726$; 95% CI = -.0293 - .1912).

Conclusions: Sleep disturbances seem to mediate the relationship between ED and RRBs, even after accounting for IQ and sex. Specifically, sleep disturbances appear to mediate the relationship between ED and low-order but not high-order RRBs. Understanding the connections between RRBs and behavioral (i.e., ED) and psychophysical (i.e., sleep disturbances) symptoms could enhance treatment strategies and improve long-term outcomes for autistic individuals.

Future research should adopt a longitudinal approach to characterize deeply current preliminary findings.

326.004 Impairment in Visual-Motor Coordination in Children and Adolescents with Autism Spectrum Disorder and Intellectual Disability.

G. Valagussa^{1,2,3}, F. I. Bianchi¹, A. Mari¹, P. Della Cagnoletta², E. Castagna³, E. Grossi⁴, C. Perin² and **G. Purpura**², (1)Autism Research Unit, Villa Santa Maria Institute, Tavernerio, Como, Italy, (2)School of Medicine and Surgery, University of Milano-Bicocca, Milano, Milano, Italy, (3)PhD Program in Neuroscience, University of Milano-Bicocca, Milano, Milano, Italy, (4)Autism Research Unit, Villa Santa Maria SCS, Tavernerio, Como, Italy, (5)Autism Research Unit, VILLA SANTA MARIA SCS, Tavernerio, Italy

Background: Difficulties in visual behaviour are frequently reported in children with autism spectrum disorder (ASD), as well as motor impairments, which several authors described as pervasive in this population. Moreover, early visual-motor abilities predict social communication skills during childhood. However, although the importance of sensory-motor coordination is recognized in neurodevelopment, its evaluation is not always considered, particularly in low-functioning ASD individuals. Conversely, visuomotor assessment could play a crucial role in planning specific interventions, in particular in ASD children with intellectual disability who show worse difficulties in adaptation to the social environment. **Objectives:** To assess visual-motor coordination in children and adolescents with autism spectrum disorder and intellectual disability.

Methods: Thirty low-functioning ASD subjects (age range: 5-13 years; 23 males) were recruited. Global functioning was investigated using the Vineland-II - Adaptive Behaviour Scale and Childhood Autism Rating Scale – Second Edition (CARS-2). Sensory Profile - Second Edition (SP-2) and Repetitive Behaviour Scale - Revised (RBSR) questionnaires were administered to caregivers to investigate the sensory-motor profile.

Moreover, neuro-visual assessment, including ocular motility (i.e. visual pursuit and saccadic movements), visual acuity resolution, stereopsis, visual field and contrast sensitivity, and the Developmental Coordination Disorder Questionnaire (DCD-Q) used as a checklist were performed by neuro-psychomotor therapists with specific expertise. The Spearman Correlation Test was used to analyze the relationship between different outcome measures. A p-value <0.05 was considered as significant.

Results: In our sample, 53.33% of children showed difficulties in visual pursuit, 40% showed dysfunctions in saccadic movements, and 23.33% deficit in contrast sensitivity. Moreover, a partial correlation analysis, corrected for the severity of autistic symptoms, showed that a more compromised neuro-visual profile seemed to correlate to a higher visual reactivity at SP-2 ($\rho = -0.382$; $p = 0.048$). CARS-2 scores were negatively correlated to total and subtotal DCD-Q scores ($\rho = -0.773$; $p < 0.001$), to Vineland Motor Subscale ($\rho = -0.641$; $p < 0.001$) and Vineland Daily-life Abilities Subscale ($\rho = -0.408$; $p = 0.025$) (see Figure 1). There were no correlations between CARS-2 scores and the other Vineland subscales. Finally, partial correlation analysis, corrected for age, highlighted that poorer motor performances at the general motor coordination subscale of DCD-Q were negatively related to higher intensity of stereotyped behaviours ($\rho = -0.385$; $p = 0.028$) and to higher intensity ($\rho = -0.553$; $p = 0.002$) and frequency ($\rho = -0.505$; $p = 0.005$) of self-injures behaviours assessed with the RBSR questionnaire. Similarly, poorer performances at the fine motricity subscale of DCD-Q were negatively correlated to higher intensity ($\rho = -0.430$; $p = 0.020$) and frequency of stereotyped behaviours ($\rho = -0.386$; $p = 0.038$) and to higher intensity ($\rho = -0.412$; $p = 0.027$) and frequency of self-injuries behaviours ($\rho = -0.386$; $p = 0.039$).

Conclusions: Our findings highlight the frequent presence of visual and motor impairments in children and adolescents with ASD and intellectual disability. Since visual-motor difficulties in low-functioning ASD children may be considered a clinical sign of difficulty integrating perception with action to control movement, with cascading effects on overall functioning, these results emphasize the link between motor and "core" symptoms in ASD and underline the importance of explicitly considering visual-motor skills in early interventions, as in low-functioning children.

327.001 “Evaluation of the Efficacy of Oral Probiotics Supplementation in Children with Autism Spectrum Disorders (ASDs): A Randomized Double Blind, Placebo Controlled Trial”

S. Gulati¹, S. Grover², H. M. Rashmi³, S. Ojha⁴, A. Chaudhary⁵, G. Kamila⁶, P. Gupta⁷, S. Khan⁸, P. Bhat⁹, S. S. Kumaran⁸ and A. Upadhyay⁹,
(1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, Ansari Nagar, New Delhi, India, (2)Dairy Microbiology Division, ICAR- National Dairy Research Institute, Karnal, Haryana, India, India, (3)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (4)All India Institute of Medical Sciences, New Delhi, India, (5)Department of Pharmacology, All India Institute of Medical Sciences, New Delhi, India, (6)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (7)Department of NMR, All India Institute of Medical Sciences, New Delhi, Delhi, India, (8)Department of NMR, All India Institute of Medical Sciences, New Delhi, India, (9)Department of Biostatistics, All India Institute of Medical Sciences, New Delhi, India

Background:

Probiotics are live microorganisms that can offer health benefits when consumed in adequate amounts. It has been suggested that they may help reduce inflammation and modulate gastrointestinal (GI) and behavioral symptoms in Autism Spectrum Disorder (ASD) through the gut-brain axis.

Objectives:

This study aimed to assess the effectiveness of adding oral probiotic supplementation to standard treatment in improving core ASD symptoms using the Childhood Autism Rating Scale-2 (CARS-2) in children aged 2-18. Additionally, the study examined the impact of probiotics on behavioral comorbidities, cognition, sleep disturbances, GI dysfunction, and sensory issues. Changes in functional MRI (fMRI) brain connectivity and stool microbiota were analyzed in a subset of participants.

Methods:

This was a randomized double-blind placebo-controlled trial. Children aged 2-18 years fulfilling the diagnostic criteria as per DSM V for ASD and receiving standard treatment for at least 12 weeks were screened and randomised into two groups. Children with known chronic systemic illness, history of allergy and on alternative therapy were excluded. One group received probiotic *Lactobacillus rhamnosus* ATCC 21052, *Lactobacillus plantarum* ATCC 8014, *Bifidobacterium longum* subspecies *infantis* ATCC 15707 at dose of 1 billion CFU/g (Total 3×10^9) along with standard care whereas the other group received placebo packets along with standard care. Childhood Autism Rating Scale (CARS-2), Applied Behaviour Checklist (ABC), Child Behaviour Checklist (CBCL), Children's Sleep Habits Questionnaire (CSHQ), Development Quotient (DQ) and Sensory Profile-2 was done at baseline, 12 and 24 weeks. fMRI brain to assess functional connectivity changes and stool metagenomic DNA analysis for stool microbial composition were done randomly in 10 patients at baseline and 24 weeks. A total of 20 major bacterial genera identified including *Bifidobacterium*, *Escherichia-Shigella*, *Collinsella*, *Streptococcus*, *Faecalibacterium*, *Bacteroides*, and *Lactobacillus* were selected and their relative abundance was compared before and after the probiotic supplementation.

Results:

Total 103 subjects were enrolled and randomised (52-probiotic and 51-placebo), of which 13.5% were females and 56.4% had DQ $\leq 50\%$. The difference in mean CARS, ABC and CSHQ scores at 24 weeks follow up were :0.01(P=0.99); -5.16(P=0.1); 1.3 (P=0.5) respectively. Improvement seen in sensory issues, GI dysfunction and behavioural comorbidities was similar in both groups (P ≥ 0.05). On fMRI analysis of the probiotics group, post-intervention data as compared to the pre-intervention data showed significant (P=0.01) increase in functional connectivity between right Supramarginal gyrus (SMG) with right Sensorimotor cortex (SMC) inclusive of Pre and Post Central gyrus (PreCG, PostCG) whereas decreased connectivity was seen between right and left PreCG and Post CG. The probiotic supplementation improved the gut bacterial composition with an increased number of beneficial bacteria, *Lactobacilli* (P ≥ 0.05). However, no significant changes in *Bifidobacteria* were observed and the pathogenic flora like *Clostridium*, *Escherichia* and *Shigella* showed substantial reduction in both the placebo and probiotic groups.

Conclusions:

In conclusion, the study found no significant advantage of adding probiotics to standard care in improving core ASD symptoms or related issues. However, probiotics did enhance the composition of beneficial gut bacteria. Prospective multicentric studies and larger RCTs may further help in deciding the efficacy of probiotics.

327.002 Results from the Phase 2 Randomized Controlled Trial of Alogabat in Autistic Adolescents and Adults

J. Tillmann¹, P. Garces², J. F. Hipp³, C. Goeldner⁴, G. Gvozdanovic⁵, M. C. Hernandez⁵, G. Hooper⁶, M. Mehdi⁵, M. Morrison⁷, M. del Valle Rubido⁸, P. Schoenenberger⁹, L. Shafe¹⁰, D. Volz¹¹, C. Wandel¹², Y. Yamamoto⁵ and L. Murtagh⁹, (1)F. Hoffman La Roche Ltd., Basel, Basel-Stadt, Switzerland, (2)Neuroscience and Rare Diseases, Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basel, Switzerland, (3)Neuroscience and Rare Diseases (NRD), Pharma Research & Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche AG, Basel, Switzerland, (4)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (5)F. Hoffmann-La Roche Ltd, Basel, Basel, Switzerland, (6)F. Hoffmann-La Roche Ltd, Welwyn, Hertfordshire, United Kingdom, (7)Roche Products Ltd, Welwyn, Hertfordshire, United Kingdom, (8)Hoffmann- La Roche Ltd., Basel, Switzerland, (9)Neuroscience & Rare Diseases, Pharma Research & Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche AG, Basel, Switzerland, (10)Roche Products Ltd, Welwyn Garden City, UNITED KINGDOM, (11)Department of Biometrics, F. Hoffmann-La Roche AG, Basel, Switzerland, (12)F. Hoffmann-La Roche AG, Basel, Switzerland

Background: Alogabat is a small molecule, selective positive allosteric modulator of the gamma-aminobutyric acid type A $\alpha 5$ subunit-containing receptors (GABAA $\alpha 5$ R) with the potential to improve core autism symptoms - social communication/interaction and restricted and repetitive behaviors (RRBs) - by restoring excitatory-inhibitory balance in key brain regions implicated in autism.

Objectives: Aurora Borealis was a Phase II (NCT04299464), three arm, randomized, double-blind, placebo-controlled, multicenter study to investigate the efficacy, safety and tolerability of alogabat in 15-45 years old autistic participants with an IQ score of at least 50.

Methods: 104 participants were randomized to daily alogabat 20mg (n=34), or 60mg (n=36) or placebo (n=34). The primary endpoint was change from baseline (CfB) in Vineland-3 Adaptive Behavior Composite (ABC) at week 12. Key secondary endpoints included safety/tolerability and measuring RRBs including the Repetitive Behavior Scale-Revised (RBS-R), Childhood Routine Inventory-Revised (CRI-R) and Clinical Global Impression scales of Improvement (CGI-I). Anxiety and sensory symptoms were also evaluated. Furthermore, a comprehensive array of biomarkers was used to confirm pharmacodynamic effects on qEEG and evaluate candidates of treatment-predictive and response biomarkers.

Results: At baseline, participants had a mean age of 25 years (SD=7.5) and mean IQ of 98 (SD=18.7), with 75% of male participants. Alogabat was well tolerated at doses up to 60mg/day for the applied treatment duration of 12 weeks. Overall, there were neither clinically nor statistically meaningful differences detected between either of the two tested doses of alogabat and placebo on the primary Vineland-3 endpoint capturing global adaptive functioning, or on any of the key secondary endpoints including the Vineland-3 socialization and communication domain scores, and RBS-R total score. Subgroup analyses for IQ categories (IQ $\geq$ 70 vs. IQ $\geq$ 50-69) and age categories (15-17 years vs. 18 years), and further exploratory efficacy analyses were consistent with these observations. Pharmacokinetic (PK) analyses confirmed target exposure and predicted receptor occupancy. Pharmacodynamic (PD) effects were consistent with phase 1 results, showing a significant dose-dependent increase in qEEG beta-band power. This effect persisted from week 2 to week 12. Exploratory biomarker analyses to predict response to treatment - using baseline qEEG beta-band power or genetics - did not yield robust results. ERPs to faces (N170) that have been reported previously to be prolonged in autistic individuals, showed an increased latency at the highest dose. Other exploratory biomarkers that measure effects on brain circuitry underlying social function (including eye-tracking of social images/videos and digital biomarkers of speech) did not show treatment-related effects.

Conclusions: Overall, alogabat was considered safe and tolerated in autistic adult and adolescent participants. However, despite PK and PD results demonstrating clear target and circuit engagement of alogabat in autistic adolescents and adults, the evaluation of efficacy did not show any favorable effect of alogabat. State-of-the-art biomarker deployment and implemented clinical learnings from prior clinical studies in autism translated into an ambitious and high quality study that generates important learnings for future clinical trials in autism.

327.003 Inflammatory Cytokines As Biologic Signatures of the Effect of Dietary Supplementation with Omega Fatty Acids on Autism Symptoms Among Young Children: A Randomized Controlled Trial

S. A. Keim^{1,2}, **P. Taylor**¹, **D. Coury**^{2,3}, **L. Rogers**², **K. McNally**^{2,4}, **J. Rausch**^{1,2} and **L. Sun**⁵, (1)Center for Biobehavioral Health, The Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)Developmental-Behavioral Pediatrics, Nationwide Children's Hospital, Columbus, OH, (4)Neuropsychology, Nationwide Children's Hospital, Columbus, OH, (5)Center for Biobehavioral Health, Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH

Background:

Dietary supplementation with omega fatty acids has shown mixed evidence for efficacy for autism and related symptoms. Supplementation in early childhood and the particular combination of fatty acids may be critical. Mechanisms of effect are unclear, but children with ASD have elevated inflammatory markers, and certain fatty acids are anti-inflammatory. We previously reported some reductions in inflammation with fatty acid supplementation in the first Omega Heroes trial.

Objectives:

The primary objective of the second Omega Heroes trial (ClinicalTrials.gov NCT04312932) was to evaluate the efficacy of daily dietary supplementation with omega-3 and -6 fatty acids versus placebo on inflammation and to correlate changes in inflammation with changes in ASD symptoms. A second objective was to evaluate the effect of fatty acid supplementation on ASD symptoms.

Methods:

The second Omega Heroes was a single-site, fully blind, randomized, placebo-controlled trial involving 96 children ages 2-6 years with ASD. Children were allocated 1:1 to 90 days of fish plus borage oil ("fatty acids") supplementation or canola oil ("placebo"). Plasma cytokines and caregiver-reported ASD symptoms (PDD Behavior Inventory) were measured at baseline and end of trial. Changes in cytokines were tested for correlation with changes in ASD symptoms using correlation coefficients. Mixed models compared the fatty acids group to the placebo group on pre-post change in outcomes, including pre-specified tests of moderation by sex and age.

Results:

Of 96 children, 74 (77%) males, 22 (22.9%) females; 34 (35%) were ages 2-3 years, 62 (65%) were ages 4-6 years. The fatty acids and placebo groups did not differ on the change in inflammation from baseline to the end of the trial (Table 1). Changes in inflammatory markers were not correlated with changes in ASD symptoms (all Pearson r ranged -0.18 to 0.01, all $p \geq 0.10$). No main effect of fatty acid supplementation on autism symptoms was observed. There was a suggestive interaction between sex and assignment to fatty acids versus placebo (Table 2, $p=0.055$), but models stratified by sex revealed no clear effect on autism symptoms. No age-specific effects of fatty acids on autism symptoms were observed.

Conclusions:

Any effect of omega-3 and -6 fatty acids on caregiver-reported autism symptoms as measured by the PDD Behavior Inventory does not appear to operate through inflammatory pathways. Secondary outcomes including those measured by direct assessment will be examined as a next step.

Future larger studies should examine sex-specific effects in larger samples.

327.004 Improvement of Autism Spectrum Disorder Socialization Impairment after Treatment with Alpha-Methyl-Para-Tyrosine. Results and Subanalyses from the Randomized Placebo Control Parallel Cohort of a Crossover Trial

J. T. Megerian¹, **S. Golla**², **T. Fischer**³, **U. Nguyen**⁴ and **D. Q. Beversdorf**⁵, (1)Thompson Autism and Neurodevelopmental Center at CHOC, Ladera Ranch, CA, (2)Texas Institute for Neurological Disorders, Frisco, TX, (3)Yamo Pharmaceuticals, New York, NY, (4)Yamo Pharmaceuticals, Tampa, FL, (5)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, MO

Background:

There are no pharmacological interventions available to address the socialization impairments in Autism Spectrum Disorder (ASD). Catecholaminergic signaling has been implicated in regulating some behaviors in ASD, making it a potential target for treatment.

Objectives:

Determine the efficacy, safety and tolerability of the tyrosine hydroxylase inhibitor, d,l alpha-methyl-para-tyrosine (L1-79) for the treatment of socialization impairments in ASD. Subgroup analyses and a responder analysis were explored for the Vineland-3 Socialization Domain.

Methods:

Male and female subjects 12-21 years of age with ASD meeting inclusion criteria (See <https://clinicaltrials.gov/study/NCT05067582>) were randomized in a double-blind, placebo-controlled crossover study. Subjects were assigned to active (L1-79 200mg or 300mg BID) or placebo for 12 weeks, with 6-week washout, then the alternate treatment for 12 weeks. The primary outcome assessment was the Vineland-3 Socialization Domain. Clinical global impression of severity/change (CGI-S/CGI-C) and caregiver global impression of change of 3 most bothersome symptoms of ASD (CGI-3P) were key secondary measures. Analyses for crossover (N= 41, study completers) and parallel design (N=44, period 1 completers, 23 L1-79, 21 placebo) were conducted using a mixed repeated measures model with least square means comparisons. Vineland-3 Socialization Domain data were evaluated for the following subgroups: Socialization Standard Score (VSSS) <75 at baseline (ie, less than 5th percentile), IQ (WASI-II ≤93 and >93), and age (12-15 and 16-21 years). A responder analysis using different thresholds for improvement in the VSSS was also evaluated.

Results:

Carryover effects invalidated the crossover design, therefore parallel group data from period 1 completers were analyzed as the primary efficacy population. There were statistically and clinically significant improvements in the VSSS for L1-79 versus placebo treatment (difference: 7.94, p=0.0115). Improvements resulted from Play and Leisure (difference 2.8, p=0.01); and Interpersonal Relationships (difference = 1.5, p = 0.145) subdomains. Similar findings were seen for CGI-S and CGI-3P (CGI-S difference: -0.62, p=0.0155; CGI-3P Symptom 1: -0.6, p=0.0293, Symptom 2: -0.48, p=0.0399; Symptom 3: -0.61, p=0.0469). Subgroup analyses revealed greater improvements in the VSSS for individuals functioning below the 5th percentile at baseline (difference, 10.76, p=.008). Response was greater in higher IQ and younger age groups. The predefined responder analysis (3-point improvement from baseline in VSSS, or 1-point improvement in 2 of 3 subdomains) did not show significant separation between active and placebo. However, using larger change from baseline (CFB) as the responder definition demonstrated nearly 2x greater number of responders for those receiving L1-79 vs placebo over a range of responder definitions (e.g., 5-to-15-point CFB in the VSSS). L1-79 was well tolerated with no serious adverse events or adverse events leading to withdrawal.

Conclusions:

L1-79 demonstrated statistically significant and clinically meaningful improvements in socialization as measured by the VSSS and socialization focused clinician and parent rating scales. A larger magnitude of response was seen in individuals with greater social impairment present at baseline, higher IQ and younger age. response rates for active treatment were consistent over a wide range of responder definitions. Larger trials are warranted to explore the efficacy of this agent for socialization in ASD.

**Oral Session -****328 - Mechanisms and Therapeutic Development in Genetic Neurodevelopmental Disorders**

May 2nd, 2025, 5:30 PM - 6:30 PM - 4C-1,2

Moderator: Suma Jacob, UCLA, Los Angeles, CA

328.001 Developing a Targeted Genetic Therapy for SYNGAP1-Related Intellectual Disabilities

J. L. Silverman¹, R. Ben-Shalom², T. A. Fenton³, E. R. Monsen⁴, K. Fink⁵, J. Halmi⁶ and P. Vij⁷, (1)Department of Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Neurology, UC Davis School of Medicine, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, UC Davis School of Medicine, Sacramento, CA, (4)Psychiatry and Behavioral Sciences, UC Davis School of Medicine MIND Institute, Sacramento, CA, (5)Department of Neurology, Institute for Regenerative Cures (IRC) UC Davis School of Medicine, Sacramento, CA, (6)Neurology, University of California Davis School of Medicine, Sacramento, CA, (7)Institute for Stem and Gen Cell Therapy, University of California-Davis School of Medicine, Sacramento, CA

Background: *SYNGAP1* is a critical gene for neuronal development, synaptic structure, and neuronal function. Loss at the synapse leads to aberrant neuronal communication. In addition to the dysregulation of synaptic signaling, loss of SynGAP1 also results in dysregulated Ras GTPase cellular signaling and RAS/MAPK pathway disruption. Clinically, this dual dysregulation of inter- and intracellular communication results in debilitating and severe consequences. Mutations in SynGAP1 cause a severe neurodevelopmental disorder (NDD), characterized by global developmental delay, intellectual disabilities (ID), hypotonia and motor impairments, ASD, and recurring seizures that result in developmental epileptic encephalopathy (DEE). Although SynGAP1-related ID (SRID) is a rare disorder, it is one of the most common IDs, accounting for ~1-2% of IDs, with genetic etiology. Currently, there are no therapies or treatments targeted for SRID, marking a critical unmet medical need.

Objectives: To restore lifelong restoration of SYNGAP1 gene and protein expression by leveraging the endogenous allele by targeted gene regulation, capturing all isoforms and post-transcriptional modifications.

Methods: We have developed a novel modular CRISPR activation system for gene regulation. Preliminary data generated a lead guide therapeutic construct that increased SYNGAP1 mRNA and SynGAP1 protein expression using patient-derived iPSCs. An initial panel of 15-30 sgRNAs were designed using the CHOPCHOP online algorithm and are screened via transient transfections in human iPSC cells to evaluate gene activation. All experiments are performed with an unguided dCas9 (NG) and a dCas9-No Effector, to serve as negative controls. Each experiment is performed in biological triplicate (independently reproduced at least 3 times), as per prior studies. Demonstration of therapeutic lead efficacy is measured by RT-qPCR adhering to the MIQE guidelines (dMIQE), and Western blots and/or human SYNGAP1 Elisa kits (commercially available), validated by our group. Functional efficacy will be determined by high density microelectrode array recordings (HD-MEA), using 2D and 3D models of patient derived iPSCs, and primary neurons from the humanized Prosser mouse model. In vivo translational rescue was performed by behavioral and neurophysiological assays previously published by the Silverman laboratory.

Results: Previously, we have also reported behavioral impairments, resulting from the loss of *Syngap1*^{-/-}, and impairments in the translational biomarkers of sleep, power spectral density bands using EEG, local network bursting anomalies and hyperexcitability, recently published in Fenton et al. (2024), bridging neuronal network firing patterns *in vitro* to neurophysiological phenotypes *in vivo*. We crossed the humanized backbone Prosser *SYNGAP1* mouse with the Hugarir *Syngap1*^{-/-} mutant mouse to discover that mutant phenotypes and effect size, remained fully intact. We have started assessing therapeutic efficacy in primary neurons from the humanized mouse and iPSCs, along with optimizing translational neurophysiological outcomes for *in vivo* reversal.

Conclusions: We will employed a battery of behavioral, seizure and neurophysiological assays, to inform us, if functional reversal of Syngap1 by AAV-CRISPRa therapeutic is feasible. Upon completion, this work would advance a targeted therapeutic for SRID while also advancing translational science for precision therapeutics for individuals with genetic NDDs.

328.002 Defining Mechanisms of TBR1 Syndrome Using Diverse Allelic Variants

M. Col^{1,2}, G. K. O'Brien¹, D. J. Weingarten², B. L. O'Connell¹, C. L. Le Moing², A. C. Adey^{1,3}, S. L. Jackman², K. M. Wright² and B. J. O'Roak¹,

(1)Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR, (2)Vollum Institute, Oregon Health & Science University, Portland, OR, (3)Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR

Background: Heterozygous *de novo* variants in *TBR1* cause a rare form of autism called TBR1 Syndrome, which involves intellectual disability, behavioral challenges, and speech and motor impairments. *TBR1* encodes a neuronally expressed transcription factor (TF) considered a “master regulator” of autism risk gene expression in the developing cortex. The types and genomic locations of patient-associated *TBR1* variants predict at least three major functional subclasses: (1) **early-truncating variants** leading to *TBR1* haploinsufficiency, (2) **missense variants** impacting the T-box DNA-binding domain, and (3) **late-truncating variants** impacting the T-box TF-associated domain, the function of which is unknown. Late-truncating variants, including a highly recurrent frameshift variant p.T532Rfs*144, are associated with more severe clinical phenotypes than other *TBR1* variants. Across all variant subclasses, *TBR1* heterozygosity leads to reduction of the anterior commissure (AC), an axon tract linking ventral cortical areas between brain hemispheres. *Tbr1* haploinsufficient mice show altered autism-related behaviors and reduction of the AC, but the phenotypes and underlying mechanisms associated with missense and late-truncating variants have not been fully characterized.

Objectives: We sought to identify the molecular and cellular mechanisms by which *TBR1* variant subclasses contribute to shared autism risk as well as phenotypic heterogeneity in TBR1 Syndrome.

Methods: Using CRISPR-Cas9, we generated an allelic series of *Tbr1* mutant mice representing three predicted *TBR1* variant subclasses. We used biochemical, histological, genomic, and behavioral assays to assess the impacts of variant subclasses on TBR1 levels, brain morphology, gene regulation, and social and motor phenotypes. CRISPR-generated *Tbr1* mutants were also compared to previously generated *Tbr1*-null alleles.

Results: We found that in early postnatal cortex, early-truncating variants led to decreased TBR1 protein, the missense variant p.K228E led to increased TBR1, and late-truncating frameshift variants led to increased or decreased TBR1 depending on the open reading frame generated. We observed dissimilar cortical phenotypes among homozygotes of each variant, suggesting varying degrees of *Tbr1* functionality across variant subclasses. However, we observed similar AC phenotypes across heterozygotes, suggesting sensitivity of this brain structure to *Tbr1* perturbation. Across early-truncating, missense, and *Tbr1*-null variants, we identified convergent dysregulation of extracellular matrix, neurotrophin, and Wnt signaling-related transcripts in embryonic *Tbr1* heterozygous cortex. We also identified altered social interaction and increased open field activity in early-truncating and missense *Tbr1* mutants. Ongoing experiments will further examine gene regulation and behavioral phenotypes in *Tbr1* mutant mice, including late-truncating frameshifts.

Conclusions: Using CRISPR-generated mouse models with patient-associated *Tbr1* variants, we provide evidence for variant subclass-specific effects on TBR1 protein levels in the developing brain. These variants show functional differences at homozygosity but converge to impact axon tract development and autism-related behaviors at heterozygosity, indicating face validity for TBR1 Syndrome. Future studies will harness this allelic series to elucidate molecular interaction networks altered in broader autism and evaluate potential therapeutic approaches for alleviating autism symptoms.

328.003 A Single Patient Trial of Fluoxetine in KCNC1-Related Disorder

D. A. Baribeau¹, G. Costain², E. Anagnostou¹, E. Heon², A. Vincent², J. Vorstman², C. Gorodetsky², J. Dowling², M. Bedford² and K. Amburgey²,

(1)University of Toronto, Toronto, ON, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: With advances in genetic testing, a growing number of children with neurodevelopmental disabilities are being diagnosed with rare genetic conditions. Research evidence to guide care in these rare genetic neurodevelopmental conditions is lacking, yet large scale clinical trials are unfeasible due to small sample sizes. KCNC1 related disorder, for example, is an ultra-rare neurologic and developmental disorder caused by a genetic variant in the gene coding for a potassium channel subunit (Kv3.1). Potassium channels are important to regulating neuronal firing and resting membrane potentials; KCNC1 related disorder is associated with developmental delays and seizures. A 2023 case report described a child with epilepsy and a missense variant in KCNC1 resulting in a gain of function effect on the Kv3 channel and hyperpolarization of the resting membrane. Fluoxetine has been shown to have inhibitory effects on the Kv3.1 subunit in vitro. In vitro cellular kinetics were improved with fluoxetine treatment, and clinical treatment with fluoxetine was noted to improve the child's motor delays (1).

Objectives: The primary objective of this study was to objectively evaluate the safety and effectiveness of fluoxetine to treat motor delays in a child with KCNC1 related disorder and a gain of function variant.

Methods: Whole-cell voltage clamp electrophysiological studies confirmed a hyperpolarizing/ gain of function effect (2). Using a randomized, double-blind (within subject) multiple baseline ABA-phase design clinical trial, the effects of fluoxetine in a single preschool aged child with KCNC1 related disorder were examined over 40 weeks. Here, the participant started on placebo (A), and then the active treatment start (B) and stop (A) moments, as well as dose transition moments, were blinded and randomized. The primary outcome was motor development as measured by weekly parent report on the Early Motor Questionnaire, as well as safety as measured by adverse event reporting and the Clinical Global Impression Scale. Clinical biomarkers were collected in parallel, including electroencephalography, electroretinography, and optical coherence tomography.

Results: Full trial results are expected December 2024 and will be presented. This session will also a) present design elements and methodological considerations related to single subject trials in ultra rare conditions broadly, b) discuss considerations for co-designing a study with a single participant family, and c) review complexities related to regulated single subject trials in rare paediatric conditions.

Conclusions: Accessible opportunities for individualized clinical research in rare genetic conditions will be essential for building treatment evidence to guide care. This work is very much in line with the goal of personalized care for autistic individuals and their families, many of whom have been diagnosed with rare and/or genetic conditions.

328.004 Using Mouse Models to Help Subgroup Participants for Clinical Trials

J. Ellegood¹, A. Beauchamp², J. P. Lerch² and E. Anagnostou¹, (1)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Mouse Imaging Centre, The Hospital for Sick Children, Toronto, ON, Canada, (3)Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, ON, United Kingdom

Background: The heterogeneity of Autism and other Neurodevelopmental Conditions (NDCs) makes it difficult to understand the underlying biology and hinders the ability to run a successful clinical trial. It is likely that there are distinct clusters or subgroups within the clinical population that would lead to a more successful trial, but how one identifies these subgroups is debatable. One promising approach is to use structural MRI. However, in human participants, neuroanatomical clustering provides limited information into the molecular basis in identified clusters.

Objectives: Use cross-species analytics to provide molecular signatures to human subgroups to streamline treatment and aid in clinical trial outcomes.

Methods: Four data sets were used: 1. T1w MRI scans from 700+ individuals in the POND Network, 2. T2w MRI scans from 4000+ mice across 135 different genetic mouse lines related to NDCs, 3. T1w MRI scans from 1000+ individuals from the Healthy Brain Network (HBN), as a replication cohort, and 4. Mouse and human gene expression data from the Allen Institute.

Creating neuroanatomical clusters – The MRI scans were registered together separately for each species. Using absolute and relative volume information, we computed effect size maps with respect to controls. We then used similarity network fusion (Wang et al., 2014) and spectral clustering to identify neuroanatomical clusters in the mouse and two human datasets.

Linking clusters across species – We evaluated the similarity across species using a gene expression common space (Beauchamp et al. 2022). We created a gene expression signature for every cluster by averaging the expression of 2835 homologous genes over all voxels and correlated the expression signatures between mouse and human clusters.

Annotating biological pathways – For the mouse clusters, we expanded our cluster gene sets into gene neighbourhoods by using the STRING database (<https://string-db.org>) to identify one-hop protein-protein interactions. We used the Reactome database (<https://reactome.org/>) in combination with gene annotations from the Bader Lab (<https://baderlab.org>) to evaluate the over-representation of molecular pathways in each cluster.

Results: The optimal human and mouse cluster solutions, derived based on the distributions of the spectral clustering eigengap metric, indicate a 2-cluster solution for the human participants from the POND cohort, a 3-cluster solution for the human participants from the HBN cohort and a 4-cluster solution for the mouse. There were two 3-way matches at the optimal solutions (Figure 1). This demonstrates that the clusters identified are not specific to one cohort, instead they capture robust patterns of neuroanatomical organization among individuals with NDCs. This work lays the framework for participant selection in clinical trials and individualized treatment as a gene list of interest can be used to measure enrichment cross species. Additionally, neuroanatomical differences alone in an individual can help to sub-categorize them and streamline treatment.

Conclusions: The heterogeneity of Autism and NDCs suggest that the current diagnostic classification does not reflect a unique biological category. The identification of sub-groups with convergent biology is crucial for the development of effective therapies. The novel data-driven methods for linking brains across species provides a promising avenue towards this goal.

417.001 Age-Dependent Effects of PI3K Inhibition on Autism-Relevant Neurodevelopmental Phenotypes in a Model of PTEN Haploinsufficiency

K. Espinoza¹, A. E. Clipperton-Allen², A. Zucca² and D. T. Page^{1,3}, (1)Norcliffe Foundation Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA, (2)Neuroscience, The Herbert Wertheim UF Scripps Institute for Biomedical Innovation & Technology, Jupiter, FL, (3)Department of Pediatrics, University of Washington, Seattle, WA

Background: Dysregulation of the PI3K-Akt-mTOR signaling pathway, essential for regulating cell growth, survival, and protein synthesis, has been linked to macrocephaly and autism spectrum disorder (ASD). *PTEN* encodes a phosphatase that negatively regulates phosphoinositide-3-kinase (PI3K). In individuals with ASD and macrocephaly, *PTEN* loss-of-function mutations are present in 10–20% of cases. Despite this, the contributions of PI3K activity to neurodevelopmental phenotypes in *PTEN*-ASD remain poorly understood.

Objectives: This study aims to determine whether pharmacological inhibition of PI3K can rescue ASD-relevant phenotypes in a model of *Pten* haploinsufficiency and to identify critical periods for effective intervention.

Methods: Juvenile (postnatal days 4–14) and adult (postnatal days 30–50) *Pten* haploinsufficient (*Pten*^{+/−}) and control mice received daily doses of the brain-penetrant PI3K inhibitor GDC-0084. Neuroanatomical assessments included measurements of brain mass, cortical layer V neuron size, and corpus callosum thickness at the midline.

Results: Consistent with previous findings, both juvenile and adult *Pten*^{+/−} mice exhibited heavier brains, larger cortical layer V neurons, and thicker corpus callosum compared to controls. Following GDC-0084 treatment, no change in brain mass was observed in either age group. In juveniles, drug-treated *Pten*^{+/−} mice showed a significant decrease in the size of layer V cortical neurons, with no change in corpus callosum thickness. In contrast, in adults, we observed a partial rescue of corpus callosum thickness in drug-treated *Pten*^{+/−} mice while layer V cortical hypertrophy remained unchanged.

Conclusions: These findings suggest age-dependent differential effects of PI3K inhibition. In juveniles, the rescue of cortical layer V hypertrophy—but not brain overgrowth or white matter abnormalities—may indicate that PI3K/mTOR-independent mechanisms underlie these phenotypes. In adults, the rescue of corpus callosum overgrowth could suggest a drug effect that impacts glial cell populations. Ongoing experiments are exploring the role of glial cells in mediating these effects, ultimately aiming to diversify potential therapeutic targets for individuals with *PTEN*-ASD. This study addresses a critical gap in understanding the contributions of PI3K activity to neurodevelopmental phenotypes in *PTEN*-ASD models and highlights the importance of identifying age-dependent critical periods of PI3K inhibition in developing targeted therapies.

417.002 Atypical Behaviours in the Offspring of Vitamin D Insufficient Female RATS Replicate Autism Spectrum Disorder Phenotype

R. L. George¹, K. S. Nair², N. A. Thomas³, K. P. Mohanakumar³ and U. Rajamma³, (1)INTER UNIVERSITY CENTER FOR BIOMEDICAL RESEARCH AND SUPER SPECIALITY HOSPITAL (IUCBR & SSH), Kottayam, Kerala, India, (2)Inter University Centre for Biomedical Research & Super Specialty Hospital, Kottayam, Kerala, India, (3)Inter University Centre for Biomedical Research & Super Specialty Hospital, Mahatma Gandhi University Campus at Thalappady, Kottayam, Kerala, India

Background: In recent years, significant attention has been given to the importance of maternal nutrition in influencing behavioral outcomes in offspring, particularly concerning neurodevelopmental disorders. Among various nutrients, Vitamin D is a crucial factor affecting neurodevelopment during critical prenatal periods. Insufficient Vitamin D levels in expectant mothers can hinder neural development and potentially lead to behavioral abnormalities associated with autism spectrum disorder (ASD). Research suggests low levels of Vitamin D are associated with a higher risk of psychiatric disorders, including ASD. Therefore, it is essential to use animal models to study the effects of Vitamin D deficiency during development to understand whether maternal Vitamin D deficiency is a risk factor for ASD and to clarify the mechanisms through which such deficiency may contribute to neurodevelopmental deficits. Studies in animals have demonstrated maternal Vitamin D deficiency can result in social deficits, repetitive behaviors, and impaired communication in offspring, which aligns with the diagnostic criteria for ASD. Due to the complex nature of ASD, exploration of the relationship between Vitamin D insufficiency and its associated risks is warranted.

Objectives: Investigation of the impact of maternal vitamin D insufficiency on the vitamin D status, early developmental trajectories, and autism spectrum disorder (ASD)-related behavioral characteristics of offspring.

Methods: Female Sprague Dawley rats, one month old, were fed vitamin D-deficient rodent diet (AIN-93G) and exposed to incandescent lighting for a period of six weeks and were kept on this diet until weaning. Vitamin D level was tested using ELISA technique. Pups were monitored at specific postnatal days (P5, P8, and P17) for parameters such as body weight, nose-tail length, righting reflex, and negative geotaxis. Behavioral experiments were conducted on P30, including marble burying, infrared actimeter, social play assessments, three-chambered sociability, and elevated plus maze tests.

Results: Pups of female rats fed on vitamin D-depleted AIN 93G diet exhibited a vitamin D insufficiency of 55.5% compared to pups from control diet. The offspring demonstrated significantly reduced body weight and diminished nose-to-tail length compared to controls. Additionally, they exhibited significantly longer negative geotaxis response time on P17 compared to controls. The DVD group buried significantly fewer marbles, and mainly stayed along the arena's boundaries. In contrast, control group dug, played, and explored the entire platform. In IR actimeter experiment, DVD rats exhibited significantly lower global activity, fewer rearing episodes, and lesser distance traveled than the controls. In the Plus Maze test, DVD rats spent more time in closed arms, though they made fewer entries into the closed arms than the controls and their movements in closed arms appeared more stereotyped. In the 3-chambered test and social play analysis, the DVD rats spent significantly more time exploring novel rat chamber and showed more pouncing and wrestling activities with the novel rat than the control group.

Conclusions: Atypical behaviors observed in the offspring of Vitamin D-insufficient female rats parallel established ASD phenotypes in children. By examining these behaviors through neurobiological and environmental interactions, we will elucidate the mechanisms by which maternal Vitamin D deficiency predispose offspring to ASD.

417.003 Chd8-Dependent Molecular and Functional Vulnerabilities in the Developed Cerebellum

E. M. Merino¹, S. J. Jung¹, N. Seban², K. Cichewicz², M. R. Mbah¹, D. Rivera¹, C. Bazan¹, E. G. Antzoulatos¹, C. P. Canales³, A. S. Nord³ and D. Fioravante⁴, (1)University of California Davis, Davis, CA, (2)UC Davis Center for Neuroscience, Davis, CA, (3)Department of Psychiatry and Behavioral Sciences, UC Davis Center for Neuroscience, Davis, CA, (4)Neurobiology, Physiology and Behavior Center for Neuroscience, UC Davis Center for Neuroscience, Davis, CA

Background: Even though the cerebellum has been consistently and causally associated with autism spectrum disorders (ASD), cerebellar contributions to ASD-relevant pathology remain understudied compared to forebrain regions. The chromatin remodeler *CHD8* represents a model for rare monogenic neurodevelopmental disorders with a core set of symptoms associated with ASD. *CHD8* is highly expressed throughout the brain early in development and remains elevated in the adult cerebellum but not adult forebrain. This raises the previously unexplored hypothesis that *CHD8* may continue to contribute to cerebellar function and ASD pathology in the adult.

Objectives: Define the impact of *Chd8* ablation on adult cerebellar function across genomic, electrophysiological and behavioral dimensions.

Methods: We applied genomic, electrophysiological and behavioral assays to examine deficits in adult cerebellar physiology and function. We analyzed differential gene expression via RNA sequencing from *Chd8* heterozygous mutants and wild-type littermates. Using the same model system, we examined electrophysiological signatures of cerebellar output neurons in vivo. Finally, using conditional genetic manipulations of *Chd8* that were spatially and temporally restricted to the adult cerebellum, we investigated impacts on motor performance and learning, affective state, regulation of learned fear and social behaviors.

Results: We identified differentially-expressed genes (DEGs) that indicated perturbation to metabolic and synaptic pathways, with gene targets that bore relevance to cellular electrophysiological properties. We detected disrupted neural activity profiles in the deep cerebellar nuclei consistent with neural hyperexcitability and elevated cerebellar output. Finally, we uncovered behavioral deficits specifically in motor learning and preference for social novelty.

Conclusions: Our findings point to novel *Chd8*-dependent molecular and functional vulnerabilities in the adult cerebellum with relevance to ASD. Ongoing work will resolve specific cell types and molecular cascades in identified neural circuits that drive neuropathology and motor and social deficits. By pinpointing biological processes and circuits that remain vulnerable to *Chd8* ablation in the developed cerebellum, this line of research has the potential to identify novel therapeutic targets over a time-extended treatment window.

417.004 Differential Expression of Synaptic Genes in the Amygdala: Comparing Autism Spectrum Disorder and Nonhuman Primate Models of Maternal Immune Activation

H. C. Zakharenkov^{1,2}, E. L. Carlson^{2,3}, M. Duong^{1,2}, B. Ander^{2,4}, K. L. Hanson^{2,3}, S. Kamboj^{1,5}, K. D. Murray⁶, A. S. Fox^{1,5}, M. D. Bauman^{1,2,6} and C. M. Schumann^{2,3}, (1)California National Primate Research Center, Davis, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA, (4)Neurology, University of California Davis, Davis, CA, (5)Psychology, University of California Davis, Davis, CA, (6)Physiology and Membrane Biology, University of California Davis, Davis, CA

Background:

Children prenatally exposed to maternal infection have an increased risk of neurodevelopmental disorders, such as autism spectrum disorder (ASD) and schizophrenia. Preclinical models of maternal immune activation (MIA) suggest the maternal immune response can lead to long-term changes in brain development and behavior in offspring. Alterations in socioemotional development have emerged as a common feature of MIA-exposed offspring, which implicate disruptions to core functions of the amygdala. Identifying cell-specific transcriptional changes in amygdala may serve as a crucial translational bridge for understanding the association between MIA and the risk of neurodevelopmental disorders.

We previously conducted single-nucleus RNA sequencing (snRNA-seq) on amygdala brain tissue obtained from MIA-exposed nonhuman primate offspring at 4 years of age and identified dysregulated genes linked to synaptic structure and function, with significant overlap among genes associated with ASD. We intend to explore the relationship between amygdala synaptic gene dysregulation in MIA-exposed offspring and human neurodevelopmental disorders.

Objectives:

We use a multi-tiered approach aimed to: (1) perform overrepresentation analysis with disorder-related gene databases to investigate MIA-related transcriptional changes, (2) measure gene expression changes of synaptic genes in the amygdala of individuals with ASD, (3) compare gene expression patterns between MIA-exposed nonhuman primates and individuals with ASD within amygdala, and (4) map synaptic gene expression in the amygdala across human and nonhuman primate models.

Methods:

First, we performed an overrepresentation analysis of nonhuman primate MIA amygdala (lateral nucleus) snRNA-seq data and compared differentially expressed genes with risk genes for autism, anxiety, schizophrenia, and other disorders to determine overlap with the MIA model. Next we measured the expression levels of targeted synapse-related transcripts in postmortem ASD and control amygdala using the QuantiGene Plex Assay kit. We then used RNAscope HiPlex on human and non-human primate amygdala tissue sections to map synapse-related transcripts in identified cell types.

Results:

Overrepresentation analysis of differentially expressed genes in the amygdala of MIA-exposed nonhuman primates revealed significant overlap with ASD and schizophrenia related gene databases but not in other datasets linked to anxiety or non-psychiatric disorders. In human ASD amygdala, the expression of genes associated with synaptic function (*GRIN2B*, *GRIA2*, *NRXN1*, *SHANK2*, *GRIA3*, *SYN1*, *HOMER1*, *SHANK3*, *SYNGAP1*, *SHANK1*) was significantly upregulated. However, synaptic genes in MIA neuron subclusters were largely downregulated for many of these same transcripts.

Conclusions:

Our study found significant changes in synaptic gene regulation in both human ASD and MIA-exposed nonhuman primate amygdala. MIA exposure led to the downregulation of many accepted ASD risk genes, while human ASD samples showed upregulation of the same genes. Both patterns of differential gene expression point to synaptic dysregulation, which can impact neurodevelopment and daily neural functions. Transcriptional changes in MIA were largely in excitatory neuron clusters and could therefore upset the balance of excitatory/inhibitory synaptic tone, a critical factor for normal development and function. In amygdala, these changes could influence key social and emotional behaviors seen in ASD. Knowledge of the molecular and cellular changes associated with neurodevelopmental disorders such as ASD enables us to better focus future research on their underlying mechanisms.

417.005 Dissecting KMT5B's Role in Motor Function Using Conditional Knockout Mice

H. F. Feser Stessman, J. Hulen and J. Hallgren, Pharmacology & Neuroscience, Creighton University School of Medicine, Omaha, NE

Background: Germline heterozygous disruptive variants in lysine methyl transferase 5B (KMT5B/SUV420H1) have been linked to a syndrome characterized by developmental delays, intellectual disability, autism spectrum disorder, and a high rate of motor deficiencies in humans. Using a mouse model of this condition, we have previously reported early motor reflex deficits, decreased hindlimb skeletal muscle weights, decreased neuromuscular strength, and increased neuromuscular junction fragmentation in the germline *Kmt5b* heterozygous (HET) state compared to wild-type (WT) littermates. Paradoxically, these phenotypes were underscored at the histopathological level by increased numbers of fast-twitch myofibers that were significantly smaller in size in HET compared to WT muscles. The source of these motor phenotypes is currently unknown.

Objectives: To utilize conditional mouse genetic knockout models to better understand whether KMT5B-linked motor phenotypes are driven by KMT5B-specific regulation of skeletal muscle and/or motor neuron function.

Methods: Floxed *Kmt5b* mice were crossed to a B6.129S1-*Mnx1^{mt(cre)Tmj/J}* line expressing cre-recombinase driven by the *Mnx1* promoter for motor neuron-specific *Kmt5b* knockout ("mn") and a B6.Cg-Tg(*ACTA1-cre*)79Jme/J line expressing cre-recombinase driven by the *ACTA1* promoter for skeletal muscle-specific *Kmt5b* knockout ("sm"). From both lines, conditional WT, HET, and knockout (KO) progeny were subjected to a small battery of early motor reflex and strength testing. Mice were then sacrificed, hindlimb soleus (SOL) and extensor digitorum longus (EDL) muscles were weighed, and additional molecular experiments were performed. Independent cohorts of male and female mice were tested in all experiments. Groups were compared using a 2-way ANOVA (variables of genotype and sex) or repeated measures ANOVA with post hoc testing (Šidák's test or similar).

Results: Knockout of *Kmt5b* contained to skeletal muscles/sm or motor neurons/mn was postnatally viable (Chi-square test not significant), in contrast to germline *Kmt5b* KO. While early motor reflexes (surface righting and grasping strength) were not changed in mn mice, surface righting time was significantly slower in smHET compared to smWT female mice ($p=0.0248$; Šidák's test). Weekly measures of strength collected from postnatal day (P) 17-59 showed a significant interaction between age and genotype ($F_{(6, 177)}=2.681$; $p=0.0163$) driven primarily by females in the mn model. While strength was also reduced in smHET and smKO mice, this was not statistically significant. Skeletal muscle weights (SOL and EDL) collected from adolescent (P17) and young adult (P59) mice showed no significant differences in the sm model as well as no change in total body weights over time. Interestingly, there was a significant effect of genotype ($F_{(2, 56)}=15.26$; $p<0.0001$) on P59 EDL weight driven by large increases in mnHET males and females. MnHET animals also had higher body weights than their mnWT littermates which reached statistical significance in males ($F_{(2, 59)}=3.955$; $p=0.0244$).

Conclusions: Our data suggest that the increased myofiber counts reported in the germline *Kmt5b* model could be due to specific KMT5B effects on motor neuron function rather than skeletal muscle development. Further, our data suggest that the full spectrum of motor deficits identified in germline *Kmt5b* mice are likely due to impacts on multiple systems.

417.006 Loss of m6A mRNA Readers in Zebrafish Model Impacts Head Size Phenotypes Implicated in AutismG. N. La¹, N. K. Haghighi¹ and M. Y. Dennis², (1)Biochemistry and Molecular Medicine, University of California, Davis, Davis, CA, (2)Biochemistry & Molecular Medicine, MIND Institute, Genome Center, University of California Davis, Davis, CA

Background: Autism (ASD) is a complex neurodevelopmental condition encompassing a diverse range of phenotypes. ASD is highly heterogeneous in both phenotypic presentation and genetic predisposition, leaving much to be uncovered regarding its genetic etiology. Focusing on disproportionate megalencephaly (DM), a subphenotype of ASD where individuals have an enlarged brain disproportionate to their height, we identified two probands harboring cases of *de novo* mutations in two m⁶A-mRNA reader genes with no prior association with ASD — a duplication of *YTHDF2* and a loss of function mutation in *YTHDC1*, respectively. Within the m⁶A mRNA pathway, readers are proteins that bind and interact with m⁶A-modified transcripts in the nucleus and cytoplasm, dictating the balance and timely export, translation, stabilization, and degradation of their target transcripts. For example, YTHDF2 promotes degradation of m⁶A-mRNAs in the cytoplasm, while YTHDC1 resides in the nucleus, facilitating alternative splicing, polyadenylation, and nuclear export. Our preliminary data using zebrafish show that knocking out *ythdf2* yielded smaller brain area (Wilcoxon T-test p-value <0.01 , $n=42$) and overexpression via injected in vitro transcribed mRNAs resulted in larger brain area (Wilcoxon T-test p-value of 0.0013, $n=56$), recapitulating patient phenotypes.

Objectives: Following these results, we aimed to look towards other m⁶A mRNA reader genes including *ythdc1*, *ythdc2*, *ythdf1*, and *ythdf3*, to see how loss of function may also impact head and brain size phenotypes in our zebrafish model. Like YTHDF2, we believe additional m⁶A-mRNA readers may play a role in dictating the fate of m⁶A-modified transcripts relevant to neurogenesis.

Methods: Zebrafish knockouts (KOs) were facilitated by injecting CRISPR SpCas9 and a mix of guide RNAs (gRNAs), targeting the gene of interest, at the single-cell stage. KOs were compared to scrambled gRNA-injected controls. At 3 days post fertilization, high throughput imaging and morphometric screening was performed on zebrafish larvae, as seen in Figure 1A. Measurements, such as distance between the eyes and telencephalon serve as proxies for head size and may be indicative of brain size. Current use of lightsheet microscopy and analysis of brain area in transgenic larvae expressing GFP as a broad neuronal marker, aim to validate these findings.

Results: Upon knocking out these genes, we see significantly smaller head sizes in *ythdc1* KOs, showing decreased distance between the eyes, and significantly larger head sizes in *ythdf3* KOs, demonstrated by increased telencephalon and distance between the eyes, at 3 days post fertilization (refer to Figure 1B). Additionally, we see potential developmental delay among *ythdc1*, *ythdf1*, and *ythdf3* knockouts, indicated by reductions in body length compared to control. Relevant to ASD-DM, *ythdf3* KOs exhibit disproportionately larger head sizes, despite being smaller compared to controls.

Conclusions: Altered m⁶A mRNA modifications and expression of readers have been found to impact early neurodevelopment. Our work expands our mechanistic understanding of m⁶A-mRNA readers in the context of ASD etiology, potentially connecting m⁶A mRNA modifications as a contributor to this complex condition.

**417.007** MOUSE-Decc: Maximizing Outcomes Using Smart Engine for Diverse Experimental Collaborative Cross in Autism ResearchZ. Shakkour¹, P. Carney² and C. R. Shyu³, (1)MU Institute for Data Science and Informatics, University of Missouri, Columbia, MO, (2)Neurology, University of Missouri, Columbia, MO, (3)Institute for Data Science and Informatics, University of Missouri - Columbia, Columbia, MO

Background: Collaborative Cross (CC) mouse lines are a valuable platform for preclinical research, capturing the genetic diversity of human populations. Derived from eight founder strains, these lines represent approximately 90% of the common genetic variation in *Mus musculus*, encompassing over 40 million SNPs and a diverse array of haplotypes. This extensive genetic diversity provides a broader phenotypic spectrum, which is particularly critical for autism research due to the complex interplay of genetic and environmental factors influencing autism spectrum disorders (ASD).

Objectives: The study aims to address the challenges researchers face in selecting CC strains for autism research, focusing on improving the strain selection process to facilitate the investigation of genes, pathways, and phenotypes associated with ASD.

Methods: MOUSE-DECC (Maximizing Outcomes Using Smart Engine for Diverse Experimental Collaborative Cross) utilizes a systematic, data-driven approach to optimize strain selection. By integrating comprehensive genotype-phenotype data, the platform identifies strains with genetic susceptibility or resilience to ASD-related traits and links optimized strain selection to relevant behavioral assays, such as social interaction and repetitive behavior assessments.

Results: MOUSE-DECC enhances research efficiency by allowing for more accurate predictions of strain-specific behavioral outcomes, minimizing the number of animals required for testing. The streamlined selection process is expected to save resources, reduce costs, and decrease the overall number of mice needed for experiments.

Conclusions: By facilitating a more tailored and efficient approach to CC strain selection, MOUSE-DECC addresses the urgent need for preclinical models that reflect the multifactorial nature of ASD and other complex diseases, enabling targeted investigations into specific genetic variants and their impacts on treatment responses.

417.008 Motor and Cognitive Behavior of Young and Aged FMR1 Knockout Rats

B. Sivayokan¹ and B. Plakke², (1)Kansas State University, Manhattan, KS, (2)Psychological Sciences, Kansas State University, Manhattan, KS

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by difficulties in social interaction and communication, and repeated or restricted behaviors and interests. Fragile X syndrome (FXS) is a leading single-gene cause of ASD as well as the most common cause of intellectual disability. It is caused by loss of the protein FMRP due to expansions in the *FMR1* gene, leading to hyperconnectivity and hyperexcitability. This causes motor deficits and cognitive impairment. Carriers of the *FMR1* premutation also develop these deficits as they age.

Objectives: This study uses an *FMR1* knockout rodent model to examine motor and cognitive behaviors in young and old age.

Methods: Wildtype, homozygous, and heterozygous *FMR1* knockout Long-Evans rats (at least 12 per group) were used in this study. These animals underwent the novel object recognition test, rotarod test, and grip strength test at postnatal day (P) 50-75 and after reaching 12 months. All animals were given 2 trials in the rotarod test, with an intertrial interval of 10 minutes. The grip strength test was carried out over three days with one trial given per day. The novel object recognition test was also carried out over three days. The animals were allowed to habituate to the empty arena for 5 minutes on the first day. On the second day, two identical objects were given, and the animals were allowed to explore for 10 minutes. On the final day, one object was replaced with a new object, and the animals were allowed to explore for 10 minutes. All tests were carried out by blind-to-condition researchers. Data were analyzed using linear mixed effects models.

Results: In the rotarod test, the latency to fall did not vary significantly by genotype. However, the latency was greater in both trials in old age than young age ($p < .001$ for both trials). Furthermore, all animals stayed on the rod significantly longer during trial 2 than trial 1 when they were old ($p = .001$) but not when they were young, suggesting possible acquisition of repetitive motor behavior as they age. In the grip strength test, the relative strength (grip strength/weight) was measured and found to be greater in old age than young age, irrespective of genotype ($p < .001$).

Wildtype animals had lower relative strength than the knockout animals, but this difference was not statistically significant. Homozygous knockout animals had a lower novel object discrimination ratio than heterozygous knockout or wildtype animals in young age, but this did not reach statistical significance. In this age group, there was a trend of homozygous knockouts showing less rearing behavior than the heterozygous knockout ($p = .067$). The novel object test data for old animals have been collected and analysis is in progress.

Conclusions: They *FMR1* knockout animals develop repetitive motor behavior as they age, but do not show impairment in grip strength. These animals also do not show memory impairment early in their lifespan.

417.009 Ondansetron Treatment Attenuates the Effects on Prenatal Stress on Repetitive Motor Behaviors and Pro-Inflammatory Cytokines in Adolescent Male Fmr1 Knockout Mice

M. Ragozzino¹, K. Amodeo² and H. Dzielawa², (1)University of Illinois Chicago, Chicago, IL, (2)Psychology, Univ. of Illinois at Chicago, Chicago, IL

Background: Fragile X Syndrome (FXS) is an intellectual disability syndrome, in which one-third of affected individuals exhibit autistic features. FXS is caused by transcriptional silencing of *FMRI*, a gene encoding an RNA-binding protein. FXS individuals with autism spectrum disorder (ASD) exhibit heterogeneity in symptoms. There is increasing support that ASD arises from a complex interaction of environmental and genetic risk factors, including for monogenic syndromes, i.e. FXS. Past studies indicate that maternal stress during pregnancy may increase risk for ASD by glial reactivity producing neuroinflammatory responses in offspring. Past findings suggest that 5-HT₃ receptor antagonist treatment reduces glial reactivity and elevated central cytokine release. Thus, treatment with a 5-HT₃ receptor antagonist treatment may be effective in attenuating the effects of prenatal stress on ASD risk.

Objectives: The present experiment investigated whether the 5-HT₃ receptor antagonist, ondansetron attenuated the effects of prenatal stress on repetitive motor behaviors and brain inflammatory responses in male *Fmr1* knockout (KO) and wildtype mice.

Methods: Pregnant dams were exposed to two 30 minute restraint stress sessions during gestation days 10-16. At 4 weeks of age, offspring received a daily injection of ondansetron (1 mg/kg) or saline for seven consecutive days. One day after the last injection, mice received a nesting removal test (repetitive digging behavior) and zero maze test (anxiety-like behavior). After behavioral testing, mice were sacrificed with frontal cortex and striatal tissue dissected out and used to prepare RNA, and real time qPCR used to quantify levels of relevant inflammatory markers including IL6 and TNF-alpha. At least 4 biological replicates were used per group, target mRNA levels were normalized to levels measured for 3 housekeeping genes (GAPDH, b-actin, a-tubulin).

Results: Prenatal stress elevated digging behavior in WT and *Fmr1* KO mice with a significantly greater effect in *Fmr1* KO mice. Preliminary findings indicate that subchronic treatment with ondansetron significantly attenuated the prenatal stress induced elevation in repetitive digging behavior in both WT and *Fmr1* KO mice. Prenatal stress had no effect on locomotor activity in the nesting removal test or anxiety-like behavior in the zero maze, nor did ondansetron treatment affect these measures. Prenatal stress elevated IL6 and TNF-alpha in the frontal cortex of both WT and *Fmr1* KO mice. Ondansetron attenuated this elevation in both WT and *Fmr1* KO mice.

Conclusions: These results suggest that prenatal stress may interact with genetic factors to increase risk for autism-like behaviors. Further, the effects of prenatal stress on autism-like behaviors is attenuated by a 5-HT₃ receptor antagonist possibly by producing an anti-inflammatory response in neural circuitry underlying repetitive behaviors.

417.010 Profiling Oral Microbiota to Elucidate Gut-Brain Axis Alteration in Autism Spectrum Disorder

A. Anamika¹ and **S. Dwivedi²**, (1)Department of Pharmaceutical Sciences, UPES, Dehradun, Uttarakhand, India, (2)School of Health Sciences and Technology, UPES, Dehradun, Uttarakhand, India

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition characterised by deficits in social communication, restricted interests, and repetitive behaviours. Despite the increasing global prevalence of ASD, its underlying mechanisms remain poorly understood, and no definitive biological markers have been identified. Diagnosis primarily relies on behavioural assessments, often leading to delayed intervention. While extensive research has been conducted on the gut microbiota's role in ASD, there is a significant lack of microbiota data, particularly within the Indian population.

Objectives:

This study aims to explore the potential contribution of oral microbiota to ASD through its impact on the gut-brain axis, a growing area of interest in ASD research. By profiling microbial differences in oral samples from individuals with ASD and neurotypical controls, the study seeks to identify microbial signatures that could serve as early, non-invasive diagnostic markers.

Methods:

A systematic literature review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, identifying key bacterial species potentially associated with ASD. These species were evaluated and ranked based on their relevance, data quality, and prevalence across studies. To further validate these findings, saliva samples from ASD individuals and neurotypical controls (n=30) are being collected. These samples will also support future gene expression studies, aiming to confirm observed microbial differences in line with the literature.

Results:

Analysis revealed 20 bacterial species significantly more abundant in individuals diagnosed with ASD. The most prominent genera included *Clostridium*, *Bacteroides fragilis*, and *Prevotella*, underscoring the diversity of microbial communities associated with ASD. The findings reinforce the hypothesis that these species may influence neurodevelopment through the gut-brain axis. Of particular interest is the role of microbial metabolites in triggering neuroinflammatory responses and behavioral changes, offering new insights into ASD pathophysiology.

Conclusions:

This study establishes a potential link between oral microbiota and ASD, providing a foundation for developing microbiota-based diagnostic tools. Such tools could enable early, non-invasive detection of ASD, especially in regions with limited microbiota data, like India.

417.011 Targeting Pparalpha Ameliorates Social Behaviour and Restores the Endocannabinoid Signalling in the Rat Valproic Acid of Autism

N. Battista¹, **S. Salviati²**, **G. Sabatini³**, **E. Corridori²**, **F. Fanti²**, **C. Gambarana²** and **S. Scheggi²**, (1)Department of Bioscience and Technology for Food, Agriculture and Environment, University of Teramo, Teramo, Italy, (2)University of Siena, Siena, Italy, Italy, (3)University of Teramo, Teramo, Italy, Italy

Background:

Autism spectrum disorder (ASD) is a neurodevelopmental condition defined by deficits in social interaction and communication, typically appearing in early childhood and leading to substantial impairments in the development of social skills. The endocannabinoid system (ECS) is critically involved in the maturation and regulation of social behaviors and has been linked to the underlying causes of ASD. Notably, the neuromodulator *N*-arachidonylethanolamine (anandamide, AEA), which is produced by *N*-acyl-phosphatidylethanolamine-phospholipase D (NAPE-PLD) and broken down by fatty acid amide hydrolase (FAAH), plays a key role in governing social and emotional behaviors, particularly in mediating social reward mechanisms. Additionally, the activity of the ECS is influenced by peroxisome proliferator-activated receptor alpha (PPAR α), which has been implicated in ASD pathophysiology based on various preclinical findings. For instance, prolonged pharmacological activation of PPAR α using the agonist fenofibrate (FBR) can restore social behaviors disrupted by prenatal exposure to valproic acid (VPA).

Objectives:

Building on this foundation, the current study explores the hypothesis that primary deficits in ASD may originate from early dysfunctions in the ECS, particularly in brain regions involved in processing social rewards, such as the medial prefrontal cortex (mPFC) and nucleus accumbens (NAc).

Methods:

We employed the VPA-induced rat model of ASD to trace the progression of the ASD phenotype and uncover potential dysfunctions in the ECS. Specifically, we examined the expression levels of CB1 receptors, FAAH, NAPE-PLD, and PPAR α in the mPFC and NAc during postnatal development (from postnatal day 7 to adulthood) using immunoblotting techniques. Additionally, the levels of the main endocannabinoids (eCBs), AEA and 2-arachidonoylglycerol (2-AG), as well as endocannabinoid-like mediators, were analyzed by ultra performance liquid chromatography coupled with mass spectrometry (UPLC/MS-MS) in brain samples. As our findings indicated region-specific alterations in the ECS of VPA-exposed rats, we further investigated whether fenofibrate (FBR) administration could restore ECS signaling in adult VPA-exposed rats.

Results:

VPA-exposed pups exhibited reduced social interactions at postnatal days 14 and 21, which correlated with a decrease in CB1 receptor expression and a trend towards increased FAAH levels, while NAPE-PLD levels remained unchanged. Additionally, transient elevations in PPAR α expression were observed at these same developmental stages (PND 14 and 21). In adult VPA-exposed rats, a significant imbalance was detected in the expression of the ECS enzymes, with elevated FAAH levels and reduced NAPE-PLD levels. The results obtained from UPLC-MS/MS showed significant alterations in several endocannabinoids which might be responsible for the social impairments exhibited by VPA-exposed rats. Notably, prolonged FBR administration to VPA exposed rats was able to rescue the social deficits and some of the alterations in the endocannabinoid system.

Conclusions:

The study indicates that developmental alterations in the ECS and the PPAR α pathway may play a role in the ASD-like phenotype observed in rats prenatally exposed to VPA. Moreover, pharmacologically targeting PPAR α with the agonist FBR improved social behavior and partially restored ECS signaling in this murine model, highlighting a promising potential therapeutic strategy for ASD.

417.012 The Effect of an Erythropoietin Derivative on Autism-Related Behaviors in Model Mice

A. D. Kloth¹, R. Bundy^{1,2}, N. Everson¹, Z. Stanz¹, P. Vogel¹, M. Sathyanesan^{3,4} and S. S. Newton^{3,4}, (1)Department of Biology, Augustana University, Sioux Falls, SD, (2)Medical Student Research Program, University of South Dakota Sanford School of Medicine, Vermillion, SD, (3)Division of Basic Biomedical Research and Center for Brain and Behavior Research, University of South Dakota Sanford School of Medicine, Vermillion, SD, (4)VA Sioux Falls, Sioux Falls, SD

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication and interaction, alongside restrictive and repetitive behaviors. ASD affects 1 in 36 children in the United States and is caused by both genetic and environmental factors. While therapy can be used to treat ASD, there are no known pharmacological treatments that rescue social deficits in ASD patients.

Erythropoietin (EPO) is an interesting candidate treatment for ASD due to its neurogenic, neurotrophic, and neuroplastic effects. However, EPO has not yet been examined for use in ASD patients, and there is limited existing work on preclinical animal models bearing out the effects of erythropoietin on autism-like phenotypes. Moreover, EPO has unfavorable hematopoietic effects at high doses, limiting its use to only those with anemia. Therefore, in order to gauge the potential of EPO as a potential treatment for autism, it is necessary to test non-hematopoietic derivatives.

Objectives: We examined whether QPO--a recombinant, non-hematopoietic derivative of erythropoietin that has been demonstrated to rescue depression-like behaviors in mice and enhance neurotrophic mechanisms in the brain--can rescue autism-related behavioral phenotypes in the BALB/c mouse model.

Methods: We evaluated the effects of QPO on BALB/c mice (BALB), an idiopathic mouse model of autism noted for its low sociability that has been used in prior erythropoietin derivative studies, as well as C57BL6/J mice as a control. Mice received intraperitoneal injections of QPO (50 μ g/kg) or vehicle every other day over a three-week period. In each of the four experimental groups (mouse strain $\pm$ treatment), there were ≥ 16 mice, evenly divided by sex. To avoid possible confounds of the estrous cycle on social behavior, all experiments took place prior to postnatal day 56. The mice were divided into QPO and vehicle groups, receiving 11 injections, every other day for 22 days. The three chamber social approach task with age-, sex-, and strain-matched stranger mice was used to assess sociability, and open field and elevated plus maze tasks were used to assess activity and anxiety. The forced swim task was used as a comparison to prior BALB/c studies.

Results: When we examined mixed-sex cohorts of mice, we found a significant improvement in sociability in the three-chamber task in BALB mice that had received QPO mice over their vehicle counterparts; no similar difference was seen in C57 mice. Notably, this effect was largely driven by improvement in the male mice, which spent more time interacting with the stranger mouse and less time interacting with the non-social object. We saw no improvement in open field or elevated plus behavior in either the mixed-sex cohort or in single-sex cohorts. We saw a significant decrease in immobility in the forced swim task in male, but not female mice.

Conclusions: Based on our findings, QPO has the potential to rescue autism-related behavioral traits and is emerging as a prospective treatment. Future work will examine the underlying mechanisms of these findings, and how broadly these findings apply across mouse models.

Poster Session**418 - Coexisting Medical, Neurodevelopmental, and Mental Health Conditions I**

May 2nd, 2025, 12:30 PM - 1:30 PM - Hall 4A

418.013 2000 Ideas for Suicide Prevention: Shared and Differing Priorities from Autistic People and Those Who Support Them.

R. L. Moseley¹, T. L. Procyshyn², T. A. Chikaura³, S. J. Marsden⁴, T. Parsons⁵, S. A. Cassidy⁶, C. Allison⁷, M. Pelton⁸, E. M. Weir⁹, D. Crichton⁴, D. Mosse⁹, J. Rodgers¹⁰, I. Hall¹¹, L. Owens¹² and S. Baron-Cohen⁷, (1)Department of Psychology, Bournemouth University, Poole, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, NA, United Kingdom, (3)Psychiatry, Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, Cambridgeshire, United Kingdom, (4)United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, Cambridge, United Kingdom, (6)School of Psychology, University of Nottingham, Nottingham, Nottinghamshire, UNITED KINGDOM, (7)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, Cambridgeshire, United Kingdom, (8)University of Cambridge, Cambridge, Cambridgeshire, United Kingdom, (9)Department of Anthropology and Sociology, SOAS University of London, London, United Kingdom, (10)Population Health Sciences Institute, Newcastle University, Newcastle, Newcastle upon Tyne, United Kingdom, (11)East London NHS Foundation Trust, London, London, United Kingdom, (12)EdmissionUK, London, London, United Kingdom

Background:

Across the world, suicide is a leading cause of death for autistic people without intellectual disabilities (Santomauro et al., 2024). Despite a 515% increase in autistic suicide research since 2018 (Brown et al., 2024), research addressing the *assessment* and *treatment* of suicidal thoughts and behaviour comprises a mere 10% of publications in that timeframe. While this demonstrates clear growth in our understanding of suicide in autistic people, our practical knowledge around *preventing* suicide remains severely underdeveloped. As a result, national suicide prevention strategies lack specific, concrete policies to reduce suicide in autistic people, who are unrecognised as a high-risk group in many countries.

Objectives:

Building on a previous, research-focused priority-setting exercise for autism and suicide (Cassidy et al., 2021), we aimed to first gather ideas from the autism community for policies and interventions aimed at preventing suicide (Phase 1, complete). Subsequently, we will identify the community's priorities for which ideas warrant further development (Phase 2, commencing November 2024; results ready for INSAR). Herein, we present our methods and findings from Phase 1.

Methods:

In Phase 1, we collected ideas via an online survey between January-July 2024. Participants were 1481 autistic people without intellectual disabilities (average age: 36.7 [SD: 15]), with experience of suicidal thoughts and behaviour; 52% were cisgender women (23% gender-divergent, 24% cisgender men). Participants also included 274 people who support autistic people (henceforth 'supporters'), 72% of whom were parents of autistic people who had experienced suicidal thoughts and behaviour (the autistic children of these parents were aged 7-49 [average 21 years, SD: 7]). Most participants (94%) were British. During the survey, they were asked to provide up to 3 ideas to prevent suicide in autistic people, which were analysed thematically by four researchers.

Results:

We analysed 1796 ideas from 1079 autistic participants, and 295 ideas from 190 supporters. Across a range of ideas varying in concreteness (some of which conveyed multiple essential points), we identified the most frequently occurring broad themes. While the same themes were identified in both groups, the relative frequency of their occurrence differed markedly (see Figure 1). Autistic people prioritised societal stigma/discrimination and expediting autism diagnoses more than supporters; supporters prioritised improving *existing* services and support above developing autism-specific services and support, while the latter was a higher priority for autistic people. Similarly, while autistic people prioritised peer support, supporters prioritised social support more broadly.

Within the 10 most frequent themes mentioned by autistic people, we identified 63 more specific, concrete ideas recurrent in both participant groups (Figure 2). These ideas will be ranked in Phase 2 by a larger pool of autistic people and supporters.

Conclusions:

While we await findings from the priority-setting exercise, Phase 1 highlights the need for societal and systemic change in response to suicide in the autistic community. Though ideas for suicide prevention policy and practice spanned multiple arenas from health- to social care, autistic people prioritised *autism-specific* and *peer* support, underscoring the need for co-production in steps towards suicide prevention.

**418.014** A New Approach to the Early Identification and Care of Children Experiencing Symptoms of Developmental Regression

K. J. Furley^{1,2}, **K. Williams^{3,4}**, M. Leo⁵ and E. Andersson⁶, (1)Developmental Paediatrics, Monash University, Melbourne, VIC, Australia, (2)Paediatrics, Monash University, Melbourne, VIC, Australia, (3)Paediatrics, Monash University & Monash Health, Melbourne, VIC, Australia, (4)Developmental Paediatrics, Monash Children's Hospital, Melbourne, VIC, Australia, (5)Developmental Paediatrics, Monash Children's Hospital, Melbourne, VIC, Australia, (6)Developmental Paediatrics, Monash Health, Melbourne, VIC, Australia

Background:

Developmental regression is the loss of previously established skill/s and is reported to occur in at least one third of children who are later diagnosed with autism. Early identification, and access to interventions improves child and family outcomes yet children with developmental regression currently wait for extended periods on various subspecialty waiting lists. The lack of a specific assessment and investigation pathway may result in delays to accessing tailored interventions and optimal child and family supports. Research involvement for children with symptoms of developmental regression may be limited if they are yet to receive a diagnosis.

Objectives:

To establish a research-embedded multi specialist assessment clinic to see children who have lost skills in the last year, in a children's hospital in Melbourne, Australia. To document clinical presentations and associated assessment and investigation findings. Here we present the establishment of the clinic and preliminary results from the first 21 eligible referrals.

Methods:

The clinic opened in April 2024. Assessments include a combination of questionnaires to evaluate the child (e.g. Vineland Adaptive Behaviours Scales (VABS)), parent questionnaires to evaluate quality of life and empowerment, clinician interviews and standardised assessments. A paediatric neurologist and clinical geneticist provide an opinion on recommended investigations. Appointments are scheduled at 3 and 6 months to review developmental progression. Institutional Human Research Ethics Committee approval was sought to invite families to consent to share videos for research and data storage in the Skills Loss Registry.

Results:

The clinic received 21 eligible referrals with fourteen children seen to date (n=11, 79% consenting to research), three awaiting assessment and four receiving secondary consultation (n=2, 50% consenting to research). Of the eleven children seen one child was ten years, one was five years at time of assessment, the remaining children were aged 18 months to 32 months. Domains of skill loss included language (n=11), social (n=9), motor (n=3) and cognitive (n=1). Trajectory of regression onset was sudden (n=4), gradual (n=4) or uncertain (n=3). Concurrent events at time of loss were reported for nine children (81.2%). Eight children (72.7%) had parent reported delayed development prior to regression and three (27.3%) achieved age expected developmental milestones prior to loss. At assessment all children seen scored low to moderately-low on the VABS and cognitive development was significantly lower than age expectations (1st percentile). Investigations requested for each child included bloods (n=7), metabolic tests (n=6), chromosomal microarray and Fragile X (n=7), electroencephalograms (n=8) and MRI-brain (n=4). Trio exome sequencing was requested for three children, two diagnostic and one result pending.

Conclusions:

Most children reviewed in clinic were younger than three years old with loss of language and social skills most often reported. Trajectory of loss may be sudden or gradual and concurrent events are common. Two children received a diagnosis via exome sequencing that has assisted their access to services, and tailored interventions and child and family supports. A de-identified skills loss registry is being established and videos collated that will be used to identify further early identification and clinician training opportunities.

418.015 A Service Improvement Project, Exploring Management and Prevalence of Sensory Eating Difficulties, Including Arfid, in Children within the Autism Assessment Pathway in a Local Child Development Centre – Is There Need for a Local Support Service?
C. Cox¹ and **I. A. Male²**, (1)Brighton and Sussex Medical School, Brighton, East Sussex, United Kingdom, (2)Mid Sussex Child Development Team, Sussex Community NHS trust, Haywards Heath, United Kingdom

Background: Avoidant restrictive food intake disorder (ARFID) has only been a recognised eating disorder since 2013. Research suggests children with Autism are at increased risk of developing ARFID although prevalence is uncertain. ARFID more commonly affects younger children and can result in serious mental and physical health conditions.

We currently have no local service for children with ARFID, although parents can access a webinar offering advice on management. Current treatment requires referral to a tertiary multidisciplinary feeding service with children needing to be identified and remain under local paediatricians throughout. This project was designed to support the case for creating a locally based service, given the number of children attending local autism diagnostic services who also have limited diets.

Objectives: A proforma looked at various clinical factors and aimed to provide data for the following aims:

- To look at how many children with autism or possible autism have sensory eating issues.
- To check whether growth centiles are regularly checked.
- To look at how often blood biochemistry for nutritional status are being sent.
- To create evidence supporting the need for a local service to be commissioned for children with sensory eating issues.
- To consider the impact of the current pathway for these children.

Methods: Prospective data was retrieved from a local child development centre, between November 2023 and February 2024.

The proforma was filled in prospectively, by clinicians seeing children at various points along the autism assessment pathway, including initial screening appointments, follow ups, diagnostic appointments and educational health and care plan (EHCP) reviews.

Results: Data was taken from 52 children with an age range of 8 months -18 years. 50 children were referred for, or were already diagnosed, with Social Communication Difficulties and/or Autism. Other existing diagnoses included, learning disability and attention deficit hyperactivity disorder. 29 children (55.8%) had a limited food intake and of those 29 children, 12 (42.85%) ate less than 10 foods.

Overall, 41.4% of 50 children had blood biochemistry completed, 62.1% were receiving vitamin supplements, and 57% had weight/growth centiles checked.

Conclusions: Sensory driven limited food intake was identified in over half the children attending the local service for possible autism. Given the numbers of children being seen (The current waiting list is 477 children with a local child population of 30,000), and the frequency of limited diets, results suggest there is need for a locally delivered multidisciplinary service able to support families to increase dietary range and intake for those children, whilst linking with specialist services for more complex cases, e.g. where gastrostomy feeding is being considered. A diagnosis of ARFID, and tertiary referral requires evidence of impaired growth, and/or nutritional status, yet blood testing and growth measurement was often not performed. This current treatment pathway and strict referral criteria, causes delay to treatment of an estimated 3 years. ARFID within the autistic community can be more severe and more resistant to treatment and therefore screening as well as access to local intervention, should be part of routine assessment within autism diagnostic services.

418.016 A Transdiagnostic Understanding of Externalizing Behaviors in Autism

C. J. Kim¹, C. Faulk¹, R. M. Benecke¹, Y. Y. Yu², J. Foy³, Z. Algaze⁴, F. Kuhney⁵, L. K. Steinbeck¹, L. J. Fulop¹, R. E. Lee⁶, E. A. Storch⁶, C. J. Zampella¹, R. T. Schultz⁷, J. Parish-Morris¹, B. E. Yerys¹ and J. D. Herrington¹, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Graduate School of Applied and Professional Psychology, Rutgers University - New Brunswick, Piscataway, NJ, (3)Child Psychiatry and Behavioral Science, Center for Autism Research (CHOP), Philadelphia, PA, (4)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (5)University of Illinois at Chicago, Chicago, IL, (6)Baylor College of Medicine, Houston, TX, (7)The Center for Autism Research/CHOP, Philadelphia, PA

Background: While decades of research have associated autism characteristics with externalizing behaviors (e.g., aggression, behavioral challenges/conduct problems), more recent accounts from the autism scientific and advocacy communities challenge this relationship. Awareness is growing that externalizing behaviors in autism may be better understood in terms of common, co-occurring mental health concerns such as attentional difficulties and anxiety. To date, few large-scale studies have robustly examined this, especially transdiagnostically – identifying whether autism characteristics are associated with externalizing behaviors independent of an autism diagnosis.

Objectives: To test whether externalizing behaviors are more strongly associated with anxiety and attentional difficulties than the core characteristics of autism.

Methods: 459 participants (91 female, Mean/SD age 10.50/3.06 years) completed an extensive phenotypic battery. 275 carried an autism diagnosis (AUT group), 106 carried a non-autism psychiatric diagnosis (PSY group: anxiety, depression, and/or ADHD), and 76 were neurotypical controls without any psychiatric diagnosis (NT group; see Table 1). Externalizing behaviors were measured via the externalizing subscales of either the Behavior Assessment System for Children (BASC) or the Child Behavior Checklist (CBCL – these two provide analogous *t*-scores). Core autism characteristics were captured by the Social Communication Questionnaire (SCQ) and the Autism Diagnostic Observation Schedule-Calibrated Severity Score (ADOS-CSS). Attention was measured via the Global Executive Composite (GEC) of the Behavior Rating Inventory of Executive Function (BRIEF). Anxiety was captured by child and parent versions of the Screen for Child Anxiety Related Disorders (SCARED-C/SCARED-P). To address content overlap between BRIEF and BASC/CBCL items, separate post hoc analyses examined Aggression and Conduct subdomains of these two instruments.

Results: Across all participants, zero-order correlations between externalizing and autism characteristics were modest ($r=.25, p<.001$ for SCQ, $r=.07, p=.12$ for ADOS-CSS) relative to the large effects of attention (GEC $r=.62, p<.001$) and anxiety (SCARED-P $r=.41, p<.001$). When combined in a single multiple regression model, anxiety and attentional difficulties were significant predictors of externalizing when added last ($r=.48, p<.001$), though the partial correlation for anxiety decreased ($r=.15, p<.001$). When looking at the AUT group only, correlations between autism characteristics and externalizing were near zero ($r=.03, p=.61$ for SCQ, $r=-.04, p=.47$ for ADOS-CSS), whereas attention and anxiety relationships with externalizing remained large (GEC $r=.57, p<.001$, SCARED-P $r=.36, p<.001$). This pattern persisted when examining Aggression and Conduct domains separately. Interestingly, when examining child-reported anxiety (SCARED-C), correlations with externalizing were much smaller ($r=.23, p<.001$) than parent report.

Conclusions: Study findings support the hypothesis that externalizing characteristics in autism may be more closely related to co-occurring mental health concerns than the core features of autism – whether measured by parent or clinician. The attenuation of this effect with child-reported anxiety warrants further investigation of rater effects in future studies. This finding also highlights the importance of mitigating diagnostic overshadowing, and integrating broadband mental health assessment into autism care. Overall, these data expand our view on the determinants of externalizing symptoms among autistic individuals – one focused less on core autism characteristics and more on the co-occurring concerns that are a major part of the autistic lived experience.

418.017 Adverse Childhood Experiences and Mental and Physical Health Outcomes in Autistic Adolescents: Comparing Cumulative Risk and Latent Class Approaches

S. Krishnan and **G. I. Orsmond**, *Department of Occupational Therapy, Boston University, Boston, MA*

Background: Autistic youth experience higher rates of adverse childhood experiences (ACEs) than non-autistic youth. Emerging literature shows that autistic youth who experience a higher number of ACEs are at greater risk of negative mental and physical health outcomes; however, a cumulative risk approach assumes all ACEs confer equal risk. In contrast, a latent class approach, which has not yet been used with autistic youth, groups youth by shared patterns of ACE exposure and examines how specific ACE combinations influence outcomes. Understanding the differential effects of ACEs is crucial for developing trauma-informed interventions to promote well-being in autistic youth.

Objectives: (1) To identify latent classes of ACE patterns in a nationally representative sample of autistic adolescents; (2) To examine associations among ACEs, youth characteristics, and physical and mental health outcomes using cumulative risk and latent class approaches.

Methods: We performed a secondary analysis of the National Survey of Children's Health 2021-2022, a U.S. nationally representative parent-report cross-sectional dataset. The sample included 1311 adolescents aged 12-17 with parent-reported autism diagnoses ($M_{age}=14.66$ years; 80% White; 75% male; Table 2). Exploratory latent class analysis (LCA) of 12 ACE indicators was conducted. Logistic regressions investigated associations between ACEs and mental health (anxiety or depression diagnosis) and physical health (poor/fair vs. good/excellent overall health) outcomes, controlling for youth characteristics. For each outcome, two regressions were conducted: one using cumulative risk (total ACE count, 0-12) and one using latent class membership.

Results: We tested LCA models with two to eight classes (Table 1). A three-class model provided the best-fitting solution (decreased AIC, BIC, SSAIBIC; entropy=.688; LMR-LRT $p<.001$). Class 1 exhibited high probabilities of bullying and income instability, with low probabilities of other ACEs. Class 2 showed high probabilities of discrimination due to race, disability, or sexual orientation and mid-levels of other ACEs. Class 3 had high probabilities of household disruption (parental divorce, death, incarceration, substance abuse, mental illness; home violence) and community violence.

Models with cumulative ACE count and latent class membership predicted similar variability of mental (21-23%) and physical health outcomes (13-14%; Table 2). Each additional ACE increased the odds of anxiety or depression (OR:1.291) and lower physical health (OR:1.156). Youth in Class 2 and Class 3 were >2.2 times more likely to experience anxiety or depression than Class 1. Only Class 2 was associated with greater odds of lower physical health (OR:1.757).

Youth with anxiety or depression were more likely to be female, older, not be Black or Asian, and have ADHD, no intellectual disability (ID), 'moderate' or 'severe' autism characteristics, and higher family income. Youth with low physical health were more likely to be female, have ID, and 'severe' autism characteristics (Table 2).

Conclusions: Findings provide novel insight into the differential impacts of ACEs on autistic youth. While cumulative ACE count was associated with youth health, more specifically, youth who experienced discrimination, household disruption, or community violence were at heightened risk for adverse health outcomes. Tailored interventions at the youth, family, and community levels can foster resilience to mitigate the effects of these ACEs.

418.018 An Ecological Momentary Assessment of Masking during Social Interaction and Near-Term Suicidal Ideation in the Daily Lives of Autistic Adults

J. Feldman¹, L. Antezana², X. Hu², C. M. Conner², C. A. Mazefsky², L. M. Bylsma² and L. N. Scott², (1)Psychology, University of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: Suicide is the leading cause of premature death in autistic individuals. An estimated 20% of autistic individuals will attempt suicide during their lifetime and 50% will experience suicidal ideation. Research to identify risk factors for suicidality in autistic individuals is drastically needed. One such risk factor could be masking behaviors. Autistic individuals often express distress around masking or suppressing themselves to adhere to social norms. While previous work has found cross-sectional associations between masking and suicidality, longitudinal daily life masking and its proximal association with acute changes in suicidal ideation have not yet been examined.

Objectives: We examined associations between masking during social interactions and suicidal ideation during a 2-week ecological momentary assessment (EMA) protocol. Specifically, we investigated whether masking during social interactions is temporally associated with momentary within-person fluctuations in suicidal ideation. Additionally, we examined whether individual differences in overall levels of masking during social interactions are associated with overall levels of suicidal ideation throughout the EMA protocol. We predicted that individuals who endorsed higher levels of masking in social interactions will endorse higher levels of suicidal ideation, and that within-person momentary increases in masking during social interactions will be associated with greater momentary suicidal ideation.

Methods: Data were from an ongoing study of autistic adults completing an EMA suicide and social interaction questionnaire 8 times a day. Data were from 76 participants [$M(SD)$ age =33.17(10.13) years, 25 assigned male at birth, 51 assigned female at birth]. Masking EMA items asked how much participants "suppressed stimming behaviors", "held back thoughts to not seem weird or different", "tried to keep emotional expressions neutral", and "tried to seem more interested in what someone said" since the last survey on a 0 (not at all) to 10 (very much) scale. Suicide EMA items asked the strength of participants "desire to die" and "desire to kill themselves in the present moment," on a 0 (not at all) to 10 (strongest possible) scale. Data were analyzed using random slope and intercept multilevel models with momentary observations (level 1) nested within individuals (level 2).

Results: Momentary increases relative to one's own mean of self-reported masking during social interactions was significantly associated with momentary elevations of suicidal ideation severity since the last completed survey ($\beta=0.012$, $SE=0.004$, $t=4.14$, $p<0.001$), indicating a temporal association between masking and increases in suicidal ideation. Between persons effects assessing if higher overall levels of masking indicated higher levels of suicidal ideation were insignificant. However, female sex at birth trended towards significance ($\beta=0.11$, $SE=0.06$, $t=1.99$, $p=0.05$), suggesting a possible effect on momentary suicidal ideation.

Conclusions: Masking is a significant predictor of intraindividual increases in suicidal ideation and may be a proximal risk factor for acute suicide risk. In addition, female sex at birth trends towards an increased effect on momentary suicidal ideation. As the sample increases, we will examine whether these effects are moderated by age of autism diagnosis, sex at birth, gender identity, and how these findings may inform suicide prevention/risk intervention for autistic adults.

418.019 Art Therapy for Autistic Adults Against Depression: A Multi-Perspective Study

Y. Wang^{1,2} and B. G. Digard³, (1)Department of Psychology, University of Edinburgh, Edinburgh, Scotland, United Kingdom, (2)Northwestern University, Evanston, IL, (3)University of Edinburgh, Edinburgh, Scotland, United Kingdom

Background:

Research indicates that autistic people are more likely to experience mental ill-health, especially depression, which can impact their overall well-being and quality of life. Indeed, mental health support has been highlighted as a topic of research priority by the autistic community. However, autistic people are also less likely to receive effective therapies. Over the years, art therapy has emerged as a promising intervention for autistic people with depression, yet its popularity and accessibility remain low.

Objectives:

This study aims to investigate the reasons behind this underutilisation of art therapy against depression among autistic individuals, and it explores challenges in accessing and delivering art therapy from a varied range of stakeholders such as autistic people themselves, caregivers, and healthcare professionals. This study has a primary objective of identifying factors that contribute to the underutilisation of art therapy against depression among autistic individuals. This will be achieved by 1) examining the perceptions and attitudes of professionals, caregivers, and autistic people themselves towards art therapy as a possible treatment option against depression; and 2) exploring the barriers and challenges faced by autistic people in accessing art therapy services.

Methods:

Through a mixed method online survey, responses of 20 UK-based autistic adults (60% female, mean age = 40, range = 19–67) and 10 UK-based art therapists (90% female, mean age = 42, range = 28–66) were analysed. This questionnaire is divided into different sections with different qualitative and quantitative questions for different stakeholders, and it collects the respondents' demographic information, autism and depression diagnosis or self-identification, as well as experiences and/or opinions on using art therapy for autistic people to manage depression. The qualitative responses were analysed thematically in NVivo, and descriptive statistics were conducted in R to analyse the quantitative data.

Results:

Thematic analysis revealed multidimensional challenges in implementing art therapy to treat autistic people's depression (Figure 1). Volunteers highlighted issues with 1) accessibility (i.e. affordability, availability, and simplicity); 2) professional practice (i.e. autism knowledge, concurrent diagnoses, familial support, integrated care, and relationship building); and making each experience individualised. Interestingly, there was no significant association between the number of challenges perceived (i.e. accessibility, sensory sensitivities, communication...) and confidence in the benefits of art therapy across either groups (autistic adults and art therapists).

Conclusions:

This is one of the first study to systematically report and analyse art therapy experiences on autism and depression. Based on our findings, a new framework (Figure 2) is proposed to help practitioners develop targeted strategies in promoting the use of a promising intervention for a marginalised population, all while considering the capabilities of the current UK healthcare system. Following the fundamental principles of the socio-ecological model, this new framework sets forth the following principles: Individual variability, stakeholder interaction, and leverage point. This study has implications for a range of non-pharmacological therapies to support positive mental health outcomes amongst autistic adults.

418.021 Associations between Feeding Problems and Behavioral Characteristics in Autistic Preschool Children

A. Herguner^a, S. Firat^a and S. Herguner^a, (1)Ankara, Ankara, Turkey, (2)Private Practice, Samsun, Turkey, (3)Sarıkonak Apt Çukurambar, Sabri Hergüner, Ankara, Turkey

Background: Feeding problems are common in children on the autism spectrum disorder (ASD), with reported prevalence rates of 46–89 % compared to 25 % for typically developing children. The feeding problems observed in children on the ASD typically fall into three categories: (1) food selectivity, (2) food refusal, and (3) disruptive mealtime behaviors. These problems are known to result in poorer nutrition and developmental outcomes and affect opportunities for social and community participation (1, 2, 3)

Objectives: There are limited number of studies focusing on the association of feeding problems with behavioral characteristics of ASD. The current study aims to demonstrate relationships between core and associated behaviors of ASD with feeding behaviors in children on the ASD.

Methods: We examined the relationships between feeding behaviors and social, communication, and repetitive behaviors, as well as sensory behaviors, and externalizing and internalizing behaviors in a sample of 146 children on the ASD aged between 2-6 years. Children with a diagnosis of ASD were included to the study and their parents were invited to participate. Parent reports were used to measure feeding problems (Brief Autism Mealtime Behavior Inventory), social communication behaviors (Social Responsiveness Scale), repetitive and ritualistic behaviors (The Repetitive Behavior Checklist Revised), sensory behaviors (Sensory Profile 2), behavior problems (Child Behavior Checklist 1/5-5 years).

Results: The sample included 146 children with ASD and the mean age was 47.4 months. The correlation analysis revealed associations between feeding problems and repetitive and ritualistic behaviors ($p=.000$, $r=.433$), sensory features ($p=.000$, $r=-.514$), social and communication differences ($p=.000$, $r=.327$) and externalizing ($p=.000$, $r=.467$) and internalizing behavior ($p=.000$, $r=.446$). Regression analysis indicated that age ($p=.047$, $\beta=-.117$), internalizing behavior ($p=.010$, $\beta=.312$), and sensory features ($p=.000$, $\beta=-.068$) predicted total Brief Autism Mealtime Behavior Inventory score.

Conclusions: These results demonstrate associations between mealtime behaviors and repetitive behaviors, sensory features, and externalizing and internalizing behaviors. Investigating the relationship between the behaviors exhibited by children with ASD at mealtimes and the core symptoms of ASD and behaviors outside of mealtimes can be a guide in determining appropriate intervention methods for children, such as examining not only mealtime behaviors but also interactions and areas of difficulty outside the mealtime environment.

418.022 Associations between Subjective Sleep Quality, Psychological Distress, and Autistic Traits in Young Women

M. Foster and J. Bradshaw, University of South Carolina, Columbia, SC

Background:

Increasing evidence suggests that elevated autistic traits are prevalent in young adults and have been shown to predict stress, depressive symptoms, and anxiety, particularly among females (McLeod & Anderson, 2023). Regardless of gender, young adults also appear to be especially vulnerable to sleep-wake disturbances and, similar to autistic traits, these sleep challenges have been shown to predict worsened mental health (Becker et al., 2018). In addition, autistic individuals have been shown to demonstrate significantly worsened sleep quality than their neurotypical peers across the lifespan (Fletcher et al., 2017). Yet, no research has examined the relationship between autistic traits and sleep challenges in a nonclinical sample of young women, whether clinical impairment due to autistic traits may moderate this effect, or how these factors interact to affect psychological distress.

Objectives:

The aim of this study was to investigate the relationships between sleep quality and autistic traits and how these variables predict depression, anxiety, and stress in a non-clinical sample of young women.

Methods:

Participants ($n=163$) were largely recruited from a research pool of undergraduate students in psychology and asked to complete a survey via Qualtrics software. Inclusion criteria required participants to be fluent in English, aged 18 to 25 years, and assigned female at birth. Psychological distress was assessed with the Depression Anxiety Stress Scale and provided subscale scores of depression, anxiety, and stress. Autistic traits were measured using the Autism-Spectrum Quotient. In this study, autistic traits were treated in initial analyses as a continuous variable with values ranging from 0 to 50 with higher scores indicating more autistic traits. For subsequent analyses, autistic traits were dichotomized as above or below the clinical cut-off score of 32. Subjective Sleep Quality Rating Scores were pulled from an item on Pittsburgh Sleep Quality Index in which participants are asked to report whether they rate their sleep quality as Poor or Good.

Results:

Significant main effects of sleep quality were identified for impacting psychological distress, such that people who reported poor sleep quality were more likely to report anxiety ($F(2,161)=4.83, p<.01$), depression ($F(2,161)=9.63, p<.001$), and stress ($F(2,161)=8.34, p<.001$). Meanwhile, autistic traits did not predict any aspect of psychological distress— even when conducted on a subsample of women with AQ-50 scores above the clinical cut-off value ($n=35$). Similarly, autistic traits were not associated with sleep quality.

Conclusions:

Poor sleep quality, regardless of autistic trait presentation, led to heightened stress, increased anxiety, and worsened depressive symptoms in a sample of young women. The lack of association between sleep quality and autistic traits was surprising as many studies have found that individuals with higher autistic traits tend to experience worsened sleep quality. As autistic traits were measured in this sample through a self-report questionnaire rather than through a behavioral assessment, additional research is needed to determine whether these associations persist in a sample of women diagnosed with autism spectrum disorder. Through these efforts, researchers will better support autistic women obtain improved sleep and better mental health outcomes.

**418.024 Autism and Anxiety in Girls and Boys**

C. Shulman¹, Z. Nir² and D. Bitton³, (1)*The School of Social Work, Profile Resources Group, Jerusalem*, (2)*The school of social work, The Hebrew University, Jerusalem, Israel*, (3)*The Hebrew University of Jerusalem, Jerusalem, Israel*

Background: Conflicting conclusions from studies make it difficult to research sex differences in autism. Possible explanations for the contradictory findings include underrepresentation of females in research and the difficulty comparing results because autism presentation varies across development, sex, IQ and co-occurring conditions. This research focuses on anxiety, which has been found to be a common co-occurring condition in autism. This is particularly salient as previous research has posited a relationship between sex and anxiety in typically developing children, although results regarding this association in autism have been inconclusive. This study addresses the relationship between sex and the prevalence of anxiety in children between the ages of 4 and 12, including younger children than those in previous studies.

Objectives: The purpose of this study was to explore parent-reported anxiety in girls and boys with autism. The study addresses some of the limitations of previous research by adopting a close matching design to control for male bias, while allowing for the comparison of anxiety at different ages.

Methods: Ninety parents of 45 girls and 45 boys with autism completed the Spence Children's Anxiety Scale. The boys and girls with autism were matched on age and IQ. The preschool and the school-aged forms of the SCAS were used accordingly. The preschool SCAS consists of OCD, social anxiety, separation anxiety, physical fear, and general anxiety subscales while the school-aged anxiety profile adds a panic subscale.

Results: Analyses were conducted on four groups (24 preschool girls, 26 school-aged girls, 21 preschool boys and 19 school-aged boys) in order to assess the expression of anxiety at differing ages. No group differences emerged in IQ or age between the preschool or the school-aged girls and boys. While preschool girls had significantly more parent-reported anxiety than preschool boys in all the subscales except social anxiety, in which no differences emerged, the differences between school-aged girls' and boys' anxiety profiles were more nuanced. No differences between the boys' and the girls' anxiety emerged on OCD, separation anxiety, and general anxiety, whereas the girls revealed significantly more social anxiety, panic and physical fear than the boys did at this age.

Conclusions: This study addressed sex differences in anxiety among children with autism, extending previous research by looking at parent-report anxiety in younger children as well as older ones. Similar to typically developing children, a relationship between sex and anxiety emerged, but comparing younger and older children a more nuanced profile emerged. In younger children the girls revealed more anxiety on all the subscales except for social anxiety, which could be eclipsed into the social impairments of autism criteria. As the children grow, this profile reveals some differences in anxiety presentation. It is important to understand that anxiety in autism may be different than those of typically developing children because of the underlying social difficulties inherent in autism. Thus, the profiles of anxiety in male and female children with autism warrant further investigation.

418.025 Autism in Psychiatric Inpatients with Severe Self-Harm – Screening and Clinical Correlates

A. N. Kildahl^{1,2} and S. B. Helverschou¹, (1)*Norwegian Advisory Unit for Mental Health in Intellectual Disabilities, Oslo University Hospital, Oslo, Norway*, (2)*NevSom - Norwegian Centre of Expertise for Neurodevelopmental Disorders and Hypersomnias, Oslo University Hospital, Oslo, Norway*, (3)*NevSom, Oslo University Hospital, Oslo, Norway*

Background: Autism is associated with increased risk of self-harm and suicidal behaviours, but autism may not always be recognised in mental health services. Moreover, autism is underdiagnosed in adult females, and these individuals may be at risk of being misdiagnosed with personality disorder (PD) prior to receiving autism diagnoses. However, accurate diagnosis is important to adapt treatment and services for this population. **Objectives:** To explore the prevalence of autism diagnosis, as well as of being screen positive for autism on the Ritvo Autism Asperger Diagnostic Scale-Revised (RAADS-R), in a clinical sample of psychiatric inpatients with severe self-harm.

Methods: In a national multisite cross-sectional study, 42 adults (40 females, 2 males; ages 18-49 [$M = 29$, $SD = 8$]) with either long (>4 weeks) or frequent (>5) inpatient admissions due to self-harm during the last year, were recruited mostly from acute psychiatric wards. All participants provided informed consent. Data collection included the RAADS-R, clinical diagnoses, data on self-harm and suicidal behaviours, as well as symptoms of depression (Patient Health Questionnaire-9), anxiety (Patient Health Questionnaire – General Anxiety Disorder 7), and post-traumatic stress disorder (PTSD; PTSD Checklist for the DSM-5), alexithymia (Toronto Alexithymia Scale-20), emotion regulation (Difficulties in Emotion Regulation Scale), and functioning in close relationships (Experiences in Close Relationships). In general, the sample had complex psychopathologies, with 91% meeting criteria for PD, most commonly borderline PD (66%). Major depressive disorder (81%) and post-traumatic stress disorder (57%) were common, and the participants reported high levels of childhood trauma.

Results: Four (9.5%) participants were diagnosed with autism. More than half the sample, 24/42 (57.1%) scored over the original RAADS-R cut-off (>65). Even applying the strictest cut-off from the literature (>120) resulted in the number of screen positive being almost three times as high as the number of participants diagnosed with autism (11/24, 26.2%), see Table 1. All participants who were diagnosed with autism, or screen positive at any cut-off, were female. Participants scoring >72 on the RAADS-R reported significantly more symptoms of depression, anxiety and PTSD, and were significantly more likely to be diagnosed with an anxiety disorder (Fisher's exact test, $p = .028$). In addition, these participants reported more severe alexithymia, poorer emotion regulation, and poorer functioning in close relationships, see Table 2. No significant differences were found concerning age of onset, frequency or severity of self-harm and suicidal behaviours.

Conclusions: These results are in line with previous suggestions of an autism subgroup among psychiatric inpatients with severe self-harm. Patients in this subgroup may not have been recognized as autistic, but report more mental health symptoms, as well as poorer functioning and adjustment across a range of domains. However, their pattern, frequency and severity of self-harm may not be clearly distinguishable from other patients with severe self-harm. These findings highlight the importance of screening for and assessing possible autism in psychiatric inpatients with severe self-harm, particularly in females.

418.026 Autistic Adults Experiences of Safety Planning.

C. M. Brown¹, J. Wilson², J. M. Schwartzman³, M. A. Stokes⁴, S. A. Cassidy⁵ and D. Hedley⁶, (1)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, VIC, AUSTRALIA, (2)Olga Tennison Autism Research Centre, Olga Tennison Autism Research Centre, School of Psychological Science, La Trobe University, Bundoora, VIC, Australia, (3)Pediatrics, Keck School of Medicine, University of Southern California, Los Angeles, CA, (4)Healthy Autistic Life Lab; School of Psychology, Deakin University, Burwood, VIC, Australia, (5)School of Psychology, University of Nottingham, Nottingham, Nottinghamshire, UNITED KINGDOM, (6)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia

Background:

Autistic people are at significantly increased risk of non-suicidal self-injury and suicidal thoughts and behaviours (STB) compared with non-autistic people. The use of evidence-informed interventions which prevent self-harm and STB are therefore essential for this priority population. Suicide safety planning is one of the most widely used and evaluated suicide prevention interventions. Safety plans consist of a written, prioritized list of coping strategies and sources of support that individuals in crisis can use to manage distress and remain safe. Despite safety plans being recommended by the autism community as a promising suicide prevention intervention for autistic people, few studies have explored whether, or how safety plans are currently used by the autistic community.

Objectives:

In this qualitative study, we interviewed autistic adults with lived experience of self-harm and STB, including suicide attempt, about their experience with, and views on safety planning.

Methods:

The study was approved by La Trobe University Human Ethics Committee (#HEC20235). We recruited $N = 33$ formally diagnosed autistic adults without co-occurring intellectual disability ($n = 16$ women, $n = 14$ men, $n = 3$ non-binary) aged 21 to 68 years ($M_{age} = 41.72$, $SD = 11.49$). All participants had a history of STB. Using qualitative interview questions we asked participants about their prior use and experiences with safety plans in both formal and informal settings. E.g., “Do you have a safety plan in place for when you are feeling suicidal?”; “Can you tell me a bit about what the plan involves? When you might use it? How was it developed, and with whom?”. We used a reflexive thematic analysis approach to examine open-ended responses to prompt questions, and an iterative, inductive process with both latent and semantic coding.

Results:

Approximately 30% ($n = 8$) of participants had experience developing a formal safety plan with the assistance of a mental health professional. A further 11% ($n = 3$) of participants considered themselves to have an informal safety plan (developed by the participant themselves, or in collaboration with a family member). While the remaining 59% ($n = 16$) of participants did not believe they had a safety plan, over half (56%; $n = 9$) described a planned range of strategies that could be considered an informal safety plan. Three main themes and several sub-themes were constructed from the transcribed interviews, reflecting participants' lived experiences and knowledge of safety planning. 1) Having a safety plan that is developed as a personalized, autism-adapted, living document, is crucial to its usefulness. 2) Having a trusted adviser to assist with the development of a safety plan was considered to be essential to the success of the intervention. 3) While safety plans were considered as somewhat useful, demonstrated a limited understanding of both the intent and the application of safety planning.

Conclusions:

Our findings indicate that care needs to be taken to ensure that safety plans are understood in a contextualised way by both the mental healthcare professional implementing the intervention, and the autistic individual receiving the intervention.

418.027 Autistic Adults and Supporters Experiences of Completing Autism Adapted Safety Plans: Lessons Learned for Future Implementation.

S. A. Cassidy¹, J. Rodgers², M. Pelton³, J. Goodwin⁴, J. Wagnild⁵, N. Bhattarai⁶, I. Gordon⁷, C. Wilson⁸, P. Heslop⁹, E. Ogundimu¹⁰, R. O'Connor¹¹, S. E. Ramsay⁶, E. Townsend¹² and L. Vale⁶, (1)School of Psychology, University of Nottingham, Nottingham, Nottinghamshire, UNITED KINGDOM, (2)Population Health Sciences Institute, Newcastle University, Newcastle, Newcastle upon Tyne, United Kingdom, (3)University of Cambridge, Cambridge, Cambridgeshire, United Kingdom, (4)Other, Newcastle Upon Tyne, United Kingdom, (5)Durham University, Durham, Durham, United Kingdom, (6)Newcastle University, Newcastle Upon Tyne, United Kingdom, (7)University of Nottingham, Nottingham, Nottinghamshire, United Kingdom, (8)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (9)Northumbria University, Newcastle Upon Tyne, Newcastle, United Kingdom, (10)Durham University, Durham, United Kingdom, (11)University of Glasgow, Glasgow, United Kingdom, (12)School of Psychology, University of Nottingham, Nottingham, Nottinghamshire, United Kingdom

Background:

Autistic people are at increased risk for self-harm and suicide, but few studies have developed or tested suicide prevention interventions for this group. Autism Adapted Safety Plans (AASP) were developed with and for autistic adults and those who support them to reduce self-harm, suicidal thoughts and behaviours.

Objectives:

To explore the experiences of autistic adults who completed AASP, and those who supported them to complete AASP. In particular, whether participants would recommend AASP to others, whether they found it useful for themselves/the autistic person they support, and whether any adaptations or considerations are needed for AASP. We also explored evidence of initial effects of AASP in reducing self-harm, suicidal thoughts and suicidal behaviours in autistic adults.

Methods:

Data were collected as part of a pilot feasibility randomised controlled trial of AASPs. Autistic adults were recruited via community organisations and self-referral. Participants were randomised without stratification to usual care +/- AASP. The AASP was completed by the autistic adults with someone trained to support them. Research staff completing follow-up assessments were blind to participant allocation. Participants were assessed at baseline, 1- and 6-months. The researchers conducted interviews with 47 participants (autistic adults who had completed AASP, and professionals who supported them) 6-months after completing AASP. Data from the interviews were analysed using thematic analysis. Logistic regression compared suicide outcome measures between the treatment and control arm at 1- and 6-month follow-up.

Results:

Many participants were satisfied and would recommend AASP to others. Participants acknowledged that AASP were not appropriate for everyone, and that ongoing appropriate mental health support, and support of a trusted person, were important to successfully complete and use AASP. It was important for professionals to manage the expectations of autistic people and what to do if AASP was not right for them. The visual resources, staged nature and clear structure of AASP, and focus on practical strategies were seen as helpful. AASP could be improved by providing more examples of strategies to incorporate into the plan, having a short version for quick access, and being able to personalise the AASP format, questions and sections much more. In particular, the focus on people to contact for help was particularly difficult for many autistic participants to complete, given social isolation, or not being able to speak or seek help during a crisis. Alternative options and wording could help many more autistic people successfully complete a safety plan. Autistic adults were significantly less likely to report planning suicide at 1-month and 6-months after completing an AASP compared with autistic adults who received usual care.

Conclusions:

AASPs are a potentially valuable intervention for autistic adults, provided that the process of creating it is flexible and sensitive to individual needs. Use of technology, such as in an app could give autistic people much more freedom in personalising AASP maximise its usefulness to themselves. Further adaption and testing of the AASP in different formats to assess its clinical and cost effectiveness in reducing suicidal behaviour could provide a life-saving intervention for autistic adults.

418.028 Autistic Voices on Substance Use Disorders: Navigating Stigma, Treatment, and Recovery

L. Graham Holmes¹, **M. Mueller²**, L. Valvano³, E. E. McKenney⁴ and E. F. Rothman⁵, (1)Silberman School of Social Work, Hunter College, CUNY, New York, NY, (2)Columbia University, New York, NY, (3)Department of Psychiatry, CUNY Graduate Center, New York City, NY, (4)Department of Psychology, Rowan University, Glassboro, NJ, (5)Occupational Therapy, Boston University, Sargent College, Boston, MA

Background:

Substance use disorders (SUDs) are a public health problem with serious implications for relationships, education prospects, employment and health. SUDs may be just as prevalent, or even more prevalent, among autistic adults versus non-autistic adults. Autistic people experience high rates of psychiatric conditions that are risk factors for SUDs or unhealthy use, including ADHD, anxiety disorders, depression, bipolar disorder, and schizophrenia. Studies suggest autistic people use substances to cope with co-occurring mental health conditions and perceived social difficulties; using substances to cope is an additional risk factor for addiction.

There is limited information about SUD treatment for autistic people. Some evidence shows that SUD treatment providers are not systematically trained to work with autistic people and find this population challenging to support effectively without training or consultation, suggesting that autistic people are less likely to benefit from such treatments. Information about SUDs, treatment experiences, and recovery for autistic people may help inform SUD care and the development of targeted interventions.

Objectives:

Investigate how autistic people experience SUDs, SUD treatment, and recovery in order to provide clinical guidance and inform intervention development.

Methods:

N=32 semi-structured, 30-60 minute interviews were conducted via Zoom. Participants were (1) over 18 years of age; (2) formally or self-diagnosed with autism; (3) English-speaking; (4) able to participate in an interview verbally or via writing; and (5) able to describe their experience with SUD and/or SUD treatment. Purposive sampling was used to recruit a diverse sample (see Table 1). We used a content analysis approach to analyze data. Autistic people with experience in recovery contributed to each part of the project.

Results:

Five themes emerged from the data (Table 2). Participants described (1) origins of SUD, including attempts to address co-occurring conditions or navigate social situations. (2) Autism had myriad effects on recovery from SUD, bringing strengths (e.g., an analytical approach to learning about substances and harm reduction) and difficulties (e.g., creating new routines, lack of social support). Participants discussed the role of (3) masking and burnout in substance use, and how understanding and embracing autism helped with recovery. Finally, participants described (4) systemic barriers to SUD treatment and (5) how to make support more accessible and relevant. Participants particularly appreciated hearing personal stories in groups, online options and accommodations, creating their own goals, having different communication styles honored, guidance for how to reduce harms associated with substance use and navigating setbacks, a holistic focus on the person rather than only focusing on autism or substance use or other mental health conditions, and autism-trained providers.

Conclusions:

Autistic individuals face systemic barriers to accessing and receiving SUD treatment that meets their needs. Targeted treatments and better training for healthcare and mental health providers are indicated. While some challenges, such as the relevance of harm reduction, align with broader use and recovery themes, autism-specific factors—like autistic burnout and masking—require flexible, individualized approaches. Further research is needed to better understand these factors and design interventions that support sustainable recovery and improved long-term outcomes.

418.029 Behavioral Inhibition and Anxiety in Autistic and Non-Autistic Children: DSM-Based CBCL Scores and the Pras-ASD

K. Liles¹, T. McFayden², J. F. Strang³, J. Parish-Morris⁴, J. S. Miller⁴ and C. Harrop⁵, (1)Department of Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill- Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (3)Gender and Autism Program, Children's National Health System, Washington, DC, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC

Background: Approximately 40% of youth with autism spectrum disorder (ASD) experience clinical levels of anxiety (van Steensel et al., 2011), however the mechanisms underlying the development and maintenance of anxiety in this population are not fully understood. Behavioral inhibition (BI), a temperament or personality trait characterized by caution, shyness, or withdrawal in unfamiliar situations, has been linked to anxiety across both autistic and non-autistic youth (Chetcuti, et al, 2023). Higher inhibitory control in novel situations may lead to heightened reactivity and increased avoidance behaviors, contributing to anxiety (Buzzell et al., 2021).

Objectives: The current study examines the relation between inhibitory control and anxiety in autistic and non-autistic children and potential moderating effects of IQ, assigned-sex, and age using a measure of anxiety specifically developed for autistic youth (Parent-Rated Anxiety Scale for ASD – PRAS-ASD; Scahill et al., 2019) and a broad-band anxiety screener (Child Behavior Checklist [CBCL], Achenbach, 2001). This analysis extends the current literature by a) exploring interactions between inhibition and demographic factors, and b) examining moderating factors driving the relation between inhibition and anxiety using the PRAS-ASD.

Methods: Participants included 147 children (n=73 autistic) aged 4-8 years ($M=6.02$, $SD=1.524$) and their parents enrolled in an ongoing longitudinal study. Parents completed several measures including the CBCL, PRAS-ASD, and Behavior Rating Inventory of Executive Functioning (BRIEF). Children completed the Differential Ability Scales on their first visit. Results were analyzed using two multi-step linear regressions predicting scores on: the 1) CBCL DSM-oriented anxiety scale and 2) PRAS-ASD. Block 1 includes demographic factors (i.e., age, assigned-sex, IQ, diagnosis), block 2 includes behavioral inhibition (i.e., BRIEF BI index), and block 3 investigates interactions between block 1 and block 2 variables.

Results: The first, $F(4,142)=11.009$, $p<.001$, and second, $F(5,141)=11.880$, $p>.001$, CBCL DSM-oriented anxiety models were both significant. The second model demonstrated significant F-change from the first model, $F\Delta(1,141)=11.963$, $p>.001$, with diagnosis, $B=5.676$, $p>.001$, IQ, $B=.114$, $p=.021$, and BI, $B=.227$, $p>.001$ demonstrating significance. Our final model was also significant, $F(7,139)=9.507$, $p<.001$, but did not demonstrate significant F-change, $F\Delta(2,139)=2.812$, $p=.063$. In the final model, only interactions between BI and diagnosis were significant, $B=.312$, $p=.028$. In the PRAS-ASD model, diagnosis, $B=6.178$, $p=.002$, and BI, $B=.346$, $p>.001$, were also significant in the first and second models, $F(5,141)=14.594$, $p>.001$, however, no significant interactions or variables were identified in the final model, $F(6,140)=12.690$, $p>.001$.

Conclusions: A significant interaction between BI and diagnostic group emerged that qualified the main effects for parent-reported anxiety scores on the CBCL. This suggests that although autism and inhibition each impacted anxiety, behavioral inhibition plays a greater role in anxiety among non-autistic children, whereas anxiety for autistic children appears elevated irrespective of inhibition (Fig.1). This interaction was found only when evaluating anxiety traits broadly (e.g., diagnostic-general anxiety screener) rather than in a diagnostic-specific context (e.g., autism-specific anxiety screener). These results may have implications for anxiety treatment in autistic children, especially the role of behavioral strategies such as inhibition and activation. Future research could explore whether autism-specific anxiety screeners better evaluate predictors of anxiety among autistic children.

418.031 Caregiver and Clinician Insights on Cochlear Implantation in Autistic Individuals

G. J. Cardon, *Communication Disorders, Brigham Young University, Provo, UT*

Background:

Approximately 70% of normal hearing (NH) autistic children develop strong oral language abilities. Additionally, most non-autistic cochlear implant (CI) users develop functional spoken language, given early implantation, consistent device use, and access to appropriate rehabilitation services. Despite these notions, existing data suggest that spoken language development is extremely difficult and not a realistic goal for autistic CI users (ACI).

Objectives:

The inconsistencies in the above prompted the current, mixed-methods study aimed at examining clinician and caregiver perspectives on spoken language development in ACIs. We hypothesized that CI function itself would not be the most significant factor in predicting language development, but that device use, behavioral and sensory processing considerations, and lack of clinician training and experience, would each play significant roles. We were also open to novel insights, especially during qualitative inquiry.

Methods:

Phase 1 (Quantitative) consisted of surveys for clinicians (n=16) and caregivers (n=6) of ACIs. Additionally, we elicited caregiver responses from groups of autistic children with normal hearing (ANH; n=4), neurotypical CI users (NTCI; n=4), and neurotypical children with normal hearing (NTNH; n=38). All child participants were between the ages of 3.5-14 years. Those with CIs had used their devices for greater than six months. Caregiver surveys included questions regarding demographics, expressive and receptive language ability, rankings of barriers/contributors to CI effectiveness, and standardized measures of sensory processing and mental health challenges. Clinician surveys incorporated similar questions and surveyed their experience in working with the ACI population. We also conducted language samples with all ACI participants. Quantitative analysis included descriptive, between-groups, and correlational statistics.

In Phase 2, we conducted semi-structured interviews with clinicians (n=9—4 speech-language pathologists and 5 Audiologists) and caregivers (n=6) of ACIs and performed qualitative thematic analysis. Results from both phases converge to triangulate the points reported below.

Results:

Both clinicians and caregivers ranked device/CI tolerance, child behavior/cooperation during intervention, and sensory processing as the top contributors to CI effectiveness and language development. Additionally, our interviews revealed that sensory seeking tendencies were associated with more consistent CI use, while sensory hypersensitivities were linked to greater difficulty tolerating CIs. Furthermore, parent advocacy and clinician training/experience stood out as significant contributors to general CI success.

Five of six ACI participants effectively used spoken language as their primary communication modality, according to our language samples and interviews. Appropriate aural rehabilitation from providers experienced with the ACI population, though scarce, was key to spoken language development. Language difficulties seemed to be more related to autism-related traits (e.g., sensory processing) than hearing loss and device function. Thus, it appears that, if desired, spoken language can be a realistic goal in the ACI population, if appropriate factors are considered. One clinician pointed out that we should not, "...[impose] preconceived limitations on autistic CI users."

Conclusions:

Overall, our results challenge and add to the literature regarding spoken language development in ACIs, in that they are more optimistic and elucidate several significant outcome-related factors not previously considered. These results have implications for future patient and family support by various clinical specialties.

418.032 Changes in Prevalence of Mental, Behavioral, and Neurodevelopmental Disorders Among Autistic Tweens and Their Peers Enrolled in Medicaid

J. Yu¹, J. Ventimiglia², S. D. Paul¹, P. H. Smith³, B. K. Lee⁴, J. E. Rast⁵, J. Rando³, K. Lyall⁵, L. Shea³, N. Rod⁵, P. H. Mullachery⁶ and D. Schendel¹,
 (1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)AJ Drexel Autism Institute, Philadelphia, PA, (4)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (5)University of Copenhagen, Copenhagen, Copenhagen, Denmark, (6)Temple University, Philadelphia, PA

Background: Children in their tween years undergo dramatic biological, social, behavioral, and developmental changes which set the stage for a variety of co-occurring health conditions, especially mental and behavioral health. Elevated rates of co-occurring conditions in autism are well-established, yet large longitudinal studies of autistic health focusing on the tween years are scarce.

Objectives: We aimed to compare age changes in prevalence of health conditions involving mental, behavioral, or neurodevelopmental (MBND) conditions between tweens with autism and their peers without autism aged 10-13 years at the start of follow-up and 14-17 years at the end.

Methods: This study used national Medicaid claims from 2008-2019, examining all persons with autism, all persons with intellectual disability without autism (ID/No Autism), and a five percent random sample of persons who have neither autism nor ID (No Autism/No ID). Individuals were ages 10-13 years at first Medicaid enrollment and continuously enrolled for a minimum of 10 months per year for five consecutive years of follow-up. We calculated the prevalence of 15 MBND conditions (based on claims-reported ICD9 or ICD10 diagnosis codes) within two-year observation windows during the first two years of follow-up (years 1-2 of follow-up=time point 1, ages 10-13) and last two years of follow-up (years 4-5 of follow-up=time point 2, ages 14-17). For each of the three study groups, we calculated prevalence per condition, per time point, and prevalence rate ratios contrasting autism with each of the other two study groups, per condition, and per time point.

Results: Tween prevalences for MBND conditions at time point 1 (10-13 years) ranged from 0.07% (Social Anxiety disorder in No Autism/No ID) to 14.6% (bipolar disorder in autism) and from 0.16% (OCD in No Autism/No ID) to 16.6% (bipolar disorder in autism) at time point 2 (14-17 years). Overall autistic tweens enrolled in Medicaid ($n=227,782$) had higher prevalences of MBND conditions both at time point 1 (0.09%-14.6%) and time point 2 (0.5%-16.6%) – highest for bipolar disorder, other anxiety disorders, conduct disorders, depressive disorders - compared to the other study groups (ID/No Autism $n=104,547$; No Autism/No ID $n=176,588$) (Figure 1). Similarly, prevalence rate ratios between autism and each of the other study groups were markedly elevated across most disorders at both time points (Figure 2), although the ratios were lower at time point 2. Autistic tweens had lower rates of substance use disorders (drug, tobacco, and alcohol) compared to other study groups (except when compared to the no Autism/no ID group at time point 1), as well as lower rates of PTSD diagnoses compared to the ID/No Autism group at both time points.

Conclusions: During the early tween years (10 to 13 years old) autistic children enrolled in Medicaid already have higher prevalences for many co-occurring MBND conditions when compared to their peers. This difference persists over later years into middle/late adolescence. These results highlight the importance of the development of policies that help identify autistic children entering their tween years who may be at an increased risk of developing MBND conditions.

418.033 Characterizing Key Correlates of Specific Sleep Domains in Youth with Autism.

E. K. Baker, E. Gropman, I. C. Reyes, J. M. Phillips, M. Uljarevic, R. Libove, M. Kawai, R. O'Hara, B. Jo, Z. Li, B. Kim, A. Y. Hardan and J. F. Hallmayer, Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA

Background: Sleep problems are one of the most common and clinically impactful co-occurring conditions in children and adolescents with autism spectrum disorder (ASD). Indeed, sleep problems during childhood have significant negative effects on both the child and their families, impacting various facets of daytime functioning including cognitive functioning, emotion regulation, repetitive and restricted behaviors, with these impacts being exacerbated in autistic individuals. However, we still lack a comprehensive understanding of the specific correlates of distinct types of sleep problems in autistic individuals. Characterizing key correlates of differing sleep profiles may aid in developing individualized sleep interventions for children with ASD.

Objectives: This study examined the relationships between core autism features, emotion dysregulation, and parental sleepiness on fine-grained domains of sleep in autistic children.

Methods: 50 children with ASD (75% male) aged 4-17 years participated in this study. Child sleep problems were assessed with the Children's Sleep Habits Questionnaire (CSHQ), core autism features with the Stanford Social Dimensions Scale and the Dimensional Assessment of Restricted and Repetitive Behaviors, emotion dysregulation with the Child Behavior Checklist (CBCL), and parental sleepiness from the parent sleep habits questionnaire.

Results: Correlation analysis showed insistence on sameness ($r_s = 0.331, p = .018$) and sensory sensitivities ($r_s = 0.358, p = .010$) to be associated with parasomnias. Parental sleepiness was significantly associated with bedtime resistance ($r_s = 0.390, p = .004$) and sleep anxiety ($r_s = 0.294, p = .034$). None of the SSDS subscales were significantly associated with sleep problems. A series of hierarchical regression models were conducted to determine unique predictors of bedtime resistance, sleep anxiety, parasomnias, daytime sleepiness, and total sleep problems. For each model, age was entered in step 1, total problem behaviors (CBCL) in step 2, sensory sensitivities in step 3, insistence on sameness in step 4, and finally parental sleepiness in step 5. Unique profiles of predictors emerged for distinct sleep problems. Specifically, total problem behaviors were associated with total sleep disturbances (beta = 0.171, $p = .004$), parasomnias (beta = 0.035, $p = .006$), and daytime sleepiness (beta = 0.057, $p = .022$), while age uniquely predicted bedtime resistance (beta = -0.346, $p = .010$) and sleep anxiety (beta = -0.269, $p = .003$).

Conclusions: The findings of the current study provide important insights with regards to the nuanced relationships between key correlates and specific sleep problems in children and youth with ASD. Age was negatively associated with bedtime resistance and sleep anxiety, suggesting that these problems are more common in younger children with ASD and targeted interventions to address these challenges may help to prevent ongoing sleep disturbances as the child gets older. Parental sleepiness may also have implications on their ability to implement good sleep hygiene practices contributing to bedtime resistance. The findings also highlight the significant impact of emotion regulation challenges on the presence of parasomnias and daytime sleepiness. Sleep interventions that simultaneously target emotion regulation challenges in children with ASD, may be effective in improving sleep outcomes.

418.034 Characterizing Patterns and Correlates of Nonsuicidal Self-Injury in Autistic Adults

L. Antezana¹, J. Feldman², L. L. Manna¹, T. Kumar², S. Eldeeb¹, C. M. Conner¹, L. N. Scott¹ and C. A. Mazefsky¹, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Department of Psychology, University of Pittsburgh, Pittsburgh, PA

Background: While approximately 50% of autistic adults report a history of NSSI, it remains understudied despite an association with suicide attempts, and autistic people's advocacy for further research (Moseley et al., 2019). Prior work has found that alexithymia and sensory sensitivities are correlates of NSSI in autistic people. Interestingly, repetitive behaviors, cognitive rigidity, emotion dysregulation, impulsivity, and social anhedonia have not been linked to NSSI in autistic samples, although these constructs have been linked to "stereotyped" self-injurious behaviors in autistic samples and/or with NSSI in nonautistic samples.

Objectives: This study aimed to (1) examine group differences in lifetime and 6-month history of NSSI in autistic vs. nonautistic adults, (2) investigate correlates of history and frequency of NSSI in autistic adults, and (3) explore associations with age of NSSI onset, number of NSSI methods, and time spent thinking about NSSI in autistic adults.

Methods: Data were from an ongoing study on mental health and suicide in autistic vs. nonautistic adults (Projected total N=300 [Autistic n=200]), with both groups oversampled for suicidality. To date, 100 participants (Autistic n=75; M(SD) age= 32.96(10.77) years; Table 1) were administered NSSI questions from the Self-Injurious Thoughts and Behaviors Interview. Participants completed self-reports, including the Comprehensive Autism Trait Inventory (repetitive behaviors, cognitive rigidity, sensory sensitivity), Perth Alexithymia Scale, Emotion Dysregulation Inventory, Emotion Regulation Questionnaire, UPPS (impulsivity), and Social Anhedonia Scale. Log transformations were conducted on 6-month NSSI frequency and number of methods as raw data were skewed. Chi-square tests were used for group differences in history of lifetime and 6-month NSSI. Within the autistic group, hierarchical logistic regressions were used to examine correlates of history of lifetime and 6-month NSSI. Hierarchical linear regressions were used to examine correlates of 6-month NSSI frequency, number of methods, age of onset, and time spent thinking about NSSI. Covariates for all regressions included age, assigned sex at birth, and IQ.

Results: Autistic adults were more likely to report history of lifetime NSSI compared to nonautistic adults (64% vs. 24%), $\chi^2=12.08$, $p<.001$. No group differences emerged for 6-month NSSI history. In autistic participants, the model was significant for history of lifetime NSSI (Nagelkerke $R^2=0.61$, $p<.001$), with more repetitive behaviors ($B=0.64$), and worse cognitive reappraisal ($B=.14$) associated with history of lifetime NSSI; no other variables significantly added to the model. Significant models emerged for 6-month NSSI history, 6-month NSSI frequency, and number of NSSI methods with similar patterns of older age, and more repetitive behavior associations ($ps<0.05$; Table 2). Models for age of NSSI onset and time spent thinking about NSSI were nonsignificant.

Conclusions: Older age and more repetitive behaviors have a strong link with history of NSSI, NSSI frequency, and number of NSSI methods in autistic adults. It will be important for future work to parse the ways in which repetitive behaviors and NSSI may be intertwined. Uncovering mechanisms related to repetitive behaviors will allow better understanding of the emergence and maintenance of NSSI and may aid in development of targeted NSSI prevention and intervention for autistic people.

418.035 Risk of Injury in Children with Autism Spectrum Disorder with or without Attention Deficit/Hyperactivity Disorder - a Retrospective Cohort Study of Pediatric Emergency Department Visits in Israel

A. Mimouni Bloch¹, D. Shmueli², I. Menashe³, T. Razi⁴ and M. Almog⁵, (1)Child Development Center, Loewenstein, Ra'anana, Israel, (2)Child Development, Clalit MHO, Jerusalem, Jerusalem, Israel, (3)Department of Epidemiology, Biostatistics, and Community Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, (4)Clalit Health Services, Tel Aviv, Tel Aviv, Israel, (5)Clalit Health Services, Hadera, Sharon, Israel

Background:

Autism Spectrum Disorder (ASD) and Attention-Deficit Hyperactivity Disorder (ADHD) are the most prevalent neurodevelopmental disorders in developed countries. While the two are considered two distinct disorders, they have overlapping symptomatology, with some patients diagnosed with both disorders. The prominent symptoms of ASD and ADHD may incline children to experience physical injuries more frequently than typically developing (TD) children. Identifying the risks of different types of injury in this vulnerable population could inform specific actions of parents and caregivers directed to reducing injuries.

Objectives:

In this retrospective cohort study we sought to identify specific patterns of emergency department (ED) visits due to physical injury of children with ASD, ADHD, or ASD+ADHD compared to TD children.

Methods:

We identified 325,412 children who are members of Clalit Health Service (CHS), the largest health service provider in Israel. These children were born between January 1st, 2005 and December 31st, 2009, and followed until December 31st, 2021. Participants were classified into four groups: ASD, ADHD, ASD+ADHD, and TD. Sociodemographic and clinical data, including ED visits and types of injuries as recorded by the ED physician, were extracted from the CHS electronic database. Negative binomial regression models were used to assess differences in incidence rate ratios (IRRs) of ED visits between the study groups and the controls. These models were adjusted for birth year, sector, and socioeconomic status. Furthermore, IRRs for specific injuries were also assessed. The statistical significance of IRRs was assessed using a 95% confidence interval.

Results:

Children with ASD, ADHD, or both were significantly more likely to visit an ED than TD children (IRR=1.48, 95%CI=1.42-1.55; IRR=1.45, 95%CI=1.39-1.52; and IRR=1.29, 95%CI=1.28-1.30, respectively). However, while children with ADHD were more susceptible to visiting the ED due to physical injuries (IRR=1.18, 95%CI=1.16-1.20), children with ASD with or without ADHD had a similar ED visit rate due to injuries compared to TD children (IRR=0.96, 95%CI=0.89-1.05, and IRR=0.91, 95%CI=0.83-1.00; respectively). A focused analysis of the injury profiles revealed that children with ASD or comorbid ASD+ADHD were more prone to ingestion and inhalation injuries (IRR=1.57, 95%CI=1.06-2.25; and IRR=1.80, 95%CI=1.28-2.48, respectively) and less prone to orthopedic injuries than TD children (IRR=0.78, 95%CI=0.69-0.89, and IRR=0.83, 95%CI=0.74-0.93; respectively).

Conclusions:

Our findings suggest that children with ASD experience fewer injuries, probably due to closer adult supervision.

418.036 Clinical Correlates and Prevalence of Insomnia Symptoms in Children with Autism Spectrum Disorder

M. L. Wenzell¹, S. P. Pulver², L. Scahill³, T. Davidson², S. Rajagopal², S. Gillespie², T. Huang², S. Griggs², M. Miao¹ and W. Sharp², (1)Frances Payne Bolton School of Nursing, Case Western Reserve University, Cleveland, OH, (2)Marcus Autism Center, Atlanta, GA, (3)Department of Pediatrics, Emory University, Atlanta, GA

Background: Prevalence estimates of insomnia symptoms (insomnia) in children with autism spectrum disorder (ASD) range from 53% to 78%, compared to 20% of children without ASD. This wide prevalence range of insomnia reflects differences in the sample size and source as well as the definition of insomnia. Most prevalence estimates of insomnia in children with ASD are based on parent ratings originally developed for use in a typically developing population. Therefore, these findings may not be generalizable to the broad population of children with ASD.

Objectives: To reduce the potential for ascertainment and measurement bias, this study examined the clinical correlates and prevalence of insomnia using a newly developed Pediatric Autism Insomnia Rating Scale (PAIRS) in children with autism spectrum disorder (ASD) ascertained from a specialty outpatient autism clinic.

Methods: A sample of 103 children 2 to 10 years (mean = 5.8 ± 2.2 , 78% male, 54.5% Non-Hispanic Black, 32.7% Non-Hispanic White, 12.9% other race/ethnicity) evaluated at the Marcus Autism Center and diagnosed with ASD were included. A multidisciplinary team (pediatric nurse practitioner and psychologist) assessed medical and psychosocial histories. Parents rated child insomnia and related impairment on the PAIRS, disruptive behavior on the Aberrant Behavior Checklist (ABC), and quality of life and family functioning on the PedsQL. Children were classified as having insomnia or no insomnia based on the PAIRS. Univariable and multivariable logistic regression modeling was used to evaluate clinical correlates with insomnia. For continuous predictors, odds ratios were scaled based on one-half (0.5) SD increases. Best subsets selection was used to determine the most important predictors for insomnia.

Results: Of 103 children, 33% ($n=34$) were classified as having insomnia; 67% ($n=69$) no insomnia. After adjusting for confounders, the odds of insomnia increased by 2.71 (95% CI: 0.97, 7.58, $p=.057$) for gastroesophageal reflux disease, 2.27 (95% CI: 0.89, 5.80, $p=.088$) for constipation, and 3.68 (95% CI: 1.24, 10.92, $p=.019$) for dietary supplements. For mealtime behavior, the odds of insomnia increased by 1.81 (95% CI: 1.32, 2.49, $p<0.001$) for every half-SD increase in BAMBI total. For disruptive behavior, the odds of insomnia increased by 1.58 (95% CI: 1.21, 2.06, $p<0.001$) for every half-SD increase in Irritability, 1.80 (95% CI: 1.28, 2.53, $p<0.001$) for Social Withdraw, 1.37 (95% CI: 1.05, 1.79, $p=.022$) for Stereotypic Behavior, 1.85 (95% CI: 1.35, 2.54, $p<0.001$) for Hyperactivity, and 1.61 (95% CI: 1.24, 2.11, $p<0.001$) for Inappropriate Speech. For child and family impact, the odds of insomnia decreased by 36% (OR: 0.64; 95% CI: 0.47, 0.85, $p=.003$) for every half-SD increase in child HRQoL, 38% (OR: 0.62; 95% CI: 0.47, 0.83, $p=0.001$) for parent HRQoL, and 38% (OR: 0.62; 95% CI: 0.47, 0.82, $p<0.001$) for family functioning. Hyperactivity/noncompliance, dietary supplements, and mealtime behaviors were the most significant predictors of insomnia in the best subset selection model (ROC = 0.842).

Conclusions: Hyperactivity/noncompliance, dietary supplements, and mealtime behaviors are the most significant predictors of insomnia in a generalized sample of children with ASD. Future epidemiological samples are recommended for a true prevalence estimate.

418.037 Clinical Profiles and Interventions Offered to Children and Adolescents in Psychiatric Care

A. Côté^{1,2}, M. Plourde³, V. Langlois⁴, P. Grégoire⁵ and V. Courchesne⁶, (1)Psychology, Université de Montréal, Montreal, QC, Canada, (2)CIUSSS du Nord-de-l'Île-de-Montréal, Montreal, QC, Canada, (3)Psychology, Université de Montréal, Montréal, QC, Canada, (4)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (5)Psychiatry and Addictology, Université de Montréal, Montréal, QC, Canada, (6)University of Montreal, Montréal, QC, Canada

Background: Approximately 70% of autistic children present at least one psychiatric comorbidity (Rosen, Mazefsky, Vasa, & Lerner, 2018), which is much higher than among non-autistic children (Joshi et al., 2010). More specifically, when looking at mental health (MH) comorbidities, 44% of autistic children between the ages of 10 and 14 have an anxiety disorder, a phobia and/or a mood disorder (Simonoff et al., 2008). Despite the significant prevalence of psychiatric disorders in autistic children, very few clinics have expertise in both autism and MH. One of the only clinics in Quebec with this dual expertise is the ASD Intervention clinic (Clinique d'intervention TSA; CITSA) of the Rivière-des-Prairies Hospital in Montreal. The CITSA serves a large population of autistic children with MH difficulties. It is therefore an exceptional source of information to better understand the presentation of psychiatric comorbidities in this population.

Objectives: Document the socio-demographic and clinical profile of the autistic children and adolescents receiving care at the CITSA and document the interventions received.

Methods: We carried out a retrospective chart review of the CITSA patient's whose follow-ups ended between April 1st 2022 and March 31st 2023 ($n=120$). An extraction grid was developed in collaboration with CITSA clinicians and validated using 30 random charts. An inter-rater agreement was also done on those 30 files using the Double Data Entry function in REDCap. General information (age, duration of the care episode and professionals seen) was extracted for all patients and more detailed information was extracted for the 30 charts used to validate the extraction grid. Detailed information includes psychiatric and medical comorbidities (as well as other problems such as suicidal ideation or self-harm), number of hospitalizations and information on pharmacotherapy and psychotherapy.

Results: The average age of patients at the first appointment was 13 years old (5 to 17) and patients were seen for 15 months on average (1 day to 5 years). All patients saw a psychiatrist, 25.8% a psychologist, 15% a neuropsychologist, 12.5% a psychoeducator, 13% a social worker, 8.3% an occupational therapist and 2.5% a speech therapist. The majority of the patients (54%) saw only a psychiatrist, 25% saw one other professional, 16% two other professionals and 5% three or more other professionals. Results from the detailed extraction of the first 30 charts showed that the autism diagnosis was removed for 4 patients (13%). The most frequent comorbidities were ADHD (11/26), behavioral or oppositional disorder (7/26) and anxiety disorders (6/26). Almost half of the patients (12/26) were hospitalized before or during their care episode. Pharmacotherapy related interventions were frequently used (21/26), while psychotherapy was offered to 30% of patients (8/26).

Conclusions: Autistic children with MH problems have unique needs in terms of care. A better understanding of the clinical profiles of autistic youth with MH difficulties can inform us on the risk factors and help focus on prevention efforts. Knowledge on the nature of the interventions offered at the CITSA could contribute to improve MH services for autistic children and adolescents.

418.038 Co-Occurrence of Epilepsy and Autism - What Should be the Primary Diagnosis?

I. Menashe¹, G. Meiri², I. Dinstein³ and N. Sadeh⁴, (1)Department of Epidemiology, Biostatistics, and Community Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, (2)26 YA'ARA ST., Beer-Sheva, Israel, (3)Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel, (4)Ben-Gurion University of the Negev, Beer Sheva, Israel

Background:

Epilepsy and autism spectrum disorder (ASD) are two prevalent neurodevelopmental conditions that together affect approximately 2-3% of children worldwide. Although ASD and epilepsy are considered two distinct conditions, they share certain pathophysiological mechanisms and clinical characteristics. Furthermore, some people are diagnosed with both conditions. In such cases, it is often unclear which condition predisposes the other one and which should be the primary diagnosis. In other words, it remains uncertain whether the co-occurrence of epilepsy and ASD represents a unique neurodevelopmental condition or if it should be classified as a subtype of one of these disorders.

Objectives:

To identify similarities and differences in sociodemographic and clinical characteristics between children with co-occurring ASD and epilepsy and those with either ASD or epilepsy alone.

Methods:

We conducted a retrospective cohort study of all children who are members of Clalit Health Services (CHS), the largest health service provider in Israel, who were born between 2010 and 2020 and followed until May 2024. We identified all children diagnosed with either epilepsy or ASD (or both) and obtained sociodemographic data, as well as data about the pregnancy, birth, and postnatal chronic diagnoses of these children from the electronic database of CHS. Finally, we compared the prevalence, sociodemographic, and clinical characteristics between three study groups: 1) children with ASD without epilepsy ("ASD"); 2) children with epilepsy without ASD ("epilepsy"); and children with co-occurring ASD and epilepsy ("ASD+epilepsy").

Results:

The study cohort included 1,465,958 live births, of which 34,277 (2.34%) of them were diagnosed with either ASD or epilepsy. Opposite trends were seen in the prevalence of ASD and epilepsy during the study period (**Figure 1A**). While ASD prevalence has more than doubled (from 1.02% for children born in 2010 to a peak of 2.26% for children born in 2018), the prevalence of epilepsy has constantly declined (from 0.84% to 0.44% in the same years). At the same time, the prevalence of children with co-occurring ASD+epilepsy remained relatively stable with similar rates of epilepsy and ASD as the primary diagnosis in these children (**Figure 1B**). Interestingly, children with co-occurring ASD+epilepsy were more similar to children with only ASD than children with only epilepsy in their sociodemographic and obstetrics characteristics. However, they had significantly higher rates of intellectual disability, ADHD, gestational problems, and motor coordination problems than children with either epilepsy or ASD alone ($p < 0.001$). Finally, higher rates of specified types of epilepsy were seen among children with only epilepsy than in children with epilepsy+ASD (21.6% vs. 16.5%; $p < 0.001$), whereas no significant differences in the severity of ASD symptoms were seen between the two ASD groups.

Conclusions:

The findings from this study suggest that the co-occurrence of epilepsy and ASD is not a distinct, homogeneous condition but rather a mixture of both conditions. Elucidating the pathophysiological mechanisms underlying the co-occurrence of these conditions may shed brighter light on this intriguing phenomenon.

418.040 Comparing Rates of Significant PTSD Symptoms and Formal Diagnosis of PTSD Among Autistic Adults

T. Andrzejewski, K. E. Breitenfeldt, A. U. Tassone and C. G. McDonnell, Department of Psychology, University of Wyoming, Laramie, WY

Background: Autistic adults experience high rates of traumatic events and high levels of symptoms of posttraumatic stress disorder (PTSD), including symptom profiles that are consistent with diagnosis of PTSD. However, autistic adults are also formally diagnosed with PTSD by healthcare providers at low rates. It is important to clarify rates of PTSD diagnosis and levels of PTSD symptoms among autistic adults and to explore variables that may be associated with the absence of community-based PTSD diagnosis to improve identification of PTSD and posttraumatic stress support.

Objectives: This study aims to (1) establish rates of probable PTSD (i.e., significant endorsement of PTSD symptoms consistent with PTSD diagnostic criteria, as measured by the PTSD Checklist for the *DSM-5* (PCL-5)), and rates of community-based PTSD diagnosis among autistic adults and self-identifying autistic adults; and (2) to identify variables that may be correlated with the absence of community-based PTSD diagnosis among those who present with significant symptoms via self-report (i.e., presentations of probable PTSD but no receipt of a community-based PTSD diagnosis).

Methods: The current study recruited 214 formally-diagnosed autistic adults (i.e., indicated having a formal autism diagnosis by a professional) and 62 self-identifying autistic adults (i.e., self-identified as autistic but had not received a formal autism diagnosis by a professional) via an online survey platform. Participants completed the Life Events Checklist for *DSM-5* (LEC-5) to screen for traumatic events, the PCL-5 to assess PTSD symptoms, and the Patient Health Questionnaire four-item version (PHQ-4) to assess depression and anxiety symptoms. Participants reported whether they currently have a formal diagnosis of PTSD given by a professional ("community-based PTSD diagnosis"). Probable PTSD was determined if PCL-5 items were endorsed at a significant level (Moderately, Quite a Bit, Extremely), if symptoms were consistent with *DSM-5* PTSD criteria (at least one re-experiencing symptom, one avoidance, two alterations in cognition/mood, two alterations in arousal/reactivity), and if total symptom scores surpassed 33 or higher.

Results: Autistic adults demonstrated high rates of probable PTSD and low rates of community-based diagnosis, and there were no differences across groups of formally-diagnosed and self-identifying autistic adults (see Table 1). Among those who self-reported symptoms of probable PTSD on the PCL-5, small percentages reported having community-based diagnoses of PTSD (36% of formally-diagnosed autistic adults, 32% of self-identifying autistic adults). Across both groups of individuals who endorsed probable PTSD, the lack of a community-based diagnosis positively correlated with levels of all PTSD symptoms (moderately) and anxiety and depression symptoms (weakly; see Table 2). Lack of a community-based PTSD diagnosis positively correlated (weakly) with the number of traumatic events that formally-diagnosed autistic adults learned about.

Conclusions: Autistic adults endorse clinically significant levels of PTSD symptoms but low rates of community-based diagnosis of PTSD. Not having a community-based PTSD diagnosis despite self-reporting probable PTSD correlated with higher mental health symptoms. High levels of mental health symptoms may relate to lower likelihood of PTSD identification, perhaps due to diagnostic overshadowing. Future research should aim to understand factors associated with diagnosis of PTSD to improve trauma-related support.

418.041 Comparison of Self-Care Development Among Children with Typical Development, Autism Spectrum Disorder, and Other Developmental Conditions

C. Y. Huang¹, P. Y. Cheng², K. L. Chen³ and I. C. Chuang⁴, (1)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (2)National Taiwan University, Taipei, None, Taiwan, (3)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan, (4)Department of Occupational Therapy and Graduate Institute of Behavioral Sciences, Chang Gung University, Taoyuan, Taiwan

Background:

Self-care involves activities that individuals perform to maintain their independence at home and school, such as eating, drinking, dressing, and toileting. Children with autism spectrum disorder (ASD) often face challenges in these activities due to their autistic traits or sensory processing difficulties.

Objectives:

To better understand self-care development and its progression, this study aimed to examine self-care performance in both children with and without ASD.

Methods:

We recruited caregivers of children aged 0 to 12 years, including children with typically development (TD), children with ASD and children with other developmental conditions (DC), based on caregiver reports. The Self-Care Performance Assessment, a caregiver-reported questionnaire, was used to assess the children's self-care abilities. Caregivers completed the questionnaire at three time points: the initial evaluation, a 6-month follow-up, and a 1-year follow-up. Children were divided into three diagnostic groups: TD, ASD, and DC. Each diagnostic group was further categorized into four age ranges: 0–3, 4–6, 7–9, and 10–12 years. Mean total scores of the SCPA were calculated for each diagnostic and age group at the three time points. An analysis of variance (ANOVA) was used to compare self-care performance across diagnostic categories within each age group.

Results:

A total of 203 children participated in the study, including 127 in the TD group, 33 in the ASD group, and 43 in the DC group. No significant age differences were found across the diagnostic groups within each age group. Compared to the TD and DC groups, the ASD group exhibited significantly lower self-care performance in the 7–9 and 10–12 age groups at all three time points. Regarding developmental changes, the TD group showed the greatest improvement at the 1-year follow-up (mean change score: 1 to 30 across different age groups), followed by the ASD group (mean change score: 9 to 20 across different age groups), with the DC group showing the least improvement (mean change score: 2 to 16 across different age groups).

Conclusions:

Our study compared self-care development across different diagnostic groups. The findings provide valuable insight into the developmental baselines for TD children and highlight potential progress patterns across diagnoses over one year. The findings suggest distinct trajectories in self-care development, particularly in children with ASD and DC. Future research is needed to explore the mechanisms underlying these changes in self-care development.

418.042 Convergent Validity of the Anxiety Scale for Autism in Adults (ASA-A)

J. N. Lukacs¹, T. Q. Boucher¹, N. E. Scheerer², P. Hood¹, V. Ly¹ and G. Iarocci¹, (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Wilfrid Laurier University, Waterloo, ON, Canada

Background:

Autistic adults experience anxiety at a higher rate than non-autistic adults (Nimmo-Smith et al., 2020). Previous research has shown that the experience of anxiety may be different for autistic people, such as experiencing worry and uncertainty about routines and novelty and social anxiety not related to evaluation (Kerns et al., 2014). The Anxiety Scale for Autism - Adults (ASA-A) is a self-report measure used to assess anxiety in autistic adults. The 21-item Depression, Anxiety and Stress Scale (DASS-21) is a commonly used measure of general symptoms of depression and anxiety in both general and clinical populations. Assessment of the convergent validity of the ASA-A would be beneficial for both the continued use of the ASA-A and the interpretation of DASS-21 scores in autistic populations.

Objectives:

Demonstrate the validity of using the ASA-A as a general measure of anxiety in autistic adults through an assessment of convergent validity with a widely used measure of depression and anxiety (DASS-21).

Methods:

As part of a secondary analysis of an existing dataset, ASA-A and DASS-21 data from 182 participants [male = 69, female = 91, gender expansive = 22, age ($M(SD)$) = 26.95(11.16)] was analyzed. In addition, the Autism Spectrum Quotient (AQ), and the Camouflaging Autistic Traits Questionnaire (CAT-Q) were also administered. Internal validity of the ASA-A for the population was assessed using inter-item correlations and Cronbach's α 's. Convergent validity between the ASA-A, the DASS-21, the AQ, and the CAT-Q was also assessed.

Results:

All ASA-A subscales were significantly related to one another ($p \leq .001$), with good internal consistency for subscales (Cronbach's α (range) = 0.859 to 0.881) and excellent total internal consistency (Cronbach's α = 0.928). The total ASA-A score showed a strong correlation with anxiety ($P = 0.758$) and stress subscales ($P = 0.748$) on the DASS-21, and a moderate correlation with depression ($P = 0.596$). In comparison, the total ASA-A score showed a correlation of moderate strength with the CAT-Q total score ($P = 0.562$) and no significant correlation with the AQ. Of the ASA-A subscales, the anxious arousal subscale showed the strongest correlation with the anxiety subscale of the DASS-21 ($P = 0.823$), and moderate correlations with the stress ($P = 0.681$), and depression ($P = 0.573$) subscales. The social anxiety and uncertainty subscales both showed moderate correlations (all $p \leq .001$) with the stress ($P_{\text{socanx}} = 0.541$; $P_{\text{unc}} = 0.685$), anxiety ($P_{\text{socanx}} = 0.508$; $P_{\text{unc}} = 0.556$), and depression ($P_{\text{socanx}} = 0.434$; $P_{\text{unc}} = 0.505$) subscales of the DASS-21.

Conclusions:

The ASA-A and the DASS-21 are significantly predictive of one another. Although the ASA-A is closely related to both the anxiety and stress subscales of the DASS-21, certain subscales may be better predictors of stress, while others may be better predictors of anxiety. The ASA-A does not assess for symptoms of depression, but is still predictive of depression scores. Continued use of a complementary depression symptom inventory is recommended.

418.043 Corticospinal Tract Microstructure Associated with Hypotonia in Young Autistic Children

H. H. Kim¹, O. J. Sargent¹, B. Heath¹, B. Restrepo², D. S. Andrews³, M. Solomon¹, S. J. Rogers⁴ and C. W. Nordahl¹, (1)Department of Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Department of Pediatrics, MIND Institute, UC Davis Medical Center, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, MIND Institute, UC Davis Medical Center, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, University California Davis, Sacramento, CA

Background: Hypotonia, or low muscle tone, is more frequently observed in young autistic children than non-autistic children. Hypotonia can cause delays in the motor skill development, which can, in turn, impact cognitive and social development during early childhood. Despite the common prevalence, the neural underpinnings of hypotonia remain poorly understood. Recently, research has begun to understand the role of sensorimotor pathways in motor abilities within the autistic population among autistic school-aged children. The corticospinal tract (CST), a key sensorimotor pathway, serves as the primary tract responsible for voluntary movement in the body. Given that differences in muscle tone often emerge in infancy, we hypothesize that structural differences in the CST may manifest even earlier. Therefore, this study seeks to investigate the developmental profiles associated with hypotonia in young autistic children, and subsequently examine the relationship between the microstructural properties of the CST and the presence of hypotonia. Given the established sex-specific developmental trajectories identified in autism, this study explored the potential moderating role of sex assigned at birth on these associations, aiming to provide deeper insights into motor impairments and inform more tailored interventions.

Objectives: 1) Compare the developmental profiles between young autistic children with hypotonia vs. without hypotonia. 2) Investigate the structural properties of corticospinal tract associated with hypotonia in young autistic children.

Methods: The current project included 171 children, who completed comprehensive assessments and met diagnostic criteria for autism spectrum disorder between the ages of 2 and 3.5 years. Developmental pediatricians conducted physical exams that included muscle tone assessments. Psychologists administered a battery of neuropsychological tests to evaluate a wide range of domains. Structural MRI scans, T1-weighted and diffusion-weighted, were obtained to assess brain structure and connectivity. Regression analyses were performed to assess the developmental characteristics and structural properties of the CST associated with hypotonia, as well as to test for moderating effects of sex on these associations.

Results: Compared to autistic children without hypotonia, autistic children with hypotonia had lower scores on the Short Sensory Profile Low Energy/Weakness Domain. However, no significant differences were found between the groups in other developmental outcomes (Table 1). There was no significant interaction between sex assigned at birth and these developmental outcomes. Sex moderated the relationships between hypotonia and fractional anisotropy of the CST. Specifically, in autistic girls, hypotonia was related with lower fractional anisotropy of the left CST, whereas in the autistic boys, hypotonia was related to with higher fractional anisotropy of the right CST (Figure 1).

Conclusions: This work suggests that the hypotonia in young autistic children is related to low energy level and strengths. The neural mechanisms of hypotonia within autistic children may vary based on the sex assigned at birth. Specifically, stronger, more coherent connections in the CST may lead to intact muscle tone development in autistic females. While future research is necessary to explore the impact of hypotonia across developmental trajectories, these findings provide insights into the biological basis of neuromotor control in autistic children and underscore the importance of assessing motor skills in this population.

**418.044** Delayed Diagnosis of Autism Due to Masking of Autism By ADHD Comorbidity and Female Gender

L. V. Gabis¹, M. Shaham², E. Yaari³, S. Kivity⁴ and M. Daloya⁵, (1)Pediatrics, Maccabi Healthcare Services, Rehovot, Israel, (2)Statistics, Haifa University, Haifa, Israel, (3)management, Maccabi Healthcare, Tel Aviv, Israel, (4)management, Maccabi Healthcare, Tel Aviv, Israel, (5)Statistics, University of Haifa, Haifa, Israel

Background:

Autism Spectrum Disorder (ASD, autism) and Attention- Deficit/ Hyperactivity Disorder (ADHD) diagnoses in childhood are more common in males, but ADHD prevalence in adults is similar between males and females. Autism diagnosis in females has increased, with male-to-female ratio dropping from 1:4-5 a decade ago to 1:2.5-3 recently. This has led to the term "camouflage," suggesting that females may exhibit different autism symptoms, causing delayed diagnosis and may delay appropriate interventions, which may influence outcome. ADHD symptoms may present early in children with autism and symptoms may overlap. Comorbidity of ASD and ADHD may further delay diagnosis of autism in both males and females.

Objectives: Using a large neurodevelopmental database, we investigated the timing of ADHD and autism diagnoses across ages, and the sex distribution of these diagnoses and comorbidities.

Methods: Data were drawn from Maccabi Healthcare's electronic records for 2.4 million individuals, including information on autism, ADHD, epilepsy, depression, anxiety, medications, demographics with emphasis on age of each diagnosis and difference from current age (up to year 2023). The autism group was divided into those with only autism (9,604 individuals) and those with both autism and ADHD (8,964 individuals). The ADHD-only group (228,668 individuals) served as the control group. We analyzed diagnosis timing and comorbidities across these groups and male to female distribution.

Results:

The study included 24,067 individuals with autism (22.8% females), diagnosed according to Israeli Ministry of Health guidelines. The control group consisted of individuals diagnosed with ADHD (42.9% females), included only if ever received medication. Almost half of the individuals with autism also had ADHD (45.3%), with significantly more males having both diagnoses (61.1%). The male-to-female ratio was similar in the autism-only and autism+ADHD groups (76% males). Among females with autism, 39.7% had ADHD as a comorbidity. Stimulant medications were used in 71.2% of males and 68.7% of females with autism+ADHD.

Epilepsy occurred in 7.51% of the autism cohort, with higher prevalence in females (9.2%) as compared to males (7%). It was more common in individuals with both autism+ADHD (7.74% males, 9.9% females). In the ADHD control group, epilepsy was diagnosed in 1.85%, comparable to general population, but interestingly with a higher rate of epilepsy in ADHD females (2.4%) as compared to males (1.8%).

Children diagnosed with ADHD before autism received their autism diagnosis 2-3 years later than those with autism only and later than with autism and subsequent ADHD diagnosis, with the gap decreasing into adulthood. Delays were more frequent before 2010, particularly in boys. However, girls experienced more consistent delays in diagnosis of autism, especially girls diagnosed initially with ADHD.

Conclusions: To avoid potential delays in ASD diagnosis, clinicians should consider ASD in persons presenting with ADHD symptoms. Additional attention should be given to girls with ADHD and observation for additional comorbidities, especially occurrence of epilepsy, should be emphasized.

418.045 Diagnosis of Autistic Spectrum Disorder in Patients with Fragile X Syndrome: A United Kingdom Database Study.

P. Conway¹, C. L. Morgan² and L. Fisher², (1)Global Market Access, Shionogi BV, London, London, United Kingdom, (2)Epidemiology, Human Data Sciences, Cardiff, United Kingdom

Background:

Fragile X syndrome (FXS) is caused by a gene mutation that leads to the absence or deficiency of fragile X messenger ribonucleoprotein, which is essential for normal brain development. FXS is suspected as a common cause of autism spectrum disorder (ASD) but also shares significant behavioural and developmental features with ASD, including social and communication difficulties, repetitive behaviors and sensory sensitivities.

Objectives:

This study explores the presence of ASD in patients with FXS.

Methods:

Patients were selected from the UK CPRD Aurum dataset, a primary care database with approximately 20% coverage of England. Data in CPRD is linked to secondary care data via Hospital Episode Statistics (HES). This study was granted CPRD Research Data Governance approval (21_000470). The study period was 01/04/2007- 31/12/2020. Patients with FXS were selected by relevant clinical code in either the CPRD Aurum or HES datasets. A prevalent FXS population was defined as patients with active registration at a CPRD practice on 1st of January 2019. Prevalent FXS patients were matched 1:1 to controls by age, gender and primary care practice. Co-existing ASD was flagged and compared between FXS cases and controls. The incident cohort were patients with continuous CPRD registration from birth, defined as a registration date being within 3 months of their month of birth or same year of birth if month of birth was missing. Index date was defined as date of first diagnosis. Presence of ASD and timing of ASD and FXS diagnoses was explored.

Results:

1,520 patients formed the prevalent. 64.7% of the cohort were male; mean age was 31.9 years. Median age at first recorded FXS diagnosis was 9.0 years. A diagnosis of ASD was recorded for 332 (21.8%) cases and 92 (1.9%) controls ($p < 0.001$). The incident cohort comprised 259 patients. ASD was recorded for 88 (34.4%) patients of whom, 38 (43.2%) had ASD diagnosed on or prior to the diagnosis of FXS and 50 (56.8%) diagnosed with ASD subsequently. Median duration between prior ASD diagnosis and FXS diagnosis was 281.5 days (Inter-quartile range [IQR] 73.25-1488.0). For 12 (28.9%) patients there was greater than three years between the diagnoses. For patients first diagnosed with FXS who were subsequently diagnosed with ASD, the median duration was 545 days (IQR 172.0-1,574.0). Median age at diagnosis of FXS was lower for those diagnosed with ASD; 3.0 (IQR 2.0-5.0) years for those with a subsequent ASD diagnosis, 4.5 (IQR 3.75-10.25) for those with a prior diagnosis compared with 5.0 (3.0-7.5) years for those with no ASD diagnosis.

Conclusions:

Approximately one-fifth of prevalent patients with FXS had a diagnosis of ASD; whilst in the incident cohort, ASD was recorded for one-third, possibly reflecting improved diagnosis at an earlier age in more recent practice. ASD may be captured in the social/educational context and thus may be missing from the data sources used in this study. In some patients with FXS and ASD there was considerable delay between both diagnoses being recognised. Screening ASD patients for FXS and vice-versa could improve diagnosis and expedite service provision..

418.046 Differential Impact of Co-Occurring Anxiety and Attention-Deficit/Hyperactivity Disorder on Males and Females with Autism

E. Wodka¹, J. Parish-Morris², L. Carpenter³, E. F. Dillon⁴, J. J. Michaelson⁵, S. H. Kim⁶, R. Landa¹ and S. M. Kanne⁷, (1)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Medical University of South Carolina, Charleston, SC, (4)Center for Autism and Related Disorders, Autism Assessment, Research, Treatment, and Services (AARTS) Center at Rush, Baltimore, MD, (5)Psychiatry, University of Iowa, Iowa City, IA, (6)School of Psychology, Korea University, Seoul, Seoul, Korea, Republic of (South), (7)Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY

Background: Autism Spectrum Disorder (ASD) impacts males more frequently than females, with an estimated male:female ratio of 3:1-4:1. Females are also underrepresented in research which further limits our understanding of their ASD symptoms, with serious downstream effects on clinical knowledge. Gaps in clinical knowledge about autistic females hinder timely and accurate diagnosis and access to effective treatments for this critically understudied and underserved subgroup. This is particularly important when designing studies that aim to reduce the impact of heterogeneity on ASD research by defining specific subtypes within the autism spectrum, including those with co-occurring psychiatric conditions. Despite the high frequency of psychiatric co-occurrence (up to 70% of those with autism have one co-occurring psychiatric condition and up to 40% have two co-occurring conditions), little is known about the impact of this co-occurrence in autistic females. However, large cohort descriptive study designs have reduced that barrier.

Objectives: We leverage a large, US national descriptive study (SPARK) to examine how behavioral and psychiatric symptoms differ between autistic girls and boys in well-defined groups (i.e., school age and adolescence; those with and without co-occurring anxiety and attention deficit/hyperactivity disorder:ADHD). We hypothesize that the presence of co-occurring anxiety will result in increased repetitive behaviors and mood concerns, and that presence of co-occurring ADHD will result in increased motor concerns, particularly for females.

Methods: Participants included 25,078 individuals registered in the SPARK cohort, aged 6-18 years. Individuals with parent-reported ASD, ASD+ADHD, ASD+Anxiety, or ASD+ADHD+Anxiety were compared on parent-report measures assessing social communication, restricted and repetitive behaviors, motor functioning, and behavioral/emotional concerns; differences between male and female profiles were examined.

Results: Significant differences in symptom presentation between females/males, school-age/adolescent individuals, and by co-occurring conditions (ASD/ADHD/Anxiety) were revealed, and the impact of co-occurring conditions differed by age and sex. For young females, the addition of co-occurring ADHD or Anxiety alone significantly increased reported ASD symptomatology. Diagnostic group differences in motor functioning were driven primarily by co-occurring conditions, particularly ADHD status (most apparent for young females, wherein young females with ASD + ADHD or ASD+ADHD+Anx had weaker motor skills than young females ASD alone). All diagnostic groups were reported to have elevated concerns for RRBs; younger children had more RRBs than older adolescents across both sexes. Within females, younger participants showed a strikingly different pattern than older females; whereas co-occurring Anxiety or ADHD was not associated with increased RRBs in young females, these co-occurring disorders were associated with increased RRBs in older females. Last, addition of co-occurring conditions increased symptoms across all behavioral/emotional scales, with nearly all subscales raising to clinical significance for the ASD+ADHD+Anx group for both age and sex groups.

Conclusions: School-aged females with ASD are at highest risk for underestimation of autism-related symptoms, including underestimation of symptoms beyond core ASD features. Across ages, particular consideration should be given when probing for social communication symptoms, RRBs, motor skills, and mood in females with ASD alone, as well as with co-occurring ADHD and/or Anxiety, including use of measures intended to more dimensionally assess particular symptom domains.

418.047 Disclosure of Suicidal Thoughts and Behaviors and Self-Harm in Autistic Adolescents from Adolescent and Parent Perspectives: A Mixed-Methods Investigation

J. M. Schwartzman¹, M. Castro² and A. H. Bettis³, (1)Pediatrics, Keck School of Medicine, University of Southern California, Los Angeles, CA, (2)Saban Research Institute, Children's Hospital Los Angeles, Los Angeles, CA, (3)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

Background: Suicidal thoughts and behaviors (STB) and self-harm are common in autistic adolescents, with few adolescents receiving supports. Disclosure is an essential component of risk assessments and prevention programs as it is the first step to detecting youth at risk and preventing future crisis. Our previous research demonstrates that half of autistic adolescents in crisis never disclose to their parents. However, disclosure experiences (e.g., barriers, facilitators, etc.) have never been investigated in autistic adolescents; this information is critical to improving risk assessments, suicide prevention programs, and parent training.

Objectives: To investigate disclosure experiences of STB and self-harm in autistic adolescents from adolescent and parent perspectives using a mixed-methods approach.

Methods: In a longitudinal investigation of depression and suicide risk in autism, 35 adolescents ($M=15.9$ years; $SD=1.2$; Range: 14-17; 14 males, 10 females, 11 gender diverse) and 35 of their parents completed an assessment battery. We plan to analyze data from an additional 30 families by May 2025. In the battery, families completed a novel measure of STB and self-harm disclosure experiences – Suicide and Self-harm Disclosure Interview (SSDI). The SSDI contains quantitative and qualitative questions about disclosure in three categories: suicidal thoughts, suicide attempts, and self-harm. For adolescents, the SSDI examines barriers and facilitators of disclosure, needed crisis supports, and likelihood of future disclosure. For parents, the SSDI contains similar questions about barriers and facilitators to discussing STB and self-harm with their child, and resources to support parents in managing crisis. The SSDI was administered to adolescents and parents separately and audio recorded, with responses transcribed and analyzed using NVivo. Descriptive statistics were employed to analyze the quantitative data, while conventional content analysis was applied to qualitative responses.

Results: All 35 adolescents reported lifetime suicidal thoughts, with some reporting a suicide attempt ($n=7$; 20%) and self-harm ($n=20$; 57%). Table 1 present some of the findings. Adolescents disclosed to different people (e.g., friends, parents, online forums), with parents as the most common, for the primary purposes of seeking help. Reactions to adolescents' disclosure were mixed (i.e., positive and negative reactions), and adolescents provided suggestions to improve disclosure experiences (e.g., "take me seriously") and resources for autistic adolescents in crisis (e.g., training for teachers, peers/friends). Of adolescents who never disclosed their crisis to others, feelings of shame and perceived burdensomeness were leading reasons for never disclosing. Differences in reports of adolescent STB and self-harm emerged between adolescents and parents, with some adolescents never disclosing to parents ($n=5$; 14%). Most parents reported a positive response to their child's disclosure, while some parents dismissed it ($n=9$; 25%). Parents identified positive (e.g., awareness of child's distress) and negative (e.g., upset, crying) aspects of their responses to their child; parents overwhelmingly reported low confidence in knowing how to respond ($n=29$; 83%). Parents also suggested critical supports for families (e.g., crisis training, mental health services).

Conclusions: Findings provide unique insights on STB and self-harm disclosure experiences among autistic adolescents, with considerations of parents' experiences. Findings directly inform STB and self-harm assessment and intervention approaches for this population.

418.048 Do Asymmetrical Developmental Bifurcations Predispose to Each Other? a Bibliometric Analysis

A. Lavigne-Champagne¹ and **L. Motttron, M.D.²**, (1)CIUSSS du Nord-de-l'Île-de-Montréal, Montreal, QC, Canada, (2)CIUSSS NIM, Montréal, QC, Canada

Background: We have proposed to integrate prototypical autism in the same category of human biological variants as twinning, left-handedness and breech presentation (BP) through the concept of asymmetrical developmental bifurcations (ADB). ADB differ from diseases and are more specifically defined that the concept of neurodiverse variant. ADB would happen in development when "frequent" and "rare" trajectories are compatible with life, and that one of them, despite its occasional adaptive cost, is preserved by evolution. Each ADB occurs at a constant rate in human species and is mostly favored by familial predispositions, occasionally powered by an indefinite series of nonstandard events. It may also occur randomly, as a human possibility that does not require external factors or biological dysfunction. Among their favoring factors, we know that some ADB influence each another, as there is a higher percentage of left-handedness among autistic people than in the general population.

Objectives: We investigate here how scientific literature may represent a proof of concept of ADBs' mutual predisposition.

Methods: In this bibliometric analysis based on performance analysis, the metric was the total number of publications and the number of meta-analyses or systematic review on each pairing of ADB. Only PubMed was searched. We used predetermined terms for each ADB and used the Boolean Operator "AND" to find articles concerning each pair. Native PubMed functions were used to for the citation extraction. Data extraction ended in July 2024. To account for the diversity of the level of research on each subject, we calculated the intersection over union for each pairing. By doing this, popular subjects that would obviously have more articles became less of a bias.

Results: Meta-analyses or systematic review were found for twinning and breech presentation, left-handedness and autism, left-handedness and twinning, as well as autism and breech presentation. ADB pairs who had relatively the most articles were twinning and breech presentation, along with left-handedness and twinning. Nonetheless, left-handedness and twinning as well as autism and twinning were individually represented by a larger number of publications (see Fig. 1). The scope of this research is limited by the fact that there was no study selection, and that definitions of most ADB are still evolving.

Conclusions: This result represents a proof of concept of the reciprocal predisposition between some ADB, adding to the redefinition of autism as the rare result of a bifurcation instead of a disease. This provides a biological justification to the alternative organizations within the social and conceptual integration of neurodiversity. Hence, if we observe that some ADB mutually influence one another, it could be an argument to confirm that they are of the same nature. Future directions will involve adding MESH terms to the search, searching other electronic databases, and adding a selection process by reading titles, then abstracts.

418.050 Echo Autism: Mental Health - Preparing Professionals to Support Autistic People with Co-Occurring Mental Health Conditions

N. Buranova¹, **B. B. Maddox²**, **K. Boles³**, **M. Mahurin⁴**, **K. Hoffman⁵** and **K. Sohl⁶**, (1)Special Education, University of Missouri, Columbia, MO, (2)TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC, (3)Child Health, University of Missouri, Columbia, MO, (4)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (5)University of Missouri, Columbia, MO, (6)ECHO Autism Communities, University of Missouri School of Medicine, Columbia, MO

Background:

The majority of autistic individuals struggle with co-occurring mental health conditions. Mental health challenges are associated with lower quality of life, reduced social activity, poor educational performance, and limited employment opportunities. However, autistic people often experience difficulties accessing mental health care. One of the well-known barriers to mental health services is a lack of training among mental health clinicians for working with autistic individuals.

Objectives:

The objective of this research is to assess the program's impact on clinicians' self-efficacy in using evidence-based practices for supporting autistic clients' mental health, identify the most valuable components of the program as perceived by participants, and explore the changes participants plan to incorporate into their clinical practice based on the knowledge gained. The main research questions are:

- Did the program increase clinicians' self-efficacy in using evidence-based practices for mental health supports of autistic clients?
- What did participants perceive to be the most valuable components of the ECHO Autism: Mental Health program?
- What changes will participants incorporate into their clinical practice as a result of knowledge acquired in the program?

Methods:

ECHO Autism: Mental Health is a virtual, de-identified case-based professional development program committed to creating a learning community of mental health clinicians supporting autistic clients. The current study investigated the experience of the clinicians in the ECHO Autism: Mental Health program from 2020-2023. A total of 72 participants completed pre- and post-program assessments to evaluate the impact and benefits of ECHO Autism: Mental Health.

Results:

Nearly all of the participants' responses (99%) stated that the program was a feasible and effective way to learn ($n=537/541$); 97% ($n=526/541$) agreed or strongly agreed that their self-efficacy increased in implementing evidence-based practice, specifically cognitive-behavioral therapy (CBT), for their autistic clients. In their open-ended responses, participants reported that they learned the most from the case studies and didactic sessions and as a result are more knowledgeable about implementing CBT, social skills interventions, exposure therapy, visual supports, and coping strategies in their clinical practice. Participants shared that they learned about the importance of collaboration with families, diagnostic procedures specifically for autism, community resources available, and suicide risk assessments.

Conclusions: Our findings highlight the success of ECHO Autism: Mental Health to deliver professional development to clinicians. This program has a potential to overcome the barriers and support clinicians in working with autistic clients who have co-occurring mental health conditions.

418.051 Effects of the October 7th Attacks and the Ensuing War on Autistic Children in Israel and Their Parents

T. Nitzan¹, S. Rozenblat², T. Matz Vaisman³, S. Govrin⁴, R. Shusel⁵, O. Golan⁶, Y. Rum⁶, I. Dinstei⁶ and J. Koller⁶, (1)Azrieli National Centre for Autism and Neurodevelopment Research, Student at Ben Gurion University of the Negev, Beer Sheva, Israel, (2)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (3)ALUT-Israeli organization for children & adults with ASD, Givatayim, Israel, (4)Department of Psychology, Bar-Ilan University, Department of Psychology, Ramat-Gan, ISRAEL, (5)Seymour Fox School of Education, Autism Research Centre - University of Cambridge, Jerusalem, United Kingdom, (6)Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel

Background: The October 7th attacks, the ensuing war, and consequent upheaval in daily life in Israel present unique challenges to autistic children, who rely on routine and predictability. This is the first ever study of the experience of autistic children and their parents in the context of war.

Objectives: To assess the psychological effects of terrorism and ongoing war on autistic children and their parents

Methods: Study 1 is a one-year longitudinal study in which parent-report of child trauma (CATS) and parental negative emotional states (DASS) has been collected on autistic ($n=57$; 32 males; mean age = 7.02 years, $SD=3.7$) and non-autistic ($n=35$; 16 males; mean age = 7.12 years, $SD=3.65$) children every two months beginning October 2024. Data from an independent study before October 7th ($N=55$; 43 males; mean age = 4.5 years, $SD=1.02$) allowed for comparison of DASS scores across pre/post-war cohorts of autistic children.

Study 2 is a complementary cross-sectional, mixed-methods study ($n=72$). Parent-report measures and interviews assessed the above constructs as well as parental trauma (PCL-5) and parental resilience (BRS).

Results: In Study 1, parents of autistic and non-autistic children report trauma above the cut-off for PTSD, with autistic children ($M=34.7$, $SD=12.5$) scoring significantly higher than their non-autistic peers ($M=28.5$, $SD=9.95$), $t_{(75.43)} = 2.47$, $p < 0.05$, $d = 0.54$. Parents of autistic children reported elevated levels of stress ($t_{(df)} = x$; $p < 0.05$, $d=0.56$) and anxiety ($t_{(df)} = x$; $p < 0.001$, $d=0.84$) compared to parents of non-autistic children. Final analyses will be conducted in November 2025 upon completion of data collection. Parental negative emotional states in parents of autistic children were 2-4 times higher in the month following October 7th than in the independent, pre-war sample ($p < 0.001$, $d=2.62-2.77$).

In Study 2, parental trauma, together with higher anxiety levels, accounted for 43.8% of the explained variance of child trauma ($R^2 = 0.438$). Quantitative and qualitative analyses are ongoing.

Conclusions: Parent-reported levels of trauma in autistic and non-autistic children post-October 7th are strikingly high, as are negative emotional states in parents. Autistic children and their parents appear to experience more pronounced distress than that of their non-autistic peers. It is essential to consider these findings in supporting children and families affected by war.

418.052 Elevated Autistic Symptoms in Parkinson's Disease and Other Motor Disorders

B. Chakrabarti¹, I. Dey², S. Chakrabarty³, M. Belmonte⁴, S. Pathak⁵, S. Choudhury⁶ and H. Kumar⁶, (1)Centre for Autism, School of Psychology and Clinical Language Sciences, University of Reading, Reading, UNITED KINGDOM, (2)India Autism Center, Kolkata, West Bengal, India, (3)India Autism Center, Kolkata, India, (4)The Com DEALL Trust, Bangalore, INDIA, (5)Insitute of Neuroscience, Kolkata, West Bengal, India, (6)Institute of Neuroscience, Kolkata, Kolkata, India

Background:

Parkinson's Disease (PD) is a motor disorder that primarily affects older adults. Recent biological and epidemiological evidence suggests significant comorbidity between PD and autism. Preliminary findings suggest that older autistic individuals are three times more likely to develop PD symptoms. However, the converse has not been directly studied, i.e., it is not known whether clinical PD is associated with greater autistic features. Additionally, it is unknown whether the putative overlap between autism and PD is exclusive to PD or extends to other, non-Parkinsonian motor disorders. Therefore, this preregistered study aimed to elucidate the degree and specificity of the relationship between autism and PD.

Objectives:

To test the specificity of the phenotypic overlap between autism and PD.

Methods:

Three groups of older adults were studied: a) people with the diagnosis of Parkinson's disease (N=110), b) people without any parkinsonism but with motor disability of neurological or neurovascular origin (OMD) (N=110), and c) typically ageing controls with no motor disorders (NT) (N=110). PD and OMD participants were recruited from the outpatient department of a tertiary neurology clinic, and all of their clinical diagnoses were verified by neurologists. N=330 age-matched participants were retained for the final analyses. All participants completed AQ-28 (as the pilot study revealed that AQ-50 was lengthy for the participants). Cognitive ability was measured using the Montreal Cognitive Assessment Scale (MoCA). The severity of PD symptoms was assessed using the Hoehn and Yahr scale. Additionally, participants also reported their sleep habits (items chosen from the Mayo Sleep Questionnaire (Boeve et al., 2011)) and a four-item questionnaire measuring GI symptoms (Hjortswang et al., 2006).

Results:

Both PD and OMD groups reported higher autistic traits compared to neurotypical controls, after accounting for differences in age and cognitive ability ($t(326) = -3.199, p = 0.002$, and $t(326) = -3.371, p < 0.001$, respectively) (Fig. 1). Exploratory analyses revealed a notable sex difference ($F(1, 315) = 5.0446, p = 0.025$): While autistic symptoms showed a group difference in males (PD males scoring highest), no such group differences were noted in females. This pattern of results was internally replicated across the three languages in which the instruments were administered (Bengali, Hindi, and English) and was not influenced by reporter identity (self or caregiver). No significant group differences were found in sleep and GI issues.

Conclusions:

The present study is the first attempt to examine the degree of overlap of autistic features in Parkinson's Disease. The findings suggest that this difference is not exclusive to PD but is also present in several other motor disorders of neurological and neurovascular origin, indicating elevated autistic traits across motor-related conditions. However, a notable sex disparity was observed, with males showing a clear difference in autistic features between the three diagnostic groups, and females showing no such group differences. This study supports the emerging view of overlap between autism and PD, and underscores the necessity of assessing autistic features in older adults diagnosed with PD or other motor disorders while planning support services.

418.054 Examining Influences of Autism Presentation on Parent-Child Agreement on Child's Anxiety

W. DeFilippo¹, C. E. Freden², T. Filstein³ and E. Kang⁴, (1)Montclair State University, Montclair, NJ, (2)The Social Competence & Treatment Lab, Stony Brook, NY, (3)Clinical Psychology, Montclair State University, Montclair, NJ, (4)Department of Psychology, Montclair State University, Montclair, NJ

Background:

Autistic and non-autistic children can report anxiety symptoms differently than their parents (Kalvin et al., 2020), suggesting that parents and children may interpret behavior differently (McMahon & Solomon, 2015). While previous literature has found consistent discrepancies in parent and child reports on psychosocial constructs (e.g., anxiety, social functioning; Lerner et al., 2012, McMahon & Solomon, 2015), there is a gap in the literature regarding how level of autistic traits may impact parent-child agreement in endorsing anxiety symptoms.

Objectives:

Examine whether parent-child agreement regarding anxiety symptomatology is moderated by the child's degree of autistic traits.

Methods:

A sample of autistic (n=43) and non-autistic (n=22) youth between the ages of 8 and 17 and their parents completed the *Multidimensional Anxiety Scale for Children, Second Edition (MASC-2; March, 2012)* and the *Anxiety Scale for Children-ASD (ASC-ASD; 2016)* self- and parent-report measures to assess anxiety symptomatology. While the MASC-2 is designed based on neurotypical anxiety symptomatology, the ASC-ASD, a newer measure, was specifically designed to capture anxiety symptomatology for autistic children (Wigham et al., 2016). Additionally, all youth were administered the *Autism Diagnostic Observation Schedule, Second Edition (ADOS-2; Lord et al., 2012)*. In this sample, the mean ADOS-2 comparison score (CS) was 5.6 (corresponding to a "moderate" degree of autism symptomatology; see Table 1 for mean anxiety scores). Using the SPSS PROCESS Macro (Hayes, 2022), a moderation analysis was run to examine how parent-child agreement differs with degree of autistic traits, with the ADOS-2 CS serving as a mean-centered moderator.

Results:

A paired-samples t-test showed significant difference between parent and child reports in mean anxiety symptomatology for both the MASC-2 and the ASC-ASD ($t(64)=-2.9, p=.006$ and $t(64)=-7.3, p<.001$ respectively), where children reported greater anxiety than their parents (see Table 1). Overall, a main effect of child-reported anxiety symptomatology in predicting parent-reported anxiety symptomatology was found for both MASC and ASC-ASD scores ($B_{MASC-2}=0.41, p_{MASC-2}=.005$ and $B_{ASC-ASD}=0.37, p_{ASC-ASD}<.001$). No main effect of autistic traits or interaction between child-reported anxiety symptomatology and autistic traits were found (all $p>.35$).

Conclusions: Overall, parent and child ratings of anxiety symptomatology in the current sample differed, wherein children reported their anxiety higher than their parents, but nonetheless child reports predicted parent ratings of their child's anxiety. Importantly, the child's level of autistic traits was not observed to influence this relationship within this sample of neurodiverse youth. Additionally, these results were found regardless of if the MASC-2 or ASD-ASC scores were used. These results suggest that, regardless of the child's potential social communication differences, autistic and non-autistic children may report anxiety symptoms higher than their parents, underscoring the importance

418.055 Experience of Outpatient Eating Disorder Treatments in Autistic Individuals and Integration of Co-Produced Research into Clinical Practice

F. Duffy¹ and E. Maloney², (1)School of Health in Social Science, University of Edinburgh, Edinburgh, United Kingdom, (2)Clinical and Health Psychology, University of Edinburgh, Edinburgh, United Kingdom

Background:

Autistic individuals are more likely to experience eating disorders (EDs) compared to neurotypical peers and between 20-40% of individuals with Anorexia Nervosa have higher levels of Autistic traits. These individuals report poorer experiences of ED treatment and are more likely to experience an inpatient admission for their ED (and for this admission to be longer). Concerns have been raised about existing outpatient ED treatments including eating disorder focused family therapy (FT-ED).

Objectives:

To explore clinicians, and families of Autistic individuals, experience of delivering or receiving FT-ED with associated adaptations

Methods:

FT-ED trained clinicians, and parents and carers and Autistic individuals, who had experience of receiving or delivering FT-ED with Autistic individuals were invited to take part in interviews. Transcripts were analysed using Reflexive Thematic Analysis.

Results:

Results will be presented separately for clinicians and parents and carers (still recruiting) Clinician only results are represented in this abstract. Eleven clinicians were interviewed from a range of clinical roles including Family Therapy (n=2), Nursing (n=5) and Clinical Psychology (n=4) (female n=9, 81%; Mean age 39.5 years, SD: 8.3, range 29–58 years; White British n=9, 81%). Analysis generated four themes and eight subthemes: (1) *Systemic context*, a theme which highlights systemic considerations beyond the young person as an individual, inclusive of three sub-themes highlighting **Neurodivergent parents and carers**, **Multiple Layers** of communication that take place within the family and therapeutic relationship, and the prior experience people bring of **Parenting an Autistic** child. (2) *Raising potential autism* refers to clinicians noting that most young people present to ED services without autism having been explored before and the pressure of contemplating an autism assessment at a point of heightened distress owing to the recent onset of the ED. (3) *Autism eating disorders crossover*, refers to the difficulties **Differentiating between Autism and Eating Disorders** when a young person is acutely starved; the **Agnostic Stance** of FT-ED and the risk of being blinkered to Autistic traits and the need for **Autistic Empowerment**, specifically the need for Autistic young people to take a more active and collaborative role in FT-ED (4) Finally in *Manual vs Adaptations*, clinicians described being caught between following the manual and developing adaptations for Autistic young people. They felt a **Tension between evidence practice and potential harm**, where they were concerned that deviating or rigidly following a manualised approach may both potentially cause harm. Clinicians who did adjust treatment described their **Autistic specific considerations**

Conclusions:

This is the first exploration of parents and clinician's experience delivering and receiving FT-ED with Autistic young people and their families and highlighted unique considerations with this population. It is an initial step to consider adaptations to the FT-ED model, with further interviews with Autistic young people with EDs planned next, with the aim of making ED treatments more effective, accessible and acceptable for Autistic young people and their families.

418.056 Experiences and Service Use of Families Whose Child Has Experienced Developmental Regression

R. P. Goin-Kochel^{1,2}, **S. S. Mire**³ and **E. Fombonne**¹, (1)Baylor College of Medicine, Houston, TX, (2)Meyer Center for Developmental Pediatrics & Autism, Texas Children's Hospital, Houston, TX, (3)Psychological, Health, and Learning Sciences, Baylor University, Houston, TX, (4)Department of Psychiatry, Oregon Health & Science University, Portland, OR

Background: Witnessing developmental regression—or skill loss—in a child can be traumatic. Caregivers who observe regression in their children report feelings of anxiety, stress, and family dysfunction, as well as sadness, loss, and confusion about the changes seen in their children. Compared to caregivers of children without regression, those reporting skill loss more often propose environmental factors (e.g., diet, pollution, vaccines) as causing their child's autism and express more guilt about the diagnosis. Collectively, these findings suggest that regression may negatively impact caregiver well-being and influence their views about autism and how they manage it (e.g., treatment). However, much of this literature is based on small samples without standardized tools to measure caregivers' mental and emotional experiences.

Objectives: To examine associations between caregiver report of regression in their children and their (1) perceptions about their child's autism, including causal attributions, and (2) adjustment to the autism diagnosis.

Methods: Participants were caregivers of individuals with autism recruited through the national SPARK study (www.sparkforautism.com) between 4/10/2019—6/18/2019 as part of a broader investigation of factors associated with parental vaccine hesitancy. Caregivers received an invitation via email to participate in a survey that included the *Illness Perception Questionnaire-Revised—ASD* version (IPQ-R; measure of cognitions about autism and causal attributions), *Family Adjustment Measure* (FAM; measure of adjustment to the autism diagnosis), and items about skill loss. All data were collected electronically through SPARK's Research Match platform. Descriptive and inferential statistics were used to characterize the sample and identify potential differences between those with and without reported skill loss.

Results: Overall, 39,461 SPARK caregivers were invited to participate and 8,389 enrolled (response rate = 21.3%). 3,536/8,389 (42.2%) reported regression in language ($n=2,787/3,536$, 78.8%) social skills ($n=2,103/3,536$, 59.5%), or other skills ($n=1,497/3,536$, 42.3%); 483/8,389 (5.8%) were unsure if their child had regressed. Based on the IPQ-R-ASD subscales, those witnessing regression perceived their child's autism as having more negative consequences, being difficult to understand, eliciting more negative feelings, being a chronic condition, and associating with a higher number of symptoms compared to caregivers whose children did not lose skills. Likewise, they reported greater levels of parental distress and lower levels of family-based and social support in their adjustment to their child's diagnosis per the FAM. With respect to beliefs about causes of autism, caregivers reporting regression and those who were unsure about skill loss (a) more frequently endorsed their own personal attributions and environmental factors and (b) less frequently endorsed biophysiological factors as causal. Most effects were small to medium. Detailed results are in Table 1. Results were broadly similar for caregivers of male versus female autistic children.

Conclusions: Caregivers observing regression in their children with autism reported poorer mental and emotional health outcomes compared to those not reporting regression. They were also more likely to blame their own actions and environmental mechanisms as causing autism. Clinicians should consider the implications of regression on caregiver and family well-being and offer supports when indicated.

**418.057** Exploring Interpersonal Physiological Synchrony during Mealtime Among Young Autistic Children

A. Wallisch¹, **B. A. Boyd**², **M. S. Goodwin**³ and **A. Davis**¹, (1)Department of Pediatrics, University of Kansas Medical Center, Kansas City, KS, (2)School of Education, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Northeastern University, Boston, MA

Background: Autistic children are 5-15x more likely to have eating problems when compared to non-autistic children (Sharp et al., 2013). Food intake is a basic need, and extreme food selectivity observed in autistic children leads to significant parental anxiety and family burden.

Longstanding research in pediatric eating behavior recognizes the importance of parent-child interactions at mealtime, and recent studies link observed parent behaviors to increased child food refusal (controlling prompts) or increased food acceptance (supportive prompts; Fries et al., 2017). One novel area to measure bidirectional mealtime interactions is interpersonal autonomic physiology (PS). PS occurs when autonomic nervous system activity “matches” between two interacting partners, and many foundational studies on child attachment find that strong parent-child relationships are linked to greater PS (Palumbo et al., 2017). However, emerging research indicates autistic children show less PS with their parents (McNaughton & Redcay, 2022). PS demonstrates promise as a marker for social interaction quality, but has yet to be used in autism to uncover how parent-child interactions may relate to challenging eating behaviors.

Objectives: The purpose of this study is to preliminarily examine the strength of relationship between parent-child electrodermal activity (EDA), a measure of sympathetic nervous system arousal, during mealtime in autistic and non-autistic children.

Methods: We collected family mealtime in the home with 8 age-matched parent-child dyads (4 with an autistic child and 4 with a TD child).

Children were between 3-9 years of age (autistic: $M= 67.25$, $SD= 26.80$; non-autistic: $M= 77.00$; $SD= 11.78$ months) and autistic children were parent-reported picky eaters and non-autistic children were not picky eaters. During mealtime observations, both the parent and child wore an E4 Empatica biosensor on their wrist to capture EDA, and time-synchronized video was captured using a GoPro camera. As a preliminary investigation we ran bivariate correlations between parent-child dyad EDA levels at mealtime.

Results: Our sample primarily included male children (75% male in the autism group and 100% male in the non-autistic group). Preliminary bivariate correlations between the EDA for an autistic child and his or her caregiver across one mealtime showed on average no relationship ($M=0.05$; $SD=0.41$) compared to the non-autistic group that showed on average a weak positive relationship ($M=0.32$; $SD=0.46$).

Conclusions: PS provides a potential novel way to quantify the bidirectional behaviors observed during parent-child interactions at mealtime. While our results are preliminary and with a small sample (additional data will be analyzed prior to the conference), it appears that PS can yield different patterns of correlations during mealtime for autistic (no relationship in EDA values between the parent and child) compared to non-autistic children (weak positive relationship in EDA values between the parent and child). Our future analyses prior to the conference will use more robust statistics (i.e., wavelet coherence analysis, granger causality analysis) and overlay behavioral mealtime to parent-child EDA levels to determine micro-level behaviors at mealtime that support PS.

418.058 Exploring the Association between Sensory Processing Disorders and Co-Occurring Physical, Mental and Neurodevelopmental Conditions in Autistic Adults

C. Jose, CMPNB, Vitalité Health Network, Moncton, NB, Canada

Background:

The increasing body of research on sensory differences in the ASD population since their introduction in the diagnostic features of ASD in the DMS-V, is mainly focused on children and on their association with autism traits or behaviors. But sensory processing disorders (SPD) can impact health beyond autistic symptoms.

The extend of the co-occurrence of SPD with other health conditions has been seldomly studied in the ASD population despite an association found in the general adult population. The goal of the study was to explore the comorbidity burden of autistic adults with and without SPD and assess the correlations between SPD and several mental, neurodevelopmental and physical health comorbidities.

Objectives:

- 1) Estimate the prevalence of sensory processing disorders in a sample of autistic adults
- 2) Evaluate the difference in the number and type of comorbidities between the groups with and without SPD

Methods:

A total of 164 autistic adults or their caregivers filled a survey asking for self-reported co-diagnoses of 34 mental, neurodevelopmental and physical health conditions. Among them, 13 conditions had a prevalence of more than 5% in the sample and were included in the analyses. T-test was used for comparisons between SPD and non-SPD groups. We performed tetrachoric correlations to assess the correlation between presence/absence of SPD and the 13 comorbidities.

Results:

The prevalence of reported SPD in our sample was 37% (n=91). There was no difference in gender and age between the groups with and without SPD (Table 1). Participants with SPD had an average of 5 comorbidities (SD=3.1), which was significantly higher than the number of comorbidities in adults without SPD (mean=2, SD=1.8). Individuals with SPD had twice the number of mental, physical, and neurodevelopmental conditions than those without SPD (Table 1). Moreover, the group with SPD perceived more barriers to healthcare than the group without SPD (55.7 and 34.0%, respectively).

Presence of SPD was strongly correlated with presence of eating disorder, auditory disorder, gastrointestinal disorder, learning disorder, musculoskeletal disorder, and body-focus and repetitive behaviors disorder (Table 2).

Conclusions:

Despite being the second most prevalent co-occurring condition in our sample, SPD were reported by only two third of adults (compared with 90-95% in autistic children), which is consistent with other lower estimates in adults, suggesting an adaptive or maturation process over time.

Nonetheless, autistic adults that do present with SPD form a sub-population with highly complex health needs.

Except for depression, OCD, epilepsy and vision disorders, all conditions were either moderately or strongly associated with SPD. Our findings align with previous studies on autistic children or on other psychiatric, neurodevelopmental, or physical conditions populations, linking sensory processing dysfunction with hyperactivity, distractibility, feeding disorders, gastrointestinal issues, musculoskeletal disorders, anxiety, and repetitive and compulsive behaviors.

Future studies assessing the association between specific sensory modalities, or their combinations (vestibular, proprioceptive, and somatosensory, tactile) with each of those conditions could unravel convergent biological pathways and lead to new therapeutic option developments that could help decrease the barriers to healthcare experienced by those adults and improve their overall health.

418.059 Exploring the Cognitive and Neurodevelopmental Difficulties within Adolescents and Young Adults with Early Onset Liver Disease

M. Earl¹, C. E. Blackmore², M. Ali³, J. Day³, E. O’Gorman⁴, G. McAlonan^{5,6} and M. Samyn⁴, (1)Kings College London, London, London, United Kingdom, (2)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (3)Kings College Hospital, London, London, United Kingdom, (4)Kings College Hospital, London, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Biomedical Research Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience and South London and Maudsley NHS Foundation Trust, London, United Kingdom

Background: The impact of a lifelong chronic condition is rarely restricted to one organ, even more so when organ dysfunction occurs at a time when the brain is most vulnerable to environmental insult, such as the neonatal period. For instance, Biliary Atresia (BA) is an early-onset, inflammatory chronic liver disease that requires immediate intervention surgery (Kasai) and is a common indication for paediatric liver transplantation (LT). Whereas neurocognitive delay is prevalent in this population (Rodijk et al, 2021; Ng et al, 2018; Ruuska et al, 2021), the frequency of neurodevelopmental difficulties has not yet been explored.

Objectives: In the most in-depth study of its kind, we aimed to identify clinically significant cognitive impairments and traits of neurodevelopmental conditions including autism and attention-deficit hyper-activity behaviours (ADHD), in a population of adolescents and young adults with BA. Furthermore, we sought to understand if age at Kasai and/or LT influenced neurodevelopmental outcomes.

Methods: 45 participants with BA (29 female, 15 male, 1 transgender) aged 11-24 years ($M=17.72$, $SD: 3.65$) enrolled into this study. Two thirds (20 female, 10 male) underwent a LT at a mean age of 4.4 years ($SD: 5.25$ years), and out of 15 surviving with their native liver (9 female, 5 male, 1 transgender), 3 were on the waiting list for a LT (2 female, 1 male). Subjects completed a Wechsler Abbreviated Scale of Intelligence (WASI-II) to measure Full-Scale-4, an Autism Diagnostic Observation Schedule – 2 (ADOS-2 Module 3/4), and an Attention and Activity Levels questionnaire to screen for ADHD behaviours.

Results: Full-Scale 4 IQ composite score was significantly lower in the BA cohort compared to the average norm (BA $M: 95.89$, $SD: 16.18$, $p = .048$), and 12 (27%) scored below normal range.

Prior to participation, 3 had a diagnosis of autism, and 5 were either diagnosed with ADHD or referred for an ADHD assessment (17.78%). From the remaining, 12 (28.6%; 9 female, 3 male) participants scored above the threshold on the ADOS-2 [mean ADOS-2 score of 5.79 ($SD: 4.59$)], and 25 (62.5%; 18 female, 7 male) on the ADHD screening tool. Seven (4 male, 3 female) scored above threshold for both.

Whilst LT was associated with lower Full-Scale 4 IQ scores compared to the patients surviving with their native liver (LT $M: 92.03$, Native $M: 106.5$, $p = .004$), no differences were found for ADOS-2 scores (LT $M: 6.36$, Native $M: 4.64$, $p = .129$) nor likelihood of scoring over threshold on the ADHD screening tool ($p = .517$). Neither age at Kasai nor age at transplantation significantly correlated with IQ scores (Kasai $r = -.098$, LT $r = .114$) nor ADOS-2 scores (Kasai $r = -.307$, LT $r = .139$).

Conclusions: Adolescents and young adults with an early onset liver condition have a higher likelihood of neurodevelopmental difficulties regardless of disease progression, including age at Kasai and/or liver transplantation, and with an equal gender distribution. Considering the impact on clinical outcomes and every-day functioning, focus should shift towards early screening and signposting to specialist services.

418.060 Exploring the Relationship between Cognitive Flexibility and Anxiety in Autistic Youth

F. Mahmud¹, R. G. McDonald², W. Bshara², S. Shahin², D. Wallace³, C. Masia² and E. Kang², (1)Department of Psychiatry, Columbia University Medical Center, New York, NY, (2)Department of Psychology, Montclair State University, Montclair, NJ, (3)Library Administration, Montclair State University, Montclair, NJ

Background: Anxiety is the most common mental health problem in autistic youth, with over 80% of autistic youth experiencing impairing anxiety symptoms (White et al., 2009). However, anxiety symptoms are frequently overlooked due to “atypical” presentations in autism, and even when detected, often not effectively treated, due to a lack of conceptual understanding of autistic cognition (Kerns et al., 2014; Wood & Gadow, 2010). Emerging literature has suggested that individual differences in cognitive flexibility (CF) among autistic youth may contribute to unique strengths, as well as greater mental health challenges, relative to allistic peers (Geurts et al., 2009; Stark et al., 2021). Better understanding of autistic CF differences may help elucidate mechanisms of anxiety vulnerability and beneficial targets of anxiety treatment for autistic youth.

Objectives: The current study utilized a multi-method approach to measuring CF, given its complexity as a multifaceted construct, in order to tease apart the relationship between CF and anxiety. We also used an autism-specific scale for measuring anxiety from both parent and child perspectives in order to capture the unique anxiety symptomatology experienced by autistic youth in relation to difficulties with flexible thinking.

Methods: Participants included forty 8–17-year-old autistic children (11 female; autism classification based on the ADOS-2; Lord et al., 2012), along with their parents (37 mothers). Over 40% of participant families identified with minoritized racial backgrounds (e.g., 17.5% Asian, 12.5% Black), and 15% of families identified as Hispanic/Latinx. Parents reported on their children’s real-world flexibility difficulties (Flexibility Scale; Strang et al., 2017), anxiety symptoms (ASC-ASD-P; Rodgers et al., 2016), and autistic traits (SRS-2; Constantino & Gruber, 2012). Children reported on their own real-world flexibility difficulties (BRIEF-SR Shift subscale; Gioia et al., 2000) and anxiety symptoms (ASC-ASD-C; Rodgers et al., 2016). Lab-based task switching measures were also administered to children (D-KEFS Trail Making, Verbal Fluency, and Color-Word Interference; Delis et al., 2001). Bivariate relationships between CF scores and anxiety scores were examined via Pearson’s correlations and linear regression analyses. Predictors in the regression models were determined by significant Pearson’s correlations, and outcome variables were self- and parent-reported anxiety.

Results: Pearson’s correlations revealed that lab-based task switching scores were not significantly associated with self-rated anxiety. On the other hand, number-letter switching performance was a significant unique predictor of parent-rated anxiety, according to linear regression analysis. In addition, real-world flexibility challenges were significant predictors of greater self- and parent-rated anxiety, while accounting for autistic traits.

Conclusions: Our findings are consistent with current literature suggesting the role of real-world flexibility challenges in anxiety vulnerability in autistic people. The current study also offers preliminary support for the distinction between real-world CF and lab-based CF with regards to their relations with anxiety among autistic youth. In addition, our findings suggest the utility of asking autistic youth, as well as their parents, about their own flexibility difficulties in daily life as a means of assessing anxiety risk. Findings may help inform targeted assessment and treatment approaches for this vulnerable population.

418.061 Exploring the Role of Race and Ethnicity on Depressive Symptoms in Autistic Adolescents

A. Manga¹, J. L. Martinez², G. B. Salinas³ and E. A. Laugeson⁴, (1)Psychiatry, University of California Los Angeles, Los Angeles, CA, (2)Department of Psychiatry, UCLA PEERS Clinic, Westwood, CA, (3)Psychiatry and Biobehavioral Sciences, UCLA PEERS Clinic, Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience and Human Behavior, UCLA PEERS® Clinic, Los Angeles, CA

Background: Many autistic adolescents face significant social and mental health challenges (Lai et al., 2019), and evidence shows racial disparities in access to healthcare and specialized services for autistic people of color (POC; Eilenberg et al., 2019). As such, minoritized autistic adults are likely underdiagnosed for mental health conditions (Ames et al., 2021). Research indicates that autistic adolescents have more depressive symptoms than those with other developmental disabilities (Wiggins et al., 2024), yet significant differences between White and POC autistic adolescents remain largely unexplored. In one small study of transition-age young adults ($N = 39$; 16-26 years old), Black autistic young people endorsed significantly higher rates of depressive symptoms than their White autistic peers (Williams et al., 2021). However, it is unknown if this pattern of results extends to adolescence, a critical period of development for autistic youth (Picci & Scherf, 2015), or more broadly to autistic young people of color, who may face additional barriers from systemic inequities and racial discrimination, exacerbating mental health issues (English et al., 2014). Addressing these gaps can inform culturally competent mental health services and promote equitable support for autistic youth from diverse backgrounds.

Objectives: This study explored whether differences in depressive symptoms exist between autistic adolescents of color as compared to autistic White adolescents in a treatment-seeking sample. We hypothesized significant group differences in depressive symptoms between POC and White autistic adolescents, extending prior literature.

Methods: Participants included 134 adolescents with pre-existing autism diagnoses (73.9% male; $M_{age} = 14.1$, $SD = 1.94$). Of these, 41.5% ($n = 56$) identified as persons of color, while 58.5% ($n = 79$) identified as White and 38.6% ($n = 51$) were in general education public schools. Additionally, 82.2% ($n = 106$) of parents had at least a bachelor's degree or above. Depressive symptoms were measured using the Children's Depression Inventory, 2nd Edition (CDI-2; Kovacs, 2012) at baseline. Independent samples t-tests were conducted to compare depressive symptom scores between White participants and participants of color. Descriptive statistics and effect sizes were calculated to examine the magnitude of group differences.

Results: Independent samples t-tests revealed no significant differences in depressive symptoms between White autistic teens ($M = 59.51$, $SD = 12.97$) and autistic teens of color ($M = 59.60$, $SD = 14.00$), $t(129) = -0.04$, $p > .05$, $d = -0.006$. Thus, depressive symptom scores were comparable across White and POC autistic teens.

Conclusions: Findings suggest no significant differences in depressive symptoms between POC and White autistic adolescents in this treatment-seeking sample. These results may indicate that depressive symptoms present similarly across racial and ethnic groups in autistic adolescents. Alternatively, this sample may reflect outcomes for highly educated families of color who were able to access specialized services for their autistic teens, despite existing disparities. Future research is warranted to better identify the mental health needs of this multiply marginalized population. A focus on systemic methods to address disparities in service access may also be explored to reduce mental health burden and ensure equity in support for autistic youth.

418.062 Gender Predicts Rates of Co-Occurring Psychiatric Conditions and Symptoms in Autistic Youth

A. B. Ratto, *Center for Autism Spectrum Disorders, Children's National, Washington, DC*

Background: Autistic individuals have elevated rates of co-occurring psychiatric conditions compared to neurotypical individuals. Some studies have explored and found differences by gender/assigned sex, with elevated psychiatric symptoms in cisgender females relative to males (e.g., Magiati et al., 2016; Rødgaard et al., 2021). The limited work across the gender spectrum has found cisgender females and gender diverse autistic adults report higher co-occurring psychiatric symptoms (Sedgewick et al., 2020). Additional research is needed to evaluate gender-based differences in the mental health of autistic youth, particularly leveraging multiple data sources.

Objectives: The present study sought to investigate the hypothesis that among autistic youth, rates of clinician-diagnosed co-occurring psychiatric conditions, as well as parent-reported and self-reported psychiatric symptoms would be elevated in cisgender girls and gender diverse youth. Additionally, an exploratory hypothesis was explored that self-reported symptoms would better predict clinician diagnosis than parent-reported symptoms.

Methods: Participants were drawn from a sample of >9,000 individuals seen for psychological or neuropsychological evaluation at an outpatient clinic at an academic medical center in the Washington, DC metropolitan area. A final sample was identified ($N=472$; ages 11-18) who received a primary diagnosis of autism from an expert clinician and had parent and self-report data available on psychiatric symptoms on the Child Behavior Checklist/Youth Self-Report (Achenbach & Rescorla, 2001). Chi-square analyses with follow-up pairwise z-tests were used to assess differences in co-occurring conditions by gender, using clinician-reported clinical diagnosis. One-way ANOVA was used to assess differences in psychiatric symptoms by gender. Logistic regression was used to assess likelihood of co-occurring diagnoses based on age, gender, and parent-reported and self-reported symptoms.

Results: Chi-square analyses revealed that rates of depression differed significantly by gender ($\chi^2=15.374$, $p<.001$), with post-hoc tests indicating such that depression was significantly higher among gender diverse youth than cisgender females and cisgender males. Anxiety also differed significantly by gender ($\chi^2=7.281$, $p=.026$), though post-hoc tests were not significant. PTSD rates did not differ significantly by gender ($\chi^2=2.767$, $p=.251$). Symptoms of anxiety, depression, and post-traumatic stress differed significantly by gender on both parent and self-report (Table 2), with gender diverse youth showing significantly higher symptoms than both cisgender males and females across measures on post-hoc testing, after applying Bonferroni correction. Logistic regression analyses showed that clinical diagnosis of depression was predicted most strongly by parent [(exp)B=1.055, $p<.001$] and self report [(exp)B=1.058, $p<.001$], as was diagnosis of anxiety [parent: (exp)B=1.067, $p<.001$] [self: (exp)B=1.029, $p=.010$]. No hypothesized predictor reached independent significance for predicting diagnosis of PTSD.

Conclusions: Findings generally supported our hypotheses that gender diverse youth would show the highest rates of co-occurring psychiatric conditions and symptoms. Though there was a trend for cisgender girls to show higher rates than cisgender males as well, these findings did not reach statistical significance. Further research is needed to elucidate the factors that make gender diverse autistic youth more susceptible to co-occurring psychiatric distress.

418.063 Genetic, Environmental, and Stochastic Contributions to Social Impairment and Sleep Problems

A. R. Halliday, *T. White and N. Sadeghi, National Institute of Mental Health, NIH, Bethesda, MD*

Background: Sleep problems affect between 50-80% of autistic youth; however, the relationship between ASD and sleep disorders remains poorly understood. Twin models are valuable tools for disentangling the genetic and environmental contributions to complex psychiatric conditions like ASD. Specifically, the bivariate ACE model leverages phenotypic correlations between monozygotic (MZ) and dizygotic (DZ) twins to estimate the proportion of phenotypic covariance attributed to additive genetic (A), common/shared environmental (C), and unique/nonshared environmental (E) factors.

Objectives: This study used ACE modeling to investigate the genetic, shared environmental, and nonshared environmental contributions to the phenotypic covariance between social impairment and sleep disorders. Understanding the genetic and environmental factors underlying this shared heritability may inform targeted treatments for autistic youth experiencing sleep disturbances.

Methods: Data were collected remotely from 684 families in the Mid-Atlantic Twin Registry with twins ($n = 578$ MZ pairs, $n = 762$ DZ pairs, $n = 698$ males, $n = 670$ females) between 6 and 17 years of age. Social impairment and sleep problems were assessed using two parent-proxy instruments, the Social Responsiveness Scale, Second Edition (SRS-2), and the Sleep Disturbance Scale for Children (SDSC). Correlations between ASD traits and sleep disturbances were computed for both MZ and DZ twin pairs, followed by bivariate ACE modeling using OpenMx. Given the well-established sex differences in ASD, separate models were estimated for males and females.

Results: Within-trait analyses showed a positive association between social impairment and sleep problems, with stronger relationships observed in MZ twins compared to DZ twins. ($r_{MZfSRS} = 0.67$, $r_{DZfSRS} = 0.44$, $r_{MZmSRS} = 0.80$, $r_{DZmSRS} = 0.34$, $r_{MZfSDSC} = 0.84$, $r_{DZfSDSC} = 0.32$, $r_{MZmSDSC} = 0.75$, $r_{DZmSDSC} = 0.53$). Nearly all of the phenotypic covariance between social impairment and sleep disturbances was explained by shared environmental influences ($C_m = 0.95$ (0.26, 1.7), $C_f = 0.98$ (0.32, 1.65)), with negligible contributions from genetic ($A_m = -0.15$ (-0.90, 0.57), $A_f = -0.13$ (-0.84, 0.56)) and nonshared environmental influences ($E_m = 0.19$ (0.08, 0.33), $E_f = 0.14$ (0.03, 0.28)).

Conclusions: While both ASD and sleep disorders show strong genetic influence and high heritability, our finding that the phenotypic covariance between social impairment and sleep disturbance is primarily driven by shared environmental factors suggests limited genetic overlap between the two conditions. These results highlight the substantial impact of environmental influences on the interaction between social impairment and sleep, suggesting that behavioral interventions may be particularly effective for improving sleep problems in autistic children.

418.064 Get to Class: The Role of Internalizing Conditions on School Absenteeism for Autistic Youth

B. W. Kiernan¹, J. G. Raven¹ and M. Mazurek², (1)Department of Education and Human Development, University of Virginia, Charlottesville, VA, (2)University of Virginia, Charlottesville, VA

Background: Non-autistic students with anxiety and depression miss more school days than their peers (Askeland et al., 2020; Lawrence et al., 2019). Compared to their non-autistic contemporaries, autistic youth experience higher rates of anxiety and depression (Bougard et al., 2021; Hudson et al., 2019) and have higher rates of school absenteeism (Nordin et al., 2024). Though there is evidence that autistic children may be absent from school more often due to school refusal, school exclusion or withdrawal, and non-problematic absenteeism (Totsika et al., 2020), there is still a need to examine how experiencing anxiety and depression may impact an autistic student's school attendance to identify mental health intervention targets designed to improve school attendance for autistic youth.

Objectives: This study examined whether internalizing mental health conditions (i.e., anxiety and depression) were significantly associated with school absenteeism for autistic children and adolescents.

Methods: Caregiver-reported data from the 2022 National Survey of Children's Health (NSCH) was used to examine the relationship between internalizing conditions and school absence in autistic youth. 1382 autistic youth (75.47% male) ages of 6 to 17 ($M = 11.78$, $SD = 3.50$) were included in the analysis. School absenteeism was measured on a scale of 0 to 4 where higher numbers represent more days of school missed (e.g., 0 = no missed school days, 1 = 1-3 days, etc.). Internalizing conditions were operationalized via a composite variable that captures the presence and potential co-occurrence of depression and anxiety. The absence of either condition was assigned a code of 0; the presence of anxiety *or* depression was assigned a code of 1; the presence of both anxiety *and* depression was assigned a code of 2. Socioeconomic status was measured via a proxy variable assessing whether the student received any free and/or reduced meals from their school. Controlling for age, sex, challenging behaviors, socioeconomic status (SES), adverse child experiences (ACEs) and intellectual disability we conducted ordinary-least squares regression (OLS) with internalizing conditions as a predictor of school absenteeism.

Results: Overall results indicated statistically significant differences in mean school absenteeism, $F(7,1327) = 12.67$, $p < .001$, $R^2 = .06$. Controlling for age, sex, challenging behaviors, socioeconomic status, ACEs and intellectual disability, we found that internalizing conditions significantly predicted increases in school absenteeism for autistic youth, $t(1327) = 6.29$, $p < .001$, $d = 0.18$.

Conclusions: Increased internalizing disorders are associated with more school absenteeism for autistic youth, even when controlling for common reasons that autistic children miss school. Importantly, school absenteeism is identified as a risk factor for mental health challenges for non-autistic youth (Epstein et al., 2020), indicating that the relationship between mental health challenges and school absenteeism are interrelated. This could also be the case for autistic youth, which begs further research on this topic. There is a need for mental health intervention for autistic youth experiencing internalizing symptoms to prevent worsening of these conditions and resulting school absenteeism. These results support the importance of adequate and timely mental health services for autistic youth to mitigate school absence.

418.065 What Helps Autistic Adults Have 'Good' Sleep? – Data-Prompted Interviews Exploring the Sleep Behaviours, Physical Activity and Affect Variability.

P. Wan¹, E. Qusted², J. McVeigh¹ and C. Thompson¹, (1)Curtin School of Allied Health, Curtin University, Perth, Western Australia, Australia, (2)Curtin School of Population Health, Curtin University, Perth, Western Australia, Australia

Background: Sleep is a critical part of daily living for the benefit of the health and wellbeing of individuals. Inadequate sleep and untreated sleep disorders may be detrimental to physical health, mental health, mood, and public safety. Sleep problems are reported in 50-80% of autistic people compared to 25-30% of non-autistic individuals. However, understanding the factors that facilitate or hinder 'good' sleep among autistic adults is underexplored. Furthermore, sleep can be considered as a behaviour, which influences the activities and individuals' affect. If sleep is considered a behaviour, it is adaptable to enable optimal sleep as perceived by autistic individuals.

Objectives: This study aimed to explore the experience of sleep by eliciting rich responses through the perspectives of autistic adults.

Methods: Data-prompted interviews (DPIs) were conducted with eight autistic adults to explore participants' experiences and perspectives of sleep behaviours. Prior to the interviews, participants completed a 10-day ecological momentary assessment (EMA) that tracked their sleep behaviours, physical activity and emotional states. In this same 10-day period, device-derived measurements of sleep were obtained using the Withings Sleep Analyzer and ActiGraph GT9X. The ActiGraph GT9X collected device-derived measurements of physical activity. The DPIs were guided by participant's data from the 10-day EMA period. The verbatim transcripts from the DPIs were analysed using reflexive thematic analysis.

Results: The analysis identified five themes. Theme one, *individual bedtime routine*: each person had a routine that led to bedtime and sleep onset. Theme two, *the next day's activities influenced sleep routine engagement*: the importance of leisure or productive activities the next day motivated individuals to engage in their sleep routine and aim to sleep adequately. Theme three, *self-awareness of perceived sleep quality influencing affect*: individuals reported a direct relationship between what felt like "enough sleep" and feeling positive emotions, and the inverse was true. Theme four, *sleep is a task*: a task-oriented approach to perceiving and achieving adequate sleep in daily living. Theme five, *'good' sleep is important and beneficial*: the importance and benefits of 'good' sleep are identified for physical and mental health. However, the perceived depth of benefits varied.

Conclusions: The findings suggest that individualised bedtime routines and motivation towards meaningful activities the following day are factors that promote 'good' sleep routines and behaviours in autistic adults. Furthermore, the association between emotional states and participation in activities were motivators to achieve adequate sleep quantities and establish sleep regularity. Autistic adults identified that objective, device-derived data of sleep behaviours, PA and affect from a 10-day EMA were an accurate representation of daily living. This study emphasises the need to identify routines and activity goals that suit individuals' preferences. This may facilitate motivation and engagement in behaviours to achieve 'good' sleep.

418.066 Heterogeneous Longitudinal Trajectories of Psychotropic Polypharmacy and Aggressive Behaviour in Children with Neurodevelopmental Conditions

A. Sivaloganathan¹, S. Lenz², J. Rapley³, C. Tsetsos⁴, E. Canning⁵, A. Kushki⁶ and D. A. Baribeau¹, (1)University of Toronto, Toronto, ON, Canada, (2)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Bloorview Research Institute, Toronto, ON, Canada, (4)Holland Bloorview, Toronto, ON, Canada, (5)Carleton University, Ottawa, ON, Canada, (6)Bloorview Research Institute, Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: Autism and intellectual disability (ID) are prevalent neurodevelopmental conditions associated with high rates of psychotropic polypharmacy—defined as the concurrent use of multiple psychotropic medications. Psychotropic medications are frequently prescribed in neurodevelopmental conditions to address mental health symptoms and/or challenging behaviours, such as aggression, which have not responded to psychosocial interventions.

Objectives: The objectives of this study were: 1) to identify heterogeneous longitudinal trajectories of psychotropic polypharmacy and aggression frequency in a cohort of children diagnosed with ID and/or autism; 2) to describe clinical correlates of polypharmacy and high-frequency aggression in this population; and 3) assess the relationship between polypharmacy trajectories and aggressive behaviour over time.

Methods: Data were derived from the longitudinal electronic health records of children/youth diagnosed with ID or autism receiving medication management for treatment-refractory behavioral and psychiatric symptoms through a large multidisciplinary tertiary psychopharmacology program between 2019 and 2022. Group-based trajectory modeling was employed to identify patient subgroups with distinct longitudinal trajectories over 3 years. Psychotropic polypharmacy was recorded as the count of psychotropic medications at each visit, while aggression frequency was assessed on a 5-point incremental scale ranging from no occurrences to multiple occurrences daily. Demographic and clinical correlates across participants were examined by their highest probability group membership using standard descriptive statistics (Fisher's exact test and χ^2 test).

Results: A total of 281 children/youth (mean age 10.4 SD 2.91) were seen for a mean of 7 visits over 3 years. We identified six distinct longitudinal trajectories of psychotropic polypharmacy, comprising two low concern low polypharmacy trajectories: less than 1 medication-stable (10.7%) and 1 medication increasing (33.5%); two moderate polypharmacy trajectories: 2 medications-stable (30.6%) and 1-2 medications-increasing (8.5%); and two high polypharmacy trajectories: 3 medications-increasing (13.5%) and 4 medications-increasing (3.2%). Children assigned to higher polypharmacy trajectories tended to be older, had higher rates of irritability, side effects, crisis events and were more likely to be taking a sleep-aid/sedative-hypnotic. We identified 5 distinct aggression trajectories: no aggression (27.5%), low-frequency aggression (11.5%), moderate aggression decreasing (33.0%), moderate aggression resolving (16.0%), and high aggression decreasing (12.0%). Children assigned to the high-aggression group were more likely to experience parent burnout, irritability, crisis service use and were more likely to have been diagnosed with an intellectual disability. Polypharmacy trajectory group membership was not significantly associated with aggression trajectory group membership.

Conclusions: For children with neurodevelopmental conditions receiving psychotropic medication management through a large tertiary care program, polypharmacy tended to be stable or increasing over time, while most children experienced a reduction in or resolution of aggressive behaviour. Results emphasize the complexity and chronicity of psychotropic polypharmacy, and further underscore the importance of research on irritability in neurodevelopmental conditions as well as pathways towards psychiatric deprescribing.

418.067 How Are Self-Regulation Difficulties Linked to Neurodevelopmental Conditions? an Umbrella Review to Enhance Conceptual and Measurement Clarity

I. Iturmendi-Sabater^{1,2}, S. Jain³, S. Turcany-Diaz⁴, R. Besa⁵, E. Anagnostou⁶, M. A. Fournier⁶, H. Y. Lin^{2,7,8} and M. C. Lai^{7,9,10}, (1)Institute of Medical Science, University of Toronto, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Dr. Kiran C. Patel College of Osteopathic Medicine, Nova Southeastern University, Fort Lauderdale, FL, (4)University of Sussex, Brighton, Brighton, United Kingdom, (5)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Department of Psychology, University of Toronto Scarborough, Toronto, ON, Canada, (7)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (8)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (9)Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (10)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom

Background: Individuals with neurodevelopmental conditions (NDCs) such as autism, attention-deficit/hyperactivity disorder (ADHD), and intellectual disabilities often experience struggles to regulate emotion and cognition, impacting their abilities to adapt behaviors to internal and external demands. These self-regulation difficulties (i.e., dysregulation) may be transdiagnostic across NDCs. However, the existing literature is heterogeneous. This inconsistency underscores a pressing need to clarify the conceptualization and measurement of dysregulation in individuals with NDCs. Further, it is crucial to determine whether these definitions and associated challenges are consistent across neurodivergent populations, or if they manifest uniquely within specific groups.

Objectives: We conducted a pre-registered umbrella review to systematically examine the published narrative reviews, systematic reviews (SRs), and meta-analyses (MAs) that address the construct, measurement, and other mechanistic and clinical relevance of self-regulation in populations clinically diagnosed with NDCs.

Methods: We pre-registered the overarching umbrella review in PROSPERO (CRD42023350582). We searched Medline, PsycINFO, Embase, Web of Science, Cochrane Central Register of Controlled Trials, and Cochrane Database of Systematic Reviews by September 5th, 2024. Of 18,821 unique citations, we included 49 narrative reviews, scoping reviews, SRs, and SRMAs. We (i)summarized the review characteristics, (ii)synthesized the definitions and constructs used to describe self-regulation, and (iii)quantified the self-regulation measures used in the primary empirical studies captured in the included SRs and MAs. We also conducted risk of bias assessments of included SRMAs through the Joanna Briggs Institute checklist.

Results: (i)We included 35 narrative reviews, 9 SRs, 2 scoping reviews, and 3 SRMAs, covering dysregulation in autism (11), ADHD (24), intellectual disabilities (5), OCD (2), and transdiagnostically (7). (ii)Self-regulation difficulties were consistently defined as a transdiagnostic phenomenon, and linked to temperamental traits in early development, social cognition, executive functions, motivation, language, and irritability. Reviews also highlighted the physiological bases, developmental pathways, temporal course, and co-regulation through caregivers, as well as distinctions between implicit and explicit self-regulation and diverse self-regulation strategies (e.g., reappraisal, suppression, acceptance). Finally, some reviews defined dysregulation as a core feature of ADHD, autism, and ID. (iii)Across 366 primary empirical studies (193 from the United States, 257 published after 2009, 126 using more than one self-regulation measure), we identified 567 self-regulation measures, most frequently questionnaires (412), followed by emotion tasks (74), cognitive tasks (50), and behavioral observation (31). For questionnaires, parent-report alone were the most common method of assessment (225), followed by self-report (128), parent- and teacher-report (26), clinician-report (12), teacher-report (9), and parent and self-report (7), with 5 additional studies not specifying who responded to the questionnaire. The six most commonly used self-regulation questionnaires across NDCs were the Child Behavior Checklist (CBCL), Aberrant Behavior Checklist (ABC), Behavior Rating Inventory of Executive Function (BRIEF), Difficulties in Emotion Regulation Scale (DERS), Conner's Rating Scale (CRS), and Emotion Regulation Checklist (ERC). The questionnaires that were most used in autism, ADHD, OCD, and ID studies were the ERC, the CRS, the DERS, and the ABC, respectively.

Conclusions: This work creates a roadmap for future research to define and operationalize self-regulation and understand its transdiagnostic nature across autism and related NDCs.

**418.068** Hypermobility in Children with Autism and Attention Deficit Hyperactivity Disorder

N. Johnston¹, M. Moses², K. Pugsley², T. Chau¹, F. Le Nepveu³, L. E. Brown⁴, M. A. Bellgrove⁵ and **B. Johnson²**, (1)Department of Paediatrics, Monash University, Clayton, VIC, Australia, (2)Monash University, Notting Hill, VIC, Australia, (3)Macedon Ranges Autism Network, Woodend, VIC, Australia, (4)School of Nursing, Midwifery and Paramedicine, Curtin University, Bentley, Western Australia, Australia, (5)Turner Institute for Brain and Mental Health, Monash University, Clayton, VIC, Australia

Background: Autism spectrum disorder (autism) and attention deficit/hyperactivity disorder (ADHD) are two common neurodevelopmental conditions that emerge in early childhood, with growing interest in their co-occurrence with medical conditions like hypermobility. Most research on hypermobility in autism and ADHD has focused on hypermobile Ehlers-Danlos syndrome, particularly in adults, and explored the prevalence of autism and ADHD within that population. A potential connection between immune-related issues, hypermobility, autism, and ADHD has been suggested, but few studies have examined hypermobility prevalence in children with autism or ADHD, or its relationship to immune history. Currently, no best practice protocols exist for identifying and managing hypermobility in these children, due clinical prioritisation of other symptoms, and the diversity of healthcare professionals involved in diagnosis and care.

Objectives: This study examined the prevalence of hypermobility among a paediatric sample of neurotypical and autistic and/or ADHD children, and possible immune-related predictors of hypermobility symptomology.

Methods: Participants were children aged 4-18, recruited through the Monash Autism-ADHD Genetics and Neurodevelopment (MAGNET) project. Children were recruited to the study if they had a diagnosis of autism and/or ADHD, alongside a neurotypical comparison group. Joint hypermobility in all participants was assessed using the Beighton Scoring System at the time of assessment. Localized joint hypermobility was defined as a score of 3 or less on the 9-point Beighton Score Scale and Generalised Joint Hypermobility was defined as a score of 4 or more on the 9-point Beighton Score Scale (BSS). The BSS uses a nine-point evaluation of four bilateral and one unilateral joint, with each joint identified with hypermobility being counted as 1 point; a total score can range from 0 to 9. Spearman's rank correlations were computed to assess the relationship between hypermobility and immune-related issues, adaptive functioning and quality of life.

Results: The sample consisted of 400 children (male: 57%, females: 43%); $n=63$ autistic, $n=67$ ADHD, $n=157$ autism+ADHD, $n=113$ neurotypical children. There was no group difference in the prevalence of localised joint hypermobility (autism 69.8%; ADHD 81.8%; autism+ADHD 72.6%; neurotypical 76.1%) or generalised joint hypermobility (autism 30.2%; ADHD 18.2%; autism+ADHD 27.4%; neurotypical 23.9%). There were no statistically significant relationships between hypermobility and immune-related issues ($r(398) = .05, p = .34$), adaptive functioning ($r(393) = -.02, p = .64$) or quality of life in the total sample.

Conclusions: Our study emphasises the need for early detection of hypermobility in autistic and ADHD children. Despite previous reports of increased hypermobility in autistic and ADHD populations, we found that the prevalence was comparable between autism, ADHD, and neurotypical peers. However, the prevalence of joint hypermobility affected around on third of children, which remains important to clinically identify for autistic and ADHD children and adolescents due to its potential impact when delivering other therapies, participation in activity and sports, and its impact on the autistic and ADHD experience of pain and its management in later life. The Beighton Scoring System (BSS) is recommended for integration into developmental assessments to improve early detection, supporting better long-term health outcomes.

418.069 Impact of Co-Occurring ADHD and Anxiety on Bullying Among Young Autistic Children

N. O. Davis¹, A. C. Henley², J. Schechter², R. E. Aiello³, D. Akinsoot⁴, A. Dea⁴, H. L. Morgan², E. Ng-Cordell¹, E. Peters⁴, M. Spanos¹, E. Tenenbaum⁶, C. Stone², C. M. Kerns⁸ and K. L. Carpenter¹, (1)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (2)Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC, (3)Duke Center for Autism and Brain Development, Duke University, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Psychology, The University of British Columbia, Vancouver, BC, Canada, (6)Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Department of Psychiatry and Behavioral Sciences, University of North Carolina Greensboro, Durham, NC, (8)University of British Columbia, Vancouver, BC, Canada

Background: Bullying is increasingly recognized as a significant stressor for autistic children. Bullying has been associated with increased anxiety and depressive symptoms among autistic youth, as well as school refusal, particularly for autistic children with ADHD. To date, most research has examined bullying among school-age or adolescent autistic youth, with limited studies on younger children and those with co-occurring ADHD and/or anxiety.

Objectives: The current study explored bullying among preschool and early school age autistic children. Study goals are to 1) characterize rates of bullying in young autistic children and 2) examine predictors of bullying including autism features, co-occurring psychiatric diagnoses, and emotional and behavioral symptoms. We hypothesized that autistic children with co-occurring ADHD and more autism features (namely social motivation and social awareness) would experience higher rates of bullying.

Methods: Participants were 92 autistic children aged 4-8 years old ($M_{age}=71.4$ months, $SD_{age}=14.2$ months; 32% female; 76% white; $M_{IQ}=96.3$, $SD_{IQ}=16.5$) from an ongoing study of autism and co-occurring ADHD and/or anxiety. The sample included four groups (autistic: $n=22$; autistic+ADHD: $n=21$; autistic+anxiety: $n=19$; autistic+anxiety+ADHD: $n=30$). ADHD and anxiety diagnoses and autism features were assessed via caregiver interviews with the Anxiety Disorders Interview Schedule – Parent version with Autism Spectrum Addendum (ADIS/ASA). Bullying was assessed using an ADIS/ASA item that characterizes frequency of bullying/significant peer rejection using a 0-3 scale ranging from none to severe. Caregivers also completed measures of emotional and behavioral symptoms (ADHD Rating Scale [ADHD-RS], Social Responsiveness Scale [SRS-2], Emotion Dysregulation Inventory [EDI]). We employed chi-square with Fisher's exact tests to examine rates of bullying (none/mild versus moderate/severe) and specific autism features, and logistic regression to compare bullying across diagnostic groups and in association with hyperactivity/impulsivity (per ADHD-RS), social communication (per SRS-2), and emotional reactivity (per EDI).

Results: Fifty-seven percent of caregivers reported that their child had experienced *any* bullying/peer rejection (i.e., even mild bullying), with 25% endorsing moderate/severe bullying. No significant relationship was found between moderate/severe bullying and children's social motivation or social awareness. Marginal associations were found between moderate/severe bullying and co-occurring psychiatric diagnoses ($\chi^2(3, N=92) = 6.6$, Fisher's exact $p=.09$). Caregivers of children with autism+ADHD and autism+ADHD+anxiety reported moderate/severe bullying more often (33% and 37%, respectively) than those with autism (14%) or autism+anxiety (11%). Co-occurring ADHD, but not anxiety, was associated with ~4 times greater likelihood of experiencing moderate/severe bullying (OR=3.92, 95% CI: 1.30–11.91, $p<0.05$). Hyperactivity/impulsivity symptoms approached statistical significance ($p=.06$) in predicting moderate/severe bullying, though no significant associations were found between social communication or emotional reactivity and bullying.

Conclusions: This study highlights that bullying and significant peer rejection can start as early as preschool for autistic children. In this young sample, autism social features were not associated with likelihood of experiencing bullying. However, autistic children with co-occurring ADHD were significantly more likely to have negative peer experiences than autistic children without ADHD. Understanding the factors that contribute to bullying may help caregivers, educators, and clinicians develop strategies to support autistic children in social settings, improving peer interactions and reducing the negative impacts of bullying.

418.070 Improving the Autistic Patient Experience on Inpatient Psychiatric Units Via a Consult/Liaison Service

C. J. Black¹, M. Gorenstein¹, H. Miller¹, K. Mickler¹, J. Winter², P. Vandana³ and S. M. Kanne⁴, (1)*The Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY*, (2)*Center for Autism and the Developing Brain, Center for Autism & the Developing Brain, NYP, White Plains, NY*, (3)*Columbia University Irving Medical Center/NYSPI, White Plains, NY*, (4)*Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY*

Background:

A recent meta-analysis documented that 54.8 % of autistic individuals meet the criteria for a psychiatric disorder (Hossain et al., 2020). The increased prevalence of psychiatric diagnoses contributes to increased rates of suicidality and aggression, which results in higher rates of inpatient hospitalizations (Devon et al., 2014; Segers & Rawana, 2014). Inpatient psychiatric treatment settings often do not address the specific needs of children and adults with autism (Way and Banks, 1990). Given the unique challenges in inpatient units, autistic patients have a significantly higher likelihood of receiving physical and pharmacologic restraints, have increased length of stay, and an increased likelihood of rehospitalization (Calabrese et al., 2023; Masserano et al., 2023; Maloret et al., 2018).

Objectives:

Given the risk of injury to patients and staff, the current study examines the effectiveness of an intellectual and developmental disability consult/liaison service on inpatient psychiatric units.

Methods:

The Positive Behavior Support (PBS) team is a novel multidisciplinary consultation care model. The team currently has clinicians from psychiatry, applied behavior analysis, speech pathology, and psychology. In order to test the effectiveness of the service, a survey was sent out unit staff who requested a consult within the past year. Twenty-five participants completed a survey to assess the effectiveness of the consultation/liaison service. Thirty-eight % were attending psychiatrists, 29 % were PCD/CNMs, 14 % were nurses, and 21 % were social workers. Questions included the reason for the consultation/liaison, helpfulness of the consult, the impact on patient care, and changes in case management. Given the sample size, descriptive statistics are utilized.

Results:

Results indicate that the most common consult was multifaceted, including behavioral management or psychotherapeutic intervention and diagnostic clarification. Specifically, in descending request order, behavioral management (86 %) was first, followed by psychotherapeutic intervention (71 %), diagnostic clarification (64%), confirmation of autism diagnosis (57 %), pharmacological interventions (36%), and disposition planning (29 %). 92 % of respondents endorsed that the service was helpful, with the majority endorsing behavioral management or numerous services being helpful. One key area endorsed was related to interdisciplinary collaboration and working with the team to improve patient care.

Conclusions:

Overall, this study demonstrates the effectiveness of a specialized consultative/liaison model of care that provides staff training and support to inpatient teams working with patients with intellectual and developmental. These goals have been achieved by interventions under multiple components, including direct clinical care, staff training and education, and system-level quality initiatives. Specifically, the PBS team has forged effective relationships with numerous teams that create a collaborative, interdisciplinary treatment team to help improve patient experience and decrease the risk of staff injury and/or burnout. Moreover, given the effectiveness of our work, future directions should include system-level training across medical and psychiatric units to achieve a larger goal to reduce the health care disparities faced by this vulnerable population by increasing staff education, bolstering system-level resources, and reducing safety events. Additionally, as the PBS team grows, extending services to medical units would help to improve patient experience across the NYP hospital system.

418.071 Increased Rates of Maladaptive Daydreaming (MD) in Individuals with Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD)

J. E. Nauman¹ and K. M. Walton², (1)*Psychology, Ohio State University, Columbus, OH*, (2)*Nisonger Center, The Ohio State University, Columbus, OH*

Background: Maladaptive Daydreaming (MD) is a condition in which daydreaming is emotionally and sensorily immersive and enjoyable, leading to addiction and neglecting responsibilities, relationships, and self-care to spend more time daydreaming (Nauman 2023; Somer 2002). MD symptoms have a high degree of overlap with autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) (Nauman 2023; West et al. 2022; West et al. 2023). Individuals with MD often report that their MD began during childhood and occurred with stereotypic movements characteristic of autism (Hedderly et al. 2024; Somer 2023). Investigating MD's overlap with neurodevelopmental conditions can help us understand and identify these unique symptoms presentation in autistic populations.

Objectives: This study's purpose is to characterize MD's association with neurodevelopmental disorders to establish a clearer picture of MD's clinical profile. We hypothesized that participants with autism and ADHD would have higher mean MD symptoms and meet the proposed MD cutoff more frequently than participants without both diagnoses. We also hypothesized that MD symptoms would be associated with significantly higher autism and ADHD symptoms.

Methods: Participants are currently being recruited via Prolific, an online recruiting platform. Data ($N = 149$) has been collected from four groups: 44 participants with autism and ADHD, 32 ADHD-only participants, 32 autism-only participants, and 41 participants without either diagnosis. Surveys measured MD symptoms (the 16-item Maladaptive Daydreaming Scale, MDS-16), restricted and repetitive behaviors (the Adult Repetitive Behavior Questionnaire Self-Report Version, RBQ), ADHD symptoms (Adult ADHD Self-Report Scale Symptom Checklist, ASRS), and ASD symptoms (Autism Spectrum Quotient, AQ).

Results: A one-way ANOVA found a significant difference among the mean MD symptoms of the four groups ($F = 8.92, p < .001$). Post-hoc analysis indicated the autism and ADHD group had significantly higher MD symptoms than the non-autism or ADHD ($p < .001$), autism-only ($p = .041$), and ADHD-only ($p = .025$) groups. There were no other significant group differences ($p's \geq .164$). Chi-square analysis revealed a significant difference between the prevalence of MD in each of our four groups, $\chi^2(3) = 10.72, p = .013$. 40.9% of the autism and ADHD group were above MDS-16's diagnostic cutoff of 40 compared to 14.6% of the non-autism or ADHD group, 15.6% of the autism-only group and 18.8% of the ADHD-only group. In a hierarchical linear regression, after controlling for age and sex, inattention ($p = .008$) and hyperactivity ($p = .037$) symptoms were significantly associated with MD symptoms, but not after AQ subscales and RBQ scores were added in step 3 ($p's \geq .137$). After controlling for age, sex, and ADHD symptoms, the AQ's social skills subscale ($p < .001$) and the RBQ scores ($p < .001$) were significantly associated with MD symptoms while the AQ's attention to detail ($p = .043$) and communication ($p = .011$) subscales were significantly inversely associated with MD symptoms.

Conclusions: MD appears to be highly prevalent in those with a co-occurring diagnosis of autism and ADHD. Future investigation may offer insight into a unique symptom profile associated with cooccurrence of these diagnoses.

418.072 Psychological Distress in Autistic and Non-Autistic Israeli Children Exposed to War and Terrorism

S. Shaked-Ashkenazi¹, I. Bar Ben Shabat², L. Oliver Aronson³, S. Eden², D. Horesh^{4,5} and O. Golan^{4,5}, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Faculty of Education, Bar-Ilan University, Ramat-Gan, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (4)OTI - The Israeli Autism Association, Givat-Shmuel, Israel, (5)Department of Psychology, Bar-Ilan University, Department of Psychology, Ramat-Gan, ISRAEL

Background: Exposure to war and terrorism is linked to psychological distress, impacting both those directly involved and their relatives. Children, who are especially vulnerable due to their developing cognitive and emotional capacities, may be more gravely affected. However, there is a lack of research on the psychological effects of war and terrorism on autistic children.

Objectives: This study examined the psychological distress experienced by Israeli autistic children compared to non-autistic children following the October 7th, 2023, terrorism attack and subsequent war.

Methods: The study involved 228 parents of children aged 4-11 (134 autistic, 94 non-autistic) who completed online questionnaires regarding (1.) their child's exposure to war events and experiences (CEE; e.g., missile attack sirens, injury or death of family members, damage to home, having to evacuate home); (2.) their child's exposure to information about the war (CEI; e.g., TV broadcasts, posters in the public domain, adult conversations); and (3.) aggravation in their child's anxiety levels since the October 7th attacks (SCAS-A), based on the Spence Children's Anxiety Scale.

Results: Nearly all children (97.4%) were exposed to at least one potentially traumatic event related to the war. Non-autistic children had higher CEE rates than autistic children, but groups did not differ on CEI rates. Autistic children exhibited greater anxiety aggravation, particularly concerning physical injury, panic attacks, and agoraphobia. Group moderated the association between exposure level and anxiety aggravation for both CEE and CEI (Figure 1).

Conclusions: These findings highlight the unique vulnerability of autistic children during severe traumatic events and emphasize the urgent need for early detection, diagnosis, and specialized treatment of trauma in autistic children in conflict affected regions.

418.073 Teaching the Traumatized Autistic Student; A Qualitative Study of What Teachers Know and Would like to Know.

A. Quinton¹, A. Ormerod¹, F. Rumball² and F. Happe³, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Adult ASD Assessment Service and Transforming Care Team, Oxleas NHS foundation trust, Kent, United Kingdom, (3)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM

Background: Autistic children and adults experience higher rates of adverse experiences than their neurotypical peers and may find a wider range of events traumatic (Rumball, Happé & Grey, 2020). The symptoms of trauma or PTSD may also present somewhat differently in autistic young people. Autistic children have largely been excluded from research on PTSD to date, despite potential challenges to self-advocate, report trauma and access care for trauma-related symptoms. Teachers with experience working with autistic children are well-placed to identify trauma-related symptoms, identify key areas for support, and address traumatised children's wellbeing in their classrooms.

Objectives: This study investigates teachers' experiences in recognising, adapting to, and supporting autistic children with trauma-related behaviours. Our goal was to identify any gaps in support for both children and their teachers, learn about successful approaches, and gain a deeper understanding of how autistic children are presenting with trauma in their day-to-day lives.

Methods: A qualitative approach was employed; fifteen teachers were recruited via convenience sampling from mainstream and special educational needs (SEN) schools in the UK, and data was collected via semi-structured interviews completed over teams. A Public and Patient Involvement (PPI) group of teachers were consulted and assisted in the design of the interview questions. Reflexive thematic analysis (Braun & Clark, 2006) identified themes across the interviews.

Results: Four themes were identified: 1) The relationship between trauma and autism, 2) Trauma-informed practice, 3) The need for a holistic approach, and 4) Insufficient support and resources. These themes are further divided into subthemes, each highlighting specific challenges and needs. Findings suggest that trauma-exposed autistic children experience similar, if not greater, difficulties in the classroom compared to a traumatised neurotypical child. Additionally, autistic children may find more seemingly every-day school experiences traumatic. Taking a whole-school approach to both trauma and neurodiversity was highlighted alongside a need for greater inter-agency collaboration. Teachers felt that appropriate context-specific training, time to build relationships and adequate school resources would be most beneficial to their ability to support the needs of individual children.

Conclusions: This is the first UK-based study exploring teachers' experiences with teaching traumatised autistic children. Our findings provide valuable insights to directly inform school policy and practices, and emphasise the need for allocation of resources to SEN and mental health support in schools, as well as the development of targeted trauma-related teacher training adapted to specific school context. Dissemination of successful approaches across mainstream and SEN schooling will be critical for establishing best practices.

418.074 Longitudinal Outcome of Patients with Profound Autism and Catatonia

J. R. Smith, Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

Background:

Catatonia is a highly morbid psychomotor and affective disorder which can affect autistic individuals with and without profound impairment. Catatonic symptoms are treatable with pharmacotherapy and electroconvulsive therapy, but the longitudinal effectiveness of these treatments has not been described. In addition, a greater focus on the outpatient management of catatonia has been highlighted in expert opinion publications. However, no data is available which supports this assumption such as a reduction in medical admissions.

Objectives:

Determine the clinical efficacy of outpatient pharmacotherapy and electroconvulsive therapy, and the possible benefit of outpatient management on preventing medical admissions for autistic individuals with catatonia.

Methods:

We conducted a prospective observational cohort study of patients with autism and co-morbid catatonia who received outpatient care in a specialized outpatient clinic from July 1st, 2021 to May 31st, 2024. Data investigating pharmacologic interventions, and clinical measures including the Bush Francis Catatonia Rating Scale (BFCRS), Kanner Catatonia Severity Scale (KCS), Kanner Catatonia Examination (KCE), and Clinical Global Impression – Improvement (CGI-I) were collected. The frequency of medical admissions pre- and post-clinic intake was collected.

Results:

Forty-five patients were identified with 39 (86.7%) meeting criteria for profound autism. All patients received pharmacotherapy. 44 (97.8%) were treated with benzodiazepines with a mean maximal daily dose of 17.4 mg (SD=15.8) lorazepam equivalents. Thirty-five patients (77.8%) required more than one medication class for treatment. Fourteen patients (31.1%) attempted to taper off benzodiazepines during the study period; of these, 5 patients (11.1%) were successfully tapered off, and the remaining 9 (17.8%) discontinued the taper due to a return of catatonic symptoms. Statistically significant improvement was observed across all clinical domains except the KCS. However, the majority remained symptomatic over the study period.

In this cohort, 29 (64.4%) of patients had a medical admission before clinical intake. After clinic intake, 9 patients (20.0%) were admitted medically. After controlling for age, sex and race, there is evidence of an association between the time of clinic intake and the risk of having medical admission ($p < 0.001$). The estimated odds ratio is 0.12 with 95% CI (0.04, 0.31), which means that, for the patients at the same age and of the same sex and gender, they have 88% lower odds of having admission after the initial clinic intake than before.

Conclusions:

In this cohort of outpatients with catatonia and autism, the prevalence of profound autism was notably elevated. Despite clinical improvements while receiving the gold standard for psychopharmacologic management of catatonia, chronic symptoms remained for the majority of catatonia patients over the study period, and few were able to taper and discontinue benzodiazepine treatment. Lastly, longitudinal follow up in a specialized clinic for autistic individuals with catatonia significantly reduced the odds of medical admission, highlighting the importance of specialized outpatient care in this population.

418.075 Hair Cortisol in Young Children with Autism and Their Parents: Associations with Child Mental Health, Eating Behavior and Weight Status.

A. L. Lubbe¹, H. Swaab², E. van den Akker³, R. Vermeiren⁴ and W. A. Ester^{1,5}, (1)Sarr Expert Centre for Autism, Youz Child- and Adolescent Psychiatry, Parnassia Group, Rotterdam, Netherlands, (2)Leiden Institute for Brain and Cognition, Leiden University, Leiden, Netherlands, (3)Erasmus Medical Center, Rotterdam, Netherlands, (4)LUMC, Leiden, Netherlands, (5)LUMC Curium - Child and Adolescent Psychiatry, Leiden University Medical Center, Oegstgeest, Netherlands

Background:

Children with Autism Spectrum Disorder (ASD) and their parents face daily challenges that may be stressful for both. However, little is known about biological stress (hair cortisol concentrations [HCC]) in these families and its connection to children's health outcomes.

Objectives:

This study investigates: 1) differences in biological stress between children with ASD and same-aged children from the general population, 2) associations between biological stress of children with ASD and their mental health, eating behavior, and Standardized Body Mass Index (BMIz) 3) associations between (self-reported and biological) stress of parents of children with ASD and the mental health, eating behavior, and BMIz of their children.

Methods:

Stress was measured in 102 young children with ASD and their parents (101 mothers, 86 fathers) using HCC and self-reported parenting stress (Parenting Stress Questionnaire [OBVL]). Child mental health was measured through autism symptoms (Autism Diagnostic Observation Scale [ADOS-2] and Social Responsiveness Scale [SRS-2]) and problem behavior (Child Behavior Checklist [CBCL]). Child eating behavior (Child Eating Behavior Questionnaire [CEBQ]) and BMIz were also measured. HCC scores of young children with ASD were compared to the reference intervals that were provided by the study of Kruijf and colleagues (2020) for children aged 3 to 7 years ($n = 82$).

Results:

Of the children with ASD, 15.3% scored above the 97.5th percentile for HCC, which was significantly higher than the reference group. Child HCC was not linked to mental health, eating behavior, or BMIz. Maternal stress (self-reported and HCC) was associated with externalizing problem behavior ($r = -.29, p < .01$), internalizing problem behavior ($r = -.22, p = .04$) and total problem behavior ($r = -.25, p = .02$) of their children with ASD, but not with ASD symptoms (ADOS-2 or SRS). In fathers, self-reported parenting stress correlated with reported autism symptoms in all domains of the SRS ($r = .24-.40, p < .05$), externalizing problem behavior ($r = .47, p < .01$), internalizing problem behavior ($r = .40, p < .01$) and total problem behavior ($r = .49, p < .01$) of their children. We did not find associations between HCC of fathers and child mental health. Both parents' self-reported stress was associated with child eating behavior, specifically child emotional overeating ($r_{\text{mothers}} = .22, p = .03, r_{\text{fathers}} = .27, p = .02$;) and child emotional undereating ($r_{\text{mothers}} = .42, p < .01, r_{\text{fathers}} = .35, p < .01$).

Conclusions:

At a young age, children with ASD display higher HCC than their peers, suggesting potential alterations in stress-regulation of young children with ASD. Given these findings, monitoring HCC in research and clinical practice could improve our understanding of stress-regulation in children with ASD. Additionally, parental stress was related to children's mental health and eating behavior, underscoring the importance of family dynamics in the investigating and supporting the well-being of children with ASD.

418.076 Chronic Parenting Stress in Parents of Children with Autism: Associations with Chronic Stress in Their Child and Parental Mental- and Physical Health

A. L. Lubbe¹, H. Swaab², R. Vermeiren³, E. F. van Rossum⁴, I. van Balkom⁵ and W. A. Ester^{1,6}, (1)Sarr Expert Centre for Autism, Youz Child- and Adolescent Psychiatry, Parnassia Group, Rotterdam, Netherlands, (2)Leiden Institute for Brain and Cognition, Leiden University, Leiden, Netherlands, (3)LUMC, Leiden, Netherlands, (4)Erasmus MC, Interne Geneeskunde, Sector Endocrinologie, Rotterdam, Netherlands, (5)Trajectum, Zwolle, Netherlands, (6)LUMC Curium - Child and Adolescent Psychiatry, Leiden University Medical Center, Oegstgeest, Netherlands

Background:

Parents of children with ASD often demonstrate high levels of stress and associated health problems. Chronic stress may impact the health of parents of young children with ASD. In addition, chronic stress may impact parenting strategies and cortisol levels in their children. Although stress in parents of children with ASD has been intensely investigated, most research has focused on the impact of subjective reports of stress and fewer studies have focused on biological stress, as measured by hair cortisol concentrations (HCC) in parents of children with ASD. In addition, the association between HCC in parents and their children with ASD has not been investigated yet. Furthermore, there is a gap in regarding the associations between chronic stress and mental and physical health of parents of young children with ASD, in which fathers have been understudied.

Objectives:

To investigate 1) associations between chronic stress of children with ASD and chronic stress in their parents, 2) associations between chronic stress and mental health in mothers and fathers and 3) associations between chronic stress and physical health in parents of children with ASD.

Methods:

In 181 parents (98 mothers, 83 fathers) of 99 young children with ASD chronic stress was measured using the Parenting Stress Questionnaire (OBVL) and hair cortisol concentration (HCC) analysis. Parental mental health was measured using the Brief Symptom Inventory (BSI). Parental Eating Behavior was measured using the Dutch Eating Behavior Questionnaire (DEBQ). Physical health was evaluated by Body Mass Index, waist circumference, blood pressure, cholesterol, triglycerides, and glucose.

Results:

As displayed in Figure 1, Child HCC was related to HCC of fathers ($r = .40, p < .01$) and to HCC of mothers ($r_{mothers} = .51, p < .01$). In mothers, HCC was associated with lower reported parenting stress ($r = -.33, p < .01$). In mothers and fathers, we found a strong relation between reported parenting stress and mental health problems ($r = .55-.61, p < .01$) and mental health problems were twice as frequent as in the norm-population (41.1-45.8% versus 20%). In mothers and fathers, reported parenting stress was associated with emotional eating behavior. HCC was associated with higher glucose levels in mothers. There were no associations between chronic stress and the other physical health measures in mothers and fathers.

Conclusions:

Parents of young children with ASD are at high risk for chronic stress, with impact for their mental and physical health. Additionally, chronic stress of parents, cannot be perceived isolated from the stress in their children with ASD. Therefore, an integrative and intergenerational approach to alleviate stress in parents and children with ASD could benefit families of children with ASD. In addition, we encourage researchers in this field to further explore this topic longitudinally to gain better understanding in the long-term effects of chronic stress on mental and physical health in parents of children with ASD.

**Poster Session****419 - Communication and Language I**

May 2nd, 2025, 12:30 PM - 1:30 PM - Hall 4A

419.076 The Relationship between Linguistic Skills and Mathematical Skills in Autistic Adolescents and Neurotypical Adolescents
O. Cohen^{1,2} and N. Sukenik¹, (1)Faculty of Education, Bar Ilan University, Ramat Gan, Israel, (2)Special Education, Kay College, Beer Sheva, Israel, Israel

Background:

With the rising prevalence of Autism Spectrum Disorder (ASD) (Davidovitch et al., 2020) [1], research has increasingly focused on this population. However, studies exploring language and academic skills in autistic adolescents remain limited (Whyte & Nelson, 2015) [2]. This study aims to advance understanding by exploring the relationship between mathematical and linguistic skills, offering valuable insights into an under-researched area. Difficulties in abstract thinking, commonly seen in autism, may influence both language and mathematical abilities (Chahboun et al., 2016; Bae et al., 2015) [3,4]. Language functions as a key cognitive tool for expressing abstract concepts, which supports the development of both linguistic and mathematical understanding (Vygotsky, 1994) [5]. Since mathematics involves the mental representation of abstract ideas and relies on higher-order thinking skills (Wilkinson & Jaime, 2016; Giaquinto, 2020) [6,7], challenges in abstract reasoning may hinder the ability to solve word problems and grasp algebraic concepts, illustrating the interconnectedness of language and mathematics.

Objectives:

Our aim was to examine both mathematical and language abilities in autistic adolescents and their neurotypical peers, as well as the relationships between these skills across the two groups. Specifically, we investigated whether the patterns of strengths and challenges in mathematics and language were distinct in the autism group, with the goal of identifying any differences that are unique to autism. This approach allowed us to explore whether the interplay between linguistic and mathematical abilities in autistic individuals follows a different pattern compared to their neurotypical peers.

Methods:

Participants included 67 adolescents (31 ASD: 24 males, 7 females; 36 TD: 27 males, 9 females; aged 12-19.2 years). The assessment process consisted of cognitive background measures, language domain tests, and mathematical assessments in verbal and written formats. Data analysis adhered to original assessment guidelines. Responses were coded by two expert raters, with inter-rater reliability ensured. T tests compared groups, and Pearson correlations examined relationships between mathematical and language domains.

Results:

Group comparisons revealed similar performance in phonology, semantics, and syntax. Autistic adolescents exhibited lower scores in morphology, pragmatics, and all mathematical domains. Analysis revealed distinct linguistic-mathematical skill relationships between groups. Neurotypical adolescents showed widespread positive correlations, with phonology, morphology, and syntax linked to all mathematical skills assessed. Autistic adolescents exhibited fewer, more specific connections, with morphology and pragmatics demonstrating notable relationships to mathematical abilities. These findings highlight divergent cognitive profiles, suggesting different language-math integration patterns in autistic and neurotypical adolescents.

Conclusions:

Difficulties in morphology and pragmatics among autistic participants align with previous research [2]. Lower mathematical performance in autism potentially relates to challenges in mental representation of abstract concepts [4]. The distinct patterns in linguistic-mathematical relationships between groups are noteworthy. Strong correlations in neurotypicals suggest interconnectedness of language and mathematical thinking [6], while fewer connections in autistic adolescents may reflect abstract thinking challenges [3]. These results emphasize the need for tailored educational approaches and comprehensive cognitive assessments in autism. Future research should explore interventions leveraging linguistic strengths to support mathematical learning in autistic adolescents, potentially leading to more effective individualized support strategies.

419.077 Perceptions of Autistic and Non-Autistic Emotional and Neutral Expressions By Autistic and Non-Autistic Raters

R. B. Grossman¹, S. B. McCullough² and E. Zane³, (1)CSD, Emerson College, Boston, MA, (2)University of Bath, Boston, MA, (3)Communication Sciences and Disorders, James Madison University, Harrisonburg, VA

Background: Autistic individuals are perceived more negatively by non-autistic individuals after brief exposures (e.g. Grossman 2015) and across different contexts (e.g. Sasson et al. 2017), although most studies analyze only impressions formed by non-autistic individuals. Recent data indicate that the emotional content of facial expressions is related to negative perceptions (Foster et al. 2024), calling into question the common autistic strategy of mimicking non-autistic emotional expressions to improve social inclusion (Miller et al. 2021). Mimicry of non-autistic expressions is even encouraged in some social intervention programs (Lindsay et al. 2013), but there is no evidence that emotional mimicry improves impressions formed by autistic or non-autistic perceivers.

Objectives: Analyze differences in the perceptions of autistic and non-autistic raters about autistic and non-autistic adolescents' facial and vocal expressions when mimicking emotional versus neutral sentence.

Methods: Autistic and non-autistic adult raters (Autistic N=120, Non-autistic N=141) watched 48 video clips of autistic and non-autistic adolescents mimicking sentences performed by a non-autistic adolescent. Half the sentences were emotional (e.g. sadness: "I'm never going to see him anymore") and half were neutral (e.g. "I walked into the kitchen"). Raters provided thin slice judgments for each video using slider bars to indicate agreement with seven statements (e.g. "This person is trustworthy" or "this person spends a lot of time alone" Sasson et al. 2017).

Results: There was no significant difference in ratings provided by autistic and non-autistic adults ($F(1, 259) = .58, p = .45$), indicating that both groups formed similar impressions of these expressions. There was a marginal effect of stimulus diagnosis, with raters reporting more favorable impressions of autistic than non-autistic adolescents ($F(1, 259) = 3.8, p = .052$). Participants also provided significantly more favorable ratings for emotional than neutral expressions ($F(1, 259) = 18.68, p < .001$). Importantly, there was a significant stimulus neurotype (autistic, non-autistic) by expression-valence (emotional, neutral) interaction ($F(1, 259) = 79.83, p < .001$). Post-hoc comparisons revealed that emotional expressions produced by autistic adolescents received significantly less favorable ratings than non-autistic emotional expressions, while neutral expressions produced by autistic adolescents were rated significantly more favorably than non-autistic neutral expressions.

Conclusions: The finding that emotionally *neutral* sentence mimicked by autistic adolescents were perceived more favorably than those of their non-autistic peers may align with research showing that autistic facial expressions are more likely to be perceived as expressing a positive emotion, even without a positive stimulus to prompt it (Costa et al. 2017, Grossman et al. 2018, Foster et al. 2024). Raters may have preferred the positive-appearing expressions of autistic adolescents to the neutral expressions of non-autistic adolescents. Conversely, when autistic adolescents mimicked *emotional* expressions, they were perceived more negatively than their non-autistic peers, even by other autistic people. These data show that autistic facial and vocal expressions are not uniformly perceived more negatively than those of their non-autistic peers and that interventions or masking strategies focused on mimicry of neurotypical emotional expressions may not be in autistic individuals' best interest.

419.078 Eye Movement Indices of Audiovisual Speech in Children with Autism Spectrum Disorders

I. Fajardo¹, N. Gomez Merino², P. Pérez-Fuster³, N. Skrobiszewska², V. Ávila² and A. Ferrer⁴. (1)University of Valencia / V.A.T ESQ4618001D, Valencia, Spain, (2)University of Valencia, Valencia, Valencia, Spain, (3)University of Valencia, Valencia, SPAIN, (4)Department of Developmental and Educational Psychology, ERI Lectura. University of Valencia, Valencia, Spain

Background: The use of visual and auditory cues during speech comprehension and its relation to other processes is subject to developmental changes. Attention to the talker mouth seems to predict lexical access and word reading acquisition in children 2 to 8 years old with typical development (TD) (Worster et al., 2018; Zamurer et al., 2023) while attention to the eyes in 12-month-old infants would predict the development of social skills (Pons et al., 2019). The literature about sensory dominance is inconclusive for children with autism spectrum disorder (ASD) in the transition between preschool and primary school (5 to 8 years), measured by eye movement indices of visual attention to the talker's eyes and mouth (Guillon et al., 2014; Jertberg et al., 2024).

Objectives: To examine the gaze patterns of 5 to 8 years old children with and without ASD towards the talker's face during storytelling by means of eye movement indices of verbal and social attention.

Methods: 20 children with ASD and typical IQ (aged 5 to 8) and 26 chronologically age-matched typically developing peers were asked to watch videos in which an adult told six stories in two presentation modalities: audiovisual or audio only (with a fixed face image) while their eye movements were monitored. After each video, the children were asked to answer 3 multiple-choice comprehension questions by pointing to the image that corresponded to the correct answer. To calculate the verbal and social attention indices, we obtained the proportion of time gazing (dwell time) the talker's eyes and mouth areas during the speech episode and during the pause pre- and post-speech.

Results: Accuracy and eye movement data were analysed using Generalized Mixed Models in R. Comprehension accuracy was similar across presentation modalities for both groups but children with TD outperformed children with ASD across conditions ($p < .03$) (Figure 1_Top). Regarding gaze patterns in the AV condition (Figure 1_Down, both groups showed a mouth versus eyes preference (TD, $p < .001$; ASD, $p < .002$) during speech but children with TD spent longer proportion of time gazing the mouth than the children with ASD both during the speech ($p < .018$) and during the pause pre-speech episode ($p < .001$). During the post-speech episode, both groups gazed longer the eyes than the mouth ($p < .015$).

Conclusions: Comprehension accuracy of talked stories was higher in 5 to 8 years old children the TD than in children with ASD, regardless the presentation modality. The gaze patterns to the talker's face seemed to be dissimilar between groups, indicating that eye movement indices of verbal (eyes-mouth synchronization) and social attention (pause-speech synchronization) could be used as biomarkers of atypical developmental trajectories in children. These data are consistent with previous findings with other speech stimulus in typical development (words and sentences). Filling the research gap for the transition between preschool to school ages would help to obtain indices of school readiness for this population as well as intervention guidelines.

419.079 A Few of My Favorite Things: Talking about a Strong Interest Affects Speech Prosody and Conversation Engagement in School-Aged Autistic and Non-Autistic Children

O. C. Putnam¹, T. Cooleen², S. Cho³, M. Lyons⁴, C. Faulk⁴, A. L. Lee⁴, S. Schillinger⁴, M. Karpinsky², J. F. Strang⁵, J. Parish-Morris⁴ and C. Harrop⁴. (1)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Linguistic Data Consortium, University of Pennsylvania, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Gender and Autism Program, Children's National Health System, Washington, DC

Background:

Speech prosody is a critical component of pragmatic language, allowing an individual to convey implicit meaning and emotional intent through the rhythm, stress, and intonation of their speech. Despite its prominent role in social interactions, prosody has overwhelmingly been measured using structured, decontextualized tasks that may miss certain nuances of social speech (Asghari et al., 2021). One key aspect of everyday conversations that could influence speech prosody is semantic *content*. Autistic people have described feeling joy and social connectivity when talking about their strong interests (Long, 2024). One previous study (Nadig et al., 2010) anecdotally described increased script-like speech, eye contact, and overall engagement when autistic individuals discussed a topic of strong interest. However, the effects of conversation topic on speech prosody have not yet been studied.

Objectives:

Our goal was to test whether conversation topic (general discussion vs. topic of strong interest) affected acoustic measures of speech prosody (speech rate, mean pitch, pitch range, and intonation).

Methods:

We recorded 10-minute “getting to know you” conversations between school-aged children ($N=39$; $n=20$ autistic; 49% female, $M_{age}=6.76$ years, $SD_{age}=1.7$ years, matched on chronological age and IQ) and an adult experimenter. Halfway through the conversation, the experimenter brought up the child’s strong interest, which was identified beforehand by a caregiver. Experimenters provided Likert ratings of the child’s perceived enjoyment and engagement with the task. Recordings were transcribed and segmented into interpausal units, which were individually coded as being related to either a “general discussion” or “strong interest” topic. Acoustic components of prosody were derived for each speech unit: Speech rate (syllables per second), mean pitch (semitones), pitch range (semitones), and intonation (pitch turns per second, Wehrle et al., 2018). A two-level linear mixed model was run for each prosodic element, with topic (general discussion or strong interest) as a predictor and child-level variables (see Table 1) as covariates.

Results:

In models controlling for child-level characteristics, there was a significant effect of conversation type on speech rate and intonation, such that children spoke faster and more dynamically when speaking about a topic of strong interest (Table 1, Figure 1). Increased speech rates ($\beta=0.78$, $p=.02$) and more animated intonation ($\beta=0.31$, $p=.04$) were also significant predictors of increased experimenter-rated engagement with the task, and intonation ($\beta=1.64$, $p=.03$) was a significant predictor of greater child enjoyment as rated by the experimenter. A greater proportion of interest-related speech segments had trending effects on both engagement ($\beta=2.24$, $p=.05$) and enjoyment ($\beta=6.45$, $p=.05$).

Conclusions:

These results underscore the importance of considering conversational content when examining and describing prosody in children, as it can impact some of the most commonly measured and perceptually salient elements of prosodic speech. Regardless of neurotype, school-aged children produced faster and more animated speech when speaking about topics of strong personal interest. These elements of prosodic speech also predicted experimenter-rated ease of conversational engagement, and experimenter perceptions of child conversational enjoyment. Future research is necessary to fully understand the effects of conversational topic on prosodic variability in children throughout development and into adulthood.

419.080 A Study on Semantic Processing in Children with Autism Spectrum Disorders Based on ERP and Phase Amplitude Analysis
Y. WANG, School of Communication Science, Beijing Language and Culture University, Beijing, Beijing, China

Background:

The semantic processing mechanisms of the children with autism is generally abnormal and heterogeneous. This may be one of the potentially reasons for their communication deficits. The semantic processing mechanism of ASD remains unclear till now. The current study employed the picture semantic priming paradigm to investigate the temporal dynamics of semantic processing in ASD by comparing N400 components between ASD and control groups. Additionally, we employ neural oscillation analysis through “Gamma/Theta phase-amplitude coupling” (PAC) to explore the specificity of picture semantic memory retrieval in ASD during picture priming tasks.

Objectives:

Integrating cognitive tasks with neural oscillation analysis, this study examines the time-frequency dynamics of semantic processing mechanisms in ASD by analyzing N400 components and PAC features. The goal is to elucidate the underlying mechanisms contributing to communication impairments in individuals with ASD.

Methods:

Participants with ASD (age range 5-10 years, $M = 6.57$; $SD = 1.718$) were recruited through the China Rehabilitation Research Center. The age matched controls (age range 5-10 years, $M = 7.14$; $SD = 1.952$) were recruited through advertisements in the local media.

During the picture priming semantic paradigm, high functioning ASD children and the controls participated in the experiment, in which a visual picture presents an auditory target word that is consistent or inconsistent with the picture. The obtained EEG data is used to analyze N400 indicators related to semantic processing and Theta-Gamma PAC indicators related to picture memory retrieval.

Results:

The results showed that the N400 response was significant in both the ASD

and TD groups. The average amplitude of the N400 response in the ASD group was significantly greater than that in the TD group ($F = 4.888$, $p = 0.047$, $p < 0.05$). Based on the results of the ERPs, it can be concluded that children with ASD may have stronger neural responses to semantic or contextual inconsistencies, which may indicate that they are more sensitive to mismatches in semantic expectations. The PAC analysis shows that in the picture semantic priming paradigm, picture recognition tasks involve memory retrieval and extraction, and the coupling strength between the left frontal lobe Theta phase and the posterior parietal occipital lobe Gamma amplitude in ASD children is reduced compared to TD children. Based on the results, it can be concluded that the decrease in Theta-Gamma PAC intensity in children with ASD may correspond to a decrease in communication and synchronization between brain regions involved in memory retrieval and visual processing.

Conclusions:

The conclusion of this study indicates that there is a certain degree of delay in semantic information processing speed. During the entire time process of the picture-priming semantic paradigm, there are certain difficulties in memory retrieval at specific stages when visual pictures appear. Generally speaking, a decrease in the functional role of image memory retrieval in children with ASD may affect the integration of semantic information in subsequent stages. However, whether there is a causal relationship between the two is difficult to conclude in this study and further exploration is needed in the future.

419.081 A Systematic Review of Language Interventions for Minimally Verbal Individuals

J. T. Ong¹, A. R. Morgan² and R. Osnaya², (1)Special Education, University of Missouri - Columbia, Columbia, MO, (2)University of Missouri - Columbia, Columbia, MO

Background: Language allows individuals to communicate their wants and needs, and those who are affected by language difficulty puts them at a higher risk of adverse outcomes related to various aspects of their lives, that may pose barriers in the academic, social, and behavioral domains. Research supports a correlation between language difficulty and problem behavior (Chow & Wehby, 2016). Children who are minimally verbal or nonverbal often have a diagnosis that fits under the Individualized Education Plan (IEP) categories, such as autism spectrum disorder (ASD) or individuals with neurological differences (Tager-Flusberg & Kasari, 2013; Vrečar et al., 2017). However, most evidence-based practices for minimally verbal individuals are for individuals with ASD (Chenau et al., 2021; Koegel et al., 2019). Hence, families and practitioners may struggle to select resources relevant to their context and client characteristics. Thus, identifying the current best practices aimed at summarizing the evidence base for interventions for minimally verbal individuals would assist in identifying the current knowledge base and gaps to guide future research.

Objectives: This systematic review aims to summarize the research on language interventions for individuals who are minimally verbal with a focus on improving verbal expressive communication by a) describing prelinguistic skills targeted in interventions, b) mediators of interventions, c) intervention setting, d) characteristics of participants (e.g., autism vs. other diagnosis and age).

Methods: Guidelines proposed by the Preferred Reporting Items of Systematic Reviews and Meta-Analyses (PRISMA) were followed, and a total of 131 intervention studies were reviewed. Both group and single-subject research designs were included.

Results: Across studies, interventions mainly targeted prelinguistic skills such as joint attention, play, and imitation. Most studies utilized researchers or clinicians as interventionists in experimental settings. However, there is an increasing presence of other personnel as interventionists, such as caregivers and peers, allowing the setting to be expanded to applied settings (e.g., classrooms and homes). There was also an imbalance in the age and diagnosis of participants. The majority of studies included individuals in the younger age groups, such as preschool or elementary children, with few studies including adults or adolescents. Participants were mostly diagnosed with autism compared to other disorders such as down syndrome.

Conclusions: Guidelines are suggested for future research to broaden the participant pool and intervention setting. Potential mechanisms of change proposed by this review should be used to advance and inform the development and selection of language interventions.

419.082 Additional Language Learning in Autistic Adults

C. L. Caldwell-Harris¹ and A. Barlowe², (1)Psychological and Brain Sciences, Boston University, Boston, MA, (2)Boston University, Boston, MA

Background:

As many as two-thirds of persons on the autism spectrum have normal intellectual ability. Such persons attend college, have careers, and study foreign languages or acquire an additional language. A subset of autistic adults has reported having languages as a special interest (Caldwell-Harris, 2021; Digard et al., 2020). In one qualitative study, this group reported learning via grammar books and self-study and being interested in language history and structure, reminiscent of what has been reported for polyglots Hyltenstam (2021).

Objectives:

Investigate the individual aptitude factors that influence additional language learning; what methods are used for learning; compare outcomes between autistic and neurotypical adults; explore the subjective experience of learning.

Methods:

Survey results obtained were from 114 self-identified autistic adults, recruited from Autism forum sites. Neurotypical participants (N=112) were recruited from general social media and an undergraduate subject pool. Participants reported a wide variety of native languages and ranged in age from 18 to 59.

Language Background

- Additional language learning history (on up to 5 languages)
- Self-ratings of speaking, reading, writing and listening
- Method of acquisition, contexts of use and amount of use
- Can Do Scale (e.g., order at a restaurant, read a newspaper)

Autism-related survey item.

- Autism Quotient (AQ; to quantify autistic traits)
- Systemizing Quotient (SQ; because systemizing ability could facilitate learning language structure)
- Autistic traits influence the language learning experience

Language aptitude (see examples in Table 1)

- Phonological Pattern Recognition ('Sound it out' task)
- Sound Symbolism (sensitivity to meaning-sound correspondences)
- Part of Speech Determination (sensitivity to grammatical structure)
- Memory test of previously seen nonsense words

Results:

Autistic participants reported learning on average 2.7 additional languages compared to 1.4 reported by neurotypical learners, a statistically reliable difference. Autism Quotient scores correlated positively with Parts of Speech and Sound it Out tests (Table 2). Autistic learners reported a tendency to use a self-taught method, whereas neurotypicals were more likely to learn an additional language through formal education. In addition, autistic learners favored media and structured learning while neurotypical learners reported more learning via social interaction and immersion. Autistic respondents rated themselves as less proficient in the languages they had studied, suggesting that they wanted to learn languages, but didn't follow-through as often as did the neurotypical respondents.

Autistic respondents more often answered affirmatively to the open-ended question, Has learning a second or foreign language improved communication in your first language? For example:

"Yes, I feel more confident speaking in English after learning Japanese, where previously my anxiety or social difficulties would prevent me from doing so."

"It greatly helped me to better communicate with my co-workers and avoid misunderstandings."

Conclusions:

Additional language learning could be an intervention to improve social functioning, for at least some persons with autism. Stakeholders and autistic individuals themselves could benefit from learning about the discrepancy between wanting to learn an additional language and being able to achieve proficiency.

419.083 Addressing the Paradox of Studying Autistic Females: Pragmatic Atypicalities in Sisters of Autistic Individuals

M. Belenger¹, C. Dumont² and M. Kissine³, (1)ACTE, Université libre de Bruxelles, Brussels, Belgium, (2)ACTE-ULB, Bruxelles, Belgium, (3)ACTE — Center of research in Linguistics — ULB Neuroscience, Université libre de Bruxelles, Brussels, Belgium

Background:

Females have historically been under-represented in autism research, and many studies are based on (almost) exclusively male participants (D'mello et al., 2022). This male-centered focus has shaped our understanding of autism, leading to biased representations, including in diagnostic practice (Cruz et al., 2024). Consequently, autism's manifestation in females is often misinterpreted or overlooked (Hull et al., 2020). For example, while socio-pragmatic atypicalities are considered a core feature of autism (Paul, 2007), recent studies have suggested that autistic females may exhibit fewer difficulties in pragmatic tasks compared to autistic males (den Hartog et al., 2023).

A key paradox in research on autism in females is the lack of data on females who are rarely diagnosed because, precisely, of a different presentation. A potential solution to better understand the subtler presentations of autism in undiagnosed females is to include participants at high likelihood for autism. As autism is highly heritable, a sibling of an autistic individual has 15 to 20 % likelihood of also being autistic (Hansen et al., 2019). We apply this approach, traditionally used in prospective studies with infants, to an adolescent population, a critical period for identifying or unmasking difficulties encountered by autistic females (Rutherford et al., 2016).

Objectives:

This study aims to investigate the linguistic profile of sisters of autistic individuals. We hypothesized that the sisters may experience communicative difficulties not captured by traditional language assessment.

Methods:

A total of 76 female participants (24 sisters; 22 autistics; 30 non-autistics) aged between 9 and 16 years ($M = 12.16$; $SD = 2.33$) took part in this study. Core language abilities were assessed using the CELF-5 (Wiig et al., 2019). Pragmatic abilities were evaluated through parental reports (CCC-2; Norbury et al., 2004) as well as a narrative task. For the narrative task, both the coherence and the fluency were analyzed. Group comparisons were conducted to examine differences between sisters, autistic and non-autistic participants. To represent individual profiles of the sisters, we calculated mean and standard deviation for each narrative measure of interest using the data from non-autistic participants. These values were then used to z -transform the individual scores of participants in the sister group.

Results:

There was no significant difference between sisters and non-autistic participants in CELF scores, however the HL group displayed significantly lower scores on the CCC-2. Six sisters met the threshold for a "communication impairment" (sic). Among them, three had a profile suggestive of autism (as per CCC-2 standardized criteria). For the narrative, the sister group did not differ from non-autistic group on any measures. However, when looking at individual profiles Half of the sisters presented a narrative profile with at least one measure above 2σ , which is to be considered as "atypical".

Conclusions:

Our results indicate that despite typical language abilities, sisters of autistic individuals exhibit subtle yet significant pragmatic difficulties. A closer look reveals that the focus should be more on individuals than groups. This study highlights the need for longitudinal studies to understand the potential evolution of these challenges into clinically significant features.

419.084 Alternative Pathway for Language Acquisition in Autism : Evidence for Enhanced Statistical Learning in Unexpected Bilingual Autistic Children

C. Dumont¹, M. Belenger², A. Destrebecqz³ and M. Kissine⁴, (1)ACTE-ULB, Bruxelles, Belgium, (2)ACTE, Université libre de Bruxelles, Brussels, Belgium, (3)Université libre de Bruxelles, Brussels, Belgium, (4)ACTE — Center of research in Linguistics — ULB Neuroscience, Université libre de Bruxelles, Brussels, Belgium

Background: In typically developing children, language acquisition is bolstered by socio-cognitive skills, such as joint attention and gaze-following behavior (Tomasello, 2010). Early onset and life-long atypicality in these socio-cognitive skills is a core characteristic of autism. Language disabilities and delays are often linked to socio-pragmatic disabilities. Evidence from retrospective studies show that difficulties in processing joint attention is linked with a higher chance of remaining minimally verbal (Anderson et al., 2007). However, there is also evidence that some autistic children acquire language despite persisting low socio-communicative abilities (Ellis Weismer & Kover, 2015; Kissine, 2021). Another kind of evidence that language acquisition can occur with little reliance on socio-communicative interaction is the phenomenon of Unexpected Bilingualism (UB) in autism (Abd El-Raziq et al., 2023; Dumont et al., 2024; Francis et al., 2024; Kadiri & Anasse, 2023; Kissine et al., 2019; Vulchanova et al., 2012; Zhukova et al., 2021). These autistic children, by only mere exposure to screens, develop advanced phonological, lexical and syntactical skills in a language that no one uses around them. However, the mechanisms enabling such atypical language acquisition remains unknown as current descriptions of UB are limited to case studies. One hypothesis could be that autistic-UB children rely more on mechanisms that do not require social interaction, such as statistical learning, i.e., the extraction of statistical regularities from the environment (Naigles, 2013, 2016). A particular type of statistical learning are non-adjacent dependencies AXB structures, where the B-element can only be predicted based on the A-element. Such dependencies are thought to be fundamental for syntax acquisition (Erickson & Thiessen, 2015).

Objectives: In this study, we used an artificial language paradigm to explore whether autistic children, with or without UB profile, have intact or even enhanced statistical learning abilities, which would enable them to acquire language from exposure to screens.

Methods: 47 9-16 years old autistic children, among which 11 with an UB profile (parental report confirmed by the CELF-V) and 47 age-matched non-autistic children took part in the study. In this task, children are exposed to an artificial grammar composed of 3-word sentences and asked to detect target elements occurring on the third location. In the training blocks, and unknown to the participants, some trials have the underlying AXB structures, such that the target in the third (B) position can be predicted based on the element in the first (A) position. In a disruption block, this underlying rule is cancelled, such that targets are replaced by fillers elements in position B.

Results: Linear mixed effect regressions on reaction times revealed that all groups exhibited an effect of disruption, meaning that all participants learned the non-adjacent dependency and were disrupted by its absence. However, the analysis on the training blocks revealed a notable group difference: the autistic-UB learned significantly faster the non-adjacent dependencies, showing a significant decrease in reaction time whereas autistic and non-autistic were flat (Figure 1).

Conclusions: These results seem to indicate a distinct cognitive profile that may underly the phenomenon of UB.

419.085 Assessing Social Communication in Autistic Children Using the Q-Social: Inter-Rater Reliability across Parents and Professionals

C. P. Akih¹ and **K. M. Walton²**, (1)*Nisonger Center, Nisonger Center, The Ohio State University, Columbus, OH*, (2)*Nisonger Center, The Ohio State University, Columbus, OH*

Background: The Q-SoCiAL (Questionnaire for Social Communication in Young Autistic Learners) is a newly developed measure designed to assess social communication skills in autistic children. Deficits in social communication are a core feature of autism. Therefore, it is important to assess these skills across various contexts and by different raters. Integrating input from parents, teachers, and clinicians provides a comprehensive view of children's abilities, as each rater observes the child in distinct environments. Measures of social communication are integral in determining areas of strength, challenges and identifying intervention goals for children. Evaluating the psychometric properties of measures under development is a fundamental step in measure development. Inter-rater reliability is particularly important as high levels indicate the measure assesses the same construct and is interpreted similarly across raters.

Objectives: The current study examines the inter-rater agreement of parent-parent and parent-professional dyads' reports of children's social communication skills. Another objective of the study is to identify factors that influence the convergence or divergence of parent and professional ratings of social communication skills.

Methods: The social communication skills of 113 children aged 3 to 7 years ($M = 5.10$, $SD = 1.03$) were evaluated by parents and professionals who work with the child (48% teachers, 35% childcare providers, and 17% ABA therapists). This resulted in 65 parent-to-parent and 48 parent-to-professional dyads. The sample consisted of 84 boys and 29 girls and was moderately diverse with 74% of the children identified as white. To determine inter-rater reliability and potential variables that influence ratings, bivariate correlations and linear regression analyses were conducted. Correlations for total scores across all subscales and correlations between each subscale were calculated. Additionally, correlations on a subscale focused on challenges in social communication were calculated.

Results: All total and subscale scores of parent-parent and parent-professional dyads were significantly correlated. Total scores between parent-to-parent dyads were correlated at $r(65) = .86$, $p < .001$, indicating strong inter-rater agreement. Subscale correlations within parent-parent dyads ranged from .50 to .82, with the challenges in social communication subscale correlated at $r(65) = .59$, $p < .001$, indicating moderate to high agreement. Total scores for parent-professional dyads were highly correlated at $r(48) = .87$, $p < .001$. Subscale correlations for parent-professional dyads ranged from .39 to .86 with the challenges in social communication subscale correlated at $r(48) = .39$, $p = .006$. Regression analyses indicate that rater agreement was not significantly influenced by the child's total social communication score, age, gender, native language, family income, rater's gender, professional type (child care provider, teacher, or ABA therapist), or professional's years of experience.

Conclusions: The high levels of inter-rater reliability across both parent-parent and parent-professional dyads indicate that the Q-SoCiAL is a reliable tool for assessing social communication skills in autistic children. The high levels of convergence across dyads who observe the children in different contexts indicate that patterns in the children's strengths and challenges in social communication across contexts were adequately captured.

**419.086** At Home Spontaneous (pre-)Linguistic Productions: Clustering Patterns to Define Language Profiles of Young Autistic Children

F. Beccaria¹, **K. Vertongen²**, **B. BeLAS Consortium³**, **E. Demurie⁴**, **I. Noens⁵**, **H. Roeyers⁶**, **L. van Esch³**, **M. Weyland⁶**, **I. Zink²** and **M. Kissine⁷**, (1)*Autism in Context. Theory and Experiment (ACTE), Université Libre de Bruxelles, Brussels, Belgium*, (2)*KU Leuven, Leuven, Belgium, Belgium*, (3)*Université Libre de Bruxelles, KU Leuven, UGent, Brussels, Belgium, Belgium*, (4)*Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*, (5)*Parenting and Special Education Research Unit, Faculty of Educational Sciences, KU Leuven, Leuven, Belgium*, (6)*ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium*, (7)*ACTE — Center of research in Linguistics — ULB Neuroscience, Université libre de Bruxelles, Brussels, Belgium*

Background:

Language development in autistic children varies widely, from near-typical profiles to little or no functional verbal communication. While many studies have relied on standardized measures to assess language profiles, such tests often fail to capture the full complexity of spontaneous speech. Naturalistic recordings provide a more ecological method window on autistic children's spontaneous productions in everyday contexts. Quantitative measures, such as the frequency and duration of vocalizations, provide important insights into (pre-)linguistic development in autism. However, manual coding and transcription allow for a more qualitative analysis of vocalizations, yielding a more nuanced sub-typing strategy. It is customary to categorize young autistic children as either verbal or minimally verbal, framing this as a dichotomy. However, emerging evidence suggests that language skills in autism should rather be conceived of as a continuum, with varying degrees of linguistic and pre-linguistic productions. This study contributes to this more gradual approach by examining spontaneous vocal productions in a large, bilingual sample of autistic children.

Objectives:

This research presents preliminary findings from the Belgian Language in Autism Study and explores language profiles of 88 autistic children aged 2 to 5 years from French and Dutch-speaking regions. The primary aim is to delineate the language profiles of these children by analyzing their spontaneous speech, focusing on how linguistic and pre-linguistic vocalizations may correspond to different language subtypes.

Methods:

We collected six hours of naturalistic speech recordings from each of the 88 participants. For each six-hour recordings, we selected the hour which contained the highest rate of child production, using a deep learning approach. All productions within these hour-long samples were next categorized into three types: linguistic productions (words, sentences, proto-words), pre-linguistic productions (vocalizations containing vowels but not forming full words), and other sounds (laughing, coughing). Using k-means clustering, we identified five distinct clusters based on the distribution of these vocalizations, employing the Elbow and Silhouette methods for descriptive analysis.

Results:

The figure below presents the results of our clustering analysis, which illustrates a continuum of language abilities. Cluster 2, comprising 19 participants, included children with the lowest rates of both types of vocal productions. Cluster 4, the largest group with 23 participants, represented children whose communication was predominantly pre-linguistic. Cluster 3, consisting of 16 participants, displayed a heterogeneous profile, with children exhibiting a mix of pre-linguistic and linguistic vocalizations, but still low overall language production. Lastly, Clusters 1, 5, and 6, with 13, 9, and 8 participants respectively, showed the highest rates of linguistic output, suggesting a more advanced stage of linguistic development.

Conclusions:

This study emphasizes that language abilities in autistic children cannot be easily divided into verbal and minimally verbal categories. Instead, a continuum better reflects the diversity in young autistic children's vocal productions. Future research should continue to explore both qualitative and quantitative aspects of vocal productions in autistic children to provide a more comprehensive understanding of their language development trajectory. These insights underscore the importance of studying spontaneous speech in natural contexts to capture the full range of communicative abilities in autism.

**419.087 Autistic Adult Perspectives on Self-Report Communication Measurement**

H. S. Cheng¹, M. Brown², T. Garfield³, Z. Inkeles³, R. Landa⁴, D. M. Raymaker⁵ and A. de Marchena³, (1)A.J. Drexel Autism Institute, A. J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, A.J. Drexel Autism Institute, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (5)School of Social Work, Portland State University, Portland, OR

Background: Historically, the field of autism research has centered autistic children, with parents and clinicians as primary stakeholders. However, autistic individuals have significant stakes in research priorities, and autistic adults have repeatedly pointed out the gap between their lived experiences and how researchers have characterized their experiences. While self-advocates and researchers agree that communication is often a challenge for autistic individuals, there is a gap in how the research and self-advocate communities define autism communication neurodivergences. Accurate and socially valid communication assessment tools are needed to address this gap.

The only existing self-report communication measure for adults is the Communication Checklist – Self-Report (CC-SR). The CC-SR is a 70-item self-report adaptation of the Communication Checklist – Adult, an extension of the Children’s Communication Checklist-2 (CCC-2). While the CCC-2 has been used extensively to analyze children’s communication skills and has shown utility in identifying autistic children, the CC-SR has not been validated in autistic samples. In this study, we examine autistic adults’ opinions on the CC-SR and how their perceptions of this tool can be used to improve communication measurements for this population.

Objectives: Our objective is to summarize autistic adults’ feedback on the CC-SR using quantitative content analysis, with the long-term goal of improving communication measurement in this population.

Methods: As part of a larger study on autistic adults’ experiences with nonverbal communication, N = 400 autistic adults completed the CC-SR and several other self-report measures. Participants completed surveys online and were screened for fraudulence to maintain data integrity. After completing all measures, we invited participants to provide feedback via a free-write box, reading: “If you have any general feedback about the study, please write it here (optional).” We then completed a latent quantitative content analysis of all write-ins referencing the CC-SR, with each write-in considered a single unit of analysis. The first author coded all write-ins; the senior author coded 20% for inter-rater reliability (Cohen’s κ = .63-1.00; Table 1).

Results: Although participants were not specifically asked to provide feedback about the CC-SR, 40 participants (10% of the total sample, 31% of all write-ins) spontaneously did so. Definitions and examples of codes are shown in Table 1; frequency counts are shown in Figure 1. The most common feedback related to response options’ misalignment with item wording and confusion over certain survey items. One-third of participants’ feedback provided constructive suggestions on how to improve the measure. Participants’ concerns and critiques suggest that the CC-SR is not an ideal tool for gauging communication in autistic adults.

Conclusions: These critiques highlight how existing measures developed and tested with neurotypical individuals may lack validity when administered to autistic samples. Autistic individuals must be consulted during autism measure creation to generate valid results. Measures created via community-academic partnerships, such as the Self-Assessment of Autistic Traits (Ratto et al., 2023), show promise for this approach. Outside of autism research, these results demonstrate how crucial involving target populations in the initial conceptualization and validation of measurements is for creating valid and reliable tools.

419.088 Autistic Adults’ Experiences with Nonverbal Communication Interventions

M. Brown¹, H. S. Cheng², T. Garfield², Z. Inkeles², R. Landa³, D. M. Raymaker⁴ and A. de Marchena², (1)A.J. Drexel Autism Institute, AJ Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (4)School of Social Work, Portland State University, Portland, OR

Background:

Nonverbal communication (NVC) differences, including using and interpreting facial expressions, tone of voice, eye contact, and body language, are a core diagnostic criterion for autism. Lack of understanding and support around these differences presents significant challenges for many autistic adults. NVC provides emotional context and reinforces verbal messages, helping individuals interpret the underlying meaning of social interactions. When NVC cues are absent, misread, or misinterpreted, communication can break down leading to misunderstandings resulting in negative consequences. Despite NVC's critical role in communication, there is limited research on the availability and effectiveness of NVC interventions for autistic adults. This study examines access to, and characteristics of, NVC interventions, as described by autistic adults.

Objectives:

The primary objective of this community-based participatory research study is to assess the prevalence of autistic adults receiving NVC support and predictors of access. The secondary objective is to evaluate intervention characteristics, including the perceived helpfulness and harms of these interventions.

Methods:

Participants were 371 autistic adults aged 20-78; see Table. Using a community-based participatory research approach, we developed an online survey about NVC experiences and interventions. Those who received NVC interventions as adults shared information about their experience, including how long they received intervention, specific NVC modalities and social contexts targeted, and whether the intervention was client- (e.g., one-on-one therapy) or partner-focused (i.e., involving a communication partner). Participants rated the perceived helpfulness and harms of these interventions. We performed logistic regression to identify predictors of intervention access and collaboratively interpreted the results.

Results:

12.1% of participants (n=45) reported receiving NVC interventions as adults. Higher Autism Spectrum Quotient (AQ-10) scores predicted access to interventions ($p=0.024$). Interventions tended to be long-term (57% exceeding one year) and mostly targeted body language (82%), tone of voice (71%), and eye contact (71%). Participants reported receiving support in various social contexts, including family gatherings, job interviews, and crowded social events. Notably, 40% of participants received partner-focused interventions, involving family members, romantic partners, and employers. Helpfulness ratings, measured on a scale of 1 (most helpful) to 5 (least helpful), were mixed. Interventions targeting body language (mean=2.84) and tone of voice (mean=3.11) were rated moderately helpful, while interventions targeting eye contact (mean=4.37) were rated least helpful. Strikingly, 64% of participants who received NVC intervention as adults reported harms, with 58% indicating the intervention encouraged them to mask, leading to additional problems.

Conclusions:

This study highlights the limited access to sensitive and responsive NVC interventions for autistic adults and reveals substantial variability in their perceived effectiveness, as well as potential for harm. NVC interventions should address autistic individuals' needs and the needs of people they communicate with, in a variety of contexts. Providers must understand and respect differences in autistic NVC and minimize the risk of harm to autistic individuals. Future intervention research must actively involve autistic adults, centering their priorities, preferences, and expertise. These interventions should not only affirm autistic communication but also recognize that meaningful change will occur when mainstream society and systems are equally and actively engaged in improving communication experiences.

419.089 Autistic Prosody: Relationship between Self-Reported Experiences, Acoustic Measures, and Autism Traits

A. M. O'Brien¹, A. L. Cardinaux², C. E. Li³, L. Quan² and J. D. E. Gabrieli⁴, (1)Speech and Hearing, Bioscience and Technology, Harvard University, Cambridge, MA, (2)McGovern Institute for Brain Research, Massachusetts Institute of Technology, Cambridge, MA, (3)Hock E. Tan and K. Lisa Yang Center for Autism Research, MIT, Cambridge, MA, (4)Brain and Cognitive Sciences, MIT, Cambridge, MA

Background:

Social communication and interaction challenges are core diagnostic criteria for autism (APA, 2012). While substantial research has investigated autistic communication—including the use of prosody (pitch, timing, volume)—minimal research has characterized autistic experiences of prosody. No work relates prosody experiences to acoustic measures of prosody production, or other validated measures of autism traits. Improving understanding of the relationship between prosody experiences and other facets of social interaction would provide novel insight into how prosody impacts autistic communication.

Objectives:

1. Characterize self-reported experiences and acoustic features (pitch and pauses) of prosody in autistic and non-autistic adults.
2. Examine the relationship between self-reported prosody experiences with prosodic acoustic features and autism traits.

Methods:

US-based adult participants were recruited via the SPARK (autism, $n=60$; 26F; $M_{age}=29.3$ years) and Prolific (non-autism, $n=51$; 27F; $M_{age}=32.6$ years) platforms and participated online after consenting.

Language- and IQ-matched participants completed an open-ended picture description task, novel self-report questionnaire about prosody experiences (co-designed with autistic consultants), and three characterization measures: language (Vocabulary Size Test; Nation & Beglar, 2012); autism traits (Comprehensive Autistic Trait Inventory; cati-autism.com); Nonverbal IQ (Test My Brain; Testmybrain.org).

The self-report questionnaire included questions about prosody experiences and self-perception of one's own prosody. Two subscores were calculated: "Composite" (16 items, describing prosody difficulties) and "Self-Perception" (5 items, rating one's own speech features (e.g., pauses, pitch)).

During the 60-second picture description task, participants described an illustration while their speech was recorded. Acoustic parameters (pitch, pauses) were extracted from the audio in 10ms increments. Silent increments were removed prior to pitch analysis. Pitch mean and standard deviation and the total duration and number of pauses were calculated for each participant.

An ANOVA was used to relate autism traits (CATI) and relevant objective acoustic measures to self-reported prosody experiences.

Results:

Responses from the prosody survey (Composite subscore) revealed that the autistic adults reported greater difficulty with prosody production and perception than non-autistic participants ($p<0.0001$). Acoustic measures of autistic speech features showed longer duration of pauses ($p<0.05$), consistent with self-report ($p<0.001$). There were no group differences in the number of pauses or in pitch. Autistic males had higher pitch than non-autistic males, and there was an interaction between sex and diagnosis for standard deviation of pitch (Figure 1). An ANOVA revealed that Composite subscores were predicted by CATI scores ($p<0.0001$) and diagnosis ($p<0.0001$), but not the extracted acoustic features.

Figure 1. A. Self-report of prosody experiences and speech features. B. Acoustic features (pauses, pitch) extracted from the picture description task.

Conclusions:

The results suggest a greater degree of self-reported challenges with prosody in autistic adults relative to language- and IQ-matched non-autistic adults. These challenges were related to autism traits but not the acoustic measures investigated in this study. Further mixed-methods research is merited to characterize additional acoustic parameters of speech across communication contexts. Examining these acoustic measures in relation to self-report of prosody and broader communication strengths and challenges (e.g. autism traits, learned strategies, masking, gender differences) will better illuminate the role of prosody in autistic social interaction.

419.090 Autistic Traits and Visual Language Proficiency Interact in Comprehending Visual Narratives

E. L. Coderre¹, E. Zane², N. Cohn³, **D. Rosner¹** and K. Fantoni¹, (1)University of Vermont, Burlington, VT, (2)Communication Sciences and Disorders, James Madison University, Harrisonburg, VA, (3)Tilburg University, Tilburg, Netherlands

Background: Pictures are often assumed to be “easier” for autistic individuals to understand compared to verbal stimuli. This assumption underlies the common practice of using of picture stories to support language. However, just like verbal language, understanding picture stories (hereafter “visual narratives”) requires proficiency and relies on numerous cognitive skills (e.g., theory of mind, inference generation, attention) that vary between individuals. Thus, visual narrative comprehension may not necessarily be “easier” for autistic individuals. If visual narrative comprehension is susceptible to individual differences, this necessitates a way of measuring one’s comprehension abilities, just as we measure reading abilities. While self-report measures of visual narrative experience exist, no standardized assessments of comprehension have been developed.

Objectives: To develop an assessment of visual narrative comprehension and explore whether scores are modulated by visual language fluency and/or autistic traits.

Methods: Autistic and non-autistic adults ($n=46$) were recruited as part of a larger ongoing study. Participants completed the Autism Quotient (AQ), a self-report measure of autistic traits, and the Visual Language Fluency Index (VLFI), a self-report questionnaire assessing experience with visual narratives (Table 1). The VLFI has proven valid in predicting various behavioral and neurocognitive measures of visual narrative comprehension. Stimuli were comics in three difficulty levels, with 5 comics per level: 1) Easy: Garfield comics (3 left-to-right panels; simple, concrete narrative events); 2) Medium: Peanuts comics (5-6 panels; more narratively complex storylines); 3) Difficult: Calvin & Hobbes (C&H) comics (more complex layouts; storylines based on imagination and fantasy). For each comic, participants first arranged scrambled panels into a coherent story. We coded whether they arranged panels in the same order as the original comic and how often they identified the same two sequential panels as in the original. Participants then narrated their story and we coded how well they represented the main idea of the original comic. Finally, participants completed 8 comprehension questions by selecting one of two pictures that best answered a written question (correct/incorrect). Multilevel models included *total score* on each comic as an outcome measure, *VLFI* and *AQ* as fixed effects, and *subject* and *item* as random effects.

Results: For overall comprehension scores (all levels), higher VLFI was marginally predictive of higher comprehension ($t=1.92, p=0.06$). We also analyzed each difficulty level individually. No effects of VLFI and/or AQ occurred in Garfield or Peanuts comics. For C&H, AQ and VLFI interacted ($t=-2.58, p<0.05$): increasing VLFI was associated with better comprehension on the C&H strips for participants with lower AQ ($r=0.57, p<0.01$) but not higher AQ ($r=-0.06, p=0.77$; Figure 1).

Conclusions: Participants’ overall comic comprehension was marginally associated with their comic experience, which provides preliminary evidence for our measure’s validity. Comic experience also interacted with autistic traits in the most difficult comics: VLFI was positively associated with comprehension for participants with lower but not higher AQ. These results suggest that proficiency is highly relevant for visual narrative comprehension and operates differentially for different levels of autistic traits. Thus, any use of visual narratives with autistic individuals needs to also consider visual narrative proficiency.

419.091 Beyond Caregiver Input in the Complex Syntax of Autistic Children: A Study of Ba and Bei Constructions in Mandarin
C. Nie¹, Y. E. Su² and S. Durrleman³, (1)Central South University, Changsha, Hunan, China, (2)Child Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China, (3)Faculty of Science and Medicine, University of Fribourg, Fribourg, Switzerland

Background: Children experience extensive exposure to caregiver utterances, though the impact of caregiver input on language development in autistic children remains debated. Some studies emphasize the importance of caregiver input for autistic children’s language development (Fusaroli, 2019; Swanson, 2020), while others suggest it plays a limited role (Chawarska et al., 2013; Green et al., 2017). However, research on the influence of caregiver input on complex syntax in autistic children is still sparse, and further exploration is needed to determine which side it supports.

Objectives: This study aims to determine whether and to what extent autistic children can learn Mandarin *ba* (e.g., *ta ba shu nazou* “He took the book away”) and *bei* constructions (e.g., *shu bei ta nazou* “The book was taken away by him”) from caregiver input. These constructions involve unique grammatical markers (*ba* and *bei*) and require advanced syntactic processing as they deviate from typical subject-verb-object (SVO) word order. Findings can inform if and how caregiver input should be adjusted to support linguistic development in autism.

Methods: Fifty-four Mandarin-speaking autistic children (mean age = 4;06) and 56 typically developing (TD) children (mean age = 2;03), matched on expressive vocabulary levels, participated in 30-minute semi-structured play sessions with their caregivers, which were recorded and transcribed using the Codes for the Human Analysis of Transcripts (CHAT; MacWhinney, 2000). Correlation analyses examined the relationship between caregiver input—specifically their use of *ba* and *bei* constructions and their mean length of utterance (MLU)—and the children’s use of *ba* and *bei* constructions.

Results: Correlations tests showed no significant relationship between *ba* production in caregivers’ speech and that of either autistic or TD children. However, a positive correlation was found between caregivers’ MLU and use of *ba* constructions by TD children ($r_s = .426, p < .01$), although not by autistic children. Children’s use of *ba* constructions was also positively correlated with their own MLU (autistic group: $r_s = .487, p < .001$; TD group: $r_s = .717, p < .001$).

Conclusions: The *ba* constructions of both autistic and TD children can be predicted by their MLU, suggesting that children’s production of complex syntax is related to their own syntactic abilities. The absence of a correlation between the use of *ba* constructions by caregivers and both autistic and TD children suggests that caregiver input of these specific constructions plays a limited role in shaping children’s use of them. However, the positive correlation between TD children’s use of *ba* constructions and their caregivers’ MLU, alongside the absence of such a correlation in autistic children, implies that the MLU of the linguistic input may enhance production of *ba* selectively in TD, while development of such constructions may depend less on such input in autism, arguably due to attentional resources. Future research could explore links between attention and syntactic development, guiding interventions that improve focus to support the acquisition of complex syntax in autism.

419.092 Caregiver Speech Input to Infants at Elevated Likelihood for Autism: An Evaluation from Speech Samples Extracted from Day Long Audio Recordings from India

D. Swaminathan¹, S. Murali¹, R. Raju², M. Srikar¹, S. Amudhan¹ and S. S. Meera¹, (1)National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore, Karnataka, India, (2)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, Bangalore, Karnataka, India

Background: Caregiver speech (CGS) input, part of bi-directional interaction with their infants, is crucial for promoting vocabulary, cognitive skills and language abilities⁽¹⁻³⁾. Evaluating CGS in infants who may have social communication and language delays (e.g., infant siblings of autistic children who are at an elevated likelihood for autism; EL-A) is important since these infants may not participate fully in this bi-directional interaction⁽⁴⁾. Most literature around CGS is in western contexts and little is known about CGS in EL-A in India. Indeed, CGS is influenced by culture. Next, most studies have used short- home/lab-based recordings that are usually based on a pre-defined context or a free play video. More recently, day-long audio recording methods (DLAR), such as Language ENvironment Analysis (LENA®), have been used to provide a more naturalistic sampling of caregiver speech (CGS). Evaluating CGS extracted from DLAR may offer insights that previous studies may not have captured.

Objectives: Thus, the current study aimed to (1) evaluate differences in CGS input provided to EL-A and low likelihood for autism (LL-A) infants between 9-12 months (2) assess the association between CGS input and infant's concurrent language abilities

Methods: Forty-seven infants (24-EL-A; 23-LL-A) between 9-12 months were recruited from NIMHANS, India. Following consent, infants completed one day of recording using LENA®. A 10-minute sample with the highest conversational turns (metric provided by LENA) was extracted. The EUDICO Linguistic Annotator software was used to segment and transcribe the sample manually whenever identifiable speech from adults were present. The following CGS parameters were assessed: quantitative - total number of words, utterance length; qualitative - total number of different words and type token ratio. A total of 470 minutes of CGS input was hand annotated. A subsample (20%) was annotated by a second annotator for inter-rater reliability (IRR). Receptive Expressive Emergent Language Test-3 (REEL-3) was used to evaluate infant language abilities. Cohen's kappa (k) was used to measure IRR. Mann-Whitney U test was used to measure CGS input between groups and partial correlation was used to understand the association between CGS input and language abilities controlling for age.

Results: IRR of .97 (strong agreement) was achieved. Groups were matched on demographic variables (**Table 1**) including age ($t=-1, p=.31$) and sex ($\chi^2=2.58, p=.10$). Results indicated significantly lower number of words (U-178, $p=.03$) and shorter utterance length (U-180, $p=.04$) in the EL-A group (**Table-1**). Amongst all CGS parameters, only total number of words showed significant correlation with receptive language ($p=.322, p<.020$) (**Table-2**).

Conclusions: Findings demonstrate that EL-A infants hear significantly fewer words and shorter utterances in their natural environment compared to infants to LL-A infants similar to findings from west^(5,6). Importantly, the correlation between total number of words spoken to the child and receptive language abilities reinforces the critical role that CGS plays in shaping early language development. Despite limited resources for annotation and prohibitive costs of DLAR devices, this study with a small sample was conducted with methodological rigor and is the first to evaluate CGS in EL-A in India that used DLAR.

419.093 Caregiver and Researcher Administration of a Naturalistic, Play-Based Communication Measure: Similarities, Differences, and Implications

J. R. Steinbrenner¹, B. A. Boyd², S. W. Nowell³ and L. Woolf⁴, (1)Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)School of Education, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Health Sciences, Division of Speech and Hearing Sciences, UNC Chapel Hill, Chapel Hill, NC, (4)Health Sciences, Division of Speech and Hearing Sciences, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Communication is a core area of need and commonly addressed skill in interventions for young autistic children. However, there are few measures designed to be sensitive to change and capture the impact of interventions. As part of a larger study, our team aimed to adapt and validate the Early Communication Indicator (ECI) for young autistic children. The ECI is a naturalistic play-based assessment administered by a familiar play partner (e.g., caregiver, teacher) that measures gestures, vocalizations, words and multiple words. It has strong psychometric properties including sensitivity to change (Greenwood et al., 2010; Buzhardt et al., 2021). The ECI-Autism (or ECI-A) adds four elicitation activities to measure initiation of joint attention (IJA) and directed communication, two aspects of communication that are common intervention goals. This tool could fill a needed gap in progress monitoring tools for communication in research and practice.

Objectives: The goal of the current study is to examine and compare ECI-A communication scores when administered by a caregiver (i.e., familiar adult) as compared to a researcher (i.e., unfamiliar adult). Examining similarities and differences in children's demonstrated communication across contexts (i.e., familiar versus unfamiliar play partner) has important implications for use of the ECI-A as an outcome measure in research.

Methods: As part of the larger validation study, a subset of young autistic children ($n=68$, 50 males), ages 20 - 60 months, participated in the ECI-A with both their caregiver and a research team member during the initial assessment. The participants were racially and ethnically diverse (44% were white, non-Hispanic) and had a range of household incomes (28% had income $< \$40K$). The ECI-A takes approximately 10-12 minutes to administer and includes 6-minutes of play with a toy set (house or barn) with four elicitation tasks that are embedded before, during, and after the 6-minute play. Play partners are directed to engage with the child and follow the child's lead during the play-based activities. The ECI-A was video-recorded and then scored by trained coders. The scores include a weighted communication rate (calculated from ECI variables of gestures, vocalizations, single words, and multiple words), a proportion of IJA (presence of IJA during each of four tasks) and mean ratings of directed communication (0-3 scale for each of four tasks). For the analyses, we examined descriptive statistics for each of the variables. We also conducted paired-sample t-tests and calculated Pearson's correlations between the same variables from the caregiver- and researcher-administered ECI-A.

Results: Most of the communication scores did not significantly differ between caregiver and researcher-administered ECI-As except for vocalizations ($t = 2.29, p = 0.025$). The correlations were all statistically significant but ranged from weak (gestures) to moderate (vocalizations, single words, IJA) to strong (multiple words, weighted communication score, directed communication). See Table 1 for full results.

Conclusions: Overall, the communication scores are similar between caregiver- and researcher-administered ECI-A. However, there are some differences (vocalizations) as well as outliers among participants. The importance of considering context (e.g., familiarity of play partner) in measurement of communication will be discussed.

419.094 Caregivers' Intervention Fidelity Via Online Learning: Early Response to Intervention and Impact on Children's Outcomes

S. Y. Shire¹, E. Kong¹, Y. Jiang², W. Bao³, M. Crain² and W. I. Shih³, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)University of Oregon, Eugene, OR, (3)University of California - Los Angeles, Los Angeles, CA

Background: Caregiver-mediated interventions where caregivers learn synchronously and asynchronously online have experienced rapid growth since the pandemic. However, little is understood about how caregivers are learning to implement the strategies and the impact on children's outcomes in programs adapted for online delivery.

Objectives: The objectives are: (a) to compare caregivers' early/slower response at midpoint between caregivers randomized to immediate intervention (IM) vs. waitlist (WL), and (b) within the Immediate group, examine whether caregivers' implementation at midpoint predicts children's engagement and spontaneous communication at intervention exit.

Methods: This is a secondary data analysis including 49 caregiver-child dyads from a pilot randomized controlled trial comparing immediate access to a 12-week online adaptation (self-directed learning and weekly 20-minute interventionist call) of caregiver-mediated Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2021) intervention versus waitlist.

Participants included children ($M=56.6$ months, $SD=14.4$; Vineland ABC $M=71.0$, $SD=16.0$) with their caregivers ($n=46$ mothers, $n=2$ fathers, $n=1$ grandparent). Caregivers reported child race/ethnicity as Asian ($n=28$), Black ($n=1$), Hispanic ($n=5$), Multiracial ($n=9$), and White ($n=8$).

Caregivers ($n=33$) reported speaking multiple languages at home including Mandarin, Spanish, Greek, Russian, and Telugu.

A 10-minute caregiver-child interaction (CCX: adapted Kasari et al., 2010) was captured at entry, week-6 midpoint and week-12 exit. The Short Play and Communication Evaluation (SPACE: Shire et al., 2018) was also collected at entry and exit. Families were shipped a standard kit of CCX and SPACE toys to be used only during assessment visits. A blinded researcher joined the family synchronously on Zoom to record and support delivery of the SPACE.

Clinical Global Impressions-Severity (CGI-Severity) and Clinical Global Impressions-Improvement (CGI-Improvement) are coded from the CCX by independent reliable coders blinded to intervention allocation for caregivers' behavior including responsivity and JASPER fidelity. CGI-Severity is scored from 7 (no JASPER strategies, not responsive) through 1 (highly responsive, consistent and appropriate strategy use). CGI-Improvement indicates entry to 6-week change from 7 (significantly worse) to 1 (very much improved).

Children's time jointly engaged (JE: coordinating adult and shared activity) was coded second by second using an established protocol (Shire et al., 2015) by reliable coders ($ICC=0.88$) from the CCX. Frequency of children's initiations of gaze, gesture, and language for joint attention and requesting (total social communication: $ICC=0.82-0.91$) was coded from the SPACE. Coders were blinded to timepoint and condition.

Results: Of 47 dyads with complete data, caregivers in IM showed significantly greater reductions in CGI-Severity at 6 weeks (Fisher exact, $p<0.001$) with 14/23 rated with CGI-Improvement ≤ 2 indicating early response while 0/24 WL caregivers showed early response.

Using linear regression, within the IM group, decreased CGI-Severity score at week 6 is associated with significant increases in children's exit total social communication ($t(18)=-2.47$, $p=0.02$) and JE ($t(18)=-3.31$, $p=0.02$).

Conclusions: Caregivers are making significant gains in responsive implementation of JASPER strategies after 6 weeks of primarily self-directed learning which was associated with children's social communication outcomes. Identification of caregivers showing a slower response at midpoint can facilitate exploration of adaptive implementation strategies to personalize caregiver supports.

419.095 Caregivers' Linguistic Alignment to Autistic and Neurotypical Teenagers

G. Corrigan^{1,2}, **R. Fusaroli**³, **E. Weed**³ and **L. R. Naigles**², (1)Communicative Sciences and Disorders, Michigan State University, East Lansing, MI, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Aarhus University, Aarhus, Denmark

Background: Linguistic alignment refers to the reuse of a conversation partner's lexical items (LexAlign), syntactic structure (SynAlign), and/or semantic content (SemAlign)^[1]. Caregiver-to-child alignment is important: greater alignment by caregivers to neurotypical children ("NT caregivers") positively predicts their preschool-aged children's later language^[1,3]. Few studies have examined alignment by caregivers to autistic children ("ASD caregivers"), and only one distinguished alignment rate (frequency) and level (degree)^[1]. LexAlign/SynAlign rates/levels, as well as SemAlign levels, were higher in NT than ASD caregivers, and ASD caregivers' alignment rates/levels were positively correlated with their preschool-aged children's expressive language (EL)^[1]. It is unknown the extent to which caregivers align similarly or differently with their children, either neurotypical or autistic, during adolescence.

Objectives: To investigate group differences in rates and levels of caregiver-to-child alignment, as well as relationships with teenagers' EL. We also examine a longitudinal subset to determine whether early caregiver-to-child alignment relates to caregiver-to-child alignment in adolescence.

Methods: Caregivers played the Aliens Game^[4] with their adolescent children: 24 NT ($M_{age}=15.84$ years) and 19 autistic ($M_{age}=17.47$ years) teenagers whose EL^[5] raw scores differed (NT: $M(SD)=206.50(19.35)$; ASD: $M(SD)=144.37(66.13)$; $p<.001$). Dyads decided together whether to ask for a gem, steal one, run away, or hide from each of 40 cartoon aliens. The longitudinal subset's (NT: $N=18$; ASD: $N=14$) conversational data came from 30-minute parent-child play sessions when children were preschool-aged (NT $M(SD)_{age}$: 40.70(1.40) months; ASD $M(SD)_{age}$:

52.11(6.45) months). At both timepoints, conversations were recorded and transcribed, then analyzed using ALIGN^[6], an open-source alignment-calculating package. Mean caregiver-to-child alignment rate (number of the caregiver's turns in which any LexAlign/SynAlign occurred, divided by their dyad's total turns) and level (mean LexAlign/SynAlign/SemAlign value in turns with nonzero alignment) were calculated. Because LexAlign contributes to SynAlign/SemAlign, we controlled for LexAlign in analyses involving SynAlign/SemAlign.

Results: ASD and NT caregivers did not differ in LexAlign rate or SynAlign/SemAlign level ($ps>.210$). However, ASD caregivers had higher SynAlign rates than NT caregivers ($p=.020$, $F=5.92$, $\eta^2=0.13$), while NT caregivers had higher LexAlign levels than ASD caregivers ($p=.002$, $F=10.93$, $\eta^2=0.21$; Figure 1). Caregivers' LexAlign level and teenagers' EL^[5] raw scores were positively correlated (NT: $r=0.41$, $p=.044$; ASD: $r=0.54$, $p=.017$; Figure 2a). Longitudinal analyses revealed significant positive correlations between early and current caregiver-to-child LexAlign rates for both groups (NT: $r=0.48$, $p=.042$; ASD: $r=0.61$, $p=.021$; Figure 2b); no other significant relationships emerged ($ps>.054$).

Conclusions: Alignment analyses revealed both similarities and differences across groups: ASD caregivers reused their children's syntax more often, but NT caregivers reused more of their teenagers' words. Possibly, ASD caregivers were more focused on keeping their teens "on task" whereas NT caregivers were more focused on their teens' content. As teenagers' EL levels increased, more of their words were reused by their caregivers (LexAlign level); caregivers overall may have felt that alignment would be more fruitful with teenagers who used more complex language. Finally, caregiver-to-child LexAlign rate appeared to be stable from childhood to adolescence in both groups, suggesting that caregivers who initially provided more conversational scaffolding via frequent word reuse continued to do so over a decade later.

419.096 Characterizing Relationships between the Linguistic Complexity of Caregiver Input and Autistic Children's Expressive Language: Beyond Mean Length of Utterance

J. R. Mathee-Scott¹, G. Corrigan¹, Z. Hesse², J. Johnson² and C. E. Venker¹, (1)Communicative Sciences and Disorders, Michigan State University, East Lansing, MI, (2)Michigan State University, East Lansing, MI

Background: Caregiver language input plays an important role in the broader language development of autistic children (Bang & Nadig, 2015; Fusaroli et al., 2019). Prior research has demonstrated that caregivers of neurotypical children, children with Down Syndrome, and children with language impairments fine-tune their linguistic input based on their children's language level (Bird & Cleave, 2016; Leung et al., 2021). Traditional language sample analysis approaches heavily rely on Mean Length of Utterance (MLU) as a measure of linguistic complexity. However, means are not sensitive to spread or variability in data. Thus, MLU may obscure some important information. Better understanding how caregivers of autistic children adjust their linguistic input based on their child's language level will provide important information to guide parent-implemented language interventions.

Objectives: Examine a novel approach to characterizing the linguistic complexity of caregiver input to autistic children and investigate relationships between parent- and child-level linguistic complexity measures.

Methods: Participants were 29 autistic children (6 F) and their caregivers who participated in a larger study. An experienced clinical team confirmed children's autism diagnoses using the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2; Lord et al., 2012) and clinical judgement. Children were between two and five years old ($M = 43.52$ months; $SD = 10.51$). Caregiver-child dyads participated in 10-minute play-based language samples with a standard set of toys. Samples were transcribed and analyzed using Systematic Analysis of Language Transcripts software (SALT; Miller & Nockerts, 2024). Measures included (for both caregivers and children): Range of Length of Utterance (RLU; Longest Utterance – Shortest Utterance), Total Utterances (TU), Standard Deviation of Length of Utterance (SDLU), and Mean Length of Utterance (MLU). Each measure was computed in morphemes, from all complete and intelligible utterances.

Results: For each measure, we fit a linear regression in which the dependent variable was the caregiver-level complexity measure (RLU, TU, SDLU, MLU) and the independent variable was the corresponding child-level measure. Independent variables were mean-centered for all models. Results revealed that child RLU significantly predicted caregiver RLU ($\beta = 1.71$, $t = 2.898$, $p < .01$, Fig.1), child SDLU significantly predicted caregiver SDLU ($\beta = 0.356$, $t = 5.701$, $p < .001$, Fig.2), and child MLU significantly predicted caregiver MLU ($\beta = 0.514$, $t = 4.827$, $p < .001$). Children who produced zero utterances ($n = 4$) were excluded from the MLU model, as an MLU could not be calculated. Children who produced one or fewer utterances ($n = 7$) were excluded from the SDLU model as standard deviation could not be calculated. Child TU did not significantly predict caregiver TU ($\beta = 7.435$, $t = 0.805$, $p = .428$).

Conclusions: Results suggest that variability in utterance length may be a useful measure of linguistic complexity as a complement to MLU and that caregivers adapt the linguistic complexity of their input, but not the total quantity of input, based on the complexity of their autistic children's expressive language, in real time.

**419.097** Comparing Social Communication and Interaction during Structured and Unstructured Activities in Verbal and Minimally Verbal Autistic Children

Y. Chen¹, C. Gaynor¹ and H. Tager-Flusberg², (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA

Background: Social communication and interaction difficulties are core symptoms of autism spectrum disorder. However, little is known about whether the quality and quantity of social communication and interaction in autistic children are affected by the type of activity and whether this association differs between verbal and minimally verbal (MV) autistic children. It also remains unclear how executive function and language skills interact to affect naturalistic social communication and interaction in verbal and MV autistic children.

Objectives: Comparing the quality and amount of social communication and interaction during structured versus unstructured activities in verbal and MV autistic children; Examining the association between executive function, language skills, social communication and interaction between verbal and MV autistic children.

Methods: 31 verbal (ADOS Mod 2/3) and 23 MV (ADOS Mod1) autistic children ($M_{age} = 4.87$ years, ranging from 3.5 to 6.8) were included in this study. A four-point Likert scale was adapted from the original ADOS protocol to code the quality and amount of social overtures, the quality of social responses, and the overall quality of social rapport in one structured and one unstructured activity from ADOS Mod 1 to 3, with lower scores indicating fewer social communication difficulties. Structured activities with specific sequences and prompts include a birthday party in Mod 1 and 2 and an interview in Mod 3. Unstructured activities include free play in Mod 1 and 2 and joint-interactive play in Mod 3. Two ADOS-reliable coders reached intraclass correlation coefficients from 0.84 to 0.96 across all coding. Executive function was reported by parents on the BRIEF-P. Receptive language was assessed using the PLS-5, and the number of different words (NDWs) was derived from another natural language sample. Linear mixed models with a random intercept of each participant tested whether the effect of activity type on social communication variables differs between verbal and MV autistic children. Multiple regression models were used to test the association between the study variables.

Results: MV autistic children initiated more social overtures during unstructured than structured activities, $\beta = -0.33$, $p = 0.04$, and had better overall quality of social rapport in unstructured activities, $\beta = -0.39$, $p = 0.01$, while neurotypical children did not show significant differences (Figure 1). Better executive function and receptive and expressive language were associated with better social communication and interaction in the whole autistic sample (Figure 2). After taking verbal status into account, receptive language emerged as the single significant factor predicting the quality ($\beta = -0.02$, $p = 0.03$) and amount of social overtures ($\beta = -0.02$, $p = 0.02$) and the overall quality of social rapport ($\beta = -0.02$, $p = 0.005$, but not the quality of social response) in MV autistic children. MV autistic children with better emotional control had fewer changes in their quality of social responses between structured and unstructured activity, $\beta = 0.03$, $p = 0.03$.

Conclusions: Unstructured activity with toys at different play levels and without specific prompts facilitates social overtures and improves social rapport in MV autistic children during naturalistic interactions. Better emotion regulation helps maintain a stable social response quality in MV autistic children, and better receptive language supports their social overtures and overall social rapport.

419.098 Conversational Topic Management in Autistic and Typically Developing Children: Evidence from Spanish
Z. Ábalos, B. Vicente and E. Castroviejo, University of the Basque Country (UPV/EHU), Vitoria-Gasteiz, Álava, Spain

Background: The present study is the first to examine topic maintenance and topic shifts in Spanish-speaking autistic and typically developing (TD) children. Keeping track of the interlocutor's previous topic is an essential skill to engage in coherent conversations. Notably, off-topic responses can lead to negative social judgments and consequences (McGuinness et al., in press; Abbot-Smith et al., 2024). While research suggests that autistic children face greater challenges than TD children in elaborating on immediately prior topics (Ying-Sng et al., 2018), a recent study by Abbot-Smith et al. (2024) found both groups equally capable. Furthermore, research specifically addressing topic shifts is scarce and often mixed with other variables (Ying-Sng et al., 2018). Given that social interaction challenges are a core aspect of autism, grasping the nuances of conversational topic management is particularly relevant.

Objectives: This study aims at contributing to the understanding of conversational dynamics in autistic children, focusing on the similarities and differences they exhibit compared to TD children in topic maintenance and topic shifting.

Methods: Participants included 43 autistic and 45 TD Spanish-speaking children (5.6-12.11 years), matched on chronological age ($W = 1059, p = 0.45$). Autistic children had a non-verbal IQ above 80 in the Leiter-3 ($M = 105, SD = 10.6$), and age-appropriate receptive vocabulary (Peabody scores: $M = 101, SD = 21.1$). Each child engaged in a 25-minute semi-spontaneous conversation with the examiner using the *Eliciting Language Samples for Analysis* protocol (Barokova et al., 2021). We developed our own coding scheme (particularly expanding on topic shifts), while reanalyzing some of our variables to align with Abbot-Smith et al. (2024). Coded response types included: contingent responses (elaborating on the previous topic), minimal (topic-supporting responses without elaboration, e.g., "yeah"), topic shifts, missing, and other (not fitting into any other category).

Results: A negative binomial regression, controlling for age and total number of conversational turns, revealed significant group-response type interactions. Post-hoc analyses indicated that autistic (ASD) children produced significantly more topic shifts ($\beta = 1.31, SE = 0.17, z = 7.83, p < .001$), missing responses ($\beta = 0.89, SE = 0.14, z = 6.33, p < .001$) and other responses ($\beta = 0.95, SE = 0.15, z = 6.29, p < .001$). No significant differences were detected for minimal ($\beta = -0.24, SE = 0.13, z = -1.90, p = 0.06$) and contingent responses ($\beta = -0.07, SE = 0.13, z = -0.58, p = 0.57$). Results are illustrated in Figure 1, with summary statistics in Table 1.

Conclusions: Our findings suggest that autistic children can effectively maintain and develop the interlocutor's previous topic. However, they still deviate from the topic more frequently than TD children. These results raise the possibility that when TD kids do not fully grasp the conversational topic, they tend to give minimal responses, while autistic children go for shifting topics. The next step in our research will involve examining the types of topic shifts children produce, which may provide further insights. Results will be available at the conference.

419.099 Cross-Context Question-Asking in Autistic Children: Frequency, Form and Function

B. C. Armstrong¹, R. J. Luyster² and S. Arunachalam³, (1)Emerson College, Boston, MA, (2)Communication Sciences and Disorders, Emerson College, Boston, MA, (3)Communicative Sciences and Disorders, New York University, New York, NY

Background: Literature on question-asking behaviors in autistic children has predominantly focused on interventions designed to increase question-asking frequency. There is a gap in the autism literature concerning question-asking behaviors in young children. Recent research has shown that autistic children ask questions to serve similar functions as their typically developing peers but at a significantly lower rate (Luyster et al., 2023). However, little is known about the contextual influence on question-asking behavior in autistic children.

Objectives: This study aimed to investigate the frequency, form, and function of questions produced by autistic children in semi-structured and unstructured contexts.

Methods: English-speaking autistic children 4;3-6;6 years old participated in (1) a semi-structured question-eliciting task on a tablet using Greif et al.'s (2006) protocol and (2) a naturalistic play session. In the semi-structured task, children were presented with images of unfamiliar animals and objects and invited to ask as many questions as they liked. In the naturalistic play session, children and their caregiver(s) were provided with playdough, snack boxes, unfamiliar objects, magna tiles, and three books. Each session was transcribed and question form and function were coded by trained examiners.

Results: Data collection was completed with 15 participants. Their average age was 5;6 years ($SD=10.08$ months); the group had an average NVIQ of 95.93 ($SD=27.90$) and expressive language score on the CELF P2 of 97.20 ($SD=17.13$). Preliminary analyses are included and mostly descriptive; further analyses will be conducted in the months ahead. Children asked 111 questions during the semi-structured task and 344 questions during the naturalistic play session. When adjusted for task duration (in minutes), children asked an average of .81 questions/minute ($SD=1.10$) during the semi-structured task and 1.09 questions/minute ($SD=.64$) during the play session. A within-subjects Cohen's d revealed a small difference between conditions ($d=.22$), although a Wilcoxon signed-ranks test indicated that the two conditions were not significantly different ($Z=1.10, p=.272$). During the semi-structured task, 11% of questions were yes/no, 85% were wh-, and 4% were intonation-based. During the play session, 38% of questions were yes/no, 50% were wh-, and 9% were intonation-based. During the semi-structured task, 95% of questions were information-seeking, 5% were initiation and maintenance, and <1% were directive. During the play session, 55% of questions were information-seeking, 24% were initiation/maintenance, and 14% were directive.

Conclusions: While context does not significantly impact the question-asking rate of autistic children, context can contribute to variability in question form and function. Variability in question form/function across settings is a novel finding that advances previous literature to suggest autistic children are adapting their inquiries to the context. Autistic children appear to have a wider variety of questions during play-based, low-expectation interactions with a familiar communication partner. Contextual effects should be considered in characterizing and supporting active learning in autistic children.

419.100 Developing a New Toddler Measure of Social Communication for Use in a Clinical Trial Initiated during COVID-19: My Toddler's Social Communication (MTSC)

A. S. Carter¹, L. B. Cunningham², S. M. Attar³ and W. L. Stone², (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)Psychology, University of Massachusetts, Boston, Boston, MA, (3)Psychology, University of Washington, Seattle, WA

Background:

The onset of COVID-19, which ushered in an era of mandated social distancing, had a profound impact on researchers conducting clinical trials. Many established in-person measures of social communication were not feasible, creating a need to pivot to new approaches for measuring social communication. Our research group embarked on a large, multi-site, community-based clinical trial involving Part C Early intervention (EI) providers, toddlers, and their caregivers in the midst of the initial stay-at-home mandates. One inclusion criterion was that toddlers display either social-communication challenges or an increased likelihood for autism. Unable to use the planned interactive screening tool for autism, we developed a new caregiver-report measure, My Toddler's Social Communication (MTSC). Our priorities for the MTSC were that it be relatively brief, include photos along with simple written descriptions of each social communication behavior, and illustrate cultural diversity. The final version comprised 11 items (See Example) and one question about social communication concern.

Objectives:

To examine psychometric properties of the MTSC including the factor structure, internal consistency, sex differences, and concurrent validity.

Methods:

Participants (N=328) were referred to the study by their EI providers, who had enrolled in an ongoing implementation/effectiveness trial in Part C early intervention programs. Providers referred families when they had concerns about the children's social communication. Caregivers were diverse with respect to race, ethnicity, education, and poverty status (See Table 1). Children (68.1% boys; 31.9% girls) were between 16- and 35-months of age (mean=25.9, SD=4.04). Caregivers completed the initial screening questionnaires for the study, which included the MTSC, the Brief Infant-Toddler Social Emotional Assessment (BITSEA; Briggs-Gowan & Carter, 2006), a nationally normed autism and mental health screening tool, and demographic characteristics.

Results:

An exploratory factor analysis yielded a single factor solution, (Eigen Value=4.61) with factor loadings ranging from .481 to .750 (Mean=.629). Consistent with a single factor, Cronbach's alpha for the 11 items was .876. There were no child sex differences for the total scale, with two items significant with small effect sizes. Boys were rated higher on "Looks at you to share his or her enjoyment" (Cohen's $d=.25$), while girls were rated higher on "Used toys as if they were the real object" (Cohen's $d=.28$). There were no caregiver education effects for the full MTSC scale, with two items significant with small effects sizes. Caregivers with college degrees rated their children higher on two pointing items, (i.e., seeking help and sharing interest) than less educated caregivers, (Cohen's $d=.276$ and $.248$). The MTSC was correlated significantly with BITSEA autism competence and problem scores ($r_s = .77$ and $-.48$ respectively). The number of caregivers who rated concern about social communication was 264 (80.5%) with 64 reporting no concern (19.5%).

Conclusions:

Preliminary analyses of the MTSC in a highly diverse sample of caregivers provide strong evidence for high internal consistency and concurrent validity. There was some evidence for individual item differences for child sex and caregiver education, but none for caregiver race/ethnicity effects. Future work in the larger study will focus on predictive validity to autism diagnosis.

419.101 Developing a Sense of Meaning: Changes in Neurophysiological Correlates of Semantic Comprehension during Language Maturation in Children with and without Autism

K. Toffolo¹, M. Tivarus², Z. Christensen³, E. G. Freedman⁴ and J. J. Foxe⁴, (1)University of Rochester, Cognitive Neurophysiology Lab, Rochester, NY, (2)Neuroscience and Imaging Sciences, University of Rochester, Rochester, NY, (3)University of Rochester, Rochester, NY, (4)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY

Background: Comprehending language requires understanding the meaning of individual words and their context within a sentence. How one processes this semantic information can be measured by changes in amplitude of the N400 event related potential (ERP) and late positivity component (LPC/P600), both of which are robustly evoked when errors are introduced into sentences. Additionally, functional magnetic resonance imaging (fMRI) studies show that different areas of the brain are activated in response to changes in semantic congruency, including the Inferior Frontal Gyrus (IFG) and Superior Temporal Gyrus (STG). Throughout typical language development, a child's semantic processing skills are refined. This is reflected in amplitude and latency decreases of these ERP components and broad activation becomes localized to language areas with adult like patterns appearing between 10-12 years. Behavioral research suggests that individuals with autism often have developmental language differences including difficulty comprehending pragmatic and semantic information. Studies using neurophysiological or neuroimaging methods also generally show atypical responses to language information. However, there is no consensus on whether the N400 and/or the LPC/P600 are present, altered, or absent in individuals with autism among these studies, and few have investigated the development of auditory semantic comprehension across childhood using both electroencephalography (EEG) and fMRI. Paired with cognitive measures, this research could inform whether language differences in children with autism are due to a language delay, an alternative language trajectory, or both.

Objectives: The purpose of this study was to characterize the development of auditory semantic comprehension in children with and without autism utilizing EEG and fMRI across 4 age bands.

Methods: Brain activity was recorded via EEG and fMRI while auditory sentences with and without semantic errors were played (stimuli from Toffolo et al. 2022). Responses were compared between neurotypical (NT; n=38) and autistic (n=25) children across four age bands: 6-7, 8-9, 10-12, and 13-15 years.

Results: The N400 and LPC/P600 ERP components of both groups matured throughout language development in response to semantic errors, showing reductions in amplitude and latency with age. There were also differences in functional activation between older and younger children, with older children showing activation in the IFG and STG in response to semantic errors. Interestingly, the N400 ERP component of older children with autism had reduced amplitudes when compared to their NT peers. However, these amplitudes were similar to younger NT children, making older autistic children appear to have "younger" ERPs. Functional activation was also different between groups, with activation only in the LIFG of NT children but bilateral IFG activation in autistic children.

Conclusions: Preliminary data show effects of semantic congruency and age on activation and ERP response amplitude, latency, and topography. Albeit a small sample size, there are differences in activation and N400 component amplitude between older children with and without autism. These data suggest differences in how semantic information is processed children with autism and how these skills develop. Once completed, the outcomes of this study will provide information on developmental language trajectory with complementary information from fMRI and EEG methodologies.

419.102 Developing an Augmentative and Alternative Communication (AAC) Lab and Lending Library in a Low-and Middle-Income Country (LMIC)

N. Muttiah¹, C. Y. Kumarage², S. Imeshika³, G. Kodituwakku⁴, S. Sumanasena⁵ and D. V. Vipulaguna⁶, (1)Department of Disability Studies , Faculty of Medicine , University of Kelaniya, Ragama, Sri Lanka, (2)Ayati National Centre for Children with Disabilities, Ragama, Western province, Sri Lanka, (3)Ayati National Centre for Children with Disabilities, Ragama, Western Province, Sri Lanka, (4)Department of Disability Studies, Faculty of Medicine, University of Kelaniya, Ragama, Western Province, Sri Lanka, (5)Department of Disability Studies, Faculty of Medicine University of Kelaniya, Ragama, Sri Lanka, (6)Ministry of Health, Sri Lanka, Colombo, Western, Sri Lanka

Background:

The challenges with providing communication services in LMICs like Sri Lanka are significant. An increasing number of families with children with communication difficulties are using iPads and other tablet and mobile technologies as AAC systems (Caron, Costello, & Shane, 2014). The use of this type of technology has been successful in providing children with communication difficulties unique ways of communicating using communication apps.

Objectives:

The purpose of this study was to describe the processes involved in the development of an AAC lab and lending library to serve individuals with autism in a LMIC. We will provide descriptive statistics of patterns of consumer use and activities undertaken by the lab. The AAC lab called Dhvani, and lending library could be a good model for other professionals in other LMICs to replicate in their settings.

Methods:**1). Establishment of the AAC lab - Dhvani:**

The AAC lab Dhvani was established through two external grants in May 2020. One grant enabled the purchase of a laminator and a printer to be used to develop low-tech AAC materials. The second grant enabled the purchase of tablet devices and communication apps. This includes Avaz Sri Lanka a communication app that was developed specifically for the Sri Lankan population in the two local languages spoken in Sri Lanka.

2). Creating awareness and training:

Currently, there is very limited awareness regarding AAC in Sri Lanka (Muttiah et al., 2021). This is among both professionals and parents. The Dhvani lab provides both awareness and training among caregivers.

3). Lending library:

The lending library allows families the opportunity to loan tablet devices with AAC apps to trial at home for a period of 1 month (and more). This allows the families to see the usability of the AAC device or assistive technology tool with their child in a real-world situation.

Results:

Results will be presented on each of the four areas mentioned above drawing from data collected over the past 4 years.

1). Establishment of the AAC lab - Dhvani:

The lab has provided access to AAC and other assistive technology equipment. The lab has developed 113 low-tech AACs for families. High-tech AAC apps were trialed with 306 children with CCN. Other types of assistive technology have been trialed with 5 children with disabilities.

2). Creating awareness and training:

The lab has trained over 275 parents of children with CCN on how to use high-tech AAC apps. The lab has conducted 9 parent workshops. A total of 693 participants have attended the workshops conducted through the Dhvani lab.

3). Lending library:

The assistive technology lending library has loaned tabs with communication apps to 115 children with disabilities. The lab has loaned other types of assistive technology equipment to 2 children with disabilities. In addition, the lab was able to source donations of tablet devices and apps for 14 children who were not able to afford it.

Conclusions:

The Dhvani lab and lending library have resulted in many children with CCN having access to AAC services.

419.103 Differences in Basic Auditory Processing and Expressive Language in Autistic Youth with and without History of Late Talking

K. Wong¹ and **C. Demopoulos²**, (1)Psychiatry & Behavioral Sciences, UCSF, San Francisco, CA, (2)Psychiatry & Behavioral Sciences, UCSF Center for ASD and NDDs, San Francisco, CA

Background:

Some children with autism have a history of being late talkers, some of whom eventually catch up in their language development while others do not. Delayed cortical auditory response and impaired rapid auditory processing have been associated with verbal abilities in ASD; however, our understanding of the developmental onset and consequences of these auditory differences is still emerging.

Objectives:

We examined performance on neuropsychological measures of rapid auditory processing and auditory reaction time in relation to both history of late talking (LT) as well as current language abilities in typically developing controls (TDC) and youth with ASD to understand the relation of auditory deficits to historical presence of speech delay and persistence of expressive language impairment (ELI).

Methods:

Participants were 128 children and adolescents ages 8-17 years (43 TDC; 56 ASD-LT; 29 ASD+LT). LT history was defined by first words after 18 months, phrase speech after 36 months, and/or 6-8-word sentences after 48 months. Participants with current CELF-5 Expressive Language Index score below 80 were additionally classified as having current ELI.

Group differences were examined on measures of rapid auditory processing (SCAN-3 Gap Detection test) and auditory reaction time (CATA). Correlations were performed between these scores and CELF-5 Expressive Language Index, mean auditory and visual naming response times (AVNT-C), and rapid naming speed (NEPSY-II). Lastly, we subdivided groups based on LT history and current ELI to examine auditory group differences in those whose language delays did versus did not resolve. Bonferroni corrections were applied to significance thresholds to control for familywise error.

Results:

The ASD+LT group had significantly lower Expressive Language scores compared to both the TDC and ASD-LT groups ($p < 0.001$). Within the ASD+LT group, 48.3% had current ELI (Table 1).

The ASD+LT group had slower auditory reaction times and poorer rapid auditory processing ($p = 0.016$) compared to the TDC group. Additionally, slower auditory reaction time was associated with lower Expressive Language scores in both ASD groups (ASD+LT: $\rho = -0.476$, $p = 0.014$; ASD-LT: $\rho = -0.286$, $p = 0.033$). Furthermore, better rapid auditory processing performance was associated with higher Expressive Language ($\rho = 0.372$, $p = 0.047$) and rapid naming scores ($\rho = 0.406$, $p = 0.036$) in the ASD+LT group.

Finally, we explored auditory processing differences based on LT history and current ELI (Table 1). The ASD-LT+ELI group was not included in these analyses because only 4 participants met these criteria. Compared to TDC and ASD-LT-ELI, the ASD+LT+ELI group had significantly slower auditory reaction times (ASD-LT-ELI: $p = 0.0008$, TDC: $p = 0.0003$) and worse rapid auditory processing (ASD-LT-ELI: $p = 0.0035$, TDC: $p = 0.0004$). Analyses were not sufficiently powered to detect statistically significant differences between the two LT groups; however, compared to the ASD+LT-ELI group, ASD+LT+ELI group had on average, slower reaction time (ASD+LT+ELI: $M = 52.33$, $SD = 13.153$; ASD+LT-ELI: $M = 43.06$, $SD = 9.692$) and worse rapid auditory processing (ASD+LT+ELI: $M = 5.92$, $SD = 2.466$; ASD+LT-ELI: $M = 6.69$, $SD = 2.774$) (Figure 1).

Conclusions:

Basic auditory processing was associated with history of LT and current expressive language abilities in autistic youth. Continued auditory dysfunction may play a role in the persistence of language impairment in children who were late to talk.

419.104 Early Joint Attention Abilities Predict Subsequent Expressive Language Abilities in Young Autistic Children

T. Nitzan¹, M. Bachrach², M. Ilan³, M. Faroy⁴, D. Waissengreen⁵, A. Michaelovski⁶, D. Zagdon⁷, Y. Sadaka⁸, G. Meiri⁹, I. Menashe¹⁰, J. Koller¹¹ and I. Dinstein¹². (1)Azrieli National Centre for Autism and Neurodevelopment Research, Student at Ben Gurion University of the Negev, Beer Sheva, Israel, (2)Ben Gurion University in the Negev, Beer Sheva, South, Israel, (3)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (4)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (5)Israel National Autism Research Center, Be'er Sheba, Israel, (6)Child Development Center, Soroka University Medical Center, Beer-Sheva, Israel, (7)4. Zusman Child Development Center, Soroka University Medical Center, Beer Sheva, Negev, Israel, (8)Child Development Center, Ministry of Health, Beer Sheva, Israel, (9)26 YA'ARA ST., Beer-Sheva, Israel, (10)Department of Epidemiology, Biostatistics, and Community Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, (11)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (12)Cognitive and Brain Sciences Department, Ben Gurion University, Beer-Sheva, Israel

Background: Most autistic children exhibit early language delays with 25-30% remaining minimally verbal (MV) throughout life. Hence, expressive language is a key area for early intervention that is critical for successful outcome. Previous studies have suggested that autistic children with better social communication and joint attention abilities early in development were more likely to successfully develop expressive language abilities later.

Objectives: To identify early predictors of expressive language development in MV 1-4-year-old autistic children using ADOS-2 and cognitive test variables at diagnosis.

Methods: We analyzed retrospective data from 101 children (83 boys), 13-50 months old at diagnosis ($M=27.4$, $SD=7.20$). All children completed two ADOS-2 assessments, one at diagnosis and another at follow up, 12-24 months later. We used the coding system developed by Visser et al., (2017) to create a common 8-point scale across ADOS-2 modules, thereby transforming A1 item scores into scores ranging from 0 (Children use sentences in a largely correct fashion) to 7 (No language production at all). All the selected children in the current study were classified as MV at diagnosis according to this scale. Children were divided into three groups based on their verbal ability at follow-up: MV (scores 6-7), one-word phase (scores 4-5), phrases (scores 2-3) and fluent speech (0-1). Joint attention (JA) was calculated according to the scale developed by Gotham et al. (2007), by summing the following 6 items from the different ADOS-2 modules: Pointing, Gesturing, Showing, Initiation of Joint Attention, Unusual Eye Contact, and Reaction to Joint Attention.

Results: Children who developed expressive language abilities at follow-up (scores of 0-5) had significantly higher ADOS-2 Social Affect (SA) Calibrated Severity Scores (CSS) at diagnosis ($F(2, 98)=5.531$, $p=0.005$). Logistic regression models revealed that both ADOS-2 SA-CSS (Estimated=0.46, $SE=0.33$, $p=0.007$, $OR=2.44$, 95% CI [1.33, 4.95]) and JA (Estimate=0.22, $SE=0.31$, $p=0.013$, $OR=2.16$, 95% CI [1.22, 4.19]) scores, at diagnosis, were significant predictors of expressive language abilities at follow-up. In contrast, cognitive scores and ADOS-2 Restricted and Repetitive Behaviors (RRB) CSS at diagnosis did not differ significantly across children who remained MV or developed expressive language. Additionally, when analyzing changes in ADOS-2 SA-CSS, ADOS-2 RRB-CSS, and JA scores over time, only the changes in JA scores showed a significant difference between groups ($F(97, 2) = 9.65$, $p = 0.001$).

Conclusions: In line with previous studies, we demonstrate that early social abilities and primarily joint attention abilities are associated with better development of expressive language in preschool autistic children (i.e., "the rich get richer"). This demonstrates that JA scores extracted from the ADOS-2 represent a meaningful prognostic measure for estimating outcome, as proposed previously with more elaborate methods for assessing JA. Further studies examining these predictors in different intervention settings are highly warranted.

419.105 Early Word Acquisition Predicts Cognitive Ability, Adaptive Behavior, and Symptom Severity in Young Children with Autism Spectrum Disorder

T. J. Chang¹ and **C. C. Wu²**, (1)Kaohsiung Medical University, Kaohsiung, Kaohsiung, Taiwan, (2)Department of Psychology, Kaohsiung Medical University, Kaohsiung, Taiwan

Background: Autism spectrum disorder (ASD) involves deficits in social communication and interaction. While language delay was a core symptom in DSM-IV, it's now a specifier in DSM-5 due to variability in language development. Researches link language ability to cognitive abilities, adaptive behaviors, and symptom severity, with early acquisition predicting outcomes. This study explored how early language development predicts future abilities in ASD, emphasizing the need for early intervention.

Objectives: The study aimed to (1) determine if early word production in young children with ASD affects follow-up outcomes in cognitive abilities, adaptive behaviors, and autistic symptoms; (2) whether the age of word acquisition is the best predictor of later outcomes; and (3) whether the Mullen Scales of Early Learning (MSEL) or the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) is a better tool for measuring word production.

Methods: This study recruited 158 young children with ASD (134 boys, 24 girls) aged 17 to 35 months at Time 1, along with their parents. Follow-up assessments were conducted 12 to 19 months later at Time 2. Children were divided into three age-based groups: Group 1 (< 25 months), Group 2 (25-29 months), and Group 3 (≥ 30 months). Language ability at Time 1 was assessed using MSEL and ADOS-2. At Time 2, cognitive abilities and four sub-scales were measured by MSEL, autistic symptom severity by ADOS-2, and adaptive behaviors by the Vineland Adaptive Behavior Scales, Third Edition (VABS-III) or the Adaptive Behavior Assessment System, Second Edition (ABAS-II), completed by parents.

Results: Children from all three groups who produced words by Time 1, as measured by MSEL, consistently showed better performance at Time 2 in developmental quotient (DQ), MSEL sub-scales, and adaptive behaviors. Similar patterns were observed in young children assessed by ADOS-2, who consistently showed higher DQ, sub-scale scores, adaptive behaviors, and certain autistic symptoms at Time 2. Compared to MSEL, ADOS-2 better predicted autistic symptoms, with spoken words leading to significantly better performance. Moreover, significant differences were observed across all groups, with earlier word expression linked to better developmental outcomes. Children who had spoken words by 24, 29, and 35 months all showed superior performance across these domains compared to those who began speaking after 36 months. Upon closer examination, the MSEL data revealed that children who began using words before 25 months showed significantly preferable outcomes in language expression ($p=.027$), overall language development ($p=.041$), adaptive behaviors ($p=.020$), communication ($p=.009$), and socialization ($p=.032$) compared to those who spoke after 30 months. Children in the 25-29 month group performed finer than those in the 30-month group in communication skills ($p=.039$).

Conclusions: This study emphasized the significance of early language emergence in young children with ASD, with earlier word expression predicting better cognitive, language, and adaptive outcomes. The findings highlighted the importance of early intervention to improve developmental trajectories in them.

419.106 Encoding of Sentiment in Autistic and Non-Autistic Adults

S. Dickner¹, **B. Chouinard²** and **A. Fyshe³**, (1)School and Applied Child Psychology, University of Calgary, Calgary, AB, Canada, (2)Computing Science, University of Alberta, Edmonton, AB, Canada, (3)University of Alberta, Edmonton, AB, Canada

Background: The salience of social/emotional experiences has implications for whether and how emotional association, or sentiment, is encoded during language development. If these experiences are less rewarding for autistic compared to non-autistic people, this could lead to differences in how strongly sentiment is encoded during language learning; that is, how strongly sentiment is bound to vocabulary. This study investigates sentiment encoding using two-word phrases that are either congruent, where both words share the same sentiment as each other and as the resulting phrase (e.g., "super awesome", "ugly downfall"); or incongruent, where one positive and one negative word combine to produce phrases that are either positive (e.g., "bloody hilarious") or negative (e.g., "super pissed"). Understanding the strength of sentiment encoding can provide valuable information regarding how social/emotional stimuli are processed.

Objectives: This study investigated sentiment encoding by having autistic and non-autistic people make sentiment judgements about two-word phrases. We hypothesized that if sentiment was tightly bound at the word-level, then two-word phrases where both words have similar sentiment (i.e., congruent), would be quickly categorized; and incongruent phrases, where the two words have opposite sentiment, would induce cognitive interference leading to longer judgement times compared to congruent phrases.

Methods: Data from 26 autistic (7 male; mean age = 27.04 ± 7.10 years) and 17 non-autistic (9 male; mean age = 26.53 ± 6.92 years) adults were used in the study. Groups were matched for age, gender, and language and reading abilities. Stimuli comprised 60 unique phrases presented in random order, three times each, using rapid serial visual presentation; totaling 180 trials. Participants judged each stimulus as positive or negative while we captured response times and accuracy. One participant's data from each group had been excluded due to <95% accuracy. For remaining participants, only accurate trials with response times >250 ms or within 3SD of each participant's average were included. Paired t-tests were used within each group to determine whether incongruent phrases required significantly longer to judge than congruent phrases.

Results: Independent samples t-tests indicated no difference for number of unusable datasets (autistic=1.02%, non-autistic=0.98%) or trials (autistic=3.57%, non-autistic=5.6%) between the groups (both $p < 0.05$). The non-autistic group required longer to judge incongruent (mean = 1678.38, SD = 306.55) than congruent (mean = 1614.37, SD = 299.27) phrases ($t(16) = -1.83$, $p = 0.04$). Similarly, the autistic group required longer to judge incongruent (mean = 1634.38, SD = 270.36) than congruent (mean = 1584.30, SD = 282.18) phrases ($t(25) = -2.23$, $p = 0.02$). However, unique to the autistic group, there was a trend between higher autism spectrum quotient scores and larger incongruency effects ($r = 0.38$, $p = 0.06$).

Conclusions: This study enhances understanding of sentiment encoding and language processing. Our findings indicate that both autistic and non-autistic people encode sentiment at the word level despite different social/emotional experiential salience during development. However, in autistic individuals there was a positive relationship between number of autistic-like traits and amount of cognitive interference, suggesting potential processing differences or strategies. Our findings suggest that individual differences in autistic traits influence the processing of sentiment in language.

419.107 Enhancing ASD Detection with Machine Learning and Deep Learning: Insights from Eye-Tracking Data during Audiovisual Speech Perception

Y. Weng¹, Y. Emarat², G. Peng³ and Y. Zhang⁴, (1)Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, China, (2)Department of Computer Science & Engineering, University of Minnesota, Minneapolis, MN, (3)Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Kowloon, Hong Kong SAR, China, (4)Department of Speech-Language-Hearing Sciences, University of Minnesota, Minneapolis, MN

Background: Accurate and early diagnosis of Autism Spectrum Disorder (ASD) is beneficial for providing appropriate and timely interventions, especially for children. Traditional diagnostic protocols based on behavioral observations can be subjective and time-consuming, leading to inaccuracies as well as delays in diagnosis. Recent advancements in machine learning and deep learning offer the potential to improve diagnostic efficiency by analyzing more refined and complex data such as eye movements.

Objectives: This study aims to develop and evaluate a hybrid approach combining machine learning and deep learning techniques to classify children with ASD from their typically-developing (TD) peers based on eye-tracking data. By leveraging both time-series data and image-based features, the objective is to create a model with high diagnostic accuracy.

Methods: Eye-tracking data collected from 70 Hong Kong Cantonese-speaking children (26 diagnosed with ASD) aged 7 to 12 years when completing audiovisual speech perception tasks. Eye movements when scanning the talking face of a female speaker were processed as time-series data for machine learning models and as heatmaps and trail maps for deep learning. The machine learning approach involved feature engineering and training ensemble models combining Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Random Forest through voting or meta-classifiers. For the deep learning approach, Convolutional Neural Networks (CNNs) were trained on eye-tracking heatmaps and trail maps. The two approaches were combined to maximize diagnostic performance.

Results: The combined machine learning and deep learning approach achieved a satisfactory accuracy of over 95% in diagnosing ASD. The ensemble models provided robust performance on time-series data, while CNNs effectively captured spatial patterns from eye-tracking heatmaps. The integration of both methods significantly improved the overall accuracy and robustness of the diagnostic tool.

Conclusions: Our hybrid approach of combining traditional machine learning with deep learning models offers a promising method for improving the diagnosis of ASD in children. The use of eye-tracking data as a non-invasive diagnostic tool, combined with sophisticated algorithms, provides a reliable and

highly promising alternative to current diagnostic protocols. Further research and validation in larger clinical settings are necessary to refine the models and ensure their broader applicability.

419.108 Environmental Influences on Language Development in Autistic Children: Socioeconomic Status, Shared Book Reading, and Screen Time

A. Geffin and M. Pecukonis, Lurie Center for Autism, Massachusetts General Hospital, Lexington, MA

Background: Studies have shown that distal environmental factors, like socioeconomic status (SES), and household activities within the proximal environment, like shared book reading and screen time, influence language development in neurotypical children. More specifically, annual household income, parent education level, and shared book reading frequency have been positively linked to language skills (Dickinson et al., 2012; Letourneau et al., 2013), while screen time has been negatively linked to language skills, in neurotypical children (Madigan et al., 2020). However, little research has focused on understanding how the environment shapes language development in children with autism.

Objectives: This study aimed to 1) explore the associations between SES, shared book reading frequency, screen time, and expressive and receptive language skills in autistic children; and 2) determine if shared book reading frequency and screen time mediate the association between SES and children's language skills.

Methods: This study used data from the 2018-2022 United States National Survey of Children's Health, a nationwide parent-report survey that collects data on determinants of children's health and well-being. The sample included 1217 autistic children, 2 to 5 years old ($M=3.83$). Structural equation modeling (SEM), a statistical method that allows for the exploration of associations between observed variables and latent factors by combining principles of factor analysis with multiple regression analysis, was used to examine the associations between SES, shared book reading frequency, screen time, and language skills. SES was measured using parent education level and family poverty ratio (FPL). Shared book reading and screen time were measured using questions about weekly shared book reading frequency (days/week) and daily screen-based media use (hours/day). Expressive and receptive language skills were measured using questions about children's abilities to use single and multi-word phrases, ask questions, tell stories, understand and follow directions, and recognize sounds.

Results: The final structural model (Figure 1) included three latent factors – SES, expressive language (EL), and receptive language (RL). Shared book reading frequency and screen time were included as observed variables, and child age and sex were included as observed covariates. Higher SES was significantly associated with more frequent shared book reading, less screen time, and higher expressive and receptive language skills. More frequent shared book reading was significantly associated with higher expressive and receptive language skills, while screen time was not significantly associated with either language factor. Shared book reading partially mediated the association between SES and both expressive ($\beta=.050$, $p<.001$) and receptive ($\beta=.044$, $p<.001$) language skills. The final structural model fit well ($X^2(111)=362.114$, $p<.001$; CFI=.966; TLI=.954; RMSEA=.043; SRMR=.032) and explained 24.3% and 27.1% of the variance in expressive and receptive language skills, respectively.

Conclusions: Findings suggest that the environment plays an important role in language development for children with autism. Autistic children from higher SES households experienced more frequent shared book reading, which was associated with stronger language skills. Contrary to what has been found in neurotypical children, screen time was not associated with autistic children's language skills. Findings offer implications for clinical practice, as encouraging shared book reading may support autistic children's language development.

419.110 Exploring Language Dynamics in Hispanic American Autistic Bilinguals Using Naturalistic Language Sampling

P. Maes¹, M. Tafolla Magana², N. Benrey Grinberg³, N. E. Rosen², H. Tager-Flusberg⁴ and C. Lord⁵, (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Psychiatry, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (4)Psychological and Brain Sciences, Boston University, Boston, MA, (5)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

Background: Research on bilingualism in autism is limited, especially in the U.S., likely due to clinical advice for families to use one language with their child. Existing studies have focused on parental decisions regarding language use, effects of bilingualism on cognitive functioning, and language proficiency relative to monolinguals using standardized testing. Bilingualism does not seem to have a cost on language in autistic individuals. However, it has not been looked at in more ecological contexts, using naturalistic language sampling (NLS), which would enable observation of real-world bilingual dynamics.

Objectives: We seek to analyze spoken language in autistic individuals who are English-Spanish bilinguals using NLS by (a) comparing participants' English and Spanish language proficiency and (b) measuring participants' use of code-switching.

Methods: Sixteen 2- to 31-year-old Hispanic American English-Spanish autistic bilinguals were recruited as part of a larger study on autism symptoms manifestation across languages. Naturalistic language samples were gathered from video-recordings of the Brief Observation of Autism Symptoms (BOSA), a 12- to 14-minute semi-structured interaction based on play and/or conversation. Each participant completed two BOSAs, one in each language. The language context (English vs. Spanish) of the BOSA was established by the examiner. Each BOSA was transcribed using SALT conventions for English and Spanish. Utterances were further coded as (a) 'target language' (matching the context), (b) 'inter-sentential code-switching' (using the non-contextual language), or (c) 'intra-sentential code-switching' (mixing both languages). Data on language proficiency and code-switching behaviors were extracted using SALT software. Language proficiency was measured in English and Spanish separately as total number of utterances (nUtt), mean length of utterance in morphemes (MLUm) and number of different words (NDW). Code-switching behaviors were measured using rates of utterance for each coded category in each language context.

Results: English proficiency appeared stronger than Spanish (see Fig. 1). Linear regression models, controlling for age, confirmed significant between-language differences in nUtt ($\beta = -54.06$, $SE = 22.19$, $p = .02$) and NDW ($\beta = -57.94$, $SE = 24.8$, $p = .03$), but not in MLUm ($p = .05$). Pearson correlations revealed strong positive associations between English and Spanish proficiency (nUtt: $r = .82$, $p < .001$; MLUm: $r = .88$, $p < .001$; NDW: $r = .89$, $p < .001$). Pairwise comparisons on a linear regression model with the Code-switching behavior x Language context interaction as fixed effect, controlling for age, showed higher rates of target language utterances in English vs. Spanish contexts ($\beta = .26$, $SE = .06$, $p < .001$), and more inter-sentential code-switching in Spanish vs. English contexts ($\beta = -.19$, $SE = .06$, $p < .01$). No between-context difference was found in intra-sentential code-switching ($p = .6$).

Conclusions: Overall, participants were proficient in both languages, but English appeared stronger than Spanish. Code-switching occurred more frequently when participants used their weaker and culturally non-dominant language (Spanish). Our findings highlight the need for education and service providers who are proficient in both languages to support autistic bilinguals in Hispanic communities in the U.S.

419.111 Exploring the Cerebellar Sensitive Period Hypothesis of Autism Using Language and Motor Tasks in Children

A. Gladfelter^a, M. Buac^a, Z. Wang^a, S. Onal^b and D. Wallace^c, (1)*Speech-Language Pathology, Northern Illinois University, DeKalb, IL,* (2)*Industrial and Systems Engineering, Northern Illinois University, DeKalb, IL,* (3)*Industrial Engineering, Southern Illinois University, Edwardsville, Edwardsville, IL,* (4)*Psychology, Northern Illinois University, DeKalb, IL*

Background: The Cerebellar Sensitive-Period Hypothesis posits that a perinatal cerebellar disruption is an underlying factor in the developmental manifestation of autism (Wang et al., 2014). Beyond motor skills (e.g., coordination and balance), the cerebellum also shapes non-motor functions relating to cognition, affect, language, and social interaction skills (Adamaszek & Kirkby, 2015; Koziol, Barker, & Jansons, 2015), areas that commonly differ in autistic individuals. However, research on cerebellar deficits has primarily focused on adults, and child research is necessary to test this developmental hypothesis.

Objectives: To bridge this gap, we conducted a series of studies comparing the performance of autistic and non-autistic children, ages 3 – 12, on various language and motor tasks known to involve the cerebellum.

Methods: Across studies, three areas of language (morphosyntax, semantics, and pragmatics), and six areas of motor skill (bimanual coordination, walking gait, balance, manual dexterity, aiming/catching, and speech motor coordination) were analyzed using spontaneous language sampling, standardized motor assessment, and kinematic measures extracted from traditional motion capture systems (Optotrak) and innovative machine-learning (DeepLabCut) and video analysis (OpenPose) tools. For the autistic children to be included, autism status was based on two criteria, 1) formal autism diagnosis according to parent report, and 2) scoring within the autism range on the Autism Diagnostic Observation Schedule-2nd edition and/or the Social Responsiveness Scale-2nd edition upon starting the study. For the non-autistic children to be included, they must 1) have no reported history of autism, and 2) score within the minimal-to-no symptoms range on the Childhood Autism Rating Scale-2nd edition and/or the Social Responsiveness Scale-2nd edition at the time of participation in the study. To be included in the studies with language tasks, all children were required to: 1) be native English speakers, 2) pass a hearing screening and oral mechanism examination, and 3) use oral speech as their primary means of communication (rather than augmentative or alternative forms of communication). Sample sizes varied from 24 to 44 across studies, depending on the recruitment period (e.g., currently ongoing, closed during COVID-19 lockdowns). For language-based studies, autistic and non-autistic children did not significantly differ on age, receptive vocabulary, expressive vocabulary, or nonverbal intelligence.

Results: Most findings supported the Cerebellar Sensitive-Period Hypothesis in both the language and motor domains. Specifically, performance differences in tasks assessing semantics, pragmatics, speech motor coordination, manual dexterity, and balance aligned with the predictions put forth in the Cerebellar Sensitive-Period Hypothesis in children. The use of early developing morphosyntactic measures, rather than grammatically complex measures, may have contributed to the lack of differences between groups on these language tasks. Ongoing analyses are underway.

Results to date are summarized in Table 1.

Conclusions: These studies add to a growing body of evidence that the cerebellum plays an integral role in the presentation of autism in children across a range of language and motor tasks. Speech-language pathologists, psychologists, occupational therapists, and physical therapists should consider co-treating or providing services collaboratively to maximize therapeutic benefits and to better understand the role of the cerebellum across their autistic clients' day-to-day tasks.

**419.112 Exploring the Effects of Peer and Teacher Interactions on Vocalizations in Preschool Children with Autism**

C. Romero^a, D. S. Messinger^a, L. K. Perry^a, L. Estrada^a and L. Vitale^a, (1)*University of Miami, Coral Gables, FL,* (2)*Department of Psychology, University of Miami, Coral Gables, FL*

Background: Understanding the factors that influence social communication in preschool-aged children with autism spectrum disorder (ASD) and developmental disabilities (DD) is essential for developing effective interventions. Prior research has shown that children's vocalizations can vary significantly depending on their communication partner, whether peers or teachers. The nature of these interactions is particularly important, as peers and teachers may foster different communication skills.

Objectives: This study investigates how different partner interactions and the severity of social communication difficulties, as measured by the Social Responsiveness Scale (SRS), predict the frequency of vocalizations among young children with ASD and DD. We examine associations of social responsiveness, partner vocalization input, partner type (peer vs. teacher), with children's vocalizations to peers and teachers.

Methods: The study involved 27 preschool children aged 3 to 5 years from three classrooms, including 11 identified with a primary IEP eligibility category of Autism Spectrum Disorder (ASD), 11 with developmental delay (DD), and 5 children not having an IEP (i.e., typically developing). Vocalizations were measured using Language ENvironment Analysis (LENA) audio recorders. UbiSense system was used to track children's location to assess children's rates of social contact (based on proximity and mutual orientation) with peers in the classroom. Teachers completed the Social Responsiveness Scale-2 (SRS-2) for each child to assess social communication difficulties. Higher SRS scores indicate greater difficulties in social communication, while lower scores reflect more typical social communication abilities. A linear mixed-effects model examined the influence of partner vocalization input, partner type (peer or teacher), and SRS scores on children's vocalizations to peers and teachers while in social contact with those partners, as well as the 2-way interactions between these variables, with vocalization data (level 1) nested within children (level 2).

Results: There was no main effect of SRS scores, $p=.207$, suggesting similar overall levels of child vocalizations regardless of social communication difficulties when accounting for partner input. Partner input had a significant effect on children's vocalizations, $p<.0001$, such that children who heard more vocalizations from peers and teachers produced more vocalizations themselves. However, there was also a significant interaction between partner input and partner type, $p<.0001$, such that input from peers had a stronger effect on children's own vocalizations than input from teachers (see **Figure 1** and **Table 1**). Finally, there was an interaction between SRS scores and partner input, $p<.0001$, such that partner input was more strongly associated with children's vocalization among children with lower SRS scores.

Conclusions: Together the results reveal that partner vocalization input is significantly associated with children's vocalizations, but that this effect is stronger for children with lower SRS scores, indexing fewer social communication difficulties. Additionally, in general children produced more vocalizations while in social contact with peers than teachers. These results suggest one potentially promising direction for early interventions could be to support peer interactions to enhance communicative behaviors in young children with ASD and other developmental disabilities.

419.113 Language Comprehension and Speech Production in Preschool Children with Autism Spectrum Disorder

H. Diab¹ and **E. Dromi²**, (1)*School of Education, Tel Aviv University, Tel Aviv, Tel Aviv, Israel*, (2)*Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel*

Background:

Children with autism spectrum disorder (ASD) demonstrate remarkable individual differences in their early developmental processes. This variability is obvious when examining their language comprehension and speech production skills. Research shows that many children with ASD exhibit linguistic impairments, however some may not experience any linguistic challenges. Studies on language development in preschool children with ASD are sparse and have raised questions about the stability of language profiles over time (Broome, 2023; Weismer & Kover, 2017). The present study reports on a longitudinal follow-up of language comprehension and speech production by Hebrew-speaking preschool children with ASD.

Objectives:

1. To examine the variability and consistency of the linguistic profiles in preschool children with ASD over a period of one year.
2. To explore the relationship between language comprehension and speech production among our participants.

Methods:

32 children aged 3–5 years old who were diagnosed with ASD participated in the study (Lord, 2008). The design employed three repeated measurements that took place every four months, in the participants' homes. The following diagnostic tools were administered: the Preschool Language Scale (PLS-4) (Zimmerman, Steiner, & Pond, 2002), the Autism Intervention Goals Questionnaire (Dromi & Diab, 2019), the Mullen Scales of Early Learning (Mullen, 1995), the Repetitive Behavior Scale-Revised (RRB-I) (Bodfish et al., 2000). These means provided an overall picture of each participant linguistic profile at each assessment point.

Results:

An examination of the overall linguistic profile of all participants at the beginning of study revealed four distinct groups: a. children with mild language delays; b. children with moderate language delays; c. children with significant language delays; and d. children with no language delays. Repeated measures revealed that approximately half (56%) of the children (17 participants) exhibited a consistent linguistics profile throughout the study. In contrast, about one-third (34%) (12 participant) showed with time a larger gap between their chronological age and language age. Only three participants (9.3%) decreased this gap between the first and third assessments. The results of the first assessment were a strong predictor of the profile obtained in the third assessment.

Conclusions:

The results of the present study indicated that:

- 1) Preschool children with ASD indeed show individual variability with respect to their early linguistic skills.
- 2) Over the course of one year notable consistency was found in the linguistic profiles, particularly in those participants with significant language delays at the beginning of the study
- 3) The early assessment and early intervention in the areas of language comprehension and speech production is essential as it predicts later attainments in these areas.

419.114 The Development of Mental State Verb Use Among Children with Autism

I. Eilon¹ and **R. Novogrodsky²**, (1)*University of Haifa, Israel, Haifa, Israel*, (2)*University of Haifa, Haifa, Israel*

Background:

Mental State Verbs (MSVs) are a way to describe people's internal states and processes. MSVs include verbs from different semantic categories: cognitive verbs (e.g., know), emotion verbs (e.g., afraid), perception verbs (e.g., see), physiological verbs (e.g., tired) and desires verbs (e.g., want). In young, typically developing (TD) children, research showed that the use of desires, perception and physiological verbs precedes the use of cognitive and emotion verbs. When examining the use of MSV in children with autistic spectrum disorder (ASD), the results of school-age children are contradictory, and little is known about the developmental trajectories of these verbs in preschool children with ASD.

Objectives:

The current study aimed to examine the developmental gap in children with ASD by exploring MSV use in these children as compared to TD children throughout childhood. In addition, the study investigated the effect of task (parental questionnaires versus narrative task) as representing the use of MSVs and the influence of age, group (TD versus ASD), syntax and Theory of Mind (TOM) abilities on MSV development.

Methods:

A total of 118 children ages 3–10 years participated in the study (59 ASD and 59 TD children). Parents of the children filled out a questionnaire of MSV from different semantic categories used by their child. In addition, all children participated in a narrative task that was designed to elicit MSV use. Furthermore, two variables that influence MSV were examined: sentence repetition for estimating syntax abilities and a battery of three tasks: different desires and first and second false belief tasks for measuring TOM abilities.

Results:

According to the parental questionnaire, cognitive and emotion verbs have a more protracted developmental trajectory in both ASD (Figure 2) and TD (Figure 1) children than other MSV categories (desire, perception and physiologic verbs), and they are more challenging for children with ASD in comparison to TD children. No differences were found between the groups in other MSV categories. In addition, a weak-to-moderate correlation ($r = 0.35$, $p < .001$) was found between MSV use in the parental questionnaire and the use of MSVs in the narrative task, but no difference was found between groups in the narrative task. Regarding variables related to MSV use, the model explained 57% of the variance of the average score of cognitive and emotion verbs, while age explained 30%, syntax 21.7%, TOM 4.1% and group 2%.

Conclusions:

The findings of this study indicate a specific and significant linguistic difference between ASD and TD children in the development of cognitive and emotion verbs. This gap was evident in the MSV parental questionnaire but not in the narrative task, possibly due to the small number of verbs used by both groups in this task. The study also highlights the role of syntax, TOM, and autism as related to the development of these verbs, supporting the notion of complex developmental conditions associated with MSV development and thus, the need to evaluate them in children with ASD.

419.115 Giving Time to Process: Caregiver Wait-Time during Naturalistic Interaction for Autistic and Non-Autistic Preschoolers
M. Chan¹, T. Buonocore², K. Steen³, L. Adam Ali¹, M. Cannon¹, M. DiGiorgio¹, L. Rees⁴, K. Tandon¹, R. J. Luyster² and S. Arunachalam⁵, (1)Emerson College, Boston, MA, (2)Communication Sciences and Disorders, Emerson College, Boston, MA, (3)New York University, New York, NY, (4)University of Bath, Claverton Down, Bath, United Kingdom, (5)Communicative Sciences and Disorders, New York University, New York, NY

Background: The adjusting, or “tuning”, of language has been observed in caregivers when communicating with children. Many measures of “tuning” have focused on the caregiver’s verbal utterances; however, little research has investigated the amount of time parents wait after asking a question. Sufficient wait-time, particularly for open-ended questions requiring more than a yes/no response, can be an important tool for supporting information processing (Wasik & Hindman, 2018). Especially for autistic children who may have slower language processing speed relative to non-autistic children (Williams, 2012; Hartley et al, 2020).

Objectives:

- Calculate caregiver wait-time for autistic and non-autistic children during naturalistic caregiver-child play.
- Determine whether wait-time differs across groups and question-types (open and closed).

Methods: Two groups of children (autistic and non-autistic) aged 24-71.9 months completed a Zoom-recorded 15-minute, naturalistic play-based interaction with their caregiver. Data collection is complete, with a final sample of 30 children per group. Here, we report preliminary analyses of 6 child-caregiver dyads including 3 autistic and 3 non-autistic children (mean child age: 52.73, 29.18 months respectively). Expressive vocabulary size on the MacArthur Bates Communicative Development Inventory 3 (Fenson et al., 2000) in this subsample did not differ significantly across groups ($t(4) = 0.21, p = 0.83$).

Using transcriptions of these interactions, timestamps were placed at the offset of caregiver-questions directed at the child, and at the onset of the caregiver’s next utterance (if coded as the next-turn; $kappa = 0.803, 3$ raters). This elapsed time between offset and onset thus yielded “caregiver wait-time”. Since wait-time can vary based on question-type, we also coded questions as open (“wh-” and “how”) or closed (yes/no, choices, confirmations); $kappa = 0.93, 2$ raters.

Results: From our sample ($n = 6$), caregivers of autistic children directed 103 questions at the child — 79.61% (82) closed, 20.39% (21) open — and for non-autistic children, 142 questions — 76.06% (108) closed, 23.94% (34) open. Using a significance level of 0.05 and a two-tailed, Welch’s t -test, wait-time for closed questions was not found to be significant between groups ($t(188) = 1.27, p = 0.34$), while wait-time for open questions was ($t(53) = 1.93, p = 0.049$). Here, caregivers of autistic children were shown to wait *less* for a child-response compared to the non-autistic group; *Figure 1*. Additionally, we found no differences between open and closed questions in either group; (ASD: $t(4) = 1.21, p = 0.30$; NonASD: $t(4) = 0.55, p = 0.63$).

Conclusions: We explored whether caregiver wait-time differed between groups and question types. While we saw no differences in wait-time for closed questions between groups, groups *did* differ in open questions; contrary to predictions, caregivers in the autistic group waited *less* than those in the non-autistic group. Also, within each group, caregivers did not exhibit a significant difference in wait-time between question-type, despite the fact that the former inherently calls for a longer response. Analyses will continue in the coming months to see if these patterns persist.

419.116 Parental Verbal Responsiveness to Autistic Children: A Closer Look

R. V. Shannon¹, J. Delafield-Butt¹ and S. McCool², (1)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)School of Psychological Sciences and Health, University of Strathclyde, Glasgow, Lanarkshire, United Kingdom

Background: Parental verbal responsiveness (PVR) is a verbal manifestation of intersubjectivity, demonstrating responsiveness, reciprocity, affective sensitivity, and close attention to another. It responds to a child’s focus or communicative act (McDuffie & Yoder, 2010), is valuable in engaging children with their parents, and promotes language development (Haebig et al., 2013). It benefits autistic children who struggle shifting attention or responding to others’ initiations (Tomasello & Todd, 1983). It is unclear when PVR is most likely delivered within interactions, therefore, this work sought to identify this point using the narrative framework (Bruner, 1990). It proposes that over four phases, interactions with narrative structure demonstrate concordant intersubjectivity (Minnis et al., 2006). They begin with an introduction; develop reciprocal cycles of expression and interest; reach a peak of shared excitement at climax; and conclude as interactors return to quiescence to separate or re-engage (Trevarthen & Delafield-Butt, 2013). We hypothesise that if PVR delivery aligns with the energy contour and connectedness of each narrative phase, the amount of PVR should increase towards climax and fall away at conclusion.

Objectives: Identify whether the proportion of PVR, as compared to non-responsive parental input, differs by narrative phase.

Methods: Data was collected from 5 parent-autistic child (1F) pairs during 10-minute free-play sessions. The children (2;10-5;2) had limited spoken language confirmed through CDI parental reports, and diagnosis was confirmed using ADOS. Two video cameras recorded videos later coded for PVR and narrative using ELAN (Sloetjes & Wittenburg, 2008). Agreement >80% was reached between coders.

Results: Across all narrative phases, more PVR is provided than non-responsive speech. In the introduction, 80% of parental speech is responsive; 98% of speech is responsive in the development; 100% is responsive at the climax; and 75% is responsive in the conclusion (Figure 1). None of the differences between the proportions of PVR vs. non-responsive speech in the phases are significant, though some are approaching significance: introduction vs. development ($p=0.08$), development vs. climax ($p=0.07$), climax vs. conclusion ($p=0.08$), introduction vs. climax ($p=0.06$) (Table 1).

[FIGURE 1]

[TABLE 1]

Conclusions: The fact that the differences in PVR vs. non-responsive speech between phases begin to reach significance sometimes may suggest that parents of the autistic children follow a clear pattern of PVR and interest alignment. This may be unexpected because there is debate around whether autistic children are able to co-create narrative with their parents at all. Perhaps, then, using language to guide its structure, parents of autistic children are leading the co-creation of narrative and allowing their children to participate in these close engagements. That is, with the help of a supportive other who is attuned to their interests and who verbalises their thoughts and reflections on their actions, autistic children may be able to co-create rich narratives and reap their benefits. The limitations of a small sample size are recognised, and it is possible that with a larger sample, some of the results approaching significance could have reached the threshold. Future work should therefore examine this same phenomenon in a larger group.

419.117 The Acquisition of Relative Clause Sentences Contributes to Theory of Mind Abilities in Mandarin-Speaking Children with and without ASD

M. Zhou¹, Y. E. Su¹ and M. Burnel², (1)Child Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China, (2)Cognition and Learning Research Center, University of Poitiers, Poitiers, Vienne, France

Background: This study attempts to clarify the relationship between the acquisition of Relative Clause Sentences (RCS) with varying levels of embedding and Theory of Mind (ToM) abilities in Mandarin-speaking children with and without autism spectrum disorder (ASD). In typically developing (TD) children, only double-event RCS (e.g. *The girl kicked the man that jumped over the wall*) significantly predicted ToM abilities, whereas single-event RCS (e.g. *The girl kicked the man who is wearing a hat*) failed, indicating that the meta-representation in double-event RCS is the crucial ingredient to ToM development (Smith et al., 2003). Whether this also applies to children with ASD remains unclear. While a link between RCS embedding and ToM has been suggested in children with ASD (Durrleman et al., 2018), prior research has not distinguished between the contributions of single- and double-event RCS in autism.

Objectives: We evaluated the link between single-event RCS, double-event RCS and ToM skills in Mandarin-speaking children with and without ASD, to determine the extent to which RCS acquisition supports child ToM development.

Methods: Our participants included 35 4-12-year-old Mandarin-speaking children with ASD and 35 3-6-year-old TD children, matched on scores of the Chinese Peabody Picture Vocabulary Test and the Combined Raven's Test (Table 1). We administered a computer-based Truth Value Judgment task to assess children's knowledge of two RCS (i.e., single-event RCS and double-event RCS); the low-verbal ToM scale (Burnel et al., 2018) was adopted to evaluate children's ToM abilities.

Results: The two groups did not differ in their ToM (TD: 11.11 ± 3.79 , ASD: 10.00 ± 4.26 , $p > .05$) and single-event RCS scores (TD: 5.54 ± 0.85 , ASD: 5.06 ± 1.35 , $p > .05$). However, the ASD group exhibited a significantly lower score of the double event RCS than that of the TD group (TD: 5.29 ± 1.15 , ASD: 4.63 ± 1.37 , $t = -2.168$, $p = .034$). Correlation analyses revealed significant associations between ToM performance and RCS scores in both TD (single-event RCS: $r = .56$, $p = .001$; double-event RCS: $r = .52$, $p = .001$) and ASD group (single-event RCS: $r = .48$, $p = .004$; double-event RCS: $r = .53$, $p = .001$). However, stepwise regression analyses indicated that although single-event RCS is a significant predictor of ToM in TD children [$F(1, 33) = 16.11$, $p = .000$], only double-event RCS significantly predicted ToM abilities in autistic children [$F(1, 33) = 8.95$, $p = .005$] (Figure 1).

Conclusions: The findings suggest that single-event RCS significantly predicts ToM abilities in Mandarin-speaking TD children while double-event RCS plays a more prominent role in children with ASD, highlighting differences in the linguistic basis of mentalizing between ASD and TD children. Given the role of meta-representation in processing double-event RCS and its importance for ToM development in autism, targeting this syntactic structure could enhance ToM and social cognition in autistic children.

**419.118** Word Repetition Priming Defines Subpopulations of Autistic Children: Digital Pitch Shifting Can Restore Priming Effects Lost to Speaker Pitch Differences

T. Roberts¹, L. Bloy¹, M. Melch¹, L. Blaskey¹, K. Schuler² and D. Embick³, (1)Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)Department of Linguistics, University of Pennsylvania, Philadelphia, PA

Background:

Some autistic children have difficulty suppressing irrelevant sensory detail, compromising perceptual object formation. In real-time speech processing this may lead to delays in interactive communication or, more severely, difficulty establishing rudiments of a language faculty, with downstream language impairment. Given autistic heterogeneity, this is likely not ubiquitous, but confined to a sub-population. If such a subpopulation could be identified, it would conceptually lead to optimized support/treatment management. One example of the need for suppressing meaning-irrelevant details is processing of speech from speakers with different acoustic parameters, e.g. pitch.

Objectives:

To determine the impact of speaker differences on repetition priming, we developed a paradigm of modified repetition priming (RepPrim) in which listeners heard pairs of similar or different words as well as pairs of similar words spoken by speakers with different pitch (male vs. female). A further objective was to explore a pathway towards future intervention, by remediating the potential impact of male vs. female speaker differences with digital pitch shifting, raising the male utterance 7 semitones and lowering the female 5 semitones - approximately pitch equivalence.

Methods:

The priming experiment examines the reaction time (RT) to the second word, which may be modulated by context (priming). We conducted this paradigm in 27 autistic children, 8-12yrs, using at least 25 exemplar pairs of (i) different words, (ii) repeated words, (iii) repeated words with different speakers and (iv) different words with different speakers, subject to pitch-shifting to match pitches, interleaved with other foil stimulus tokens. All words were simple English monosyllabic language words (e.g. *cry*, *dirt*, *doll*), with average word frequency of 3.095. Foils included plausible, pronounceable non-words, as RT was measured in a lexical decision (word vs. non-word) task on the second element of each pair. RT's were evaluated using a linear mixed model with condition as a fixed effect, age as a covariate and subject as a random effect.

Results:

24 autistic children tolerated sufficient stimuli to obtain evaluable RT responses to each condition. In 2/24 participants there was no evidence for canonical repetition priming (no RT facilitation for repeated words vs. different words); data from these were excluded. In the remaining 22/24, all exhibited canonical RepPrim - unprimed RT: 1.83 ± 0.09 s; RepPrim: 1.61 ± 0.08 s, $p < 0.001$. With word pairs primed by a speaker of different pitch, RT responses identified two subtypes: (A) partial RT facilitation ($n=16$: unprimed RT: 1.84 ± 0.11 s; different pitch RepPrim: 1.56 ± 0.09 s, $p < 0.001$ vs unprimed) and (B) absent facilitation or even "distracted" RT delay ($n=6$: unprimed RT: 1.80 ± 0.18 s; different pitch RepPrim: 1.88 ± 0.18 s vs same speaker, 1.66 ± 0.18 s, $p < 0.01$). In class B only, digital pitch manipulation led to normalization of RT: 1.64 ± 0.15 s, $p < 0.01$.

Conclusions:

The modified repetition priming paradigm was able to identify a subpopulation of autistic children with disturbed priming responses in the face of acoustic difference (pitch). This population does exhibit dramatic restoration of RT priming effects upon pitch shifting of auditory input, perhaps paving the way for a new class of support/intervention potentially realizable in a hearing aid form factor.

**Poster Session****420 - Early Development (< 48 months) II**

May 2nd, 2025, 12:30 PM - 1:30 PM - Hall 4A

420.119 Early Literacy, a Tool to Foster Relational Health and Positive Shared Interactions between Children with Neurodevelopmental Disabilities and Their Caregivers

G. Anzueto¹, K. Pope² and A. Dauenhauer², (1)Pediatrics/McGovern Medical School at the University of Texas Health Science Center at Houston, Developmental and Behavioral Pediatrics Program at the Dan L Duncan Children's Neurodevelopmental Center at The Children's Learning Institute, Houston, TX, (2)Pediatrics, Developmental and Behavioral Pediatrics Program at the Dan L Duncan Children's Neurodevelopmental Center at The Children's Learning Institute, Houston, TX

Background:

Early relational health is the connection young children and caregivers experience, beginning at birth, which is essential for children's growth and development, along with family wellbeing. Positive, shared interactions between caregiver and child, such as reading, nurture foundational relationships and can have a lasting impact on the health and wellbeing of children and their families. These shared interactions, however, can be challenging for families with a child diagnosed with a neurodevelopmental disability.

Objectives:

Our clinic partnered with Reach Out and Read (ROR) Texas to promote positive, shared interactions between children with neurodevelopmental disabilities and their caregivers. Our goal was to educate on the importance of early relational health with the caregivers in our clinic, an approach not formally undertaken. We also strived to implement the ROR program in our neurodevelopmental clinic, passing out books given to our patients along with caregiver reading guides tailored to the child's specific neurodevelopmental condition in either English or Spanish. All this with the ultimate goal to further support reading as an early relational health activity.

Methods:

Each clinician completed training on both the importance of early relational health and reading promotion for children with developmental disabilities. Early relational health was discussed and a statement was incorporated into clinic visit notes. Children ages 6 months to 5 years, randomly chosen as their clinic visit occurred during the intervention timeframe, were provided a book, along with caregiver guides on reading to a child with a specific developmental disability. Early Relational Health statements and book distribution numbers were tracked over the course of 6 months from our baseline of 0. Additional supports, such as electronic medical record smart phrases, reading posters in provider pods, easy access to books for the clinicians, and resident training were implemented to encourage early relational health promotion and book distribution.

Results:

Over the course of 6 months, the three medical providers in our clinic were able to increase the number of patients exposed to early relational health and educated on its importance. Providers more than doubled the number of patients exposed to early relational health education, increasing from 16 out of 60 patients to 40 out of 60 patients. Once additional clinic supports were implemented, the number of books and caregiver developmental disability guide distribution also increased. Book distribution and developmental disability guide distribution increased from 42% to 72%. One hundred sixty patients received early relational health education and two hundred and nineteen families of children with neurodevelopmental disabilities were provided with a book and caregiver developmental disability guides.

Conclusions:

In offering provider training and clinical supports via a quality improvement framework, we were able to implement a novel literacy and early relational health program by educating caregivers of children with developmental disabilities on the importance of early relational health. We were also able to increase the number of books given to patients with developmental disabilities in order to help support early relational health and early literacy exposure in the family's home environment from our baseline.

420.120 How Income, Parental Education, and Developmental Skills Shape Language in Latino Autistic Toddlers

I. C. McGuire¹, V. L. Villarreal², A. C. Ramirez³, M. Montenegro⁴ and C. Montiel-Nava¹, (1)Psychology, The University of Texas Rio Grande Valley, Edinburg, TX, (2)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (3)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (4)University of Texas Rio Grande Valley, Edinburg, TX

Background: Variability in language outcomes in autistic children is influenced by early cognitive, motor, and communicative skills (Mouga et al., 2019; Tager-Flusberg, 2018). Socioeconomic factors, such as family income and parent education, also play a significant role in language development in autistic children (Olson et al., 2021; Pecukonis et al., 2024), though this remains less explored. Understanding how these factors interact, especially in Latino populations with more disadvantaged backgrounds, could inform more effective, comprehensive, tailored intervention strategies.

Objectives: This study investigated environmental and developmental predictors of language in Latino autistic children. Specifically, the study (1) identified environmental factors that influence language outcomes and (2) explored how these factors interact with cognitive and motor skills. These analyses provided insights into the relative contribution of environmental and developmental factors in shaping early language abilities.

Methods: Data comes from an ongoing study of language development in autistic toddlers. Preliminary results for this abstract include data from 27 Latino autistic children (male = 18, female = 9, $M_{age} = 2.89$ years, $SD = .97$ years, Table 1). Participants underwent a comprehensive evaluation, which included the Mullen Early Learning Scales and ADOS-2. Caregivers completed a demographic questionnaire, the Vineland Adaptive Scales-3rd edition, the Toddlers Autism Semi Structure Interview (TASI), the Social Communication Questionnaire (SCQ), and the Modified Checklist for Autism in Toddlers (M-CHAT). All measures were provided in Spanish. Simultaneous multiple regression analysis was used to examine if cognitive and motor skills predict receptive and expressive language. Further moderation analysis included two socioeconomic factors, family income and parent education level, in the relationships. Results are presented in Table 2.

Results: These results demonstrated that fine motor skills and cognitive skills are significant predictors of both expressive and receptive language abilities, explaining 48% and 66% of the variance in expressive and receptive language abilities, respectively (Table 2). Family income and parent education were analyzed as moderators, revealing that parent education significantly moderated the relationship between fine motor skills and expressive language ($\beta = .379$, $t(23) = 2.756$, $p = .011$) as well as receptive language ($\beta = .315$, $t(23) = 2.532$, $p = .019$), suggesting that higher education levels enhance the impact of motor skills on language development. The interaction between cognitive skills and family income was marginally significant ($\beta = -.352$, $t(23) = -2.057$, $p = .051$). This suggests that the impact of cognitive skills on expressive language may vary based on family income levels, with lower family income weakening the positive relationship between cognitive skills and expressive language.

Conclusions: The results emphasize the importance of motor and cognitive skills in language development, particularly when considering the moderating effects of family income and parent education. This has implications for early interventions targeting motor skill development and the need to address educational disparities to enhance language outcomes in young children with autism. Also, interventions focusing on cognitive development may need to account for socioeconomic disparities to be more effective.

**420.121 Infant Neurobehavioral Development and Autism Emergence across the First Two Years of Life**

T. Djiko¹, E. Dixon², E. Platt² and J. Bradshaw², (1)The University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC

Background: Healthy neurobehavioral functioning in early infancy may have cascading effects on the infant's ability to attend to their environment, form interactive patterns with caregivers, and has implications for long-term developmental outcomes. Researchers have found associations between early attention-related neurobehavior and later social communication skills (Bradshaw et al., 2020; 2022). However, a gap remains in our understanding of how neurobehavior in early infancy may predict the emergence of both restricted/repetitive and social communicative ASD symptoms.

Objectives: We aim to explore the predictive utility of neurobehavior during early infancy and later autism symptoms. Aim 1: explore group differences in 2-month neurobehavior between typically developing versus autistic children. Aim 2: examine associations between neurobehavior and ASD symptoms at 24-months.

Methods: Participants included 50 infants (n=23 female) at either low (typically developing sibling, n=32) or elevated (autistic sibling, n=18) familial likelihood for ASD as part of a larger longitudinal study. At 2-months, infant neurobehavior was assessed via the NeoNatal Neurobehavioral Scale (NNNS; Lester & Tronick, 2004). Specific NNNS summary scores examined in the present study included Attention, Handling, Self-Regulation, Arousal, Tone, Non-Optimal Reflexes, Quality of Movement, and Stress/Abstinence. At 24-months, the Autism Diagnostic Observation Schedule, 2nd Edition, Toddler-Module (ADOS-T; Lorde et al., 2012) was administered. The ADOS-T provides calibrated severity scores (CSS) for the Social Affect and Restricted/Repetitive Behaviors domains, with higher CSS scores indicative of increased symptom severity. At 24-months+, clinical best estimate (CBE) diagnoses were determined resulting in n=10 participants with ASD and n=26 typically developing children. CBE outcome was not available for 14 participants due to attrition.

Results: Aim 1: group differences by CBE diagnosis were found in the Stress/Abstinence summary score ($t(22.2)=-3.14, p=.004$) and Handling summary score ($t(32.0)=-3.35, p=.002$). Autistic children were found to display significantly fewer stress signs ($M=1.48$) compared to typically developing children ($M=1.89$). Autistic children were also found to require significantly less ($M=1.33$) handling/consoling by the examiner to maintain a calm state compared to typically developing children ($M=3.27$). Aim 2: Stress/Abstinence and Handling scores were utilized in subsequent analyses. Four separate simple linear regressions were performed to examine Stress/Abstinence or Handling as predictors for Social Affect CSS or Restricted/Repetitive CSS. Stress/Abstinence was found to significantly predict Social Affect CSS ($F(1,29)=6.20, p=.02$, adjusted $R^2=.15$) and Restricted/Repetitive CSS ($F(1,29)=9.51, p=.004$, adjusted $R^2=.22$). Handling was not found to significantly predict CSS scores. A separate linear regression model was performed with the addition of an interaction term between Stress/Abstinence score and CBE diagnosis. No significant main effects of Stress/Abstinence or CBE diagnosis were found, and the interaction term between these predictors did not significantly predict Social Affect or Restricted/Repetitive CSS scores.

Conclusions: Findings show that autistic children demonstrate reduced responsivity to environmental stress during early infancy. This may have downstream consequences on developmental outcomes, with infants who demonstrate lower registration of environmental stimuli displaying increased autism symptom severity at 24-months across both symptom domains. Our results add to the literature on early biomarkers, highlighting how measurement of infant responsivity to environmental stressors may help advance early screening.

420.122 Infant Temperament Differentially Predicts Internalizing and Externalizing Problems at Late School Age in Children with Elevated Likelihood of Autism

J. H. Leef¹, L. A. Sacrey², J. A. Brian³, I. M. Smith⁴, S. E. Bryson⁵ and L. Zwaigenbaum⁶, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Research Centre, University of Alberta, Edmonton, AB, Canada, (3)Holland Bloorview Kids Rehab Hospital, Toronto, ON, Canada, (4)Dalhousie University / IWK Health, Halifax, NS, Canada, (5)Dalhousie University, Halifax, NS, Canada, (6)University of Alberta, Edmonton, AB, Canada

Background: Infants' temperamental characteristics have been identified as predictors of later mental health problems in childhood and adolescence. Such findings, primarily characterized through samples without a family history of neurodevelopmental disorders (i.e., "neurotypical"), inform clinical practice through early monitoring and application of relevant clinical interventions. Autistic children have a higher likelihood of experiencing both internalizing (e.g., anxiety, depression) and externalizing (e.g., inattention, hyperactivity) problems. Previous longitudinal research identified infant temperamental characteristics that predict internalizing and externalizing challenges at age 5 in younger siblings of children with autism, who have an elevated likelihood (EL) of receiving an autism diagnosis. Yet, the question of whether infant temperament predicts mental health problems amongst EL siblings into late childhood and early adolescence remains unclear. Given the high rate of mental health problems autistic youth experience, characterizing early predictive factors may inform intervention.

Objectives: To explore the role of infant temperament in the development of mid-to-late- childhood internalizing and externalizing features amongst siblings with EL of autism.

Methods: Participants were siblings of autistic children who were themselves diagnosed (ASD; n=34; 25 boys) or not diagnosed (non-ASD; n=70; 33 boys) with autism at age three. Regression analyses (using PROCESS) were conducted to determine the moderating effect of group (ASD or non-ASD) on infant temperament collected at 12 months using the Infant Behavior Questionnaire (IBQ; subscales: Activity, Distress to Limits, Distress Latency, Orienting, Smiling, and Soothing) and internalizing and externalizing problems via the Child Behavior Checklist (CBCL) collected at age 8-12 years. We used bootstrapping (5000) and continuous variable centering.

Results: Groups did not differ on age at infancy ($M=12.31$ vs. 12.56 months) or follow-up ($M=113.05$ vs. 113.40), nor 12-month temperament measures (all p 's $>.05$). Significant group differences were found for internalizing ($p=.03$) and externalizing problems ($p=.003$) at 8-12 years.

Internalizing Problems: Group moderated the relation between Smiling and CBCL Internalizing Problems ($b=-6.61, SE=2.80, p=.02$). No moderation was seen on the significant relation with Distress Latency ($b=-4.20, SE=2.31, p=.07$) nor significant relations between remaining IBQ subscales and internalizing problems. **Externalizing Problems:** Diagnostic group moderated relation between IBQ subscales of Distress Latency ($b=-7.16, p=.01$); Activity ($b=-6.57, p=.01$), Distress to Limits ($b=-6.79, p=.01$), Orienting ($b=-6.33, p=.02$), Smiling ($b=-6.69, p=.01$), and Soothing ($b=-6.93, p=.01$) and CBCL Externalizing Problems.

Conclusions: Infant temperament significantly predicted later mental health problems in 8- to-12-year-old younger siblings of autistic children. This predictive relationship differed depending on whether the sibling was diagnosed with autism at age 3. Findings elucidate which temperament characteristics are most predictive of later externalizing problems amongst autistic children. Internalizing problems were less predictable from infant temperament characteristics for the autistic group; only Smiling differentiated them. In contrast, early Distress Latency significantly predicted internalizing problems for both autistic and non-autistic siblings; no other temperament subscales predicted internalizing problems.

420.123 Investigating the Effects of Prenatal Heavy Metal Exposure on Toddler Neurodevelopment in Suriname

E. Dolan¹, C. R. Newsom², M. Smith³, R. Patel⁴, M. Lichtveld⁵, W. Zijlmans⁶, H. Covert⁷, A. Hindori-Mohangoo⁸, A. Gokoel⁹ and J. Wickliffe¹⁰, (1)Neuroscience, University of Alabama at Birmingham, Birmingham, AL, (2)Department of Neurobiology, The University of Alabama at Birmingham, Birmingham, AL, (3)Biostatistics, University of Alabama at Birmingham, Birmingham, AL, (4)Neuroscience, University of Alabama at Birmingham, Birmingham, AL, (5)School of Public Health, University of Pittsburgh, Pittsburgh, PA, (6)Medical Sciences, Anton De Kam University, Diakonessenhuis, Paramaribo, Suriname, (7)Environmental and Occupational health, University of Pittsburgh, Pittsburgh, PA, (8)Foundation for Perinatal Interventions and Research in Suriname, Paramaribo, Paramaribo, Suriname, (9)Academic Hospital Paramaribo, Paramaribo, Paramaribo, Suriname, (10)Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL

Background: The prevalence of neurodevelopmental disorders, including Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD), continues to rise, and etiology is likely a complex interplay of genetic and environmental factors arising in the preconception through perinatal period. Investigating the impact of various environmental factors on neurodevelopmental outcomes is an important step in guiding future research into gene-environment interactions. This study examines the potential impact of prenatal exposure to heavy metals, specifically Lead and Mercury, on neurodevelopmental outcomes in children in Suriname, a LMIC in South America. The diverse cohort consists of 708 mother-child pairs, with mothers varying in age, ethnicity, economic status, education level, and geographic region within Suriname. **Objectives:** This study aims to determine how prenatal exposure to heavy metals, such as Lead and Mercury, influences neurodevelopment in toddlers. The focus is on assessing behavioral outcomes and functional development, including motor skills, communication, and cognitive abilities.

Methods: Data were sourced from the Caribbean Consortium for Research in Environmental and Occupational Health (CCREOH), which collected biological and assessment data from mothers and children in Suriname. Blood samples from pregnant women were collected during the late first and early second trimesters to measure Lead and Mercury levels. Lead was measured in micrograms per deciliter (µg/dL), while Mercury was measured in micrograms per liter (µg/L).

When the children were 2-3 years old, clinicians assessed neurodevelopment using the Bayley Scales of Infant and Toddler Development-III (BSID-III), a validated tool for use in Suriname. The Child Behavior Checklist (CBCL) was also completed by the mothers to evaluate their children's behavioral outcomes. Heavy metal concentrations were log-transformed to evaluate their associations with neurodevelopmental outcomes. The relationship between heavy metal exposure and measures from BSID-III and CBCL was visualized using Locally Estimated Scatterplot Smoothing (LOESS). Correlations were evaluated using Spearman's Rho, and an ANOVA was conducted to analyze differences in heavy metal exposure across different regions of Suriname.

Results: For the BSID-III, prenatal Lead exposure was significantly correlated ($p < 0.001$) with lower scores in Expressive Communication, Receptive Communication, and Gross Motor domains, while Mercury exposure was significantly correlated ($p = 0.007$) with lower Expressive Communication scores. In the CBCL assessment, Lead exposure showed strong correlations ($p < 0.001$) with increased internalizing problems and lower total raw scores, while Mercury exposure was significantly correlated ($p < 0.001$) with increased internalizing problems. ANOVA results revealed that Lead and Mercury exposure levels were highest in Suriname's interior regions and lower in agricultural and urban areas.

Conclusions: The observed significant correlations between prenatal exposure to Lead and Mercury and decreased scores on the BSID-III and CBCL suggest that exposure to heavy metals is associated with adverse behavioral and neurodevelopmental outcomes in children. These findings serve as an essential first step in understanding the impact of heavy metals on neurodevelopment. Further, they highlight potential environmental sources of exposure, such as unregulated gold mining and pesticide use, underscoring the need for effective regulation and intervention to minimize exposure risks in affected regions.

420.124 Limitations in Using “Worry” As a Screening Tool for ASD in Part C Early Intervention

L. B. Cunningham¹, S. Heath² and A. S. Carter³, (1)Psychology, University of Massachusetts, Boston, Boston, MA, (2)University of Massachusetts Boston, Boston, MA, (3)Department of Psychology, University of Massachusetts Boston, Boston, MA

Background:

Identifying Autism Spectrum Disorder (ASD) in Early Intervention (EI) can facilitate access to autism-tailored services (Eisenhower et al., 2021), which has been shown to greatly benefit autistic children (Dawson et al., 2010). Although screening for ASD in pediatrics can lead to access to EI services, autism diagnostic services are not always pursued. Autism screening in EI is often initiated following caregiver reports of worry; however, waiting until a caregiver reports worry to screen, might lead to under-identification, as autism characteristics can be endorsed but misattributed as commonly occurring aspects of children's development (Hallyburton, 2022). Effective screening methods are essential in identifying autistic children while they are eligible for autism-tailored services within EI.

Objectives:

For this submission, we compare rates caregiver reported a) worry and b) elevated social-emotional behavior (SEB) problems, and/or delays in SEB competencies in a sample of diagnosed autistic toddlers.

Methods:

Participants (N=109) were recruited through an ongoing implementation/effectiveness trial in Part-C early intervention programs. Eligible families had children between 16- to 32-months old with delays in social communication. For this study, the sample was further restricted to children who went on to receive an ASD diagnosis. Caregivers completed the 42-item Brief Infant-Toddler Social and Emotional Assessment (BITSEA), a nationally standardized screener for 12- to 36-month olds, reflecting on child behaviors over the previous month from 0 (Not True/Rarely) to 2 (Very True/Often). The autism problem (10 items) and autism competence (9 items) scales were employed. Caregiver reports of worry was evaluated using the BITSEA item: "How worried are you about your child's behavior, emotions and relationships?" rated on a four-point scale, and further dichotomized for analyses (0=Little to No Worry, 1=Worried to Very Worried).

Results:

The BITSEA autism scales identified 95.5% of autistic toddlers in this sample (104 of 109). The autism competence scale, using a cut-score of 11.5, identified 102 of the 109 autistic toddlers (93.5%). Two additional children were identified based on an elevated cut score (greater than 4.5) on the autism problem scale (1.8%). In contrast, 53 caregivers reported that they were "Worried" to "Very Worried" (45.3%) and 23 and 37 reported "No" (21.14%) or "A little worry" (33.9%) respectively. Reporting worry was related to the BITSEA autism problem and competence scores. None of the 5 caregivers reporting no autism concerns on the BITSEA reported being "Worried" to "Very Worried." Caregivers who reported both "Of Concern" autism problems and competencies reported greater worry (60%) than those with only a single "Of Concern" autism domain (40%); $\chi^2(1, N=104)=11.55, p=.001$.

Conclusions:

The majority of caregivers with toddlers who go on to be diagnosed with ASD— even in a sample selected from families who had accessed EI services and participated in a hybrid-effectiveness clinical trial— were not worried about their children's behaviors, emotions, or relationships. In contrast, almost all children were identified with caregiver ratings of specific autism-related competence, and to a lesser extent, problem behaviors. Although worry is predicted by behavior ratings, findings highlight the value of autism screening in EI irrespective of caregiver worry.

420.125 Longitudinal Trajectories of Parenting Stress in Caregivers of Children at Elevated Likelihood for Autism or ADHD

H. Elahi¹, G. Kadlaskar² and M. Miller³, (1)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Psychiatry & Behavioral Sciences, University of Nevada, Reno, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, UC Davis Health, MIND Institute, Sacramento, CA

Background: Prior research has established that caregivers of children with neurodevelopmental conditions experience higher levels of parenting stress compared to caregivers of typically developing children. However, less is known about similarities and differences between longitudinal trajectories of parenting stress among caregivers of children demonstrating emerging autism- or ADHD-related behaviors over the first years of life. Focusing on both autism and ADHD in concert is important because these conditions often co-occur and may share overlapping early phenotypes. The influence of emerging autism- and ADHD-related behaviors on parenting stress remains unclear, particularly during early childhood, when they first arise.

Objectives: This study aims to address these gaps by (1) examining trajectories of parenting stress among parents of infants, ages 12-36 months, who are at elevated likelihood for autism or ADHD, and (2) exploring how early autism- and ADHD-related behaviors influence parenting stress over time, thereby contributing to our understanding of the impact of neurodevelopmental conditions on caregiver well-being.

Methods: Data were drawn from a prospective longitudinal investigation of infants/toddlers at high and low familial likelihood for autism and ADHD. A total of 113 participants were classified into one of three outcome groups at 24 or 36 months of age: Autism ($n = 18$), ADHD Concerns ($n = 26$), or Comparison ($n = 69$). Participants were administered developmental evaluations at 12-, 18-, 24-, and 36-months of age. Primary measures were collected at each timepoint, including the Parenting Stress Index-Short Form, Behavior Rating Inventory for Children (BRIC; measure of ADHD-related behaviors), and examiner-rated social engagement (measure of autism-related behaviors). Trajectories of parenting stress were analyzed using generalized estimating equations (GEE). Associations were examined using correlational analyses, while predictors of parenting stress were assessed through multiple linear regression.

Results: The GEE model revealed a significant main effect of outcome group ($\chi^2 = 13.03, p < 0.001$) such that parenting stress was elevated overall in the autism group when compared to other groups, but there was no main effect of visit and no outcome group by time interaction ($p = 0.77$).

Both examiner-rated social engagement and ADHD-related behaviors were associated with heightened parenting stress. After accounting for baseline stress levels, lower examiner-rated social engagement at 18 months of age emerged as a predictor of higher parenting stress at 24 months ($p = 0.003$).

Conclusions: Parenting stress was significantly higher in the Autism group overall. In addition, trajectories of parenting stress were relatively stable across the three groups, suggesting that parents of children with autism experience consistently elevated levels of parenting stress. These findings highlight the importance of providing comprehensive support and resources to caregivers of children displaying autism-related behaviors as they navigate the unique demands associated with their caregiving roles. ADHD-related behaviors did not significantly predict parenting stress, suggesting that other factors may have a greater influence on stress levels among caregivers of children with ADHD Concerns.

420.126 Machine Learning Analysis of Key Screening Questionnaire Items for Early Detection of Autism Spectrum Disorder in Children Aged 18-48 Months

H. Sim¹, R. Do¹, H. Kim¹, D. Seo¹, D. Y. Kim^{2,3}, Y. Shin^{2,3}, Y. G. Kim^{2,4,5} and B. N. Kim^{1,6}, (1)Division of Child and Adolescent Psychiatry, Department of Neuropsychiatry, Seoul National University Hospital, Jongno-gu, Seoul, Korea, Republic of (South), (2)Department of Transdisciplinary Medicine, Seoul National University Hospital, Jongno-gu, Seoul, Korea, Republic of (South), (3)Interdisciplinary Program in Bioengineering, College of Engineering, Seoul National University, Gwanak-gu, Seoul, Korea, Republic of (South), (4)Department of Medicine, Seoul National University College of Medicine, Jongno-gu, Seoul, Korea, Republic of (South), (5)Innovative Medical Technology Research Institute, Seoul National University Hospital, Jongno-gu, Seoul, Korea, Republic of (South), (6)Division of Children and Adolescent Psychiatry, Department of Psychiatry, Seoul National University College of Medicine, Jongno-gu, Seoul, Korea, Republic of (South)

Background: Despite the importance of early identification of autism spectrum disorder (ASD) and various questionnaires assessing ASD, there is limited analysis of how specific items during infancy differentiate ASD from typical development (TD).

Objectives: This study aimed to examine which screening items are important for distinguishing between ASD and TD in infancy, using machine learning methods.

Methods: The study included 645 children at the age of 18–48 months in South Korea (Table 1). The classification of TD and ASD used the Korean versions of the ADOS-2 and CARS-2. Autism screening questionnaires included the Korean-developed BeDevel-Q and the Korean versions of Q-CHAT, M-CHAT, SCQ, and SRS-2. A dataset was selected by age-appropriate items for multiple questionnaires (Table1). Then, the dataset for each age group was split using the stratified k-Fold method, with 20% set aside as a holdout test set.

Various classifiers were employed, including linear-based models (logistic regression), tree-based methods (LightGBM, XGBoost, CatBoost, Random Forest, Gradient Boosting Classifier, AdaBoost), Support Vector Machines, k-Nearest Neighbors and Multi-Layer Perceptron methods. Each model was trained separately for each age group to capture age-specific variations. The best-performing classifier was selected from these models based on performance metrics (accuracy, area under the receiver operating characteristic curve (AUC)). Recursive Feature Elimination with Cross-Validation was then applied to identify a minimal set of features necessary to achieve comparable performance to models trained with all items (DeLong's p-value > 0.05). One to three items per group were sufficient to maintain high accuracy and AUC. We then retrained the selected model using these key items and validated it on the same hold-out test set. The simplified model performed comparably to those trained with the full dataset.

Results: The findings showed key items, specifically highlighting those that distinguish ASD from TD children. Table 2 shows the sets of one to three key items identified by the ML models as most important for distinguishing ASD from TD children in each age group (18-23 month: Q-CHAT2. How easy is it for you to make eye contact with a child?; 24-30 month: Q-CHAT 2, BeDevel-Q 26; 31~42 month: SRS-2 13, SRS-2 44; 43~48 month: SRS-2 13, SRS-2 22, SRS-2 44). These items were selected based on feature importance analysis and demonstrate that even with a small subset of items, the models maintained high classification accuracy.

Early on (18-30 months), basic social responsiveness like eye contact and language are crucial. As children grow older, social domains such as social skills with peers and understanding (31-48 months) become more important in distinguishing TD from ASD. Notably, models trained with only one to three key items maintained high accuracy.

Conclusions: The present study, based on machine learning model analysis, demonstrated the potential for ASD screening using 2-3 items, with eye contact and language development-related items being effective for children under 30 months, and social interaction and play-related items for children aged 31-48 months. These findings are expected to play a role in understanding important variables for the screening of children with autism.

**420.127** Measurements of Joint Attention in Naturalistic Play

B. Villanueva¹, J. Panganiban², C. Kasari³ and Y. C. Chang⁴, (1)University of California, Los Angeles, Los Angeles, CA, (2)Semel Institute, University of California Los Angeles, Los Angeles, CA, (3)Education and Psychiatry, University of California Los Angeles, Los Angeles, CA, (4)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA

Background: Joint attention skills (sharing attention with a social partner through prelinguistic gestures including showing, pointing and giving to share) have long been viewed as important to children's language development (Tomasello, M., 1988). These skills, and specifically initiating joint attention, are delayed in children with autism (Paparella, T., Goods, K. S., Freeman, S., & Kasari, C., 2011). Assessments like the Early Social-Communication Scales, or ESCS (Mundy et al., 2003), allow interventionists to measure joint attention skills. The ESCS provides a controlled environment (i.e., an assessment room free of distractions) with opportunities that are intricately set up by the assessor for children to demonstrate their joint attention and requesting skills. Importantly, researchers and clinicians may benefit from expanding their methods of joint attention assessment into naturalistic contexts, providing more opportunities for assessing joint attention skills that can also improve ecological validity. **Objectives:** The current study aims to explore the validity of measuring joint attention within unstructured play interactions with a teacher by comparing joint attention used in this context with joint attention skills demonstrated in the ESCS.

Methods: The same joint attention skills that are typically codified from videotaped ESCS assessments were instead coded from unstructured teacher-student interactions administered to 66 autistic preschoolers, ages 2 to 5 years. Of the total sample size ($n = 66$), 83% were boys and 11% were girls, with the majority of students being of either Hispanic or Caucasian backgrounds. These teacher-child play interactions (TCX) were ten-minute long videotaped sessions in which instructors engaged their students – either one-on-one or in a group setting – using a variety of developmentally appropriate toys. A naturalistic observation of how children and adults interact with one another through the use of toys, the TCX has no set guidelines on “how to play.”

Results: On average, children displayed 12.98 joint attention gestures ($SD = 9.06$) in the ESCS. During the TCX, children displayed an average of 6.53 joint attention gestures ($SD = 6.96$). Correlation analysis show moderate positive correlations between child initiated joint attention in unstructured play ($r(62) = .33, p = .007$) when compared to the ESCS. Comparison of correlation coefficient rates across measurement contexts provides evidence of convergent validity for measuring joint attention skills through unstructured play.

Conclusions: While the ESCS excels at measuring a child's joint attention initiations, the correlation analysis illustrated that an unstructured play environment can be a supplemental tool of representing skills, especially in community settings in which performing an ESCS are not easily feasible. Future studies are needed that can devise quick coding methods to be used in natural contexts, and probes for generalization of skills from familiar to unfamiliar partners.

420.128 Multimodal Clinical and Neurofunctional Social Subtyping Reveals Three Highly Validated Autism Subtypes

V. Taluja¹, S. Nazari², J. Zahiri³, L. Garmire⁴, K. Pierce⁵, Y. Xiao⁶ and E. Courchesne⁷, (1)Neurosciences Graduate Program, UC San Diego Autism Center of Excellence, La Jolla, CA, (2)UC San Diego, La Jolla, CA, (3)Autism Center of Excellence, UCSD, San Diego, CA, (4)University of Michigan, Ann Arbor, MI, (5)Autism Center of Excellence, Department of Neurosciences, University of California San Diego, San Diego, CA, (6)Department of Neurosciences, University of California, San Diego, La Jolla, CA, China, (7)Neuroscience, Eric Courchesne, San Diego, CA

Background: Autism spectrum disorder (ASD) is characteristically heterogeneous, particularly in the severity of social affective and communication symptoms. While the clinical manifestations of this symptom heterogeneity typically appear within the first 3 years of life, the neurobiological bases underlying this diversity is largely unknown. Many studies have tried to delineate behavioral subtypes of ASD to better understand the heterogeneity, but none have connected clinical phenotypes to underlying neurofunctional differences. Furthermore, previous attempts at subtyping included little to no validation of the clusters and varied in their inclusion of control populations, both of which bring cluster generalizability into question.

Objectives:

1. To delineate subtypes of ASD based on both social clinical abilities and social neural functioning at early ages, and specifically distinguish neural features associated with profound autism clinical phenotypes.
2. To map these autism subtypes to the broader toddler population, including typical development and other developmental delays, and determine the generalizability of our autism subtype classifications.
3. To rigorously validate our clustering with multiple statistical methods.

Methods: We used a patient subtyping method that is well-established in precision medicine research: Similarity Network Fusion (SNF). With this data-driven method, we integrated multi-modal data spanning social neurofunctional activation and social and language clinical abilities in 137 toddlers across multiple timepoints. Our sample included 81 ASD, 23 developmentally delayed and 33 typically developing (TD) toddlers, which allowed us to study subtypes both within ASD, and in the broader context of the general toddler population. We used 5 methods for validation: cluster separation, external validity, 5-fold cross validation, normalized mutual information robustness, and independent cohort replication with 42 additional subjects.

Results: We found three robust autism subtypes delineated by social neural and social clinical features (Figure 1). This mapping revealed a prominent subtype with early-age signatures of profound ASD, including low social and language abilities, negligible social neurofunctional activation, and maintenance of low or even declining abilities over time. On the other end, we see a high ability autism subtype, with near typical scores both neurofunctionally and clinically, and overall longitudinal clinical improvement. These diverging subtypes were largely maintained when generalized among non-ASD toddlers (Figure 2). In this clustering, all of the subjects previously in the profound autism-like cluster mapped to the same “low” cluster. Furthermore, an “optimal” autism subtype was revealed that clustered more closely with TD subjects than other ASD subjects. Both rounds of clustering were highly validated.

Conclusions: These results indicate that the spectrum of heterogeneity in ASD may be less continuous than previously thought, and that different subtypes of ASD have distinct neurofunctional features. Our connection of clinical phenotypes to neural functioning indicates subtype differences are deeply rooted in autism etiology and that treatments should be created with consideration of these differences, particularly for the subtype with profound autism profiles. Finally, this work offers an explanation for the high frequency of mixed results in the field: If distinct subtypes are unequally represented or being averaged together, findings are likely to be skewed or missed entirely.

420.129 Non-Social Visual Search Advantage in ASD Emerges in Toddlerhood: A Longitudinal Study of Neurodevelopmental Outcomes

K. Hegerberg¹, R. A. Oien², K. J. Dommer³, J. Skytta⁴, M. Reninger⁵, A. Ajwani¹, H. Willis⁵, M. Aubertine¹, M. Kim⁶, B. Li⁷, A. Atyabi⁸, S. Corrigan⁴, E. Olson⁹, K. Michener³, D. Christakis¹⁰, S. J. Webb¹¹, F. Shic³ and K. D. Riley⁸, (1)Seattle Children's Hospital, Seattle, WA, (2)The Arctic University of Norway, Tromsø, NORWAY, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)Seattle Children's Hospital and Research Institute, Seattle, WA, (5)Child Health, Behavior & Development, Seattle Children's Research Institute University of Washington, Seattle, WA, (6)Seattle Children's Research Institute, Seattle, WA, (7)Computer Science and Engineering, University of Washington, Seattle, WA, (8)Seattle Children's Research Institute University of Washington, Seattle, WA, (9)University of Washington, Seattle, WA, (10)University of Washington School of Medicine, Seattle, WA, (11)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background: Infants who are later diagnosed with ASD show heightened performance in standard, nonsocial Visual Search (VS) tasks (Cheung et al, 2016). Evidence also suggests that higher VS performance at 9-months is predictive of autism symptoms later in development (Gluga et al, 2011). To our knowledge, neither the developmental course nor the social-versus-nonsocial specificity of the pop-out effect have been well investigated.

Objectives: Explore differences in developmental trajectories of the pop-out effect, stratified by developmental outcomes.

Methods: 223 infants were recruited with elevated likelihood (autistic sibling, low birthweight) or typical likelihood for ASD, and seen at 7, 14, 28, and 39-months. Participants were sorted into three outcome groups, ASD (n=42), atypical with no ASD diagnosis (ATP, n=42), or neurotypical (NT, n=139).

Participants were eye-tracked using SR Eyelink 1000+ while viewing VS stimuli (48 trials each session) shown in three conditions: Seven x's and one pop-out target face (TargetFace_DistractorX); 7 identical faces with a target "X" (TargetX_DistractorFace); and 7 Xs with a target O (TargetO_DistractorX). Each trial was preceded by a 1500ms central fixation point.

Trial-level logistic linear mixed models predicted percent of trials that (1) the target was looked at at all (%LookedAt), or (2) looked at first among all objects (%FirstLook), from independent factorial effects of age (3rd-order natural spline), group, and condition.

Results: ANOVAs from the linear mixed model for %LookedAt showed at 7-months, ASD infants were less likely than ATP to look at targets in TargetFace_DistractorX and TargetO_DistractorX ($p=.024$, $p=.009$), but more likely in TargetX_DistractorFace ($p=.015$), but only showed a marginal elevation to look at targets than NT ($p=.096$) in the TargetX_DistractorFace condition. However at 28-months, the ASD group was more likely to look at the target than the NT and ATP groups in all conditions ($p < 0.05$). There was no significant difference in looking between ASD and other groups at 14 or 39-months for any condition.

For %FirstLook, at 7-months, ASD infants were less likely than both ATP and NT groups to look at targets in TargetO_DistractorX ($p=.003$, $p=.016$), with no other significant differences. At 28-months, the ASD group was more likely to look first at the target than the ATP and NT groups only for the TargetO_DistractorX condition ($p=.040$, $p=.018$). There was no significant difference in looking between ASD and other groups at 14 or 39-months for any condition.

Conclusions: Autistic infants diverge in their developmental trajectories of VS from ATP and NT groups at 7 and 28-months. 28-month findings replicate work suggesting stronger VS capabilities in autistic toddlers (Kaldy et al, 2011), and appear more vigorous for nonsocial stimuli. 7-month findings may signal broader vulnerabilities in early attentional development in ASD. However, a lack of generalizability to the 7-month NT group may also suggest heightened ATP orienting responses. The ATP group included a larger proportion of low-birthweight children, with older chronological if not gestationally-corrected age, potentially explaining their relative VS maturity. Ongoing work is examining interactions of birth and genetic factors; these results should be considered preliminary.

**420.130** Preliminary Characterization of Longitudinal EEG Trajectories in Infants with and without Genetic Risk for Autism

Y. Hu¹, C. D'Amato², **A. Marin³**, L. Shuffrey³, R. A. Muhle⁴, D. Amso⁵, J. Veenstra-VanderWeele⁶, W. P. Fifer⁶ and N. Pini¹, (1)Department of Psychiatry, Columbia University Irving Medical Center, New York, NY, (2)Department of Psychology, Columbia University, New York, NY, (3)Department of Child and Adolescent Psychiatry, New York University Grossman School of Medicine, New York, NY, (4)Psychiatry, Columbia University, New York, NY, (5)Department of Psychiatry and Pediatrics, Columbia University Irving Medical Center, New York, NY, (6)Division of Developmental Neuroscience, Columbia University Medical Center, New York, NY

Background: Recent studies emphasize the role of *de novo* mutations in autism spectrum disorder (ASD). In infancy, genetic risk factors for autism are linked to changes in brain functioning (Girault, 2022; Hazlett, 2017). A widely utilized measure of neural functioning is resting state EEG power, which has been proposed as a candidate biomarker for early risk identification for ASD, primarily in cross-sectional studies.

Objectives: Here, we examined longitudinal EEG trajectories between infants who are at identified genetic risk (IGR) for autism and infants not at genetic risk (Non-IGR) from 4 to 15 months of age. Genetic risk is defined as a genetic mutation that has been associated with increased risk for a later ASD diagnosis, as identified through the Genomic Uniform-screening Against Rare Diseases In All Newborns (GUARDIAN) study.

Methods: This analysis included 5 IGR infants ($n=13$ datasets; $n=3$ female) and 3 non-IGR infants ($n=8$ datasets; $n=2$ female), whose EEG data was collected at multiple timepoints between 4 and 15 months of age.

Infants were seated on their caregivers' lap and watched cartoon videos while resting state EEG was recorded for 5 minutes using a high density 128-channel array (MagStim EGI Inc).

The EEG data was preprocessed using the Harvard Automated Processing Pipeline for EEG (HAPPE). Whole-brain absolute EEG power was obtained by decomposing in 2-second segments and averaged across all channels. See Table 1 for frequency band definitions.

Statistical analyses were carried out in R. Regarding within-participant analysis, we used linear regression to model each infant's change in log-transformed EEG power across the entire scalp for each frequency band as a function of log-transformed age. These regression models were used to generate individual infant's linear developmental slope values in each frequency band for between-subject analysis. We used an independent-samples *t*-test to analyze differences in slope values between the IGR and Non-IGR infants.

Results: Across all participants and timepoints, datasets had an average 162.76 (SD = +/- 34.60) seconds of usable data. Independent-sample *t*-tests revealed no significant group differences in linear developmental slope values between IGR and non-IGR infants in any frequency bands. In the delta frequency band, we saw an emerging but non-significant difference ($p=0.094$) in slope. On average, IGR infants had more positive delta slopes (Average slope value= 0.30) compared to non-IGR infants (Average slope value = -0.12). Average slope values of all frequency bands in each group are displayed in Table 1.

Conclusions: This preliminary data suggests that differences in longitudinal EEG power may exist between infants with a quantified genetic risk for autism and those without, aligning with previous research that reported that steeper increases in delta band power was associated with increased risk for ASD in the first year of life (Gabard-Durnam, 2019). Data collection is on-going and an estimated (20 additional infants) will be included in the analysis. Future exploratory work will examine regional differences in EEG power trajectories with a focus on the frontal region, given reported differential frontal alpha and beta band power in infants at familial risk for autism (Gabard-Durnam, 2019).

420.131 Remote Assessment of Infant Memory: Encoding Face and Non-Face Stimuli in Infants with and without an Autistic Sibling
A. Waterman¹, J. Markant², J. B. Wagner³, M. H. Vu⁴, M. Hare⁵, C. Stone⁶, R. Landa⁷, S. J. Sheinkopf¹, S. Jeste⁴ and E. Tenenbaum¹, (1)Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Tulane University, New Orleans, LA, (3)Department of Psychology, College of Staten Island, CUNY, Staten Island, NY, (4)Children's Hospital Los Angeles, Los Angeles, CA, (5)Department of Psychiatry and Behavioral Sciences, University of North Carolina Greensboro, Durham, NC, (6)Center for Autism Services, Science and Innovation, Kennedy Krieger Institute, Baltimore, MD, (7)Thompson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO

Background:

The time between early cognitive milestones and the typical age of autism diagnosis leaves significant gaps in identifying early markers of autism. Additionally, most studies have been limited by reliance on in-person assessments, thus limiting accessibility and generalizability of findings. To address these gaps, we developed the Remote Infant Studies of Early Learning (RISE) Battery, which remotely assesses key cognitive domains (memory, social preference, prediction, multimodal processing, and language comprehension). Here we present data from the visual paired-comparison memory task. In it, infants are familiarized with a stimulus (faces or objects) and then presented with the familiar stimulus alongside a novel stimulus of the same class (Manns et al., 2000). Previous evidence suggests that infant siblings of autistic children show atypical habituation to faces (Bradshaw et al., 2011).

Objectives:

To test memory for faces and non-face complex stimuli (Fribbles, which preserve the complexity of facial features without being social) in the remote setting in infants with and without an autistic sibling. Hypothesis 1: Memory (defined as preference for the novel stimuli at test) will be stronger at 12 months than at 6 months and stronger for faces than Fribbles. Hypothesis 2: Memory for faces (but not Fribbles) will differ for infants with and without an autistic sibling.

Methods:

55 6-month-olds ($n=55$; 31 female, 23 male) and 56 12-month-olds ($n=56$; 23 female, 33 male) (52% White, 8% Asian, 2% Black, 38% more than one race; 15% Hispanic) without an autistic sibling have been tested to date. The current analysis (restricted to infants with >33% usable frames) included 36 6-month-olds and 37 12-month-olds (cross-sectional). Infants were familiarized with faces (Asian, Black, or White) or Fribbles (Figure 2) on 6 alternating trials. Familiarization lasted 25 seconds and was followed by two test trials with location of the familiar stimulus counterbalanced across trials. Looking preferences were coded using iCatcher+ (Erel, 2023). Analyses used a linear mixed-effects model. Data collection for infant siblings of autistic children (current $n = 36$) is underway and will be available by the conference.

Results:

Both 6- and 12-month-olds demonstrated reliable preference (mean proportion > 0.50) for novel faces (12-m: 0.56 [0.52 - 0.60], $p = 0.004$; 6-m: 0.56 [0.52 - 0.60], $p = 0.006$). There was not a significant age effect. For non-face objects (Fribbles) 6-month-olds (6-m: 0.54 [0.50 - 0.58], $p = 0.041$), but not 12-month-olds (12-m: 0.54 [0.50 - 0.58], $p = 0.084$) showed reliable preference for the novel object at test (Figure 1).

Conclusions:

These results suggest promise for remote assessment of developmental milestones including memory for faces and non-face objects. We found that both 6- and 12-month-old infants showed a preference for novel faces. Contrary to our predictions, preference for the novel Fribble was reliable at 6 months, but not 12 months. This unexpected finding may be associated with perceptual narrowing for faces. Results will be discussed in the context of potential differences in memory for faces and non-face objects among infant siblings of autistic children.

420.132 Resources to Support Community Based Early Intervention Providers Un Using Caregiver Centered Evidence Based Practices: Development Process and User Data**J. Amsbary**, UNC Chapel Hill, Chapel Hill, NC

Background: When providing EI services to toddlers with autism, family-centered practices focused on family capacity building and evidence-based practices (EBPs) are recommended in order to support all children and caregivers to reach optimal outcomes (Division for Early Childhood of the Council for Exceptional Children; DEC, 2014; Dunst, 2002; Trivette et al., 2010). And when EBPs are implemented early and effectively, long term outcomes related to social skills, cognition, and engagement for children with autism and their families/caregivers are improved (Boyd et al., 2010; 2018; Dawson & Bernier, 2013). However, it is unclear how many EI providers are providing services in this way and whether they have adequate resources to support the use of EBPs in a family centered approach. Thus, additional resources could be helpful for EI providers working with caregivers of children with autism to support engagement, understanding, and empowerment in the EI system.

Objectives: This poster will describe the development process of freely available online modules to support EI providers to use a caregiver coaching model as part of their service to empower caregivers to use evidence-based practices (EBPs) in daily routines and activities. We will describe focus group findings used to inform these modules' development and user data reflective of module perspectives and learning outcomes. There are 6 existing modules focused on Parent Implemented Intervention (PII) for services delivered in family homes; Naturalistic Intervention (NI) for services delivered in early care and education settings; and 4 additional modules on focused EBPs of (a) Reinforcement, (b) Prompting, (c) Visual Supports, and (e) Addressing Interfering Behavior. The module format (including planning, using, and monitoring of each practice) will be outlined and user data related to EBP knowledge and module usefulness will be presented.

Methods: Focus groups were conducted with caregivers and providers to inform the development of the online modules. Data were analyzed using thematic qualitative analysis. In addition, user data are regularly collected as part of the module design and these data were descriptively analyzed. User data describe users' perspectives relative to the quality, usefulness, relevance and learning outcomes of the modules.

Results: Focus group data analysis led to the development of specific components in the modules such as short audio clips from providers', caregivers', and teachers' perspectives and video illustrations to demonstrate when an EBP might be a good fit to address a goal/skill in addition to videos showing how to use each EBP. Examples of module resources will be included in the poster. In addition, user data indicate that the existing modules are useful and that EI providers are learning the practices. User data indicate that over 18,000 users have accessed the modules and rate them quite positively. Specifically, module quality was rated an average of 3.5/4; module relevance was 3.6/4; module usefulness was 3.5/4; and meeting learning outcomes was 3.5/4.

Conclusions: This poster will provide information related to strategies and resources for increasing uptake and use of EBPs as part of EI family-centered services, an important step to closing the research to practice gap.

420.133 Salience Network Connectivity Relates to Sleep Disruption in Infants at High Familial Likelihood for Autism**E. Chiem¹**, L. E. Wagner² and M. Dapretto³, (1)Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Department of Psychiatry and Biobehavioral Sciences, University of California Los Angeles, Los Angeles, CA

Background:

Sleep problems are common in autism spectrum disorder (ASD) and often present prior to diagnosis (Guinchat et al., 2012). Although sleep is essential for neurodevelopment, the relationship between early sleep disruption and developing brain networks remains unclear. The salience network (SN), involved in detecting internal and external salient stimuli, is altered in ASD (Uddin et al., 2013). We recently showed atypical SN connectivity with sensorimotor and frontal regions in 1.5-month-old infants at high likelihood of ASD (Tsang et al., 2024). Interestingly, the SN is also altered in insomnia patients, suggesting a crucial role for SN connectivity in sleep regulation. Yet, the link between early sleep problems and SN connectivity in ASD remains poorly understood. Since 20% of infant siblings of autistic children will receive a diagnosis (Ozonoff et al., 2024), this population can offer important insights into the development of these early relationships.

Objectives:

This study examined how SN connectivity at 6 months relates to sleep-onset problems in infants at varying familial likelihood for ASD. Using an *a priori* approach informed by recent findings (Tsang et al., 2024), we focused on SN connectivity with sensorimotor and frontal regions.

Methods:

We used data collected as part of the Infant Brain Imaging Study (IBIS) (R01HD055741). Resting-state fMRI scans were acquired during natural sleep at 6 months (N=102) in infants with an older sibling with ASD (high likelihood: HL, N=63) and infants with no first- or second-degree relatives with ASD (typical likelihood: TL, N=39). Scans were preprocessed and analyzed using FMRIB's Software Library (FSL). Five items related to sleep initiation from the Infant Behavior Questionnaire were used to create the Infant Sleep-Onset Problems (ISOP) score, consistent with a prior study in the IBIS sample (MacDuffie et al., 2020). All analyses were conducted using the right anterior insula (rAI) - the hub of the SN - as the seed, masked by joint group-level functional connectivity maps or anatomical ROIs. ISOP scores at 6 months were used as regressors in a bottom-up analysis.

Results:

HL infants displayed weaker rAI connectivity with the right inferior frontal gyrus as compared to TL infants ($Z > 2.7$, $P < 0.05$). Regressions with 6-month ISOP scores demonstrated that HL infants with worse sleep-onset problems showed stronger rAI connectivity with right sensorimotor cortices ($Z > 2.3$, $P < 0.05$).

Conclusions:

Our finding that HL infants show weaker SN connectivity with the inferior frontal gyrus is consistent with our prior work in 1.5-month-old infants, indicating that this pattern of hypoconnectivity is consistent across the first 6 months of life. We also show that greater sleep-onset problems at 6 months are related to stronger SN connectivity with sensorimotor regions, suggesting that extraneous attention to sensory inputs may disrupt sleep in HL infants. This is in line with the literature linking sleep problems to sensory responsivity challenges in ASD (Lane et al., 2022) and suggests that the relationship between sleep patterns and sensory processing atypicalities is already present in early infancy.

420.134 Sex Differences in Developmental Trajectories of Early Vocal Contingency Predicting Later Autism Outcome**G. Ramsay¹**, M. Pileggi², N. Brane³, S. P. Pulver³ and C. Klaiman⁴, (1)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Emory University/Marcus Autism Center, Atlanta, GA

Background: Previous research on early social engagement in ASD identified developmental cascades in infant-caregiver vocal interaction within the first year of life that discriminate infants later diagnosed with autism from typically developing controls. Sex differences in infant vocal behavior have also been found that may reflect known differences in ASD prevalence between boys and girls, potentially shedding light on different pathways of disruption, but it is not yet known whether these are associated with later symptoms of autism. In this study, we aimed to determine whether trajectories of vocal development measured at the point where sex differences in ASD first emerge are related to dimensional outcomes at the age of diagnosis.

Objectives: The goal of this study was to determine whether trajectories of volubility and vocal contingency from 0-18 months predict autistic symptomatology at 2 years of age, in male and female infants.

Methods: As part of an NIH Autism Center of Excellence, we tracked vocal development in infant siblings and controls. Each child wore a LENA recorder one day every month from 0-24 months to provide audio recordings of their natural language environment. Using speech recognition technology, we identified the number of vocalizations per hour for infant and caregiver, and calculated the rate of contingent interactions based on timing statistics. Using Functional Data Analysis, we determined developmental trajectories for each child and mean developmental trajectories by group; permutation tests were used to identify significant differences between groups, based on sex and diagnosis. We also calculated the correlation between trajectory values at 6 months, when group differences first emerged, and ADOS-2 scores assessed at 24 months. In our sample, 39 children (26M:13F) were diagnosed with ASD and 94 (53M:41F) were typically developing.

Results: We found significant differences ($P<.05$) in developmental profiles for vocal contingency and infant volubility within the first year, between ASD and TD groups, and between male and female infants within each group (Figure 1). Male infants with ASD showed declines in contingency from birth, with declines in volubility from 6 months, whereas female infants with ASD recovered from deficits at birth almost to within the typical range by 12 months. Vocal contingency at 6 months significantly predicted ADOS Overall Total ($R=-0.20$, $P=.027$) and Social Affect ($R=-0.23$, $P=.011$) scores at 24 months in male but not female infants, although this may be due to sample size. No significant relationship ($P>.05$) was found between ADOS scores and infant volubility for either sex.

Conclusions: Developmental trajectories of vocal contingency within the first year predict outcome at two years, consistent with core social deficits in ASD, with significant sex differences from birth. Inflection points in infant volubility also appear around 6 months, but deficits in vocal contingency rather than infant volubility are the main predictor of autism. These results provide the earliest evidence for sex differences in ASD related to outcome, and suggest that early detection and intervention should focus on monitoring and stimulating infant-caregiver interaction from birth, but may need to be tailored to differences between boys and girls.

420.135 Sex Differences in Early Trajectories of Autism-Related Behaviors

K. Lundin Remnélius¹, T. Falck-Ytter², E. Jones³, T. Charman⁴, J. K. Buitelaar⁵, H. Roeyers⁶, M. K. J. Pijl⁷, C. van den Boomen⁸, E. Demurie⁹, P. Warreyn⁹, S. Hunnius⁹, J. Begum Ali¹⁰, G. Pasco¹¹, E. Ward¹², I. J. Servatius-Oosterling¹³ and S. Bolte¹, (1)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (3)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (5)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Center, Nijmegen, NETHERLANDS, (6)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (7)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, (8)Utrecht University, Utrecht, Netherlands, (9)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (10)Centre for Brain and Cognitive Development, Birbeck, University of London, London, United Kingdom, (11)Institute of Psychiatry, Psychology and Neuroscience, Institute of Psychiatry, London, UNITED KINGDOM, (12)Department of Experimental Psychology, University College London, London, London, United Kingdom, (13)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands

Background:

Compared to their male counterparts, autistic females are at higher risk of not receiving a timely diagnosis (McCormick et al., 2020), delaying access to support. Given that being diagnosed before four years of age rather than later is linked to improved quality of life outcomes among autistic people (Kamio et al., 2013), there is a need to facilitate timely recognition of autism. This requires an improved understanding of the autism manifestation in early childhood. However, knowledge regarding early sex differences in autism is limited and hampered by the scarcity of longitudinal research into the emergence of autistic characteristics in young girls and boys (McFayden et al., 2023). Here, prospective sibling designs following young children at elevated likelihood for autism (i.e., with an older sibling diagnosed with autism), and children at typical likelihood (with no autistic first-degree relative) can provide a platform for investigating early autism manifestations.

Objectives:

1. Investigate the male:female ratio of autism diagnosis in an elevated-likelihood sibling sample.
2. Investigate sex and group (autistic, non-autistic) differences in early developmental trajectories of autistic core domains (social communication challenges and RRBs), sensory processing, temperamental domains (negative affect, effortful control, extraversion/sociability), and language development.
3. Estimate the magnitude of differences between those diagnosed with autism at age three and non-autistic children, in boys and girls respectively.

Methods:

Participants took part in the Eurosibs project (Jones et al., 2019), and underwent assessments at five timepoints (5, 10, 14, 24, and 36 months). This study combines data from six research centers in four countries (Belgium, Netherlands, UK, Sweden). Based on sex assigned at birth and diagnostic assessments conducted at 36 months, early development in autistic and non-autistic girls and boys will be investigated. Currently, the data collection has been finalized and a complete dataset is being put together, with an estimated total sample size of $N = 757$. Mixed effect models will be utilized to investigate potential sex differences among autistic and non-autistic children in early trajectories of temperament, sensory processing, language development, and autistic characteristics.

Results:

Descriptive statistics from a currently available elevated-likelihood subsample (157 females, 174 males) indicate a male:female ratio of 1.6:1 (autistic girls, $n = 33$; autistic boys, $n = 52$; non-autistic girls, $n = 124$; non-autistic boys, $n = 122$). At age three, parent-rated autistic traits were significantly higher in autistic girls compared to non-autistic girls (mean = 73.7 vs 30.4). Similar but descriptively less pronounced differences were found when comparing autistic and non-autistic boys (65.6 vs 31.6).

Conclusions:

Our preliminary analysis suggests a substantially smaller male:female ratio than the 4:1 ratio often reported, in line with previous elevated likelihood sibling studies (Messinger et al., 2015; Zwaigenbaum et al., 2012). Girls diagnosed with autism at three years may differ more from same-aged non-autistic girls than diagnosed boys do in comparison to non-autistic boys. Planned analyses will follow up these results and investigate developmental trajectories of autism-related behaviors among girls and boys. Findings from the current study could help elucidate early emergence of autism in girls.

420.136 Shared Infant Neurostructural Substrates That Precede Auditory Processing Differences, Sensory-Related Anxiety and Autistic Traits in Toddlerhood

K. M. Chang¹, A. Tsompanidis², C. Allison³ and S. Baron-Cohen³, (1)Psychiatry, Autism Research Centre, Cambridge, Cambridgeshire, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, Cambridgeshire, United Kingdom

Background:

Most autistic people (95%) experience sensory processing differences (SP). SP may precede and is associated with toddler autistic traits and may shape the development of autism (Robertson & Baron-Cohen, 2017). However, it remains unknown if SP and autistic traits share early neurostructural substrates.

Objectives:

We aimed to identify which infant regional grey matter volumes (GMVs) are associated with i) later auditory responsivity differences or ii) SP-associated affective behaviours (anxiety and emotional reactivity) and if these overlap with GMVs associated with iii) autistic traits in toddlerhood.

Methods:**Study 1:**

Using the Cambridge Human Imaging Longitudinal Discovery [CHILD] (n=27) cohort, we conducted a whole-brain analysis to determine if regional infant GMVs were associated with auditory responsivity differences on the Infant-Toddler Sensory Profile (ITSP) (Dunn & Daniels, 2002).

Study 2:

Using the Developing Human Connectome Project [DHCP] (n=444) and CHILD (n=27) cohorts, we conducted two independent whole-brain analyses to determine if regional infant GMVs were associated with SP-associated affective behaviours on the Child Behaviour Checklist (CBCL) (Achenbach & Ruffle, 2000).

For both studies 1 and 2, we tested whether these nominally significant regions were associated with autistic traits on the Quantitative Checklist for Autism in Toddlers (Q-CHAT) (Allison et al., 2008). If significant, the interaction effect of a family history of autism was tested on the GMV association with Q-CHAT in CHILD, along with a mediation effect by the GMV on the CBCL and Q-CHAT association in DHCP.

For each analysis, we adjusted regional GMVs for age and intracranial volume (ICV). We then tested their association with the outcome of interest in multiple linear regression models, controlling for sex and age corrected for gestational age. FDR-corrected results are displayed (q).

Results:

In Study 1 with CHILD (n=27), the right superior temporal pole GMV at 10-11 weeks post-birth negatively associated with more auditory responsivity differences at 18 months ($p=0.03$; $q=0.60$) and autistic traits ($p=0.04$; $q=0.16$) at 24-36 months.

In Study 2 with CHILD (n=27), the right superior temporal pole (STP) and superior temporal gyrus (STG) GMV at 10-11 weeks post-birth were negatively associated with more SP-affective behaviour (STP: $p=0.04$; $q=0.18$; STG: $p=0.01$; $q=0.54$) and autistic traits (STP: $p=0.04$; $q=0.16$; STG: $p=0.02$; $q=0.14$) at 24-36 months. Autism in the family ($q<0.01$) significantly interacted with the association between the STG GMV and autistic traits (Figure 1).

In Study 2 with DHCP (n=444), the left parahippocampal gyrus and ambiens GMV at 1.5-1.8 weeks after birth was positively associated with SP-affective behaviour ($p=0.04$; $q=0.70$) and autistic traits ($q<0.01$) at 18 months (Figure 2) and partially mediated the association between anxious behaviour and autistic traits in the DHCP ($p=0.04$).

Conclusions:

Our findings indicate that toddler sensory processing (SP), associated emotional behaviours (such as anxiety), and autistic traits share neural correlates in the temporal lobe before 10-11 weeks. This study provides the first neurodevelopmental evidence of shared neurostructural substrates between SP and autistic traits in early infancy, based on comprehensive analyses in several cohorts. Future research will explore their shared development through connectivity.

**420.137 Sleep Problems and Emergent Indicators of Autism in the First Year of Life**

I. Camillone^a, E. M. Andres^a, G. Puggioni^b, C. M. Loncar^a, M. A. Clark^a, C. A. Cragin^a and S. J. Sheinkopf^c, (1)Women & Infants Hospital, Brown Center for Children & Families, Providence, RI, (2)Thompson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO, (3)Department of Computer Science and Statistics, University of Rhode Island, Kingston, RI, (4)Brown University, Providence, RI, (5)Brown University School of Public Health, Providence, RI

Background: Sleep difficulties commonly co-occur with autism and are associated with symptom presentation and functional status in autistic children and adolescents. Evidence from infant sibling samples suggests that sleep problems may also be present in infancy prior to diagnosis. Nonetheless, prospective data on the early emergence of sleep difficulties in relation to autism remains rather limited, especially in general birth cohorts.

Objectives: Testing the presence of sleep difficulties in infants with emerging indicators of autism in a general birth cohort accounting for racial/ethnic minority status and maternal education.

Methods: Participants were 506 children (246 females; 370 White, non-Hispanic) from an ongoing longitudinal birth cohort study. At 9 and 12 months of age, primary caregivers completed the Survey of Well-being of Young Children (SWYC), including questions about sleep. Early autism indicators were measured by the First Year Inventory-Lite (FYI-Lite, v3.1b) at 12 months, yielding the Social Communication (SC) and Sensory Regulatory (SR) scales, and an overall categorization of autism likelihood. Participants were grouped by the presence of sleep problems at both 9 and 12 months ($n=60$), at only 9 months ($n=61$), at only 12 months ($n=44$), and no sleep problems ($n=341$). ANOVAs were conducted to compare the FYI-Lite continuous SC and SR scale scores of the sleep-defined groups, with infant sex in the models. Contingency models, stratified by racial/ethnic minority status and maternal education, tested the prediction of elevated autism indicators on the FYI-Lite from the presence of sleep problems at 9 months.

Results: ANOVAs revealed a significant main effect for sleep-defined groups on the FYI-Lite SR subscale score, $F(3) = 8.73$, $p < 0.001$, but no effect of sex or sleep-group by sex interaction. Pairwise comparisons revealed that infants with sleep problems at both 9 and 12 months, and those with sleep problems at 12 months, had higher FYI-SR scores (vs no sleep problems at 12 months). The ANOVA predicting the FYI-SC subscale scores did not have any significant main effects or interaction. Contingency analyses revealed that sleep problems at 9 months predicted elevated (above threshold) autism FYI-Lite scores at 12 months as compared to infants without 9-month sleep problems ($RR = 2.33$; 95% CI: 1.35, 4.02). Stratification analyses revealed effect modification for minority status. Specifically, 9-month sleep problems predicted 12-month elevated FYI-Lite scores more strongly in minority ($RR = 4.01$, 95% CI: 2.08, 7.80) than non-minority participants ($RR = 0.89$, 95% CI: 0.31, 2.61). In contrast, there was a trend for 9-month sleep problems to more strongly predict elevated FYI-Lite scores in infants whose mothers had a college degree ($RR = 4.02$; 95% CI: 0.80, 3.11) than for those with less than a college degree ($RR = 1.58$; 95% CI: 1.55, 10.40).

Conclusions: These findings provide further evidence of emerging sleep problems as predictors of early emerging autism indicators at 12 months of age in a general population sample. Additionally, these findings indicate that demographic characteristics will need to be thoughtfully incorporated into predictive models and when assessing the relationship between infant sleep difficulties and emerging autism behaviors.

420.138 Social Communication Milestone Attainment and Emerging Autism Indicators By Caregiver Report in a General Population Birth Cohort

E. M. Andres¹, N. M. Kanne², C. A. Cragin³, C. M. Loncar⁴, M. A. Clark⁵, B. M. Lester⁶, G. Puggioni⁶ and S. J. Sheinkopf¹. (1)Thompson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO, (2)Thomson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO, (3)Brown University, Providence, RI, (4)Brown University School of Public Health, Providence, RI, (5)Department of Psychiatry and Human Behavior, The Warren Alpert Medical School of Brown University, Providence, RI, (6)Department of Computer Science and Statistics, University of Rhode Island, Kingston, RI

Background: Early developmental milestones, including social communication abilities, may be delayed in infants later diagnosed with autism. Limited data are available describing developmental trajectories associated with autism likelihood in the general population. Caregiver characteristics may impact their report of infant behavior and milestones.

Objectives: To test whether infants with elevated indicators of autism at 12 months have delayed attainment of developmental milestones earlier in infancy while accounting for maternal self-reported subclinical autism characteristics in a general birth cohort.

Methods: Participants were 212 children (108 males; 173 White/Non-Hispanic) from an ongoing longitudinal study. At 6, 9, and 12 months of age, mothers completed the Survey of Well-being of Young Children (SWYC) about their infant, including the 10-item developmental milestones scale, adapted to include key milestones at all ages. At 12 months, caregivers completed the First Year Inventory-Lite (FYI-Lite, v3.1b) about their infant, yielding two subscales of early autism indicators: Social Communication (FYI-SC) and Sensory Regulatory (FYI-SR). Mothers also completed the Broad Autism Phenotype Questionnaire (BAPQ) as a self-report of their own subclinical autistic traits, yielding three subscales: Rigid, Aloof, and Pragmatic Language. Infant FYI-Lite scores correlated significantly with maternal BAPQ scores ($p's < 0.05$), with the strongest correlation between the FYI-SC and the BAPQ-Aloof subscales ($r = 0.34$). This informed group stratification for an ANOVA comparing mean milestone scores by stratified group and age, as well as item-level descriptive analyses. We divided the participants into four groups based on mothers' BAPQ-Aloof scores and infants' FYI-SC scores: (1) dyads above both thresholds ($n=29$), (2) only mothers above threshold ($n=47$), (3) only infants above threshold ($n=22$), and (4) neither mother nor infant above either threshold ($n=108$).

Results: Significant effects were found for stratification group ($F(3) = 16.35$, $p < 0.001$), infant age ($F(2) = 21.12$, $p < 0.001$), and the group by age interaction ($F(6) = 3.92$, $p < 0.001$). Follow up tests revealed that both groups of infants who had elevated FYI-SC scores had lower SWYC milestone scores than both low FYI-SC groups, regardless of mothers BAPQ scores ($p's < 0.05$). Dyads with above threshold scores on infant and maternal measures had the lowest SWYC-milestone scores at all age points and no change over time in their milestone scores, whereas SWYC milestone scores increased by age for dyads with infants with low FYI-SC scores. Milestone scores were higher and not different from one another for dyads with infants with low FYI-SC scores (Figure 1). Item-level visualization revealed differential social communication milestone attainment between groups of infants above and below threshold on the FYI-SC, including a striking decrease in response-to-name at 12 months for both groups of infants above threshold on the FYI-SC (Figure 2).

Conclusions: Developmental and social-communication milestones are delayed at the group level in infants with emerging indicators of autism. Elevated maternal self-report of subclinical autism characteristics accounted for some but not all variation in milestone attainment. These findings have implications for understanding the emergence of autism in general population cohorts.

420.139 Stages of Brain Processing in Infants Associate with Early Versus Later Autism Diagnosis

T. Bazelmans^{1,2}, T. Charman³, C. Tye¹, M. H. Johnson^{2,4} and E. Jones^{5,6}, (1)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (4)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (5)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (6)Department of Child and Adolescent Psychiatry and MRC Centre for Neurodevelopmental Disorders, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom

Background:

The expression of autism traits sufficient to meet criteria for a diagnosis can occur early (around 2-3 years) or later (mid-childhood and onwards) in development and age of onset may serve as a useful stratification marker. Studies of infants with a family history of autism ('infant sibs') have typically reported on prognostic infant biomarkers in relation to 2- or 3-year clinical outcomes but have not commonly followed these children up to compare children later meeting diagnostic criteria for autism.

Objectives:

We report on the associations between previously established infant marker of 3-year autism outcome, namely event-related potentials (ERPs) generated by the brain when viewing faces, in relation to those with an early versus later autism outcome.

Methods:

A sample of 113 infant sibs (50% Female; all with an older diagnosed sibling) aged 6-10 months had EEG recorded whilst viewing faces (face versus noise: N290 or gaze towards versus away: P1, P400) and attended a diagnostic visit at both 3 years and mid-childhood (6-12 years). Diagnostic autism outcome was determined based on DSM-5 or ICD-10 criteria by the research team led by a clinician. Decision was based on clinical and developmental questionnaires, interviews and observations, including the autism diagnostic interview/observation schedule (ADI/ADOS). Children were then categorised in those with early autism (diagnosed at age 3 years), later autism (diagnosed at mid-childhood, but not at 3 years) and no autism. ERPs were compared using mixed models including the main and interaction effects of condition and group, followed by an ANOVA to understand significant effects. Dimensional associations between ERPs (difference scores between conditions) and mid-childhood autism traits of social communication and interaction (SCI) and restricted and repetitive behaviour (RRB) measured using the Social Responsiveness Scale were assessed using Kendall Tau correlations.

Results:

A short P1 latency response did not associate with autism outcome. There was a condition-by-group interaction effect for the mid-latency N290 component ($\chi^2(2) = 8.36, p=.015$) and an ANOVA confirmed a significant difference between the early (longer latencies to noise versus faces) versus later ($p=.024$) and no autism ($p=.007$) groups (opposite pattern). There was also a significant interaction effect for the later P400 latency component ($\chi^2(2) = 13.34, p=.001$), showing a significant difference between the early ($p=.001$) and later ($p=.035$, although .070 after correction) autism groups (longer latency to towards versus away) compared to the no autism group (opposite pattern), with no difference between early and later autism. Amplitude models did not show any significant effect of group. There was a significant association between P400 latency and both SCI (.20, $p=.005$) and RRB (.21, $p=.003$), such that a slower response to gaze towards versus away was associated with higher mid-childhood autism symptoms.

Conclusions:

Our evidence supports hypothesised causal mechanisms that are reflected in increasing effects as real-time neural processing takes place. Different stages of face processing in infancy differentially associate with age of autism presentation such that an earlier age of diagnosis is associated with earlier stage disruption within the event-related waveform in response to a social stimulus (faces).

420.140 Strategies Caregivers Use to Support Toddlers with Autism Spectrum Disorder during Moments of Dysregulation

E. C. Hayashi¹, S. T. Seese² and C. Kasari³, (1)Kasari Lab, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Education and Psychiatry, University of California Los Angeles, Los Angeles, CA

Background: Caregivers play a crucial role in supporting the development of their toddlers with autism spectrum disorder (ASD). One area of development is emotion regulation in which young children increasingly become more regulated over age with co-regulation strategies employed by their caregivers. Understanding the strategies caregivers use prior to intervention has implications for tailoring intervention approaches to the caregiver.

Objectives: This study aims to describe the strategies caregivers utilize with their toddler with ASD during periods of dysregulation (fussiness, crying).

Methods: Participants consisted of 149 toddlers with ASD (M age = 21 months) and their caregivers. Caregivers were observed and recorded playing with their toddlers for 10 minutes. The toddler's dysregulation behaviors and the caregiver's response to that behavior were coded.

Dysregulation behaviors were coded for (a) type and (b) duration (proportion of time in seconds). Caregiver strategies consisted of nine different strategies, which were then grouped into three composite codes: active (e.g., active involvement from the caregiver, redirection), avoidance (e.g., minimal involvement or ignoring from caregiver), and verbal (verbal/vocal involvement from caregiver). Proportion of time spent utilizing the caregiver strategy was used for analysis. Descriptive statistics and correlational analyses were conducted.

Results: Caregivers utilized active strategies 46% of the time, avoidance strategies 34% of the time, and verbal strategies 9% of the time. Most caregivers (44%) opted to use between two to three different strategies. 16% of caregivers utilized a much wider range of strategies (between four to six different strategies), while 19% of caregivers used only one strategy throughout the 10-minute interaction. Bivariate correlational analysis revealed that caregiver active strategies were positively associated with time dysregulated ($r(147) = .260, p = .001$). Caregivers utilized active strategies most often during specific dysregulation behaviors, including negativity (e.g., crying, upset), idiosyncratic behaviors (e.g., repetitive actions), or child avoidant behaviors (e.g., child moves away from caregiver). Caregiver's use of avoid strategies was also positively associated with time dysregulated ($r(147) = .196, p = .017$). Caregivers utilized avoid strategies most often during physical venting behaviors (e.g., child jumping up and down) and vocalizations (e.g., child singing).

Conclusions: Results suggest that caregivers are responding to their child's dysregulation utilizing a variety of strategies. Caregivers seem to use active strategies (e.g., redirection) most often during child's negative, avoidant or repetitive dysregulation behaviors, while caregivers may avoid (or ignore) when children are physically venting or vocalizing. Future studies should examine which strategies predict *less time* dysregulated over time. Understanding which strategies may improve the toddler's ability to regulate their emotions is crucial and may pave the way for supporting caregiver child relationships and increasing social communication learning opportunities.

420.141 Testing Associations between Implementation Support Networks and the Adaptive Behavior of Non-Speaking Autistic Children

H. Siddiqui¹, K. Bouvier-Weinberg², S. Dufek³, G. Vivanti⁴ and E. McGhee Hassrick⁵, (1)AJ Drexel Autism Institute, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Psychiatry and Behavioral Sciences, UC Davis Health, MIND Institute, Sacramento, CA, (4)A.J. Drexel Autism Institute, AJ Drexel Autism Institute, Philadelphia, PA, (5)A..J. Drexel Autism Institute, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA

Background: Non-speaking children on the autism spectrum with adaptive behavioral challenges are at particular risk for severe behavioral disturbances, resulting in greater safety risks, tremendous emotional, and economic burdens for their caregivers as well as enormous societal costs. Determining if modifiable factors, such as the level of implementation collaboration among professionals and caregivers, are associated with child adaptive behavior functioning, would provide guidance about how to best improve outcomes for non-speaking children on the autism spectrum. However, no research has addressed the association between collaboration dynamics in autism early intervention and adaptive behavior functioning.

Objectives: To characterize the implementation network structure of collaboration for non-speaking autistic children in school settings and examine whether variation in network structure is associated with children's overall adaptive behavior scores.

Methods: Caregivers of 18 non-speaking autistic children (mean=4.5 years) from diverse cultural and socioeconomic backgrounds were recruited. A "name generator" question (Burt, 1984) identified supporters in home, community, school, and healthcare settings. Virtual interviews (30-90 minutes) were used to collect social network data, analyzed using RStudio (v4.4.1) with the igraph package. Network structural measures (centralization, information flow, node variation) were calculated to assess network quality. Children were grouped into high ($n=8$) and low ($n=10$) adaptive behavior categories based on ABC domain scores. The Kruskal-Wallis test was used to assess statistical significance between the groups. **Results:** Mean network constraint was significantly higher ($p = 0.0025$) in the high ABC group (mean = 0.8, SD = 0.2) compared to the low ABC group (mean = 0.4, SD = 0.3), indicating that the quality of implementation collaboration was more centrally connected around a few well connected members for children with higher adaptive behaviors. Additionally, the variation in eigenvector node centrality, which measures how influential a member is within the network, was significantly higher in the high ABC group (mean = 0.4, SD = 0.1) compared to the low ABC group (mean = 0.2, SD = 0.2). This suggests that in the high ABC group, some network members have a much stronger influence than others ($p = 0.0162$). There was also a trend toward higher eigenvector network centralization in the high ABC group (mean = 0.6, SD = 0.3) compared to the low ABC group (mean = 0.4, SD = 0.3), though this did not reach statistical significance ($p = 0.075$). Other network characteristics such as network size, density, number of isolates, links, and various centrality measures (degree, betweenness, closeness) showed no significant differences between the groups (all $p > 0.05$), suggesting that overall network structure was similar regardless of adaptive behavior composite score.

Conclusions: Our findings show that non-speaking autistic children with higher adaptive behavior have more constrained, cohesive social networks, characterized by tightly knit support. In contrast, those with lower adaptive behavior have more fragmented networks. These results emphasize that network structure, not just size, influences adaptive functioning and may enhance support for these children.

420.142 The Contribution of Genes and Environments to Infant EEG Measures

T. Falck-Ytter^{1,2} and I. Hardiansyah^{2,3}, (1)Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (2)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (3)Uppsala University, Uppsala, Uppland, Sweden

Background: EEG has been used widely in infancy and ‘early autism’ research, and individual differences in some EEG metrics infancy have been linked to autism diagnosis in toddlerhood in some studies (e.g. Gabard-Durnam, L. J. et al, 2019; O’Reilly, C. et al, 2023). There is very little work on etiological factors influencing different EEG variables in infancy (Orekhova, E. V. et al, 2003). This knowledge could be informative for future studies looking into the link between early brain development and later differences in socio-communicative development.

Objectives: The overall purpose of this study is to provide an overview of early EEG measures’ etiological influences, in terms of additive genetics, shared environment and unique environment.

Methods: We assessed the contribution of genes and environments to four types of EEG measures: relative bandpower, functional connectivity, network properties, and phase-amplitude coupling in theta, alpha, and gamma brain rhythms. All measures were extracted while the infants looked at either a social video stimulus (woman talking to the child), or a non-social control stimulus (moving toys with sound). This was done in a sample of infant twins (Babytwins Study Sweden; BATSS; $n = 569$; approximately 50% were monozygotic, see Falck-Ytter et al 2021 for details). We employed a classical twin modelling approach, which involves comparing the degree of similarity between monozygotic twins, who share 100% of their segregating genetic material, and dizygotic twins, who share approximately 50%. Using univariate twin models, we estimated the relative contributions of genetic and environmental factors to the variation in a given phenotype by analyzing the correlations between twins. This variation or covariation is partitioned into three components: additive genetic influences (A, or heritability, which increases similarity between twins), non-shared environment (E, influences unique to each twin that reduce similarity, including measurement error), and shared environment (C, environmental factors that increase similarity between twins regardless of zygosity, such as family socioeconomic status). Both A and C represent familial effects, that is, traits that run in families.

Results: Relative bandpower showed substantially more familial effects (primarily additive genetic) than either functional connectivity or network properties measure. Over 83% of the band power variables showed a heritability above 40%, while only less than 3% of the functional connectivity measure and none of the network properties measure showed a heritability above 40%. **Figures 1a** and **1b** summarize the findings for bandpower.

Conclusions: That band power showed much higher familiarity (predominantly genetic effects) than the other measures suggest that these measures are stable traits that run in families and which can be reliably assessed in early infancy. Low familiarity may indicate lower reliability for some of the other EEG measures (van der Velde, B. et al 2019). Because autism is highly heritable, the current results point to band power-based measures as the most promising early EEG markers of autistic development.

Figure 1. ACE estimates of relative bandpower measures for non-social (**a**) and social stimuli (**b**). front=frontal lobe, parie=parietal lobe, ltemp=left-temporal lobe, rtemp=right-temporal lobe, occip=occipital lobe, and whole=whole scalp; alpha=alpha band, gamma=gamma band, theta=theta band.

420.143 The Impact of Developmental Delays and Gender on Play Behaviors in Children with ASD: Insights from the Escbq-2 Total and Pretend Play Scales

M. Buruma¹, M. L. Bezemer¹ and E. M. Blijd-Hoogewys², (1)INTER-PSY, Groningen, Netherlands, (2)Psychiatrie Noord, Groningen, Netherlands

Background:

Play is a critical component of early childhood development, particularly in fostering social and communicative behaviors. To assess these behaviors in children under 30 months, the Early Social Communicative Behavior Questionnaire, with 108 items (ESCBQ; Blijd-Hoogewys & Buruma, 2009), was developed. The updated version, ESCBQ-2, with 58 items, has shown strong psychometric properties, including high internal consistency and test-retest reliability. Of these items, 13 specifically assess play, with 3 focusing on pretend play. Understanding how developmental delays and gender influence these behaviors is crucial for early detection and intervention in autistic children.

Objectives:

This study aimed to examine differences in play behaviors between autistic children with and without developmental delays, taking gender into account, using the ESCBQ-2 Total Play and Pretend Play scales.

Methods:

The sample included 300 children diagnosed with ASD (208 boys, $M = 3.83$ years, $SD = 1.19$; 92 girls, $M = 3.91$ years, $SD = 1.58$). Developmental delays were present in 153 children (115 boys, 38 girls). Independent t-tests were conducted to assess group differences in play behaviors by gender and developmental delay. A two-way ANOVA further examined the interaction effects of gender and developmental delay on the ESCBQ-2 Total Play and Pretend Play scales.

Results:

No significant differences were found between autistic boys and autistic girls on the ESCBQ-2 Total Play ($t = 0.16$, $p = 0.87$) or Pretend Play scales ($t = 0.27$, $p = 0.79$). However, autistic children with developmental delays scored significantly lower on the Pretend Play scale compared to those without delays ($t = -2.12$, $p = 0.035$) (for more results, see Table1). The two-way ANOVA revealed significant interactions between gender and developmental delay for both the ESCBQ-2 Total Play ($p = 0.042$) and Pretend Play scales ($p = 0.038$), indicating that the combination of these factors affects play behavior. However, no significant main effects of gender or developmental delay alone were observed on these two scales. Developmental delay alone had a significant effect on Pretend Play ($F = 4.72$, $p = 0.031$), independent of gender.

Conclusions:

These findings highlight the complex interplay between gender and developmental delay in shaping play behaviors in autistic children. While no significant gender differences were observed, developmental delay significantly impacted pretend play, aligning with previous research suggesting minimal gender differences in play behavior among autistic children under 5 years old (Petrout et al., 2018). This underscores the importance of accounting for developmental delays when assessing social and communicative play. A key limitation of this study is the narrow focus on a subset of play items, limiting the generalizability of these results. Future research should expand the scope of play-related items to provide a more comprehensive understanding of how developmental delays and gender affect various aspects of play in autistic children.

420.144 The Impact of Parental Mental Health on Child Self-Regulation Outcomes within Behavioral Therapy for Disruptive Behavior

R. Ros-DeMarize¹, A. Marsden², C. C. Bradley³ and L. Carpenter³, (1)Department of Pediatrics, Medical University of South Carolina, Charleston, SC, (2)Medical University of South Carolina, Charleston, SC, (3)Medical University of South Carolina, Charleston, SC

Background: Children with autism spectrum disorder (ASD) experience significant impairments in self-regulation across the domains of executive functioning (EF; Anderson et al., 2015) and emotion regulation (ER; Mazefsky et al., 2013). Although parenting styles may impact self-regulation (Karreman et al., 2006), less is known about the impact of parental mental health, including distress related to parenting and diagnostic history. Given the key role that parents play within behavioral interventions for young children, it is also important to examine the stability of these associations after treatment. Although disruptive behavior problems are the target for interventions like Parent Child Interaction Therapy (PCIT), impacts on child self-regulation have been documented. It remains unknown whether parent factors may also influence post-treatment self-regulatory functioning.

Objectives: The purpose of the current study was to (a) examine the effect of parental diagnostic history and parenting stress on domains of ER and EF and (b) determine whether these associations hold after completion of a behavioral parenting intervention.

Methods: Participants included 73 children ($M_{age} = 4.9$) with a diagnosis of ASD and clinically significant disruptive behavior problems. Parents rated EF and ER on the Behavior Assessment System for Children-Third Edition. Parents also reported on their mental health diagnostic history and parental distress on the Parenting Stress Index. Children were administered the Peabody Picture Vocabulary Test as a measure of child verbal skills, which was included as a co-variate in all analyses. Child and parent ER was also measured via observational coding (ongoing). Half of the sample was randomized to receive PCIT via telehealth and all measures were repeated at post-treatment.

Results: As seen in Table 1, Parental endorsement of mental health diagnosis and higher distress were associated with higher child emotional self-control problems ($b = .24$ & $b = .27$, respectively, $p < .05$). Similarly, both parent diagnosis and distress were associated with child negative emotionality ($b = .29$, $p < .05$ & $b = .34$, $p < .01$, respectively). Conversely, only parental distress was associated with higher child executive functioning problems ($b = .34$, $p < .01$; See Table 2). These associations did not hold when examining post-treatment outcomes for families that received PCIT. Child emotional self-control, negative emotionality, and executive functioning at post-treatment were not associated with parent diagnosis or post-treatment parent distress ($n = 32/40$ complete, $ps > .10$).

Conclusions: Results highlight the association between parental mental health factors (i.e., diagnosis and distress related to parenting) and child emotion regulatory abilities across domains of ER. Findings also indicated that while these parenting factors may have a more robust effect on child ER, child EF is associated with parental distress but not parental diagnostic history. Outcomes for families that have completed therapy thus far, indicate that behavioral parenting therapies have the potential to improve these negative associations. Treatment participation may be conceptualized as a moderator of the associations between parent factors and child self-regulatory functioning.

**420.145** Towards Understanding Heterogeneity in ASD: Presence of Oppositional Behaviors in Young Children with Autism

A. Boxberger¹, A. C. Linke¹, I. Fishman², A. Rios³, J. Mahmalji⁴, M. Herrera⁴, B. Chen² and L. Olson⁴, (1)Brain Development Imaging Lab, San Diego State University, San Diego, CA, (2)Psychology, San Diego State University, San Diego, CA, (3)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (4)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA

Background: Symptoms of oppositional defiance (OD), including irritable mood and defiant behavior, are present in up to 28% of children with ASD and are associated with higher rates of depression and antisocial behaviors in adolescence than ASD alone. Although oppositional defiant disorder (ODD) is thought to be a neurodevelopmental disorder with an early onset, diagnoses are typically not made until late childhood. While functional neuroimaging studies have implicated altered amygdala connectivity in both ASD and ODD, little is known about trajectories of brain and behavioral development in young children with ASD and co-occurring OD symptoms. Understanding these trajectories will inform early interventions during a critical developmental period when they have the most potential for positive impact.

Objectives: Examine whether preschoolers with ASD and clinically significant OD symptoms (ASD+OD) differ on a) adaptive and developmental skills and autism-associated behaviors, and b) functional connectivity (FC) of the amygdala, from their peers with ASD (with no elevated OD symptoms).

Methods: Participants include 71 young children with ASD (mean age = 39.2 ± 14 mo) and 53 typically developing children (TD; mean age = 33.9 ± 16.1 mo) enrolled in the SDSU Toddler MRI Project. OD symptoms were quantified using the OD subscale of the Child Behavior Checklist, with 17 children with ASD having clinically significant OD (using $T > 65$ cutoff). Adaptive and developmental skills were assessed using the Vineland Adaptive Behavior Scales standard scores and Mullen Scales of Early Learning developmental quotient (DQ) scores, respectively, and autism-related behaviors were measured using the ADOS-2. FC between the amygdala and canonical resting state networks was estimated from fMRI data acquired during natural sleep.

Results: Overall, young children with ASD had significantly higher OD symptoms than TD peers ($\beta = 7.14$, $p < .001$). Children with ASD+OD had significantly higher developmental skills than children with ASD alone. This included greater non-verbal reasoning skills (Mullen Visual Reception: $\beta = 15.16$, $p = .045$) and expressive language ($\beta = 17.27$, $p = .018$), as well as greater overall Early Learning Composite scores ($\beta = 12.90$, $p = .011$). Children with ASD+OD did not differ from children with ASD alone on adaptive skills (all $p > .05$) or autism-related behaviors (all $p > .05$). Children with ASD+OD showed reduced FC between the amygdala and the sensorimotor ($\beta = -.07$, $p = .031$) and language ($\beta = -.07$, $p = .056$) networks.

Conclusions: These findings provide further evidence that OD symptoms are elevated in children with ASD as early as at 3 years of age. Unexpectedly, having elevated OD symptoms was associated with greater developmental skills in young children with ASD. Further, children with ASD and elevated OD symptoms had altered connectivity of the amygdala, sensorimotor, and language networks relative to their peers with ASD alone. These results suggest that early OD symptoms in ASD are associated with unique behavioral and neurodevelopmental patterns, likely contributing to the broad heterogeneity in ASD. Further longitudinal study is warranted to track these trajectories into later childhood and adolescence, to inform targeted early intervention.

420.146 Trajectories of Early Dyadic Synchrony in Infants Developing Autism or Concerns for ADHD

A. Piergies¹, A. M. Iosif², G. S. Young³, D. N. Gangi³, A. J. Schwichtenberg⁴, S. Ozonoff⁵ and M. Miller⁵, (1)Psychiatry & Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (4)Human Development and Family Studies, Purdue University, West Lafayette, IN, (5)Psychiatry and Behavioral Sciences, UC Davis Health, MIND Institute, Sacramento, CA

Background: In early life, interactions between children and caregivers become more temporally coordinated (i.e., synchronous), creating opportunities for learning that can have cascading effects on development. Synchrony has been positively associated with various developmental outcomes, including self-regulation and social communication (Leclère et al., 2014). Differences in the structure of interpersonal interactions, including reduced synchrony, have been reported in older children and adults diagnosed with autism or ADHD (Bowsher-Murray et al., 2022; Cunningham & Barkley, 1979; McNaughton & Redcay, 2020; Murat Baldwin et al., 2022; Gvirts Problovski et al., 2021; Zampella et al., 2020), neurodevelopmental conditions which commonly co-occur and have overlapping early markers. However, the literature on dyadic synchrony in the context of autism and ADHD has mainly involved infants at elevated likelihood for autism who display a wide range of clinical outcomes in addition to autism. Further, studies have been limited by cross-sectional designs with a single-condition focus, narrow age ranges, a wide range of synchrony metrics, an emphasis on familial likelihood or diagnostic outcome, and small sample sizes.

Objectives: We examined trajectories of early dyadic synchrony from 6 to 36 months of age in a prospectively followed sample of infants at elevated and average likelihood for autism or ADHD, including contributions of social partner and behavior type.

Methods: Data were gathered from infants with family histories of autism ($n=99$) or ADHD ($n=46$) or no history of either ($n=40$). At 36 months, participants were classified into one of three outcome groups: Autism ($n=20$), ADHD Concerns ($n=28$), or Comparison ($n=115$), according to pre-existing algorithms (Reetzke et al., 2022). At 6, 12, 18, 24, and 36 months, caregiver-child dyads participated in a video-recorded semi-structured play task. Behaviors of interest—gaze to faces, gaze to objects, positive affect, and vocalizations—were coded on a micro-level for each caregiver and child individually. Exchanges were considered synchronous when the behavior of one social partner matched that of the other social partner within two seconds. Linear mixed-effects models and post-hoc linear contrasts following significant interaction effects were employed to assess group differences in the percentage of synchronous behaviors (overall, by social partner, and by behavior type) over time.

Results: Across models, all three outcome groups demonstrated an increase in the percentage of synchronous behaviors from 6 to 36 months of age, with the Autism group differing from the ADHD Concerns and/or Comparison groups in rate of change (see Figure 1). Relative to the other groups, the Autism group generally had a smaller mean percentage of synchronous behaviors from 12-18 to 24-36 months (Figure 1; $ps<.05$). The ADHD Concerns group did not differ from the Comparison group in any model.

Conclusions: Early dyadic synchrony follows different trajectories in infants developing autism versus infants developing concerns for ADHD and comparison infants. However, by 36 months, synchrony in the Autism group was closer to the other groups, possibly due to the receipt of services. Future work should consider use of more refined metrics of dyadic synchrony which capture multimodal exchanges and include behaviors that are potentially more relevant to ADHD.

**420.147** Transdiagnostic Clustering of Cognitive Development and Spectral Power in Infants at Elevated Likelihood of Autism and ADHD

A. Song^{1,2,3}, J. Begum Ali⁴, M. H. Johnson⁵, T. Charman⁶, R. Haartsen⁷, F. Váša⁸, E. Jones⁹ and & The BASIS-STAARS Team^{*,9}, (1)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, London, United Kingdom, (2)Department of Neuroimaging, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, London, United Kingdom, (3)London Interdisciplinary Biosciences Consortium, University College London, London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (5)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (7)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (8)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (9)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom

Background:

High heterogeneity within autism, along with frequent overlap with ADHD, has led to a transdiagnostic approach for studying these neurodevelopmental conditions. Siugzdaite et al. (2020) used growing hierarchical self-organising maps to show that cognitive and brain profiles of children aged 5 to 18 years did not align with categorical diagnoses of ADHD, autism and dyslexia, and that relationships between individuals' cognitive and brain profiles were not one-to-one. This suggests that diagnostic categories fail to capture the underlying basis about how developmental difficulties arise and a transdiagnostic view may be more appropriate when considering the needs of children with neurodevelopmental conditions.

Objectives:

The current study aimed to use clustering to investigate the cognitive and spectral power profiles of infants from the British Autism Study of Infant Siblings (BASIS) Phase 3 - Studying Autism and ADHD in the eaRly yearS (STAARS).

Methods:

BASIS-STAARS is a prospective longitudinal study on individuals at elevated likelihood for autism and ADHD. It uses an infant-sibling design, as infants whose first-degree family member(s) have an autism diagnosis show higher likelihood for receiving a diagnosis. Mullen Scales for Early Learning subscale scores were used to stratify subjects into cognitive clusters (age=24 months, N=127). Neural clusters were derived from relative electroencephalography (EEG) power in infant beta, alpha and theta frequency bands (age=24 months, N=124). Hierarchical density-based clustering with applications to noise (HDBSCAN) was used to stratify cognitive and EEG data separately. The relationships between subgroups were examined across modalities (cognitive and EEG), as well as between subgroups of the same modality using the Vineland adaptive behaviour composite (age=24 months), ADOS-2 and ADI-R autistic traits and CBCL externalising behaviours (age = 36 months), and family history of autism and ADHD (summarised in **Figure 1**).

Results:

Clustering of cognitive and of EEG data resulted in a large, homogeneous cluster, which was compared against a subgroup made up of a small cluster, and heterogeneous points that were classified as outliers. The main cognitive cluster (prop=54%) had a higher average and lower spread in scores compared to the outlier subgroup across all scales (**Figure 2a**), as well as in adaptive behaviour. The main EEG cluster (prop=78%) had a lower average and higher spread of beta and alpha power, and higher average theta power (**Figure 2a**). Data-driven subgroups were not associated with family history of autism and/or ADHD (**Figure 2b**). Individuals from one cognitive subgroup mapped onto different EEG subgroups and vice versa, with no overall association between modalities. ADI measures of social communication and repetitive behaviours were higher in the main cognitive cluster compared to the outlier subgroup, while other diagnostic traits showed no difference. EEG subgroups did not differ in adaptive behaviour or diagnostic traits.

Conclusions:

Cluster-derived subgroups of cognitive ability did not relate to those of EEG power at 24 months, nor did they align with family history. Cognitive but not EEG subgroups showed differences in some measures of autism but not ADHD traits at 36 months. This lends support to the transdiagnostic view of neurodevelopmental conditions in early development.

420.148 Understanding Convergent and Divergent Validity across Multiple Measures of Emotion Regulation in Autistic Preschoolers

M. A. Renaud¹, K. Rowland¹ and S. R. Edmunds², (1)University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC

Background: Emotion regulation (ER) is a transdiagnostic process that involves the process of emotion reactivity and modification of arousal. As a multidimensional construct, ER is characterized both by frustration (increase in dysregulation), which appears to be similar for all toddlers and soothability (increase in regulation), which appears to be more difficult for autistic compared to neurotypical toddlers (Edmunds et al., 2024). Previous assessments for ER primarily relied on behavioral observation, clinical, and biologically based methods that have not been validated with Autistic individuals (Mazefsky et al., 2013). Thus, measures have been more recently developed to assess ER in school aged autistic children (EDI; Mazefsky et al., 2020). However, evidence suggests that there are distinct features of ER in early childhood (between ages 2 and 5) that were not captured in current measures (Day et al., 2022). As validated measures of ER in early childhood emerge, despite purporting to all measure ER or aspects of ER, their convergent validity for autistic toddlers has yet to be determined.

Objectives: In the current study, we aim to evaluate the convergent and divergent validity of three measures that index constructs within emotion regulation, to understand the variability in ER within autism.

Methods: Data were collected from 26 autistic children who participated in a study to understand challenging behavior, emotion regulation, and sleep in toddlers with Autism and typical development. The children were between the ages of 2-5 years old (M = 44 months, SD = 12 months), 69.23% male, and 38.46% white. Families completed the Vineland 3rd edition Coping Skills scale, the BREIF-P Emotional Control scale, and the EDI-YC Reactivity scale which were used to measure convergent validity. These measures were evaluated against a measure of non-verbal cognition (DAS-II or Mullen nonverbal developmental quotient) to assess divergent validity.

Results: The results indicated a significant positive correlation ($r = .56, p < .01$) between the EDI-YC reactivity measure and the Brief-P Emotional Control scale with a large effect size as indicated by a Cohen's d of 1.33. The measures were not significantly correlated with the Vineland- 3 coping skills measure, but the effect sizes were large ($ds = -.91$ and -1.07 respectively). There was a non-significant correlation of all three ER-related measures with the measure of nonverbal cognition.

Conclusions: We found mixed evidence for convergent validity across three ER measures commonly used with autistic children, as well as evidence for divergent validity (i.e., ER was not significantly correlated to an unrelated construct, nonverbal cognition). Specifically, there was stronger evidence for convergent validity for the two measures that evaluated the absence of ER skills (i.e., emotion dysregulation) in autistic children, than for the measure that assessed the presence of ER skills. Emotion regulation spans a broad skill set which may present a challenge in confirming convergent validity among the variety of ER-related measures available. These results provide initial support for understanding both the overlap and variability across measures of emotion regulation in young children with autism.

420.149 Understanding Variation in Provider Referral Rates to Early Intervention for Children with Developmental Delays

M. O. Reinitz¹, Z. Kilmer², G. Tangkilisan³, M. Solgi⁴, B. W. Sanders⁵, J. Junqua² and K. Zuckerman⁶, (1)Division of General Pediatrics, Oregon Health & Science University - CDRC, Portland, OR, (2)Oregon Health and Science University, Portland, OR, (3)Department of Pediatrics (Division of General Pediatrics), Oregon Health and Science University, Portland, OR, (4)School of Medicine, Oregon Health and Science University, Portland, OR, (5)Department of Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR, (6)Division of General Pediatrics, Oregon Health & Science University, Portland, OR

Background:

Early detection and treatment of developmental disabilities (DD), including Autism Spectrum Disorder (ASD), improves language, IQ, and adaptive outcomes. Guidelines recommend referral to Early Intervention (EI) upon positive ASD/DD screening in infant/toddler well child checks. However, children screening positive for ASD/DD are not always referred to EI.

Objectives: This project aimed to understand why pediatricians do and do not refer children with positive ASD/DD screens to EI.

Methods: We conducted qualitative interviews with pediatricians who participated in Autism ALERT, a pilot trial of family navigation for children with autism symptoms. We determined pediatrician EI referral rates after positive ASD or DD screeners using previously-collected data, then selected pediatricians with a range of referral rates for interviews. Interview guide questions probed the referral decision-making process; a Chart Stimulated Recall explored clinical management of 2 of the pediatrician's prior patient cases with positive screens. Transcripts were coded in Dedoose by 2 investigators using phenomenology; the coding framework was improved as themes emerged. Coding discrepancies were resolved by consensus.

Results:

15 pediatricians participated from 7 Oregon clinics (11 rural, 4 urban). Three themes influencing referral decisions emerged: (1) provider's clinical observations, (2) parental context, and (3) screening tool results (Figure, Table). The first theme, Providers' clinical observations, included having adequate time with child/family, clinical experience diagnosing DD, and trust building with parents.

The theme "parental context" included readiness for referral (influenced by competing resource strain, socioeconomic factors, and disability stigma) and level of parental concern surrounding developmental progress (based on prior family history and parental developmental knowledge).

The theme "screening tool results," included severity of result, and reliability in time-constrained/chaotic clinic settings, accuracy of parental inputs, and trialability of specific screener items. When these three themes were in alignment, the decision to refer was reported to be straightforward. When they were in conflict the decision to refer was more likely to be subject to providers' individual judgement.

Conclusions: Decisions to refer to EI services are complex, involving a balance between provider observations, parental contexts, and screening tool results. Understanding these complexities may raise awareness of barriers to referral and improve early referral practices.

420.150 Using Mobile Technology to Assess Age and Sex Differences in a Phenotypic Measure of Autism in a Large Cohort of Children from India and Malawi

E. H. Williams¹, N. M. Thompson¹, G. McCray², M. Crespo-Llado³, D. Gajria⁴, M. Belmonte⁵, A. Bennie⁶, S. Bhavnani⁷, S. Chandran⁸, T. Del Bianco⁹, G. Divan¹, M. Gladstone³, S. Gulati¹⁰, M. H. Johnson¹¹, E. Jones⁹, E. Mbale⁶, N. Midha⁷, D. Mukherjee¹², C. Namathanga⁶, R. Nkhata⁶, V. Harawa⁶, V. Patel¹³, A. Ranjan⁷, A. Singh⁷ and B. Chakrabarti¹⁴, (1)Centre for Autism, School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)School of Medicine, Keele University, Keele, United Kingdom, (3)Department of Women and Children's Health, Institute of Life Course and Medical Sciences, University of Liverpool, Liverpool, United Kingdom, (4)Child Development Group, Sangath India, New Delhi, India, (5)The Com DEALL Trust, Bangalore, INDIA, (6)University of Malawi, Blantyre, Malawi, (7)Child Development Group, Sangath, New Delhi, India, (8)Indian Institute of Technology-Bombay, Mumbai, India, (9)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (10)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, Ansari Nagar, New Delhi, India, (11)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (12)Indian Institute of Public Health, Public Health Foundation of India, Bengaluru, India, (13)Harvard Medical School, Boston, MA, (14)Centre for Autism, School of Psychology and Clinical Language Sciences, University of Reading, Reading, UNITED KINGDOM

Background: Reduced social attention is a well-established early feature of autism spectrum conditions (ASC) (Hedger et al., 2020). From birth, humans exhibit a preference for attending to social stimuli (e.g. faces). This attentional bias is a foundation for cognitive, social, and emotional development (Dubey et al., 2022; Portugal et al., 2024; Simion et al., 2015), and exists on a continuum throughout the general population, autistic individuals being over-represented in one tail of this distribution (Pierce et al., 2015; Frank et al., 2014). However, few studies have examined social attention in large, diverse populations across the entire early developmental period (0-6 years), with most data coming from European and North American samples.

Objectives: The STREAM project (Williams et al., 2024) has developed an open-source, scalable tablet-based app that can be administered by non-specialist workers to assess neurodevelopment in children using task-based measures of social, attentional, cognitive, and motor function. The present analysis uses a subset of data from the STREAM project, and explores the population distribution of social attention across early childhood in two large samples in India and Malawi.

Methods: N=3903 (India: n=1924; Malawi: n=1979; 49.5% female) children aged 0-6 years completed a preferential looking task administered using a tablet device. The task comprised 12 trials featuring side-by-side presentations of brief (4s) social and non-social videos (Dubey et al., 2023). Children passively watched the videos while their faces were recorded using the tablet's front-facing camera. The duration spent looking at the social and non-social stimuli was measured using a gaze classification technique (Chitnis et al., 2024), with social preference defined as the proportion of time spent looking at the social relative to the non-social stimuli.

Results: A Generalised Additive Model for Location, Scale, and Shape (GAMLSS) revealed a complex nonlinear relationship between social preference and age. Age-adjusted social preference scores were analysed via linear regression. Social preference was low in younger children, increased between 1-2.5 years, then plateaued until age 6. Girls demonstrated higher social preference than boys ($\beta = -0.16, p = 0.008$), with this difference widening between 1-2.5 years (8.6%), and stabilising at around 13.4% between 3.5-6 years (Figure 1). While social preference increased with age ($\beta < 0.001, p < 0.001$), this increase was significantly more pronounced in girls ($\beta < -0.001, p < 0.001$). These patterns were similar across cultures.

Conclusions: This study presents evidence for emerging social attentional bias in children across early development, in likely the largest sample to date. It highlights generalisable developmental patterns across two understudied cultures and reveals stable sex differences. These findings underscore the need to consider age- and sex-related variability to improve the sensitivity of this measure of social preference, building on similar paradigms used to identify autistic toddlers in USA (Moore et al., 2018; Pierce et al., 2016).

420.151 fNIRS As an Imaging Modality in Toddlers with Neurodevelopmental Conditions: A Feasibility Study

P. G. Srinivasan¹, S. Hamilton², G. K. Bell¹, S. Macari², K. Chawarska² and A. Vernetti², (1)Child Study Center, Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Child Study Center, Yale University School of Medicine, New Haven, CT

Background: Brain imaging studies using fMRI report promising results on the brain-behavior relationship in attention processing in autism (AUT) and other neurodevelopmental conditions (NDC). While task-based fMRI is effective in understanding the neural bases of behavior in older children, it is less feasible in young children. Functional near-infrared spectroscopy (fNIRS) demonstrates great promise, granting the ability to study brain activation patterns in young populations while awake and engaging in various tasks. While prior studies demonstrate success in utilizing fNIRS with infants and preschoolers with autism (Lloyd-Fox et al., 2013; Scaife et al., 2023), few studies have examined feasibility of implementing fNIRS with neurodiverse populations during toddlerhood, a period of rapid development and the earliest time when autism can be reliably diagnosed.

Objectives: 1) Present a toolbox of behavior and attention management strategies that can be implemented in fNIRS studies with neurodiverse toddlers; and 2) Evaluate the feasibility of signal acquisition and processing in neurodiverse toddlers.

Methods: Participants included 105 toddlers; 18 with AUT, 37 with NDC (e.g. language, motor delays), and 50 typically developing (TD) toddlers. Cortical activity was recorded using the NIRx NIRSport2 system as participants viewed a series of 8-second videos of an actress in which the presence of gaze and speech was manipulated. Our behavior and attention management toolbox includes a variety of tactics strategically implemented with toddlers, including child-friendly cartoons, attention getters, brief movie breaks, and experimenter guidance as needed to maintain and/or recapture participants' attention. Data were preprocessed with an in-house pipeline combining python-based MNE-fNIRS packages, a MATLAB-based global signal removal tool, R, as well as the channel-to-ROI specificity thresholds of the devFOLD toolbox for region of interest (ROI). Feasibility measures included participant retention rates after excluding participants (i) who refused to wear the fNIRS headgear (capping); (ii) whose data did not meet minimum attention requirements (>3 trials in at least 1 condition, due to fussiness or inattention); and (iii) who had poor data QC: <70% of optodes from the superior temporal gyrus (STG) regions with a scalp coupling index (SCI) threshold of 0.5.

Results: Amongst the 105 toddlers recruited for this study, 65 participants were included after the 3 stages of pre-processing: capping, attention, and data QC (Figure 1) leading to a retention rate of 65% of toddlers with and without autism. There was a high success rate with capping participants (AUT=78% (n=14); NDC=76% (n=28); TYP=84% (n=42)). Of these toddlers, many showed excellent attention to the screen (AUT=86% (n=12), NDC=68% (n=19), TD=93% (n=39)). Finally, the majority of those remaining contributed high-quality data (>70% of optodes from STG) (AUT=92% (n=11), NDC=89% (n=17), TD=95% (n=37)).

Conclusions: Participant loss due to capping, inattention and data quality was relatively low (35% attrition rate) in our study with neurodiverse toddlers. With retention rates comparable to previous studies of typically developing toddlers (30-55% attrition rate; Chiara et al., 2019; Hakuno et al., 2018), the current study establishes high feasibility of implementing fNIRS protocols with neurodiverse toddlers when utilizing a toolbox of behavior and attention management strategies.

420.152 Gut Microbiome Dysbiosis and Metagenomic Kynurenine Pathway Enrichment in Early Autism Spectrum Disorder
A. L. Carlson¹, **L. Patel²**, **L. Joseph³**, **L. Lopez⁴**, **C. Andreason⁴**, **C. Barnes⁴**, **E. Courchesne⁵**, **R. Knight⁶** and **K. Pierce⁴**, (1)Pediatrics, University of California San Diego, La Jolla, CA, (2)Bioinformatics and Systems Biology Program, University of California San Diego, San Diego, CA, (3)Department of Bioengineering, University of California San Diego, San Diego, CA, (4)Autism Center of Excellence, Department of Neurosciences, University of California San Diego, San Diego, CA, (5)Neuroscience, Eric Courchesne, San Diego, CA, (6)Department of Pediatrics, Center for Microbiome Innovation, Department of Computer Science and Engineering, University of California San Diego, San Diego, CA

Background: Preclinical research implicate a causal role for the microbiome in the development of autism through the microbiome-gut-brain axis. Clinical trials demonstrate improvement in autism symptoms after microbiome transplant from neurotypical donors. However, the development of the autism microbiome which underlie these findings remains poorly understood—with most studies conducted beyond critical periods of neurodevelopment.

Objectives: To determine the gut microbiome taxonomic composition and metagenome in early diagnosis of autism, and to test whether gut microbiome composition can predict autism diagnosis.

Methods: 83 subjects (20 typically developing, 63 autism; mean age 26 months; 65% male) completed neuropsychological testing, subphenotyping with eye tracking, and shotgun metagenomic sequencing of stool microbiome. Microbiome group differences were tested with a Bayesian inferential regression modeling computational framework (BIRDMAN). Machine learning via q2-sample-classifier tested if microbial taxonomic and functional profiles could predict diagnostic category.

Results: The autism group had significantly (credible interval exclusively negative or positive values) increased facultative anaerobic pathogens (Klebsiella, Enterococcus species) and decreased commensal obligate anaerobes (Prevotella, Dialister species). The low social/language attention eye tracking subgroup had a unique taxonomic profile with reduced Desulfovibrio desulfuricans. The autism microbial metagenome had significantly increased pathogenicity, antimicrobial resistance, and kynurenine metabolism genes favoring shunting toward neurotoxic product, quinolinic acid. Machine learning on metagenomic and KEGG orthology profiles predicted autism membership with AUC of 0.88 and 0.92, respectively.

Conclusions: This study provides novel microbiome metagenomic signatures of autism in the youngest prospective cohort to date. Findings support the need for future work to determine whether the gut microbiome can predict autism prior to neuroclinical diagnosis, and whether manipulation of the microbiome early in development is a therapeutic target in autism.

420.153 Development of the Core Characteristics of Autism: An Eye Tracking Study

J. M. Bebko¹ and **A. Porthukaran²**, (1)Psychology, (Ret) York University, Toronto, ON, Canada, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada

Background: Autism has been proposed to be a developmental response based on genetic variance interacting with environmental stimuli that manifests as a result of the child acquiring atypical learning experiences over time (Jones & Klin, 2013). The social domain is the primary area where the consequences of these learning experiences are manifested in autism (e.g., Constantino et al., 2017; Klin et al., 2015). If this process of accruing differences is accurate, then young children who have atypical learning experiences (e.g., not attending to age-appropriate social information) will first display differences that are most closely linked with the particular information that is missed. Core areas of identified difference have included eye contact (Zweigenbaum et al., 2015), gaze integration, and joint attention (Franchini et al., 2017).

Objectives: This study uses eye tracking to longitudinally predict specific areas of social difference. We hypothesized that differences in visual attention mechanistically lead to social differences, which results in observed behaviors that are at the core of autistic characteristics early in development. Eye tracking should predict the core areas of differences better than those areas that are more distal characteristics, as measured by clinician ratings on the Autism Diagnostic Observation Schedule (ADOS).

Methods: This dataset was accessed through the NIMH National Data Archive, from Volkmar & colleagues, (2007) ; there were 69 children identified as having a high risk (HR) and 32 children who were at a low risk (LR) of developing autism, tested at two time points: Time 1 mean age = 20.47 months, and Time 2 = 28.16 months. At Time 1, participants watched short videos clips of a woman performing a naturalistic caregiver interaction. Eye movements were tracked and areas of interest were identified to capture looking times in the following areas: mouth, eyes, the woman's body, or the background in the image. Participants were assessed using the ADOS at Time 1 and Time 2.

Results: The LR group spent a significantly higher proportion of their time looking at the woman's eyes, ($p = 0.004$) than the HR group, and vice-versa for the background, ($p = 0.001$). Eye-tracking was a significant predictor of ratings on the ADOS for eye contact at time 2 ($p = 0.036$), as well as gaze integration at both times ($p = 0.024$ and 0.013), and response to joint attention ($p = 0.002$ and 0.027). Eye-tracking was not generally a significant predictor of distal characteristics (e.g., imaginative play, gesture use, and giving).

Conclusions: Eye tracking in this task reflects attention to social stimuli, and different attentional patterns to informative social areas likely leads to a compounding of atypical learning experiences that lead, in turn, to some of the core differences seen in autism. Secondly, the findings suggest that the core differences in autism emerge in a manner interconnected with eye tracking, whereas other features of autism (i.e., the distal features) are less directly associated. Interventions that draw attention to socially relevant areas (e.g. eyes), while difficult to implement, may impact on the expression of core areas of autism.

420.154 Early Language Skills Explain Variance in Broad Behavioral Signs Indicating Likelihood of ASD in a Large Sample of Toddlers from the Developing Human Connectome Project (dHCP)

G. Arantes de Oliveira Campos¹, **K. R. Jobson²** and **I. Fishman³**, (1)Psychology, Brain Development Imaging Lab, San Diego State University, San Diego, CA, (2)Psychology and Neuroscience, Temple University, Philadelphia, PA, (3)Psychology, San Diego State University, San Diego, CA

Background: Studies with neurotypical infants suggest that language development might be contingent on and constrained by early reciprocal social engagement. Atypical language emergence and delays are, indeed, very common in autism spectrum disorder, which is characterized by difficulties with social engagement. However, the extent to which early language skills and social development are linked dimensionally is unclear.

Objectives: The goal of this study was to assess whether expressive and receptive language skills in toddlers are robustly linked to the behavioral signs indicating likelihood of ASD.

Methods: A subset of the large-scale and open-source data from the Developing Human Connectome Project (dHCP) was used in this study. Infants with no history of prenatal and neonatal problems or complications were recruited at St Thomas' Hospital, London (UK) and enrolled in the dHCP cohort. The final sample for the present analysis included 325 toddlers (146 females; *mean age* $\pm$ 19.0 *sd* = 1.8 months, *range* = 17-35 month) who were born at full-term (37 weeks or more). Receptive and expressive language scores for each child were obtained via administration of the Bayley Scales of Infant and Toddler Development, 3rd edition (BSID-III); the Quantitative Checklist for Autism in Toddlers (Q-CHAT) screener was administered to caregivers and will serve as a continuous measure of behaviors indicating likelihood of ASD. Sex differences in Q-CHAT scores were tested with an independent samples t-test. Backward stepwise multiple regression models were run separately for males and females, with all BSID-III scores, including motor and language skills, as well as mother's educational level, mother's and father's ages, and the child's age at testing as predictors and Q-CHAT scores as dependent variable.

Results: Replicating the known sex dimorphism effect, our results revealed that male toddlers had significantly greater Q-CHAT scores compared to female toddlers (*M females* = 29.7; *M males* = 32.2; *t* = 2.59, *p* = 0.01). Results of regression models revealed that early language abilities were ideal predictors of Q-CHAT scores in both male and female toddlers, with lower language skills significantly associated with greater Q-CHAT scores. Namely, in female toddlers, gross motor ($\beta = -0.66$, *p* = 0.04), expressive ($\beta = -0.66$, *p* = 0.02) and receptive ($\beta = -0.76$, *p* = 0.003) language skills, together, explained 26% of the variance in QCHAT scores (*adjusted r*²: 0.26, *p* < 0.001). In male toddlers, expressive ($\beta = -0.97$, *p* < 0.001) and receptive ($\beta = -1.22$, *p* < 0.001) language skills explained 36% of the variance in QCHAT scores (*adjusted r*²: 0.36, *p* < 0.001). Figure 1 illustrates the relationship between language skills and Q-CHAT scores in the entire sample.

Conclusions: These results demonstrate a clear relationship between early language skills –assessed with clinician-administered developmental measures – and broad behavioral signs considered to be indicative of ASD likelihood (reported by caregivers) in a large population-based cohort of toddlers. Although the average Q-CHAT scores were below the clinical cut-off (<39) in this cohort, children who scored above the cut-off on this autism screener had lower expressive and receptive language skills.

Poster Session

421 - High Support Needs or Profound Autism I

May 2nd, 2025, 12:30 PM - 1:30 PM - Hall 4A

421.155 The Relationship between Cognitive Abilities and Progress in Knowledge Acquisition and Functional Skills Among Autistic Adults with High Support Needs

M. Melamed^{1,2}, **E. Ben-Itzhak**³, **Y. Mazan**⁴, **Y. Schindler**⁴ and **D. A. Zachor**⁵, (1)The Autism Center, ALUT - The Israeli Society for Autistic Children and Adults, Givatayim, Israel, (2)The Bruckner Autism Research Center, Ariel University, Ariel, Israel, (3)Bruckner Center for Autism Research, Department of Communication Disorders, Ariel University, Ariel, Israel, (4)The intervention unit for adults with Autism spectrum disorder, The Autism Center/ ALUT, Givatayim, Israel, (5)ALUT The Israeli Society for autistic children, Tel-Aviv, Israel

Background:

Our previous research has demonstrated the efficacy of the Teaching Model (TM), an innovative intervention implemented in classroom settings for autistic adults with high support needs (HSN). The program promotes knowledge acquisition and functional skills enhancement. This study aims to examine the relationship between cognitive abilities and the outcomes of the TM intervention.

Objectives:

1. To evaluate the relationship between nonverbal and verbal cognitive abilities and the acquisition of new knowledge following the TM intervention among autistic adults with HSN.
2. To assess the relationship between nonverbal and verbal cognitive abilities and the enhancement of functional skills.

Methods:

The study included 70 participants (21 females), aged 23 to 57.6 years ($M=33.89/SD=8.49$), all previously diagnosed with autism, residing in sheltered frameworks for autistic adults with HSN, and received the TM intervention. Adaptive skills were assessed using the Vineland Adaptive Behavior Scales, and autism trait intensity was measured using the Social Responsiveness Scale. Cognitive assessments included the Test of Nonverbal Intelligence (TONI) for nonverbal reasoning ability and the Peabody Picture Vocabulary Test (PPVT-5) for language comprehension. The TM courses covered various topics, while integrating functional skills training. Knowledge acquisition was measured through course-specific assessments, while functional skills enhancement was evaluated across domains of social-communication, adaptive behaviors, and classroom-related independent skills. Data were collected at pre (T1) and post-intervention (T2) times.

Results:

Based on the median scores for the TONI and PPVT, participants were divided into high and low score groups. For knowledge acquisition, a 2x2 ANOVA for the TONI revealed a significant main effect for time ($p=.04$) and a significant time x group interaction ($p=.01$). Both TONI groups showed significant improvement from T1 to T2 ($p<.001$), with the low score group exhibiting a more pronounced effect. A similar analysis for the PPVT demonstrated significant main effects for time ($p=.03$) and group ($p=.001$), with a significant time x group interaction ($p=.01$). Both PPVT groups also showed significant improvements ($p<.001$), with the low score group exhibiting a more pronounced effect. Functional skills improved over time ($p<.001$) without significant differences between TONI or PPVT groups. Hierarchical linear regression analyses for predictors of knowledge acquisition were non-significant. However, regression analyses for skills assessment yielded significant results only in the social-communication domain. The model explained 72% of the variance in T2 social-communication scores, with T1 social-communication scores as the strongest predictor ($\beta=.82$, $p<.001$), while PPVT scores also made a significant contribution ($\beta=.31$, $p=.004$).

Conclusions:

Regardless of nonverbal or verbal cognitive abilities, participants improved in knowledge and functional skills following the TM courses. Notably, participants with lower TONI and PPVT scores showed the most significant gains in knowledge acquisition. Improvements in functional skills were observed across the entire cohort, independent of cognitive abilities. Additionally, verbal cognitive ability, as measured by PPVT scores, emerged as a significant predictor of enhanced social communication skills, underscoring its role in social skills acquisition. These findings highlight the potential for meaningful learning among autistic adults with HSN, especially for those with more pronounced cognitive impairments.

421.156 AI-Based Analysis and Classification of Communicative Nonverbal Vocalizations of Non- and Minimally-Speaking Individuals

S. B. Shah¹ and **K. T. Johnson²**, (1)Department of Electrical and Computer Engineering, Northeastern University, Boston, MA, (2)Northeastern University, Cambridge, MA

Background: Non- and minimally-speaking individuals with profound autism use nonverbal vocalizations like cries, grunts, and hums to express communicative functions like emotions, requests, and rejection. These vocalizations are readily understood by the individuals' caregivers but are often misinterpreted by unfamiliar individuals and standard speech-processing systems, necessitating caregiver input to accurately annotate these samples. The Rapid Online Sample of Communication (ROSCO) data collection protocol captures communicative acts from these individuals in naturalistic settings and labels them through input from their caregivers. This data can help train machine learning (ML) models to enable real-time vocalization classification in the absence of caregivers.

Objectives: This study aims to use an ML model to classify the communicative functions of nonverbal vocalizations from non- and minimally-speaking individuals. The ultimate goal of this work is to aid the development of automated augmentative technologies that can respond organically to the unique vocalizations of this population.

Methods: We analyze 25 ROSCO sessions from 21 non- and minimally-speaking individuals (age=2-12 years) with Phelan McDermid Syndrome (n=17), Tuberous Sclerosis Complex (n=3), and PTEN Hamartoma Tumor Syndrome (n=1). Vocalizations constituted 29% of observed communicative expressions, producing a dataset of 591 vocalizations across 6 communicative functions (Emotions:37% of all samples, Self-Directed Behaviors:18%, Requests:18%, Comments:12%, Rejections:11%, Social Interactions:4%). The vocalizations were augmented through noise addition, pitch-shifting, time-shifting, and time-stretching to increase sample diversity. These samples are converted into mel-spectrograms with 128 mel bands using the librosa library in Python. The Vision Transformer model is used to learn the spatial relationships within these mel-spectrograms and convert them into latent representations (dim=24). A mean vector for each class in the dataset is calculated from these latent representations for analysis and comparison. Cosine similarity is used as a quantitative metric to measure the similarity between these mean vectors.

Results: The dataset's small size combined with the significant class imbalance (Imbalance Factor=8.69) leads to relatively subpar classification performance (Acc=28.39; F1=26.34). Sample augmentation substantially improves performance (Acc=49.41; F1=43.43), indicating a lack of sample size and diversity for different classes. Request was the most globally similar function (Avg. CS=0.965), indicating a mix of affective and communicative signals within this function, while the expression of various emotions was the most globally dissimilar (Avg. CS=0.930), possibly because its larger sample size and range of affective expressions led to distinctions in the latent space. Existing speaker diarization models failed to distinguish nonverbal vocalizations from sounds produced by caregivers or augmentative and alternative communication (AAC) systems, limiting the utility of this type of data.

Conclusions: While traditional ML models are poor at processing nonverbal vocalizations from non- and minimally-speaking individuals, this study lays the groundwork for new models that can classify the sounds from small, heterogeneous samples. Future work will create novel ML algorithms to improve classification accuracy for this underrepresented data, which may be applicable as objective outcome measures for clinical interventions designed for these individuals. This research also aims to foster the development of vocalization-activated augmentative technology that increases interactions and understanding between non-speaking individuals and the general public.

421.157 Access to Augmentative and Alternative Communication Among Families of Minimally Verbal Children with Autism Spectrum Disorder

M. Hare, S. Jeste, E. McFadd and C. DiStefano, Children's Hospital Los Angeles, Los Angeles, CA

Background:

Approximately 30% of individuals with autism spectrum disorder are minimally verbal, meaning they have little to no spoken language (Tager-Flusberg & Kasari, 2013). Augmentative and Alternative Communication (AAC) refers to a variety of methods that help these individuals communicate. AAC has been shown to increase a minimally verbal individuals' capacity to communicate and promote further spoken language (DiStefano et al., 2016). However, families often report challenges accessing the devices. Past research has shown that children with autism, whose parents' primary language is not English have fewer services hours per week and are less likely to have communication skills goals listed on their individual education plans (St. Amant et al., 2018).

Objectives:

To investigate if home language is associated with AAC access. We hypothesize that families who speak a language other than English at home will report lower rates of AAC access than English-only speaking families

Methods:

A survey was sent to the families of 4,314 patients in the CHLA health system with a diagnosis of autism aged 3-18. The survey asked about access, use, and barriers to AAC and was available in English and Spanish. 475 families responded to the survey; 106 families reported their child as minimally verbal continuing onto the full survey. Access to AAC was compared using a chi-square test.

Results:

Responses were compared between families who reported speaking a non-English language at home (primary or secondary) (N=57), and families who only spoke English at home (N=39). There was a significant relationship between home language and AAC access, $\chi^2(1, N = 96) = 9.86, p < 0.01$. 64% of families in the English only group have had access to AAC, while only 32% of families in the other language group have had access to AAC (see attached figure). 56% of families in the other language group reported that they had limited knowledge of AAC prior to the survey. A two-sample t-test confirmed there was not a significant difference in age of access, $t(41) = 0.25, p = 0.80$.

Conclusions:

The results above suggest that families of minimally verbal children who speak a language other than English at home may have less access to AAC compared to their English-only counterparts, unrelated to age of acquisition. Additionally, most families without access did not have prior knowledge of AAC, meaning that they could not advocate for these devices. This suggests that families who are not introduced to these devices at the same time as their English only counterparts miss out on the intervention altogether. This is significant concern as 55% of families in Los Angeles County speak a language other than English at home (*Los Angeles County, California - Census Bureau Profile*, n.d.). This discrepancy could be a result of language barriers between the families and school and healthcare professionals, which has been found to be a significant challenge when accessing other autism services (Lim et al., 2021). Future research should be aimed at investigating the causes of this discrepancy and improving access to AAC.

421.158 Augmentative and Alternative Communication: Diverse Caregiver Perspectives on Access and Implementation

S. Jacobs, F. Menendez, S. Jeste, E. McFadd and C. DiStefano, Children's Hospital Los Angeles, Los Angeles, CA

Background: Augmentative and alternative (AAC) interventions are effective for increasing communication in children with profound autism and may promote spoken language development (DiStefano et al., 2016; White et al., 2021). However, many individuals do not have access to AAC systems or are not provided with necessary ongoing support. A recent systematic review identified numerous barriers to AAC utilization, including limited access to AAC systems and a paucity of individuals trained to provide intervention (Donato et al., 2018). Little research exists on how demographic factors that are associated with disparities in autism diagnosis and care (e.g. race/ethnicity, primary language, socio-economic status) influence AAC access and use (Pham and Charles, 2023). We sought to understand how caregivers from underrepresented communities perceive the barriers and facilitators they have experienced in obtaining AAC support for their children.

Objectives: Our objective was to identify barriers and facilitators to AAC access and implementation within a diverse group of children with profound autism, via semi-structured interviews with caregivers.

Methods: 12 caregivers were recruited from an outpatient neurogenetics clinic at a large, metropolitan children's hospital serving a highly diverse patient population (40% uninsured, 35% Medicaid-eligible, 65% Latino, 70% non-white). See Table 1 for participant information. Semi-structured interviews were conducted with caregivers to elicit their experiences with initial introduction to AAC, the evaluation process, barriers and facilitators to device acquisition, and ongoing implementation. Interviews were audio-recorded, transcribed and coded for themes using inductive methods (Braun and Clarke, 2006).

Results: Regarding barriers and facilitators to access, several themes emerged (Table 2), with two predominating: (1) the role of service providers (primarily speech language pathologists) as either a barrier or facilitator to device acquisition and engagement, and (2) caregiver research and advocacy. 92% of caregivers discussed school-based providers and half discussed private providers. 58% of caregivers identified that their child's school providers were a barrier to accessing AAC (e.g. did not feel that the child was ready), while 42% identified them as facilitators (e.g. advocating for AAC system introduction). 83% of caregivers reported self-directed research and advocacy, with half noting guidance from online resources and one third seeking legal representation.

Conclusions: Our sample of caregivers frequently identified school-based personnel as either a barrier or facilitator to AAC device acquisition and implementation. While prior research has identified providers (particularly speech-language pathologists) as instrumental in supporting AAC access, our results suggest that school-based providers may be especially relevant for diverse families. Further research is needed to explore whether this focus on school-based providers is due to lower utilization of private/clinic-based providers, or other factors. Additionally, our data extends existing caregiver engagement research by suggesting that caregivers from underrepresented groups are engaging in high rates of advocacy in order to access AAC. Future steps should (1) consider the perspectives of school personnel and examine school systems to understand differences in approaches and why barriers may be arising and (2) explore what informational outlets caregivers are most accessing to discern their credibility and engage families in discussions regarding evidence-based guidelines of AAC usage.

421.159 Autism-Related Stigma Experienced By Parents of Minimal Speaking and Verbal Autistic Children in India

S. Suswaram¹, S. Dababnah², M. Sundarajan³, T. V. Bhupathiraju⁴, K. Sun⁴, R. Ghandi⁴, R. Meyer⁵, A. Bhattashali⁶, G. Cheatham⁷ and K. Long⁵, (1)Carolina Institute for Developmental Disability, University of North Carolina at Chapel Hill, Carrboro, NC, (2)University of Maryland School of Social Work, Baltimore, MD, (3)University of the Pacific, Stockton, CA, (4)Psychological and Brain Sciences, Boston University, Boston, MA, (5)Boston University, Boston, MA, (6)University of Kansas, Lawrence, KS, (7)Special Education, University of Kansas, Lawrence, KS

Background:

Autism-related stigma (hereon stigma) significantly affects the quality of life (QoL) of autistic children and their parents, particularly those with high support needs, such as minimally speaking autistic children. In India, stigma can limit social supports, a crucial aspect of child-rearing, thereby greatly impacting a family's QoL. However, our understanding of these effects is limited. To develop tailored interventions that can support Indian autistic children and their parents, it's essential to explore and understand the nature and impact of this stigma on QoL.

Objectives:

To qualitatively explore parents' experiences with stigma and its impact on QoL in parents of minimally speaking and verbal autistic children in India.

Methods:

Parents of autistic children (N = 10) completed semi-structured interviews (140-180 minutes) focusing on understanding parents' experience of parenting an autistic child in India. Data from the interviews were systematically coded and analyzed using applied thematic analysis stratified by parents' reported child communication abilities (minimally speaking and verbal). Results specific to experiences with stigma are presented in this presentation.

Results:

Three themes were identified. First, all parents reported facing stigma from family, friends, and others. They were blamed and judged for their child's condition, attributed autism to parents' "bad karma." The child was treated as "untouchable," and socially ignored and neglected. Second, factors related to the child (e.g., support needs), the parent (e.g., education, quality of marital relationship), and the context (e.g., stigma from family vs. strangers) influence how parents respond to stigma. For example, parents who experienced stigma from close family and friends identified their children as minimally speaking, even though nine out of the ten children were minimally speaking based on clinical judgment. Third, the combined effect of stigma and parental responses had social, emotional, and health (biopsychosocial) consequences for both parents and their child. For example, parents described loneliness, strained marital relationships, decreased opportunities for respite, and negative effects on their health and parent-child relationships. Stigma from close relations was more pervasive and impactful, leading to greater biopsychosocial consequences that significantly affected child development and wellbeing.

Conclusions:

Autistic children and their parents faced pervasive stigma, which manifested as blame towards parents and derogatory treatment of children, greatly affecting family dynamics and parents' social lives. The consequences were intensified when stigma came from close relations, leaving families without familial support (e.g., respite). This potentially led parents to internalized stigma and lower expectations for their child, which was further affected by a lack of structural supports (e.g., autism awareness, parent training) in India. Parents' prolonged self-reliance with limited social and structural support might have lasting negative effects on parents and, by extension, on child development, highlighting an area for future research. The study underscores the critical role of social support in fostering resilience and mitigating adverse effects of stigma in India. Findings from this study have implications for caregiver experiences in other countries with similar social contexts and indicate a need not only for widespread education about autism but also for deliberate creation of social and structural supports.

421.160 Characterizing IQ-DLS Discrepancies from Ages 2-25 in Autistic Individuals with Co-Occurring Intellectual Disability

E. B. Clarke¹, C. Lord² and V. H. Bal¹, (1)Graduate School of Applied and Professional Psychology, Rutgers University - New Brunswick, Piscataway, NJ, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

Background: Many autistic individuals exhibit lower daily living skills (DLS) than would be expected based on their intellectual quotient (IQ) (Kanne et al., 2011). There is limited understanding of why this IQ-DLS discrepancy exists (Duncan & Bishop, 2015). Existing work is cross-sectional, has focused on autistic individuals with average or higher IQs, and has not examined discrepancies by subdomain (i.e., DLS specific to personal care, household tasks, and community skills). Autistic individuals with co-occurring ID are often excluded from research, but IQ-DLS discrepancies exist in this subgroup also (Teh et al., 2023).

Objectives: To provide a deeper understanding of the IQ-DLS discrepancy in autistic individuals with ID by exploring trajectories of IQ-DLS discrepancies by DLS subdomain (i.e., personal, domestic, community) from ages 2-25 in a well-characterized longitudinal sample.

Methods: IQ and DLS data were collected from 107 participants with autism and IQ < 70 at ages 2, 3, 5, 9, 14, 18, 21, and 25. IQ was measured via the Mullen at age 2; later assessments were selected from a standardized hierarchy based on participants' developmental abilities. DLS was measured using the Vineland Adaptive Behavior Scales (VABS) and analyzed at the subdomain level (i.e., Personal, Domestic, Community). IQ-DLS discrepancy scores were calculated by subtracting DLS subdomain age equivalents from mental ages derived from cognitive tests. Group-based trajectory analyses were conducted via Stata 17; AIC, BIC, and smallest group percentage were used to determine the best-fitting models.

Results: IQ-DLS discrepancy trajectories varied across DLS subdomains (Figure 1). For the Personal subdomain, a three-group model best fit the data (Figure 1). The first group, Low-Decreasing, was characterized by steeply declining IQ-DLS scores from early childhood into early adulthood; scores slightly increased in participants' mid-twenties. The Mid-Decreasing group was characterized by declining discrepancy scores, and the High-Stable group was characterized by discrepancy scores that changed little with age. A two-group model was the best fit for the Domestic subdomain. These two groups, Low-Decreasing and Mid-Decreasing, showed similar growth patterns to the same-named Personal subdomain trajectory groups (Figure 1). Finally, a one-group model characterized by shallow declines in discrepancy scores best fit the Community subdomain. For the Personal subdomain, African American participants were more likely to be in the Mid-Decreasing trajectory group. Otherwise, descriptive characteristics did not vary between trajectory groups (Table 1).

Conclusions: These results underscore the importance of considering DLS subdomains separately when studying the IQ-DLS discrepancy, as each subdomain showed different patterns of change. For all subdomains, most participants in this sample had IQ and DLS abilities that were commensurate (i.e. discrepancy scores close to zero). However, a small subgroup of individuals showed considerable development of Personal and Domestic DLS, as evidenced by increasingly negative IQ-DLS discrepancy scores. Consistent with other studies, findings suggest ongoing development of DLS through adolescence, but a relative slowing in young adulthood, likely underscoring a need for ongoing opportunities for adults to continue to learn and develop DLS. Follow-up analyses are underway to examine IQ-DLS discrepancy trajectories in autistic individuals with IQ $\geq$ 70.

421.161 Comparing Demographic and Clinical Correlates of Self-Injurious Behaviors of Varying Intensity and Impact in Autism

E. F. Ferguson¹, A. Y. Hardan², M. Uljarevic² and E. Spackman¹, (1)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (3)Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA

Background: Self-injurious behaviors (SIB) vary widely in form and intensity, with some behaviors greatly increasing the likelihood of immediate physical injury or hospitalization. Identifying factors that predict more immediately harmful manifestations of SIB is crucial for providing targeted and effective support. In particular, it has been theorized that distress dysregulation (e.g., distress related to changes in routines), sensory processing differences, lower communication abilities, and lower socio-economic status (SES) are associated with SIB in autism. However, it is unknown whether these features are differentially associated with SIB that may result in accrued injuries due to repetition (SIB-accrued, e.g., hair-twirling) and SIB that may be immediately injurious (SIB-immediate, e.g., head-banging).

Objectives: To explore the relative contributions of distress related to disruptions to routines (i.e., distress dysregulation), sensory symptoms, age, sex, speech level, and SES in the context of two categories of SIB differentiated based on potential for injury, SIB-accrued and SIB-immediate.

Methods: Parents of 1,892 autistic children and adolescents aged 3-19 years (22% females; 12.6% IQ < 70) were recruited through Simons Foundation Powering Autism Research for Knowledge (SPARK) to complete online questionnaires. Measures included the Sensory Experiences Questionnaire (SEQ-3.0), and the SIB and Insistence on Sameness (IS) subscales of the Dimensional Assessment of Restricted and Repetitive Behaviors (DARB). SIB items were divided into two conceptual categories: SIB-accrued and SIB-immediate. Distress dysregulation was assessed using items that captured the child's level of distress linked to endorsed IS items (e.g., Does she/he get upset if this routine is not followed?).

Hierarchical multiple linear regressions were conducted to examine unique predictors of SIB-accrued and SIB-immediate. For each model, age, sex, speech level, and SES were entered in step 1, IS distress in step 2, and sensory hypersensitivity, hyposensitivity, and seeking in step 3.

Results: Overall, the full model accounted for 23.5% of the variance in SIB-accrued, with age ($t = 7.97$), IS distress ($t = 7.07$), sex ($t = 5.19$), hypersensitivity ($t = 4.89$), and sensory-seeking behaviors ($t = 4.77$) demonstrating the strongest associations with SIB-accrued ($F(8,1548) = 59.49$, $p < .001$). Additionally, the full model accounted for 21.7% of the variance in SIB-immediate, with IS distress ($t = 8.75$), sensory-seeking behaviors ($t = 5.90$), household income ($t = -4.88$), speech level ($t = -4.56$), and hypersensitivity ($t = 3.08$) showing the strongest associations with SIB-immediate ($F(8,1548) = 53.65$, $p < .001$).

Conclusions: Findings demonstrate the complexity of SIB and highlight the need to further characterize the heterogeneity in SIB presentations.

Lower speech level may contribute to greater severity of SIB types that result in immediate physical injury or hospitalization, highlighting the importance of assessing SIB at a more granular level to identify autistic subpopulations in need of greater support. Female (sex) was associated with greater severity of SIB-accrued, while sex differences were not observed in the severity of SIB-immediate. Finally, IS-related distress dysregulation, sensory-seeking, and hypersensitivity demonstrated strong associations with both SIB-accrued and SIB-immediate. Findings underscore the importance of identifying factors that predict more immediately harmful manifestations of SIB to inform more targeted prevention and intervention efforts.

421.163 Development of a Person-Centered Coding Framework to Assess Multimodal Communication in Non-Speaking Individuals

L. Thompson¹ and K. T. Johnson², (1)Speech and Hearing Sciences, Washington State University, Spokane, WA, (2)Northeastern University, Cambridge, MA

Background:

Non- or minimally-speaking individuals with complex neurodevelopmental disorders (NDDs) often use multimodal communication, including non-speech vocalizations, gestures, body movements, facial expressions, and augmentative technology. Caregivers, familiar with these nuanced behaviors, provide valuable insights that are rarely incorporated into standardized assessments. As a result, traditional tools often fail to capture the full range of communication, leading to low assessment scores and hindering accurate characterization, progress monitoring, and the development of reliable outcome measures.

Objectives:

This project identifies and defines patterns of communication identified by caregivers but often missed by traditional assessments, creating a coding framework that clinicians can apply to capture the full range of communicative behaviors in non-speaking individuals with complex NDDs.

Methods:

Participants in the study completed a new remotely administered natural communication sampling paradigm called ROSCO (Rapid Online Samples of Communication) which consists of semi-structured developmentally appropriate activities with a caregiver administered via a video platform such as Zoom. A follow-up Post-ROSCO Interview is completed remotely between the caregiver and the researcher after completion of the ROSCO session. After reading a script of instructions, the examiner conducts the interview, pausing the recorded ROSCO session every 10 seconds. At each pause, parents indicate whether their child attempted to communicate or "send a message" during that time. They describe the behaviors used to convey the message, such as vocalizations, gestures, facial expressions, or body movements, and identify the communicative function (e.g., requesting, rejecting, commenting, or expressing emotion). Importantly, the instructions provided and interview process do not provide constraints on the behaviors or functions that caregivers can identify. Caregivers then rate their confidence in whether the behavior was intended as communication using a 5-point Likert scale. Participant descriptives are presented in Table 1.

Results:

In our pilot data, caregivers have described behaviors not typically included in early communication frameworks such as repetitive shirt rubbing, idiosyncratic mouth opening, or inaction as a form of communication. They rate behaviors as communicative that would not meet traditional definitions of directness (e.g., lacking coordination of gaze or other communicative behavior) as clearly intended for the caregiver, often with a high level of confidence. Additionally, caregivers have described that these behaviors often carried nuanced communicative functions beyond the traditional categories (e.g., behavior regulation, joint attention) such as self-stimulation or self-soothing. We are currently analyzing these patterns using formal analysis and clinical judgment to refine communication categories with precise terminology. Parent confidence ratings will guide this process, with lower-confidence behaviors reconsidered to ensure clear categorization.

Conclusions:

The initial findings highlight the need for a strength-based, person-centered approach to capturing the use of multimodal communication in non-speaking individuals with NDDs. By integrating caregivers' unique perspectives and allowing them to identify and describe their child's nuanced communication strategies, ROSCO bridges gaps in traditional assessments. This framework offers a promising new way to characterize multimodal communication that clinicians can implement as a first step towards better characterization, progress monitoring, and the development of reliable outcome measures for this population.

421.165 Examining Self-Injurious Behavior Severity and the Dysregulation Profile in Young Autistic Children

J. P. Boyle¹, C. W. Nordahl², B. Heath³, O. J. Surgent⁴, A. Dakopoulos⁴, S. J. Rogers⁵, M. Solomon² and J. K. Lee¹, (1)Psychiatry & Behavioral Sciences, M.I.N.D. Institute UC Davis, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (3)The University of Wisconsin-Madison, Madison, WI, (4)Teachers College, Columbia University, New York, NY, (5)Department of Psychiatry and Behavioral Sciences, University California Davis, Sacramento, CA

Background: Self-injurious behaviors (SIB) represent a significant area of concern and challenge for many autistic individuals. Up to 50% of autistic individuals engage in SIB at some point in their lives. Some evidence demonstrates links between SIBs and limited expressive language, lower cognitive abilities, higher rates of anxiety, elevated autism severity scores, and increased aggression. Dysregulation of emotional and physiological responses have also been widely implicated in the onset and persistence of SIB in neurotypical individuals and may be an important component to better understand severity of SIB in autistic children in early development.

Objectives: 1) To establish SIB severity as a way to measure the impact of SIB in autistic individuals. 2) to examine the contribution of dysregulation to SIB severity among autistic children between 2-4 years of age.

Methods: In this study, we analyzed SIBs among 320 (n = 213/107 (m/f); *mage* = 3.1 years, *sd* = 6.1 months) autistic children. Diagnoses were confirmed using the Autism Diagnostic Observation Schedule 2nd Edition (ADOS-2) and Autism Diagnostic Interview – Revised (ADI-R) administered by licensed clinical psychologists. Developmental level was assessed using the Mullen Scales of Early Learning (MSEL). SIB was assessed using the Repetitive Behaviors Scale-Revised (RBS-R) in which parents rate the severity of 8 SIBs on a 0-3 point likert scale, 3 indicating the behavior is a severe problem. We subdivided the cohort into four severity groupings of SIB based on their highest rating for any SIB. We then assessed dysregulation by averaging scores from CBCL subscales of attention, anxious/depressed, and aggressive behavior.

Results: Subgrouping by severity level of SIB resulted in 27% of participants in the no endorsement group (n = 87, 56 male/31 female), 35% in the mild group (n = 111, 71 male/40 female), 25% in the moderate group (n = 80, 54 male/26 female), and 13% in the severe group (n = 42, 32 male/10 female). An ANCOVA controlling for DQ revealed that the dysregulation profile score differed between SIB groups. Higher levels of dysregulation were observed in the groups with more severe SIBs $F(3,296) = 19.660, p < 0.001$. DQ was not a significant predictor in the model ($F(1,296) = 2.965, p = 0.09$). Tukey HSD post-hoc analyses indicated significant differences in dysregulation between the severe endorsement group ($M = 66.36$) and each of the other groups: no endorsement ($m = 56.81; p < 0.001$); mild ($m = 59.42; p < 0.001$), and moderate ($m = 62.21; p = 0.01$). In addition, the moderate group had significantly higher dysregulation scores compared to the no endorsement group ($p < 0.001$), and relatively higher dysregulation compared to the mild group ($p = 0.042$).

Conclusions: The present study offers an innovative approach to measure the severity of SIB which may better characterize overall impairment/impact of SIB compared to other scoring methods. We found that dysregulation was associated with increasing SIB severity above and beyond the contribution of developmental level. These findings indicate that dysregulation is an important predictor of SIB severity in very young autistic children, providing a potential target for early intervention.

421.167 Exploratory Comparison of Caregiver Report and Clinical Communication Coding for Non-Speaking Individuals with Profound Autism

E. E. McGonigle¹, L. Thompson², M. Kannisto¹ and K. T. Johnson³, (1)Northeastern University, Boston, MA, (2)Speech and Hearing Sciences, Washington State University, Spokane, WA, (3)Northeastern University, Cambridge, MA

Background: Individuals with profound autism often have complex communication profiles, utilizing multiple modes of communication. The Communication and Symbolic Behavior Scales (CSBS) quantifies communication using a developmental framework for early communicative skills; however, complex communication profiles may not be fully captured by this or similar clinically validated measures. Caregiver input can be a valuable tool in understanding less conventional, highly idiosyncratic communication. The Rapid Online Sample of Communication (ROSCO) paradigm is a new natural communication sampling protocol involving 15 minutes of in-home semi-structured caregiver-child interactions, remotely recorded over Zoom. Then, a researcher conducts a structured interview with the caregiver while rewatching the recorded ROSCO session together. Caregivers label communicative actions and provide a confidence rating (CR) on a 5-point Likert scale, with 1 indicating full confidence the act was communicative or meant to "send a message" to them, and 5 indicating it was self-directed.

Objectives: This exploratory analysis compared communicative acts described by caregivers to those captured by the existing CSBS coding framework.

Methods: Caregiver interviews were transcribed and time-synchronized to ROSCO video sessions using ELAN (n=3; 5-9y; 2M:1F), creating a coded dataset of communicative actions, functions, and caregiver confidence ratings. Participants displayed a range of communication skills, from traditionally recognized communication behaviors, to more nuanced communicative methods such as eye gaze and body movement. These videos were also coded by a trained administrator, who was blind to the caregiver interview, using the established CSBS framework. The outputs from the caregiver-informed and blind CSBS coding methods were compared manually. Results were categorized as "Congruent" when caregiver labels matched CSBS outputs and "Incongruent" when they disagreed. CRs of 4 or 5 were excluded. Counts and percentages of "incongruent" and "congruent" labels with CRs of 1-3 were calculated for the overall group.

Results: We found 70 "congruent" and 111 "incongruent" communicative behaviors from this preliminary sample (see figure). 90% of congruent behaviors were ones that caregivers had rated as being communicative with high confidence (CR=1 or 2), while 10% of the agreements had a neutral CR of 3. Surprisingly, 73% of behaviors identified as communicative by caregivers but not coded by the CSBS framework had a CR of 1 or 2; 27% had a CR of 3. Overall, caregivers described 61% more communicative acts than the CSBS.

Conclusions: While CSBS codes were congruent with caregiver reports 90% of the time, 61% of caregiver-identified communicative behaviors were not accounted for in the existing framework. Communication involving gestures, vocalizations, and touching were generally congruent between caregivers and the CSBS framework. However, caregivers often identified eye-gaze and AAC usage alone as communicative behaviors whereas the CSBS requires a paired action to be considered a communicative act. Emotional expressions and other subtle actions that elicit caregiver response are also not generally recognized as communicative in traditional frameworks. Future work will expand this preliminary analysis to a larger collected sample of 33 ROSCO sessions, and will work towards new communication coding frameworks that capture more nuanced and representative forms of communication using person-centered methods.

**421.168** Facing Your Fears in Autistic Adolescents with Intellectual Disability and Anxiety: A Randomized Controlled Trial

A. Blakeley-Smith¹, J. Reaven², R. E. Boles³, L. Hayutin¹, N. Reyes⁴, C. Middleton³, L. Olson⁵, E. Glenn⁶, K. Cosgrove⁷, R. Sandercock⁸ and A. T. Meyer⁹, (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)University of Colorado Anschutz Medical Campus, Aurora, CO, (4)University of Colorado, Anschutz Medical Campus, Aurora, CO, (5)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (6)University of Oregon, Eugene, OR, (7)CU Anschutz, Denver, CO, (8)Children's Hospital of Philadelphia, Philadelphia, PA, (9)JFK Partners, University of Colorado School of Medicine, Aurora, CO

Background: Autistic teens with intellectual developmental disability (IDD) often experience clinically interfering anxiety (Winch et al., 2022), reduced access to evidence-based mental health care, and significant health inequality (Doherty et al., 2020). Facing Your Fears (FYF), a manualized 14-week group Cognitive Behavior Therapy (CBT) intervention for anxiety in autistic youth (Reaven et al. 2011), was adapted for autistic teens with ID (FYF:IDD); results of a pilot study were promising (Blakeley-Smith et al., 2021). The present study is a more rigorous, randomized controlled trial (RCT) examining the efficacy of FYF:IDD relative to Treatment as Usual (TAU) for anxiety reduction and change in mood/emotion regulation and behavioral difficulties.

Objectives: To conduct an RCT with autistic teens with IDD and anxiety and examine: 1) anxiety reduction (primary outcome), and 2) mood, emotion regulation, and behavioral difficulties (secondary outcomes).

Methods: Seventy-three autistic teens with IDD participated in the study (72.6% male; 26% Hispanic, 72.6% white; ages 12-18 (M=15.3)). Teens were randomized to either FYF:IDD or TAU. Participants were above the autism spectrum cutoff on the ADOS-2 (Lord et al., 2012), had IQ and adaptive behavior in the ID range (FSIQ = 56.2, Adaptive Behavior Composite = 59.4), and met criteria for at least one anxiety diagnosis on the Anxiety Diagnostic Interview Schedule-Autism Addendum (ADIS-ASA, Kerns et al., 2017). Clinicians masked to condition completed Clinical Global Impression Scale-Improvement (CGI-I; Guy, 1976) ratings on the ADIS-ASA for Primary Anxiety diagnosis (i.e., diagnosis with the highest clinical severity rating at baseline), Total Anxiety (i.e., all anxiety diagnoses except specific phobias); and Specific Phobia (i.e., all phobias). Parents also completed the Anxiety Depression and Mood Scale (ADAMS, Esbensen et al., 2003), Emotion Dysregulation Inventory (EDI; Mazefsky et al., 2018), and Aberrant Behavior Checklist-Community (ABC-C, Aman, 2012). There were no pre-treatment differences in IQ, adaptive behavior, age, autism severity and anxiety symptoms. T-tests were used for primary treatment outcomes and mixed-model analyses for secondary treatment outcomes.

Results: (1) Primary treatment outcome: Teens randomized to FYF:IDD experienced significant improvement in their Primary Anxiety CGI rating relative to teens randomized to TAU ($p=.008$). There were no significant differences between groups on Total Anxiety CGI or Specific Phobia CGI. (2) Secondary Treatment outcome: Results indicated significant Group x Time interactions for ADAMS subscales: Manic-Hyperactivity ($p=.013$) and General Anxiety ($p<.045$); ABC-C Subscales: Irritability ($p=.001$), Lethargy ($p=.024$), and Hyperactivity ($p=.026$); and EDI Subscales: Dysphoria ($p=.006$) and Reactivity ($p<.003$).

Conclusions: This is the first RCT of a group CBT anxiety intervention for autistic teens with IDD. Results indicate that teens may benefit from adapted CBT approaches for interfering anxiety and that the impact of FYF:IDD may extend beyond anxiety reduction alone to include mood, regulation, and behavioral changes. This is notable given the unique impact of emotion dysregulation and behavioral difficulties on access to care for this population. The study is a critical step toward establishing an evidence base for adapted CBT treatment for autistic teens with IDD.

Limitations include parent report for outcomes. Future directions will be discussed.

421.169 Feasibility of Dyadic Physiological Research in Minimally Verbal/Nonspeaking Autistic Adolescents and Adults

K. M. Stockwell, J. K. MacCormack and V. K. Jaswal, Psychology, University of Virginia, Charlottesville, VA

Background: Heart rate and heart rate variability are often used with non-autistic and speaking autistic individuals to gain insights into emotional, motivational, and attentional processes (Appelhans & Lueken, 2005; Dijkhuis et al., 2019). Dyadic physiological research has become increasingly common over the last decade (Thorson et al., 2018), enabling the study of interpersonal processes like co-regulation and stress contagion (Dimitroff et al., 2017; Li & Lunkenheimer, 2024).

Like non-autistic people, minimally verbal/nonspeaking (MV/NS) autistic people often interact with social partners, in part due to their need for support. However, the limited physiological research with this group has focused solely on the *individual's* physiological signals (e.g., Goodwin et al., 2019).

Objectives: 1) Develop and evaluate a method for collecting electrocardiogram (ECG) data from MV/NS autistic adolescents and adults using a wireless heart sensor. 2) Assess the feasibility of a one-hour study requiring task engagement in different social contexts.

Methods: We aim to collect ECG data using MC10 BioStamp nPoint sensors from 30 autistic people (ages 15+) with phrase speech or less. In one month, 11 autistic/parent dyads have participated, and 25 additional families have contacted us.

Participants are introduced to the sensor and study via videos and modeling. ECG data are recorded during a 6-minute baseline and as the MV/NS autistic participants play an iPad game alone, with their parent, and with a stranger. ECG data are also recorded from the parent and the stranger.

Results: Of the 11 MV/NS autistic participants tested so far, 10 wore the sensor for the full hour. All 11 parents and 11 strangers wore the sensors. Mindware Technologies' Heart Rate Variability software was used for R-peak detection and trained researchers corrected artifacts. In line with prior work, data segments requiring more than 5% correction are excluded (Lu et al., 2023).

Autistic participants each provided 24 one-minute segments of ECG data. After cleaning, 92.5% (222/240 segments) of the data were usable. The parent and stranger participants each provided 12 one-minute segments. After cleaning, 90.9% (120/132 segments) of the parent data and 100% of the stranger data were usable.

To assess the availability of data for dyadic analyses, we examined the number of usable segments for both dyad members. For autistic/parent dyads, 78.3% of the common segments were usable; 88.3% were usable for autistic/stranger dyads. This exceeds the amount of usable data reported in published studies with non-autistic dyads (e.g., 47.2%; Li et al., 2021).

Conclusions: This study demonstrates the feasibility of dyadic physiological research with MV/NS autistic individuals. With careful attention to sensor choice, preparation, baseline stimuli, and task design, the majority of participants provided usable data. Our data so far meet or exceed the tolerance and usability reported in previous studies using wearable sensors with this population (Imbiriba et al., 2023). Importantly, this work extends prior research in naturalistic settings by showing that MV/NS autistic participants can engage in structured, dyadic experimental tasks. These findings provide a foundation for future research into interpersonal processes, including physiological synchrony, in MV/NS autistic individuals and their social partners.

421.170 High Support Need Groups Among Autistic Children and Youth in the U.S.: Prevalence, Overlap, and Specific Support Needs

P. H. Smith¹, J. Kim², M. A. Patti¹, J. E. Rast³, K. Lyall³, L. Shea³, E. H. Sheridan⁴ and D. Schendel¹, (1)AJ Drexel Autism Institute, Philadelphia, PA, (2)Drexel University College of Medicine, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA

Background: Identifying and supporting autistic youth with high support needs (HSN) is critical for developing assessments and implementing needed policies and programs for service delivery. Previously utilized approaches using administrative and health data are limited to intellectual or spoken language criteria and may miss autistic youth with other high support needs.

Objectives: Using U.S. nationally representative survey data we identified four HSN groups based on prior research and existing focus of policies and service delivery in the general child population: moderate-to-severe intellectual disability or speech disorder; medical complexity; social support needs; and serious mental illness. We aimed to determine 1) the sociodemographic characteristics of autistic youth belonging to each group; 2) overlap across HSN groups; and 3) associations between HSN groups and specific high support needs across family, healthcare, and service domains.

Methods: We combined four years of cross-sectional data from the National Survey of Children's Health (NSCH; 2019-2022), selecting youth aged 2-17 with a parent-reported autism diagnosis ($n = 5,230$). All measures were based on parent-reported questionnaire items. Respondents described mental health and intellectual/developmental disability diagnoses as mild, moderate, or severe. We defined the four HSN groups as follows: 1) moderate or severe intellectual disability or speech disorder diagnoses; 2) medical complexity using previously published methods; 3) social support need: household financial, food, or housing insecurity; and 4) serious mental illness: severe anxiety, depression, or behavioral diagnoses. We measured six specific support needs: 1) unmet service or healthcare needs; 2) negative healthcare provider interactions; 3) missed days of school (ages >5 years); 4) caretaker needs: time spent arranging healthcare or providing home care, reducing employment because of child's care needs, and self-reported challenges caring for the child; 5) peer relationship needs: difficulty making friends, or frequent bullying (ages <5 years); and 6) childhood adversity: ≥ 3 adverse childhood experiences (e.g., parent/guardian divorce; racial discrimination). We used regression models to determine associations between HSN groups (mutually adjusted and count) and specific support needs, adjusting for age.

Results: The prevalence of moderate-to-severe intellectual disability or speech disorder (ID/SD) was 38%; medical complexity (MC)-24%; social support need (SSN)-39%; serious mental illness (SMI)-14%. Two-thirds belonged to ≥ 1 group; one-third to ≥ 2 groups, with the three most common combinations: SSN+ID/SD-9%; MC+SSN+ID/SD-6%; and MC+ID/SD-5%. Sociodemographic characteristics (Table 1) and associations with specific support needs (Table 2) varied by HSN group. Only MC and SMI were associated with all specific support needs after adjustment. There was a dose-response relationship between HSN group count and all specific support needs.

Conclusions: Most autistic youth belonged to at least one of the four HSN groups included in this study, and all HSN groups were independently associated with greater specific support needs. Belonging to multiple groups was common and associated with greater support needs. Additional research to determine the presence and type of HSN across diverse groups is urgently needed to create equitable approaches to assessing service needs. New and modified policies and programs to improve access to services and outcomes could support individuals, families, and service system efficiency.

421.171 Identifying Depression in Minimally Verbal Adults: Parent-Reported Indicators and Potential Application of Existing Screeners

E. Wilkinson¹, R. P. Hastings², A. Jahoda³ and V. H. Bal⁴, (1)Department of Psychology, Rutgers University, Piscataway, NJ, (2)School of Social Policy and Society, University of Birmingham, Birmingham, England, United Kingdom, (3)School of Health and Wellbeing, University of Glasgow, Glasgow, Scotland, United Kingdom, (4)Graduate School of Applied and Professional Psychology, Rutgers University - New Brunswick, Piscataway, NJ

Background:

As many as 30% of autistic individuals are minimally verbal (MV; Pickles et al., 2016), yet their mental health has been largely overlooked. High rates of co-occurring depression are reported in autism (Hollocks et al., 2019), depression is common and more enduring in adults with intellectual disability (ID) than the general population (Collishaw et al., 2004), and those with severe ID may be at even greater risk for mental health problems (Flynn et al., 2017). Measures may not adequately assess depressive symptoms in MV autistic adults. Failure to consider depression in MV adults leaves a significant number of individuals without appropriate supports and has negative consequences for quality of life.

Objectives:

The current study used open-ended questions to identify potential parent-reported indicators of depression in MV autistic adults and examined the psychometric properties, feasibility, and validity of three existing instruments (ADAMS, MIPQ, GDS) originally designed to screen for depression in those with ID.

Methods:

Parents of MV autistic adults in the US were invited via email to complete a battery of surveys through SPARK research match. After consenting, parents were asked about professional diagnoses and personal perspective on presence of depression. Parents then completed depression-related surveys about their MV adults (N=177; Table 1) in a random order. Qualitative content analysis was used to identify parent-described indicators of depression and psychometrics analyses to characterize the existing surveys.

Results:

Across the sample, 9% of MV adults had a formal depression diagnosis, though 40% of parents suspected the person was depressed. In response to "what makes you believe this person is depressed?" parents reported lack of motivation (e.g., socially withdrawn, withdrawn from activities, lack of communication) most frequently (65%). Other commonly reported symptoms included sadness (e.g., crying, sad facial expression; 49%) and other mood challenges (e.g., mood swings, bad mood; 31%). See Table 2.

The ADAMS Depression subscale, MIPQ, and GDS had acceptable internal consistency (ADAMS Depression $\omega=.81$; MIPQ $\omega=.95$; GDS $\omega=.75$). Mean time to complete surveys and percentage of parents completing the measure, proxies for participant burden, were reasonable (ADAMS: $M_{\text{minutes}}=2.9$, 99%; MIPQ: $M_{\text{minutes}}=4.4$, 98%; GDS: $M_{\text{minutes}}=2.4$, 98%). Factor analyses did not indicate good fit for any of the screeners and cognitive interviews with a subset of participants (n=18) found varying content validity and ease of completion. Correlations between the measures varied between .66 and .72. Full psychometric results will be presented.

Conclusions:

Parent-reported symptoms of depression in MV autistic adults generally overlap with traditional depression symptoms (e.g., mood, activity level), while some non-traditional symptoms were reported (aggression, repetitive behaviors). Existing screeners for depression in those with ID may be useful to identify patients who require further evaluation for a mood disorder. While some psychometrics features were acceptable, the poor fit of the factor structures questions if the measures should first be adapted for this population. The cognitive interviews suggest that some items are difficult to answer or response sets unclear. Results from the current study will critically guide adaptations and development of measures to evaluate depression in MV autistic adults.

421.172 Is Statistical Learning Impaired in Young Children on the Autism Spectrum Who Are Minimally Verbal?

E. Paolizzi and **G. Vivanti**, (1)*A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, Philadelphia, PA*, (2)*A.J. Drexel Autism Institute, AJ Drexel Autism Institute, Philadelphia, PA*

Background:

There is limited knowledge on how children on the Autism Spectrum extract patterns from experience and anticipate events accordingly, i.e., statistical learning. Given the role of statistical learning for language acquisition, statistical learning skills of autistic children who are minimally verbal is of particular interest.

Objectives:

This study aims to investigate if statistical learning abilities differ between TD and autistic children, including minimally verbal children.

Methods:

A novel eye-tracking statistical learning paradigm was administered to 46 children preschoolers, including typical children and children on the autism spectrum (both verbal and minimally verbal); see table 1.

Statistical learning was indexed as the anticipatory fixations in response to the observation of patterns of events in two conditions. In the deterministic condition, a video-animation showed the following sequence across four learning trials; (a) a ball is descending down a waterfall, (b) the ball is then occluded behind a bridge, and (c) the ball descends down the left stream of the waterfall (see figure 1). In the probabilistic condition the same scenario was presented, but the ball descended down the same waterfall in three of the four learning trials, while in one trial it descends down the opposite stream. Across conditions, the four learning trials were followed by a test trial, in which the ball remains occluded behind the bridge. Participants' anticipatory gaze was computed to determine whether they gazed towards the 'target location', i.e., the stream where they had previously seen the ball descending in all trials (deterministic conditions) or most trials (probabilistic conditions; see figure 1).

Results:

Repeated Measures ANOVA focused on gaze duration during the learning trials in the **deterministic condition** revealed a Location (target vs non-target) by Trial effect ($F(3,162)=3.04$, $p=0.03$), indicating that participants increased their attention to the target location. In the test trial there was a main effect of Location, indicating greater attention towards the target versus the non-target ($F(1,41)=19.60$, $p<0.001$), as well as shorter latency towards the target compared to the non-target ($F(1,41)=19.60$, $p<0.001$). Across analyses there was no effect of group (including when all children on the autism spectrum were grouped together).

In the **probabilistic condition**, analyses of gaze duration during learning trials revealed a Location by Trial effect ($F(3,160)=7.36$, $p<0.001$). A similar Location by Trial effect was found in the analyses examining gaze latency ($F(3,166)=4.27$, $p=0.006$), indicating that over the four trials participants increased the duration of attention and decreased the latency of attention to the target location. In the test trial there was no effect of location across gaze indexes. Across analyses there was no effect of group (including when all children on the autism spectrum were grouped together).

Conclusions:

The eye-tracking statistical learning paradigm elicited anticipation of future events across most indexes in our sample. This suggests that both typical and autistic preschoolers, including those who are minimally verbal, extracted deterministic and probabilistic patterns and anticipated events accordingly. Normative performance in the task by minimally verbal autistic children suggest that language difficulties in this population might be unrelated to statistical learning.

421.173 Minimally Verbal Children with Autism 'See the Point, but Do Not Point to What They See': A Behavioral and Eye-Tracking Study in Visual Perceptual Processing

H. S. Sykes Haas^{1,2} and **Y. S. Bonne³**, (1)pre-school, Shtilim- school and preschool program for children with autism, Jerusalem, Israel, (2)School of Optometry and vision science and The Gonda Multidisciplinary Brain Research Center, Bar Ilan University, Ramat Gan, Israel, (3)School of Optometry and Vision Science, Bar-Ilan University, Ramat Gan, Israel

Background: During typical development, basic visual object recognition, unrelated to social interactions, begins to emerge within the first year of life. Shape processing involves both low-level visual cues, such as color and orientation, and more advanced mechanisms that rely on prior knowledge and inferences. However, little is known about basic, non-social, visual perceptual processing in minimally verbal children with autism (mvASD).

Objectives: Our objectives are to investigate basic, non-social, visual perceptual processing in older children with mvASD

Methods: We studied pointing and eye-gaze in twenty older (6-12 yrs) children with mvASD during low and mid-level visual processing tasks. In the oddball paradigm they pointed to an odd target among an array of distractors of varied difficulty and complexity consisting of low (e.g., color) and mid-level visual stimuli (e.g., 3D shapes). In the contour detection task, a circular contour was embedded among an increasing number of Gabor elements. In a third task a Kanizsa triangle was presented as well as modulated versions emphasizing illusory triangle (e.g a central dot in the triangle). Spontaneous pointing and eye gaze were recorded as distance from oddball target and Kanizsa center. Finally, during a computerized "Kanizsa dragging game" participants were dragging shape to correct Kanizsa.

Results: Our results suggest that children with mvASD are not a homogeneous group. While all children detected the odd target in the easiest condition of faint distractors, about half successfully detected it based on *all* low-level features. Importantly, some of these "high performers" deteriorated on mid-level visual tasks with higher stimulus complexity. Furthermore, some 'high performers' correctly detected the Kanizsa oddball but unlike TDs pointed to local inducers rather than Kanizsa center. Strikingly, mvASD participants who failed lowest level of visual oddball tasks presented with above chance eye-gaze to odd target. For the single Kanizsa, pointing and eye gaze were at the local elements, but shifted towards the center in modulated versions. 'High performers' successfully dragged shape to correct Kanizsa.

Conclusions: Participants could do the tasks, with performance sensitive to distractor saliency and stimulus complexity, but the group was not homogeneous. The results could not be explained by lack of cooperation or task comprehension. This suggests early visual processing differences among children with mvASD, and visual perception based on low-level representations with attenuated inference-based processing. However, eye gaze superior to pointing, shifting of pointing and gaze for the single Kanizsa, to the center, with minor modulations, as well as successful matching of shape to Kanizsa, indicate more complex perceptual representations *do* exist. It seems that among children with mvASD, performance does not solely rely on *what* they perceive, but also on *how* they use the visual signal to drive their behavior. They 'see the point, but do not (always) point to what they see'

421.174 Outcomes from a Statewide Dissemination of a Care Pathway for High Support Needs Autistic Youth in General Child and Adolescent Psychiatric Settings

L. Donnelly¹, L. K. Baker², E. Okparaekwe¹, F. Guo¹, A. Alejandro³, M. Perkins⁴, B. Filton¹ and S. Horwitz⁵, (1)Department of Child and Adolescent Psychiatry, NYU Langone, New York, NY, (2)Hassenfeld Children's Hospital at NYU Langone, New York, NY, (3)NYU Langone, New York, NY, (4)NYS Office of Mental Health, Albany, NY, (5)Department of Child and Adolescent Psychiatry, NYU Langone Health, New York, NY

Background: Over the past nine years, our team has developed and implemented a training model to improve care for children and adolescents with autism spectrum disorder (ASD) and high support needs in psychiatric hospital settings. Given the lack of staff training in ASD, high utilization of psychiatric services by autistic youth, and the dearth of resources for the autistic population in psychiatric settings, this program was designed to educate staff to better address the unique challenges of autistic youth with high support needs and co-occurring psychiatric conditions. This model utilizes an evidence-informed approach to educate and support staff who work with high needs autistic youth (including Intellectual Disability) within emergency departments and psychiatric inpatient settings. Previous evaluations of the model implemented at one general inpatient psychiatric unit documented improved clinical outcomes for patients, including a significant reduction in the use of crisis interventions (i.e., therapeutic holds/restraints, administration of intramuscular medications) sustained over 36-months (Cervantes et al., 2019; Kuriakose et al., 2018). **Objectives:** Assess the outcomes from this specialized, comprehensive training model delivered to frontline staff working with autistic youth with high support needs in seven emergency and psychiatric sites throughout New York State (NYS).

Methods: A four-hour training, focusing on psychoeducation and strategies for autistic youth presenting with high support needs and challenging behaviors during their psychiatric admission, was conducted at seven sites throughout NYS. Pre- and post-training data were collected from the multidisciplinary (i.e., psychology, psychiatry, social work, nursing, occupational therapy, art therapy, public health, management) and sociodemographically diverse (e.g., racially diverse; highest degree ranging from less than bachelor's degree to doctoral degrees) staff who attended the training. Attendees completed the following scales before and after the training: The Challenging Behaviour Attributions scale (CHABA; Hastings 1997) Short Form (Hastings and Brown 2002), modified version of the Confidence in Coping with Patient Aggression Instrument (Thackrey 1987), assessment of knowledge of evidence-informed strategies for working with autistic youth (Donnelly et al., 2023). Following the training, staff were asked how appealing they found the training using the Appeal subscale of the Evidence-Based Practice Attitude Scale (EBPAS; Aarons 2004). Hourly biweekly follow-up consultations for six months post-training are currently in progress.

Results: A total of 263 individuals attended the training across the seven sites and pre/post data were available from 117 participants. Statistically significant pre/post differences were observed for all outcomes of interest including perceptions of behaviors, higher levels of comfort working with the ASD population, and more knowledge of evidence-based practices ($p < .05$); however, significance varied by site (Image 1). On a 5-point Likert scale, attendees found the training to be engaging ($M = 4.21$).

Conclusions: This evidence-informed training model is effective across diverse sites in improving knowledge and increasing staff confidence for working with this population with high support needs. Importantly, sites have integrated evidence-informed strategies into their standard care model to support autistic individuals. Additional analyses of these data on the impact of 6-month follow-up consultations is in process.

**421.175 Predictors of Treatment Outcome for Autistic Teens with Intellectual Disability Receiving CBT for Anxiety**

A. T. Meyer¹, R. E. Boles², J. Reaven³, L. Hayutin², N. Reyes⁴, C. Middleton², L. Olson⁵, K. Cosgrove⁶, E. Glenn⁷, R. K. Sandercock⁸ and A. Blakeley-Smith⁹, (1)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2)University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (4)University of Colorado, Anschutz Medical Campus, Aurora, CO, (5)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (6)CU Anschutz, Denver, CO, (7)University of Oregon, Eugene, OR, (8)Department of Psychology & Neuroscience, JFK Partners/ University of Colorado School of Medicine, Chapel Hill, NC, (9)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Autistic teens with intellectual developmental disability (IDD) experience significant anxiety; although, little is known about the initial efficacy of therapeutic interventions. While early studies have shown promising effectiveness of cognitive behavioral therapy (CBT; Blakeley-Smith et al., 2021; Blakeley-Smith et al, under review) teen factors that may impact treatment outcomes are currently unknown. For autistic individuals without IDD, child characteristics do not predict anxiety treatment outcome (Van Steensel et al., 2017); however, it is unclear if these findings hold true among the highly heterogeneous IDD population. Understanding these factors may help determine best candidates for CBT and whether adaptations are necessary for certain teens.

Objectives: To assess the impact of age, gender, adaptive behavior, expressive language level, psychiatric medication use, and medical complexity on treatment response following participation in Facing Your Fears-IDD (FYF-IDD), a group CBT anxiety intervention.

Methods: Fifty-three autistic teens ($M_{age}=15.18$, 65.5% Male, 76.4% white, 21.8% Hispanic) with IDD and anxiety participated in FYF-IDD. Participants met criteria for autism (ADOS-2; Lord et al., 2012), had scores in the ID range for IQ ($M_{FSIQ}=57.02$) and adaptive behavior ($M_{ABAS-3\ ABC}=59.13$), and met criteria for at least one anxiety diagnosis from the Anxiety Diagnosis Interview Schedule-Autism Spectrum Addendum (ADIS-ASA, Kerns et al, 2017). Expressive language level was identified by ADOS-2 Module ("minimally verbal" = Module 1 or 2, $N=15$; "fluent speech"=Module 3 or 4, $N=38$). Clinical Global Impressions Scale-Improvement (CGI-I; Guy, 1976) were completed using caregiver report from the ADIS-ASA at pre- and post-treatment. CGI-I scores ranged from 1 (Very Much Improved) to 7 (Very Much Worse) for Primary Anxiety (diagnosis with the highest interference at pre-treatment), Total Anxiety (overall improvement in diagnoses, except specific phobias), and Specific Phobias (overall improvement in specific phobias). Independent samples t-tests were conducted for language level, medical complexity, psychiatric medication, gender. Regression models were conducted for continuous predictors (ABAS-3 ABC and age).

Results: Teen age, use of psychiatric medication during treatment, medical complexity, and gender were not significantly related to CGI-I scores (all $p>.05$). Expressive language level was not significantly related to CGI-I for Primary Anxiety or Specific Phobia; however, teens who were minimally verbal demonstrated *greater* improvement (lower CGI-I) for Total Anxiety compared to teens with fluent speech ($p=.04$). ABC did not significantly predict Primary or Total Anxiety; however, higher ABC scores predicted *greater* improvement in CGI scores for Specific Phobias ($p=.03$).

Conclusions: Consistent with previous research on autistic youth without IDD, (Van Steensel et al., 2017), key teen characteristics were not significantly predictive of treatment outcome. Notably, autistic teens with lower expressive language showed greater improvements in overall anxiety, and should not be excluded from adapted CBT programs. These findings are somewhat surprising, given the significant heterogeneity in this population and the long-standing belief that adapted CBT is inaccessible for people with IDD. Further research is needed to understand the elevated anxiety remaining post-treatment for many participants. Limitations include: (1) results were based on parent report; (2) limited self-report measures to assess anxiety outcome in this population, and (3) a small sample size.

421.176 Profound Autism: An Exploration in a Clinically Referred Sample

A. Hodge¹, K. A. Boulton², R. Sutherland³, S. Baracz⁴, N. Ong⁵, B. Bennett⁶, A. J. Guastella⁶ and N. Silove⁷, (1)Sydney Children's Hospital Network, Sydney, NSW, Australia, (2)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (3)University of Sydney, Sydney, NSW, Australia, (4)Sydney Children's Hospital Network, Westmead, NSW, Australia, (5)The Children's Hospital at Westmead, Sydney, NSW, Australia, (6)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (7)Sydney Children's Hospital Network, Sydney, Australia

Background: The autistic population is highly heterogeneous, with a wide range of abilities and support needs. There are considerable challenges in understanding the heterogeneous needs and characteristics of people with an autism diagnosis. To better identify those autistic individuals who may require the most intensive support, the Lancet Commission in 2021 introduced the term "profound autism." This subgroup of individuals with autism is characterized by an intelligence quotient (IQ) below 50, minimal to no functional language, the need for 24-hour supervision, and assistance with daily living activities. While these characteristics go beyond the current, more non-specific descriptions contained in the DSM-5-TR levels and provide clear, objective criteria, the use of the term "profound autism", and how it should be applied, has faced criticism over recent years.

Objectives: In this study, we aim to apply the definition of profound autism to a large dataset from a diagnostic and assessment clinic. Our goal is to identify key correlates that distinguish children with profound autism from other autistic children. The demographic variables under consideration include age at first concern, age at diagnostic assessment, autism symptom severity, child gender, diagnostic comorbidities, and parental cultural background.

Methods: Participants were 526 children aged 1.53 – 16.73 ($M=4.75$, $SD=2.32$, 75% male), attending a tertiary-level assessment service. All children received a diagnosis of autism. Children were identified as meeting criteria for profound autism if they received a developmental or intellectual quotient of less than 50, were rated as having minimal to no language, and required substantial assistance with activities of daily living, as indicated by global impairments on adaptive functioning. In total, 142 children in our sample met criteria for profound autism.

Results: Profound autism was uniquely associated with younger age at diagnosis and younger age at first concern. Concerns were raised by caregivers over 5 months earlier in this group (21.63 months, compared to 26.39 months) and they received a diagnostic assessment one year earlier on average, compared to peers without profound autism (4.04 years, compared to 4.97 years). Children with profound autism had elevated symptom severity relative to peers who did not meet these criteria and received a greater number of comorbid diagnoses on average. There were no differences in child gender for children meeting criteria for profound autism, compared to those who did not. There was some evidence of an association between profound autism and CALD background, such that profound autism was more frequently seen in children of mothers from a CALD background, compared to a non-CALD background.

Conclusions: We examined unique profiles of profound and non-profound autism in a large community sample of children. A quarter of the sample met the profound autism criteria. They were likely to receive diagnostic assessments earlier and had more symptoms of autism than non-profound children and were at risk of increased comorbidities. We discuss the need to examine whether access to interventions and supports services differs for children with profound autism, and how the construct of profound autism can be best applied in research and clinical practice hereafter.

421.177 Reading Comprehension in Nonspeaking Autistic Children: A Systematic Review

G. Pesantes¹, M. Skibicki¹ and G. Clark², (1)Montclair State University, Montclair, NJ, (2)Communication Sciences and Disorders, Montclair State University, Montclair, NJ

Background: Approximately 25% of autistic individuals are nonspeaking or minimally speaking (Rose et al., 2016) and will require augmentative and alternative communication (AAC) systems to meet their daily communication needs. Although studies have demonstrated that nonspeaking children can learn foundational literacy skills (e.g., Ainsworth et al., 2016; Caron et al., 2023; for review, see Mandak et al., 2018), it is unclear what we know about reading comprehension skills beyond simple letter-sound correspondence and single word decoding.

Objectives: To synthesize assessment and intervention procedures related to reading comprehension for autistic children who use AAC. To identify gaps in the research related to reading comprehension in nonspeaking autistic individuals.

Methods: To identify relevant studies, key words were identified and customized for each of 5 databases: PubMed, CINAHL, ERIC, PsycINFO, and SCOPUS (see Table 1). Inclusion criteria were: 1) participants under age 18, 2) participants with an autism diagnosis, 3) participants who were minimally or non-speaking and 4) measures or interventions of reading comprehension beyond single word decoding. Exclusion criteria were: 1) review studies, 2) book chapters, and 3) studies with solely fluently speaking participants. Identified articles were screened first by title and abstract; those chosen for inclusion were then read in full to determine if the study matched the inclusion and exclusion criteria. Those selected were placed into a data extraction sheet containing all critical study information such as i) quality assessment, ii) participant demographics, iii) measures, iv) results, and v) limitations. Categories were reassessed after entering 10% of the data to determine their relevance and adequacy (Pickering & Byrne, 2013).

Results: A total of 186 articles were identified through the database searches. After the removal of duplicates, 156 citations were imported into www.covidence.org. Two trained reviewers screened all articles for inclusion and 13 conflicts arose. Conflicts were resolved through discussion and vote among three team members. Through title and abstract screening, 132 articles were deemed irrelevant. Two reviewers performed a full-text review on the remaining 24 studies and 5 conflicts arose which were resolved through discussion and vote. Thirteen studies were eliminated for only including speaking participants, 2 were eliminated for including only children with intellectual disability without autism, 2 were eliminated because they only reviewed the existing literature, and 1 was eliminated because it did not include measures of reading comprehension. 6 studies were extracted for further analysis. Figure 1 reports the extraction process according to PRISMA guidelines.

Conclusions: The results of this systematic review will be discussed in light of each studies' participant characteristics and the ways that reading comprehension skills were measured and treated in nonspeaking autistic participants. We note a gap in the research literature in regards to innovative ways of measuring and improving reading comprehension in nonspeaking autistic children. The results will be used to guide the design of experimental studies on the assessment and treatment of reading comprehension skills for minimally speaking and nonspeaking autistic children.

421.178 Rosco: A Strengths-Based, Person-Centered Communication Sampling Paradigm for Non-Speaking Profoundly Autistic Individuals

K. T. Johnson¹ and **L. Thompson²**, (1)Northeastern University, Cambridge, MA, (2)Speech and Hearing Sciences, Washington State University, Spokane, WA

Background: Individuals with profound autism often remain non- or minimally-speaking throughout their lives. These individuals communicate multimodally through non-speech vocalizations, gestures, body movements, facial expressions, and augmentative communication devices.

However, they frequently score near basal levels on standardized language assessments, making it difficult to monitor their developmental progress and establish sensitive outcome measures for this population. Furthermore, logistical barriers such as geographical location, time constraints, and energy demands on caregivers limit access to clinical research, reducing participant diversity. To address these challenges, we developed ROSCO (Rapid Online Sample of Communication), a person-centered, remotely administered communication sampling paradigm that leverages caregiver knowledge to capture the full spectrum of communicative behaviors in this population.

Objectives: Design, implement, and evaluate the creation of the ROSCO paradigm.

Methods: The ROSCO paradigm was created in response to family-led requests for more accurate and sensitive communication measures for non- and minimally-speaking children [1] and has been iteratively refined based on continuous feedback from participating families using both qualitative and quantitative methods. Adjustments have been made to reduce attentional demands while balancing simplicity, engagement, and opportunities for spontaneous communication. Personalizable probes, including snack time, free play, communication temptations, and a familiar video altered to appear like it is buffering, are used to elicit naturalistic communication. The paradigm is administered entirely online via Zoom. Smartphones and tripods are sent to the families' homes to capture communication behaviors from multiple angles, ensuring high-quality data collection. Caregivers also participate in structured interviews with researchers while rewatching the recorded ROSCO session to provide additional insight into subtle communicative behaviors. Pilot testing has been conducted across 33 ROSCO sessions (n=26 unique participants) and is ongoing. Feasibility, data quality, and caregiver feedback measures have been obtained through completion rates, signal analysis, interviews and Likert-scale surveys. Preliminary data on the modality, function, and rate of communication have been obtained from samples coded using ELAN.

Results: The ROSCO paradigm has demonstrated exceptional feasibility, with 100% of sessions completed and 98% codeable data. Caregivers report high satisfaction with the remote format and appreciate the opportunity to contribute their insights into their child's communication. The paradigm has effectively captured a diverse array of quantifiable communicative behaviors, including non-speech vocalizations, gestures, body movements, facial expressions, and augmentative technology use (59.1 ± 19.2 communicative acts per session). These behaviors serve a range of functions (e.g., requesting, rejecting, commenting, and expressing emotions), underscoring the variability and complexity of communication in this population.

Conclusions: ROSCO represents a promising advancement in the naturalistic assessment of communication in non- and minimally-speaking individuals with profound autism. Its strengths-based, caregiver-informed design enables the measurement of a wide array of communicative behaviors that may be missed by traditional language assessments. The remote, accessible nature of the paradigm enhances participant diversity and provides a scalable solution for communication assessment in hard-to-reach populations. Ongoing work is focused on integrating machine learning and computer vision algorithms to scale coding efforts, as well as developing AI-enabled personalized communication technology tailored to this underrepresented population.

[1] Landlust et al., (2023)

421.180 Strategies for Engaging Adults with Profound Autism in Research: A Community-Based Participatory Research Approach to Intervention Development

A. Osuna¹, F. Zollars², M. R. Pepper³, J. Wennberg⁴, T. Rucker Coker⁵, D. Christakis⁵ and K. Bearss⁶, (1)Seattle Children's, Seattle, WA, (2)The University of Washington, Seattle, WA, (3)Alyssa Burnett Adult Life Center, Seattle Children's Alyssa Burnett Adult Life Center, Bothell, WA, (4)Alyssa Burnett Adult Life Center, Seattle Children's Hospital, Seattle, WA, (5)University of Washington School of Medicine, Seattle, WA, (6)Catalight, Seattle, WA

Background: Adults with profound autism and intellectual disabilities are often excluded from research, limiting the applicability of interventions for this population. This study addresses the need for inclusive research practices by employing Community-Based Participatory Research (CBPR) to engage individuals profoundly impacted by neurodevelopmental disabilities such as profound autism. Our partnership focused on collaboratively adapting a digital literacy intervention to reduce challenging online behaviors and enhance psychological well-being.

Objectives: The primary aim was to establish a research partnership with a community organization supporting adults with profound autism to address online behavior and safety concerns. Specifically, we utilized CBPR strategies to adapt the SELFI program (Osuna et al., 2023), a social media skills intervention originally designed for autistic adults without intellectual disability, for this population. Our goal was to develop strategies for meaningful partnerships with self-advocates, caregivers, and community organizations using participatory research methods.

Methods: Guided by the Map of Adaptation Process framework (MAP; McKleroy et al., 2006), we partnered with a community-based organization providing interventions to adults with profound autism. Collaborating with autistic self-advocates, we shaped research methodologies, intervention materials, curriculum content, and delivery approaches. Over three years, we conducted two studies: (1) technology-use surveys and interviews with 38 adults with intellectual and developmental disabilities and their caregivers, and (2) collaborative adaptation of the SELFI program (n=16). CBPR strategies used included building equitable partnerships, co-learning, co-design, shared decision-making, and dissemination of findings.

Analysis involved reviewing field notes, community feedback, and accessibility improvement strategies.

Results: The partnership effectively engaged adults with profound autism and their caregivers. An equitable research team was established, including an autistic self-advocate, a caregiver, an interventionist, and program administrators. Through co-learning, we identified intervention goals and priorities through a mixed-methods study with 38 participants. In co-design, community partners shared decision-making in study procedures and intervention development. Our self-advocate co-researcher ensured accessibility by reviewing and providing feedback on study materials, including consent documents and surveys. Collaboration was enhanced through one-on-one meetings, visual aids, and involving partners in disseminating findings.

Conclusions: This study demonstrates that CBPR can effectively include adults with profound autism in developing interventions aimed at reducing challenging online behaviors and enhancing digital well-being. Implementing these research approaches enhances the accessibility and impact of interventions by creating inclusive environments that actively involve adults with profound autism. These practical guidelines support inclusive intervention development and improve the validity and implementation of treatment interventions for people with profound autism.

Poster Session

422 - International and Cross-Cultural Perspectives II

May 2nd, 2025, 12:30 PM - 1:30 PM - Hall 4A

422.181 Access to Educational Services: Uruguay's Regulatory Dilemma

M. Montenegro¹, G. Garrido², C. Amigo³ and C. Montiel-Nava⁴, (1)University of Texas Rio Grande Valley, Edinburg, TX, (2)Universidad de la República Uruguay, Montevideo, Uruguay, (3)Universidad de la Republica Facultad de Medicina Uruguay, Montevideo, Uruguay, (4)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

Background:

Autism research has been, and continues to be, overly concentrated in high income countries. As such, the known social and cultural experiences of families raising a child with autism continue to be mostly representative of White, upper-middle-class individuals in high-income countries (Durkin et al., 2015; Talantseva et al., 2023). However, in low- and middle-income countries (LMIC), those with autism are met not only with limited community awareness and trouble accessing a diagnosis and evidence-based interventions but also with educational barriers due to fragmented infrastructure, poorly drafted policies, and limited number of trained professionals (Masri et al., 2023; McConkey, 2022; Silvestre Paula et al., 2020). In Uruguay, individuals with ASD are met with delays in identification and intervention (Montiel-Nava et al., 2020; Silvestre Paula et al., 2020), as well as barriers to educational attainment (Candido & Tilve, 2023). This in-depth exploration of cultural, social, and political influences impacting barriers to educational services in Uruguay will inform needed steps towards inclusive educational attainment and maximization of developmental outcomes.

Objectives:

Utilizing the Theory of Change (TOC) framework developed for LMIC (Divan et al., 2021), the present study explored participants' experiences regarding accessibility to autism educational services and legislation and policies in Uruguay.

Methods:

The study included semi-structured interviews with twelve caregivers of individuals with autism and four key stakeholders using purposive sampling. The interviews were guided by topics covered in the 100-Day Kit for Young CHildren (Autism Speaks, 2020). Data analysis consisted of reflexive thematic analysis with a critical realism approach and a deductive orientation to ensure the TOC framework's use to help generate codes and themes (Braun & Clarke, 2022).

Results:

Results indicated that schools are not equipped to instruct autistic children due to a lack of trained professionals or resources for special education. There are no uniform guidelines for inclusion or school attendance, resulting in denial or limits to enrollment. Another theme centers around the role of the "acompañante," a state-assigned helper for those with disabilities. Although not designed for educational supports, many schools now require them for autistic children to enroll. However, funding shortages have led to a lack of these professionals, resulting in denied enrollment, a violation of students' right to education. Another salient theme indicated that despite multiple laws being established to protect autistic individuals' rights, due to fragmented and subpar planning strategies the implementation of said laws results in a confusing and chaotic process that further delays educational access.

Conclusions:

Despite the multiple laws and policies available, much remains to be done to ensure policies are enforced due to infrastructure, financial planning, and changes in political impetus. Results here may highlight pathways towards universal access to inclusive educational services. For Uruguay and other countries, it is imperative that laws passed include planning and adequate funding. It is also essential that parents and autistic individuals are included in the process of policy making to ensure laws remain relevant independent of changing political alliances.

422.182 Implementation of Parents Taking Action: A Culturally Adapted Training for Caregivers of Young Children with Autism in Paraguay

A. K. Terol¹, H. Meadan² and S. Magana³, (1)University of California, Davis - M.I.N.D. Institute, Sacramento, CA, (2)University of North Carolina Charlotte, Charlotte, NC, (3)Steve Hicks School of Social Work, The University of Texas at Austin, Austin, TX

Background:

The demand for services and resources to support individuals with autism has increased in correspondence with the rising prevalence of autism around the globe. However, access to resources to support children with autism and their families is inequitable. Specifically, caregivers and researchers report that there is limited availability of resources and services to support autistic children and their families in low-to-middle-income settings and countries. Training caregivers and building their capacity may be a cost-effective and appropriate way to deliver support for caregivers of autistic children in low-resourced settings. Caregiver training is an evidence-based practice that leads to positive outcomes for both caregivers and their autistic children. However, to date, most caregiver training research has been conducted in high-income countries and researchers emphasize the need to consider contextual local and cultural aspects when providing caregiver training in different settings. Culturally appropriate caregiver training may be an effective way to provide support to these families.

Objectives:

1. Pilot the implementation of a culturally adapted caregiver training (i.e., Parents Taking Action) with caregivers of young autistic children in Paraguay.
2. Assess the impact of the culturally adapted training on caregivers' knowledge about autism, understanding of their children's needs and strengths, and empowerment.
3. Assess the social validity of the goals, procedures, and outcomes of the culturally adapted training.

Methods:

We used a convergent mixed-methods design including a single-arm pre-post design and semi-structured interviews, to evaluate the overall impact of the culturally adapted Parents Taking Action Program for caregivers of autistic children in Paraguay. The program included ten 2-hour long sessions and was co-delivered by caregivers of autistic children from Paraguay and a Paraguayan researcher, in an online synchronous group format over a 3-month period. Overall, 22 caregivers started the program and 17 completed the program.

Results: Results comparing pre-post scores showed statistically significant increases in caregivers' knowledge about autism, their understanding of their children's strengths and needs, and their advocacy knowledge and skills. Attrition was 22.72%. Additionally, caregivers shared their experiences with the program and valued the opportunity to access high quality information and meet other caregivers of autistic children. Through the integration of quantitative and qualitative findings we generated four meta-inferences: (a) Caregivers of autistic children in Paraguay need support and training, (b) The online group training program supported learning of new knowledge and provided a sense of belonging for caregivers of autistic children, (c) Caregivers gained knowledge and were able to better understand their autistic children's strengths and needs through the program, and (d) The program was feasible and acceptable in the Paraguayan context.

Conclusions: Caregivers of autistic children can benefit from support and training tailored to their needs. The implementation of the culturally adapted Parents Taking Action program in Paraguay yielded promising outcomes and was found to be socially valid. While research employing more rigorous designs and with larger samples is warranted, these findings highlight the feasibility and acceptability of adapting programs to expand access to support and training for caregivers of autistic children in low-to-middle-income countries.

422.183 Inclusion of Participants with Limited English Proficiency in Autism Research

A. W. Lu¹, C. Dejong², M. G. Harris³, P. Mudnal⁴, M. Johnson⁵, L. Rivas Vazquez⁶, Y. B. Espinosa⁷, C. Tran⁸, D. Kotsonis⁹, M. Ragavan¹⁰, A. Aboagye¹¹, S. Broder-Fingert¹² and K. Zuckerman¹³. (1)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (2)Oregon Health and Science University, Portland, OR, (3)Massachusetts General Hospital, Boston, MA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Tufts Medical School, Boston, MA, (6)Department of Pediatrics (Division of General Pediatrics), Oregon Health & Science University, Portland, OR, (7)Tufts Medical Center, Boston, MA, (8)Department of Pediatrics, Oregon Health and Science University, Portland, OR, (9)University of Massachusetts Chan Medical School, Worcester, MA, (10)University of Pittsburgh, Pittsburgh, PA, (11)Northern Arizona University, Flagstaff, AZ, (12)UMASS Medical School, Boston, MA, (13)Division of General Pediatrics, Oregon Health & Science University, Portland, OR

Background: Disparities exist in the quality of care and healthcare outcomes for patients with autism who speak a non-English primary language and have limited English proficiency (LEP), defined as having a limited ability to read, write, or understand English. A critical step in improving equity for LEP patients with autism is ensuring inclusion in research, however, there are no standard LEP inclusion guidelines for research and no recommended practices for translation and interpretation services. While the prevalence of autism has been increasing in the United States, we hypothesize that representation of LEP patients in autism research has not followed the same trend.

Objectives: To determine how frequently US research studies about autism include LEP participants, which languages are included, how research teams communicate with LEP participants.

Methods: All human research studies (n =872) published in *Autism*, *Autism Research*, *Journal of Autism and Developmental Disabilities*, and *Research in Autism Spectrum Disorders* from 2013-2023 in PubMed and Scopus were reviewed using Covidence systematic review software. Studies were first screened to include those that were about autism, included U.S. participants, were original research studies, and were not secondary data analyses. Studies meeting these inclusion criteria were then evaluated to determine whether they included LEP subjects, which languages were included, and methods of oral and written communication with LEP participants.

Results: Of the 872 articles screened, 282 (32%) met our inclusion criteria. Of these studies, 49 (17%) included LEP participants. Of those 49, 22 (45%) specified how oral communication occurred with participants, while 27 (55%) described how written communication occurred. The most common languages specified were Spanish (69%), American Sign Language (14%), Korean (14%), and German (14%).

Conclusions: This review of articles from four major autism journals provides preliminary evidence to suggest that LEP participants are not well-represented in U.S. research studies about autism. This research presents an opportunity to inform more accessible and inclusive healthcare practices and help facilitate institutional- and policy-level changes that improve representation in autism research and access to interventions.

422.184 Indigenous Sámi Experiences of Autism in Norway

A. Lindblom, University of Applied Sciences, University of Inland Norway, Lillehammer, Norway; Institute of Language, Duodji and Social Sciences, Sámi University of Applied Sciences, Kautokeino, Finnmark, Norway

Background:

To our knowledge there is no research about autism in Sámi contexts as well as a paucity of research about global Indigenous perspectives on autism, but we also know that Sámi are not focused on diagnoses as the case usually is in dominant Western perspectives (Lindblom and Jannok Nutti, accepted). The Sámi are the only recognized Indigenous peoples in Europe and their traditional homelands, Sápmi, spread over the northern parts of the countries now known as Norway, Sweden, Finland and the Kola peninsula in Russia. Due to colonization, Sámi no longer live solely in Sápmi. The Norwegian Autism Association states that up to 1% of the population may have autism (Norwegian Autism Association, 2024). The report to the Storting (St. Meld 13, 22-23, pp. 22) refers to statistics from GSI showing 2546 pupils receiving education in Sámi. Based on these numbers, approximately 25 Sámi children may be autistic. However, in Norway registering information on ethnicity and/or disability is not permitted. Therefore, there are no statistics on autistic Sámi (Øzerk and Øzerk, 2020). This indicates that the situation for autistic Sámi children and youth is in acute need of research to ensure that they receive special education services equitable to that of other autistic children and youth in Norway.

Objectives:

The primary objective of this presentation is to put focus on Indigenous Sámi experiences of autism utilizing previously unpublished results from a research project on Sámi perspectives on diversity, inclusion and special educational support in Norway. Literature on other Indigenous perspectives on autism will be used to contextualize the Sámi-specific.

Methods:

Research conversations were held with ten Sámi special education teachers in Norway. Autism was mentioned by four of the research partners, which was found through a word search “autism” in the transcripts of the interviews.

Results:

Sámi special education teachers need knowledge on many different conditions and disabilities, such as autism, as there are very few Sámi special education teachers who speak a Sámi language, have cultural competence, specific topic and special educational knowledge (see Lindblom and Jannok Nutti, accepted). Contrary to Western dominant perspectives, Sámi worldviews focus on equality and not on diagnoses, and many times families to autistic children may not want others to know about the diagnosis. There are no specific activities directed to autistic Sámi children.

Conclusions:

There appears to be no previous research on autism in Sámi contexts. This paper reveals some Sámi special education teacher's thoughts on autism that indicate that Sámi experiences of autism differ from dominant views. In conclusion, this topic requires more research.

422.185 International and Cross-Cultural Perspectives: Autism in Rural North Indian Villages

S. M. M. Shah, Amrita Create,, Amrita Vishwa Vidyapeetham, KOLLAM, Kerala, India

Background:

In rural India, the trend is for autistic children to remain undiagnosed and not in school. Access to health and support services is limited, as is community and professional awareness of autism. Without disability certification, children cannot receive disability pensions or access to special education and government services.

In 11 villages in Rajasthan and Bihar, 25 disabled and potentially autistic children had either not received formal diagnosis or been misdiagnosed. Only 3 of these children were in education. This is attributed to a combination of poor access to health services, expertise, and specialists and the challenge of resource-intensive, time-consuming, and bureaucratic-intensive procedures involved in diagnosis and disability certification. In these communities, there is also a lack of awareness of autism and a lack of confident, trained, and specialist teachers.

Objectives:

The research objectives are:

1. To identify autistic children in the village communities (Figure 1)
2. To identify and explore key issues that these children and their families are facing related to diagnosis and education.
3. To provide support with diagnosis, disability certification, and pensions (Figure 2)
4. To explore best practice, co-design, and implement a training program for members of the communities: raising awareness of autism; learning to screen and support autistic children; and empowering teachers to deliver inclusive education (Figure 1).

Methods:

A PhD student researcher lived in the communities for 3 to 6 months over 2 years. Applying mixed methods, a range of data collection methods were used: interviewing parents, teachers, doctors, and health workers; observing children; conducting screening; assessing children's cognitive abilities with games; ethnography; use of an autism screening tool; and 3 surveys before and after training.

Training in English was delivered for 20 PhD scholars assigned to villages in India and in Hindi for 15 village teachers, 6 early years teachers, and 5 village coordinators.

Results:

25 children were identified by community members for screening. Of 25 children, 6 children displayed strong autistic traits. The remaining children had hearing impairment, visual impairment, cerebral palsy, and other disabilities.

Some families were reluctant to accept support or pursue diagnosis because of stigma or because of the time involved and the lack of perceived advantages; in both states, the monthly pension is approximately four US dollars.

13 of the children were supported with diagnosis, disability certification, and applications for pensions. Four families had already obtained disability certification through private means. Six children were given additional support with education.

Conclusions:

Community members are equipped to support children and their families and continue to register them. Awareness of the potential benefits for children has been raised, as has their potential in education. The children in the study are more engaged and valued in the community.

Lessons learnt and the training program have the potential to benefit other communities in India as well as in rural communities in other countries.

422.186 Knowledge and Perceptions of Autism and Developmental Disabilities in Bolivia

M. Howard¹, **M. Mazurek²** and **M. DuBay²**, (1)Department of Human Services, University of Virginia, Charlottesville, VA, (2)University of Virginia, Charlottesville, VA

Background:

An estimated 240 million children worldwide are classified as having autism or other developmental disabilities (DD), a majority of whom live in low- and middle-income countries, such as Bolivia (UN Children's Fund, 2021; WHO, 2011). While progress has been made in the recognition of rights for individuals with disabilities in Bolivia, these individuals continue to face discrimination, social stigmatization, and poor education and employment outcomes (Garcia-Domingo, 2022). A lack of knowledge or general understanding about autism/DD in Bolivia may lead to these poor outcomes for individuals.

Objectives:

The objective of this qualitative study was to explore the perceptions and knowledge of autism and other DD among the general population in Bolivia.

Methods:

This qualitative study will use a phenomenological approach to assess community members' perceptions of autism/DD in Bolivia. We sampled parents of children without developmental concerns who had no formal training or experience in child development or DD. We conducted two focus groups (n=12 and n=4; parent age $M=37.27$ yrs) in Cochabamba and Tarija, Bolivia. Eleven mothers and five fathers represented 32 children (child age $M=10.74$ yrs). Participants were asked about their perceptions of the causes, courses, and appropriate treatments for autism and DD. Focus groups were audio recorded, transcribed by Bolivian professionals, and translated into English. We used a grounded theory approach to analyze transcripts, including thorough review, inductive and deductive coding, and categorization of codes. Detailed code summaries will then be followed by theme and subtheme development (Braun & Clarke, 2006). Member checking will further refine themes.

Results:

Preliminary analyses revealed topics related to a range of beliefs of the causes, onset, symptoms, and treatments of autism/DD. Common perceptions about the causes of autism/DD included those with evidence-based support (e.g. genetic and environmental factors) as well as local traditions and cultural beliefs (e.g. child traumas, timing of first haircut). Participants perceived that the onset of autism/DD could range from birth to 2-4 years of age. They described symptoms they believed were indicative of autism, including language, attention, and communication difficulties. Participants noted a variety of treatment options, from dietary cleanses and cultural healers to medication and behavioral supports. Parents described a recent change in the general population's perceptions of autism, specifically, where discrimination was quite pervasive in the past but positive perspectives of neurodiversity and inclusion are growing. Media portrayals appeared to influence participants' beliefs surrounding whether individuals with autism/DD could live a "normal" life. Some participants indicated that individuals could live a completely independent life while others argued that these individuals will always require support.

Conclusions:

Our preliminary findings underscore the importance of increasing awareness and knowledge of autism and DD in the general population in Bolivia. Educating the community on best practices for autism and other DD, especially early in life, will likely lead to improvements in care for individuals with autism and other DD in Bolivia. These findings may be relevant among other similar Latin American countries.

422.187 "I Have Never Had the Opportunity to Have Videos That Were in Our Language": Enhanced Acceptability and Effectiveness of Executive Functioning Support Videos Among Spanish-Speaking, Versus English-Speaking Parents

L. Campos¹, **J. Safer-Lichtenstein²**, **S. Mikulich³**, **J. V. Smith¹**, **T. Dahlman²**, **J. Holmes²**, **A. C. Armour¹**, **A. Verbalis¹**, **A. B. Ratto¹**, **K. Hardy¹**, **M. Gunn²**, **K. Decker²**, **D. Brown²**, **M. A. Werner⁴**, **K. C. Alexander⁵**, **L. Cannon⁶**, **B. J. Anthony²**, **L. Anthony²** and **L. Kenworthy¹**, (1)Children's National Hospital, Rockville, MD, (2)University of Colorado School of Medicine, Aurora, CO, (3)Innovations Institute, University of Connecticut School of Social Work, Hartford, CT, (4)Monica Werner Counseling, Chevy Chase, MD, (5)The Occupational Therapy Institute, La Mesa, CA, (6)Ivymount School, Rockville, MD

Background: Service systems for children with neurodivergent (ND) conditions, i.e. autism and/or ADHD, often fail to meet the treatment needs of Spanish-speaking families. We examined the acceptability and effectiveness of parent support videos for the executive functioning (EF) intervention *Unstuck and On Target (Unstuck)* between monolingual Spanish-speaking, bilingual, and monolingual English-speaking families. **Objectives:** Hispanic families with ND children face significant challenges in accessing services due to factors such as language barriers, limited awareness of the different types of available services, and socioeconomic status (SES). One promising practice to reduce barriers to access to treatment services is caregiver-mediated intervention models which aim to increase caregiver knowledge and efficacy while also reducing caregiver strain or sense of burden. Utilizing this model, a set of freely available brief videos that explain EF, how challenges with EF can present in ND children, and strategies that caregivers can use to support EF in their children were created for families of ND children.

Methods: 12 support videos developed with parents, professionals, and self-advocates were originally created in English and later translated to Spanish. 139 caregivers of ND children (English speakers $n = 87$; Spanish speakers $n = 37$; Bilingual $n = 15$) reviewed the videos and completed surveys both before and after watching them. Spanish-speaking families also completed follow-up focus groups after survey completion. Focus groups were transcribed verbatim and analyzed using rapid qualitative methods.

Results: Caregivers across language groups demonstrated improvements in EF content knowledge, $F(1) = 152.82, p < .001$, and self-reported strain over time, $F(1) = 13.04, p < .001$, with no significant group differences or group by time interactions. There were significant differences between the language groups on informativeness/usefulness, $H(2) = 31.40, p < .001$, efficacy $H(2) = 16.91, p < .001$, value $H(2) = 13.40, p = .001$, and likelihood to recommend the videos $H(2) = 11.26, p = .004$, with Spanish-speaking caregivers reporting even greater ratings of acceptability than English-speaking caregivers who had previously reviewed the same videos. Spanish-speaking caregivers reported the greatest improvements in caregiver-reported frequency of child EF difficulties, $F(1) = 40.21, p < .001$, and caregiver-reported disruptiveness of child EF difficulties, $F(1) = 16.93, p < .001$.

Rapid qualitative analysis of focus groups revealed a range of themes. These were: 1) enjoyed the videos overall and found the content useful and relevant; 2) videos changed how they conceptualized some of their child's challenges; 3) appreciated the feasible and practical delivery modality; 4) shared the videos with others; 5) noted areas where videos could be improved; and 6) provided suggestions of other topics that could be covered in additional videos. Results highlight future directions that may be helpful in improving the fit between *Unstuck* and Spanish-speaking families. **Conclusions:** Spanish-speaking caregivers rated *Unstuck* intervention and supplemental materials MORE positively and reported greater child EF improvements than their English-speaking peers. This supports the feasibility and highlights the outsized impact of providing these types of materials in both languages. Adapting the videos culturally and linguistically may be an important next step.

422.188 Let's Not Start from Scratch: Expanding Autism Clinical Capacity from Existing Cerebral Palsy Clinical Services across Mexico.

A. Pichardo¹, C. Valdes², A. Ramos¹ and G. Perez Liz³, (1)Fundación Teletón México, Tlalnepantla, EM, Mexico, (2)Fundación Teletón México, Cancun, QR, Mexico, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

Background:

Autism clinical capacity in Mexico is limited, centralized to major urban areas, and heavily reliant on private out-of-pocket service providers, leaving the most vulnerable populations unattended (Zavaleta-Ramirez et al., 2018). To improve autism care in LMICs, leveraging existing healthcare systems with innovations in community participation can help integrate specialized training and support for autism, maximizing resources and reaching more families (Divan et al., 2021). Teleton Network is a non-profit organization providing clinical services for children with cerebral palsy and other motor impairments. Teleton has been in operation for over two decades and operates 24 centers nationwide with funding from private donations, state government contracts, and federal public health funding. Starting in 2022, all Teleton centers started offering diagnostic and intervention services for children and youth on the autism spectrum, stemming from the existing infrastructure and public trust built upon their work with cerebral palsy and motor-related disabilities.

Objectives:

To conduct a program evaluation of Teleton's first 18 months of operation providing autism diagnostic and intervention services, after expanding existing clinical capacity in centers for cerebral palsy.

Methods:

Policies and procedures were documented collecting information from planning stages (prior to launching of autism services) and fidelity across centers was measured. The following variables were collected 18 months after the launch of autism services, by center: average usage of services across areas by patient, percentage of center capacity usage and percentage of waitlist from autism patients, certifications and trainings completed by center clinicians, and training needs reported by clinician specialty. In addition, entry and periodic Functional Independence Measure (WeeFIM) were assessed for patients.

Results:

Fidelity of implementation of the intake and assessment procedures indicated satisfactory implementation of autism clinical services protocols across all centers.

Twenty one of the 24 centers reported a capacity usage within the maximum allotted to autism services (30%). Seventeen centers reported a waitlist within allotted slots for autism patients (25%). The clinicians who had completed the most amount of autism-specific training were Psychologists and Speech Therapists (64% and 60%, respectively). Physical Therapists had the highest percentage of clinicians attending autism conferences (49%). The most frequently reported topics for training needs across clinical specialties were behavioral management and sensory integration.

Comparative entry and discharge daily function skills scores for patients showed that, on average, autism patients increased two points on the Cognition scale from entry to discharge, and one point on the Personal Care and Mobility scales and Overall scores, as evaluated by WeeFIM.

Conclusions:

Although centers are experiencing high demand for autism services, most of them are able to meet the capacity goals while maintaining existing clinical capacity for cerebral palsy-related services. Overall, autism patients increased their daily living skills profile during their enrollment at Teleton clinics. Streamlined procedures to shorten waitlists for autism diagnostic assessments and intensive efforts to implement parent-delivered behavioral supports are underway.

422.189 Maintaining Training Fidelity and Adaptation in Who-CST Implementation: Perspectives from Community-Based Interventions in Resource-Limited Regions in China

B. Chen¹, F. Liang², X. Zou³ and H. Deng⁴, (1)Child Development and Behavior Center, SUN YAT-SEN UNIVERSITY, Guangzhou, China, (2)Child Development and Behavior Center, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China, (3)The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China, (4)Third Hospital of SUN YAT-SEN University, Guangzhou, Guangdong, China

Background: The World Health Organization's Caregiver Skills Training (WHO-CST) aims to empower caregivers of children with developmental disabilities and Autism Spectrum Disorder (ASD) through a community-based model utilizing non-specialists as intervention mediators. This approach is particularly important for resource-limited regions in China, where it helps establish an accessible and scalable family intervention model for ASD. While exploring the effectiveness of CST for Chinese families of children with ASD, our research also investigates how to balance maintaining fidelity to the original CST facilitator training model with meeting the rapidly growing needs of families.

Objectives: To identify the factors that contribute to early success among facilitators. To assess the scalability of training non-specialist facilitators in underserved regions while maintaining intervention quality and addressing local cultural needs.

Methods: We analyzed the characteristics of facilitators trained under the CST program and their challenges encountered during post-session practices. Additionally, we examined their performance on the CST Adult/Child Interaction Fidelity Rating Scale. Specifically, we compared facilitators who passed the evaluation in the early stages (requiring ≤ 3 submissions) to those who passed later (requiring ≥ 4 submissions) to identify factors that might influence successful facilitation.

Results: Our findings indicated that 9 facilitators (60%) passed the evaluation in the early stages, whereas 6 facilitators (40%) achieved it later, with the latest facilitator passing at week 18. Early-stage passers demonstrated higher consistency in core competencies, particularly in maintaining fidelity during adult-child interactions, which may have been influenced by their baseline characteristics and adaptability to the CST training model. Conversely, those who required more attempts faced challenges in skill application, particularly in translating theoretical knowledge into effective practice during family interventions. We employed an extended ordered logistic regression model, which included an offset for work group, indicate that age group remains a statistically significant predictor of the timing of achieving fidelity ratings ($\beta = 5.13$, $SE = 1.57$, $z = 3.27$, $p = 0.001$). Participants aged over 35 years demonstrated a substantially higher likelihood of delayed success compared to their younger counterparts (≤ 35 years), with a 95% confidence interval for the coefficient ranging from 2.06 to 8.21. The model's log likelihood was -8.35, and the Wald chi-square was 10.70 ($p = 0.0011$), indicating a strong and significant overall model fit.

Conclusions: Our study highlight that specific facilitator characteristics, such as adaptability and early skill acquisition, are pivotal for early success in the CST program. Identifying and targeting these characteristics during facilitator recruitment and training could enhance the overall efficiency of the program. The findings of underscore age-related differences in the timeline for achieving fidelity ratings, with younger assistant facilitators more likely to succeed on the first attempt compared to older facilitators. This outcome suggests a need for further exploration into the factors contributing to delayed success among older participants, potentially informing tailored intervention strategies to better support diverse age groups. Tailored support and focused training on challenging aspects of adult-child interactions may help facilitators achieve proficiency sooner, ultimately benefiting families in resource-constrained settings by providing timely and effective intervention.

422.190 Navigating through Diagnosis: A Meta-Synthesis of Parental Experiences in Low- and Middle-Income Countries during the Neurodevelopmental Disabilities Diagnostic Journey for Children

A. Kaur¹, D. Gosain², A. Kurniawan³, S. Garg⁴, G. Divan⁵ and P. Bee¹, (1)Sangath, New Delhi, Delhi, India, (2)Sangath, New Delhi, New Delhi, India, (3)University of Manchester, Manchester, Manchester, United Kingdom, (4)School of Health Sciences, University of Manchester, Manchester, United Kingdom, (5)Child Development Group, Sangath India, New Delhi, India

Background:

Families of children with neurodevelopmental disabilities (NDDs) in low- and middle-income countries (LMICs) face significant challenges in obtaining an accurate diagnosis. These include logistical barriers such as geographical and financial constraints, as well as systemic issues like the lack of trained professionals, misdiagnoses, and long referral processes. The emotional toll on parents, coupled with inconsistent support from healthcare providers, further complicates the diagnostic journey. Understanding these experiences is essential for improving care and addressing gaps in service delivery.

Objectives:

This meta-synthesis aims to consolidate qualitative and mixed-methods research exploring the experiences of parents as they navigate the process of obtaining a diagnosis for their child's NDD in LMICs. It seeks to understand key themes such as healthcare interactions, emotional reactions, coping mechanisms, and overall satisfaction with the diagnostic process, with the goal of informing strategies to improve diagnostic pathways and support systems.

Methods:

A systematic search across six major databases—PsycINFO, EMBASE, MEDLINE, ProQuest, CINAHL, and PubMed—was conducted to identify studies published between 2004 and 2024. Qualitative and mixed-methods studies were included if they focused on parental experiences of NDD diagnosis in LMICs. A total of 3,076 articles were screened, with 22 meeting the inclusion criteria. The studies were appraised using the Critical Appraisal Skills Programme (CASP) tool for qualitative research and the Mixed Methods Appraisal Tool (MMAT) for mixed-methods research. A meta-synthesis was performed using thematic synthesis to integrate findings across studies, identifying cross-cutting themes.

Results:

The findings revealed recurring challenges faced by parents, including prolonged diagnostic timelines, frequent misdiagnoses, and inadequate healthcare provider knowledge. Many parents reported experiencing emotional turbulence, ranging from denial and guilt to relief after receiving a diagnosis. The lack of accessible and reliable post-diagnostic support services further compounded these difficulties, leaving families feeling isolated. Financial strains and interpersonal relationship stress were also commonly reported, particularly in resource-limited settings.

Conclusions:

This meta-synthesis highlights critical gaps in the diagnostic processes for NDDs in LMICs, emphasizing the need for better-trained healthcare professionals, streamlined diagnostic pathways, and enhanced support systems for families. These findings underscore the importance of culturally sensitive, family-centred policies to improve both the diagnostic journey and long-term outcomes for children with NDDs in LMICs.

422.191 Parent-Child Interaction Therapy for Toddlers in a Sample of Japanese Autistic Children

E. A. S. del Rosario¹, P. Moreno², A. P. Houck³, H. Onovbiona⁴, L. B. Quetsch¹ and E. Girard⁵, (1)University of Arkansas, Fayetteville, AR, (2)University of Arkansas, 72701, AR, (3)Stony Brook University, Stony Brook, NY, (4)University of Arkansas - Fayetteville, AR, Fayetteville, AR, (5)University of California, Riverside, Riverside, CA

Background: Autism diagnoses have been increasing in prevalence in Japan (with a recent rate of 3.22%; Saito et al., 2020), and other statistics show that 6.5% elementary- and middle-school children have mild developmental disabilities (including autism, attention deficit/hyperactivity disorder, and learning disability; Mithout, 2016). Caregivers of children with developmental delays have shown an increased risk for elevated stress and negative mental health (Tomanik et al., 2004). This is important as parental mental health problems may decrease a caregiver's ability to respond and communicate effectively with their autistic or developmentally delayed child, decrease their feelings of closeness to their child, and increase their risk of child abuse (Davis & Carter, 2008; Farrugia, 2009; Kimura & Yamazaki, 2016; Mak & Kwok, 2010). Parent-Child Interaction Therapy is an effective treatment targeting behavioral concerns and emotional dysregulation for children aged 2-7 years (Eyberg & Funderburk, 2011). To address the need for family-based preventative intervention options for children below 24 months, PCIT for Toddlers (PCIT-T) was developed with an emphasis on the fundamental role attachment plays for emotion and behavior regulation (Girard et al., 2018).

Objectives: The present study explored if participation in PCIT-T led to changes in child social and emotional development.

Methods: To address the need for preventative interventions, PCIT-T was implemented in a community sample with Japanese clinicians and families. Seventeen autistic children ($n = 17$) and their families received PCIT-T and completed the Devereaux Early Childhood Assessment (DECA; LeBuffe & Naglieri, 1999) to measure child social and emotional development (36-item measure, 5-point scale [0 = Never, 4 = Very Frequently]). The DECA yields scores for an Initiative scale, an Attachment/Relationships scale, and a Total Protective Factors scale.

Results: The differences between the pre- and post-treatment DECA t -scores for the Initiative ($t(10) = -2.96$, $p = .014$), Attachment/Relationships ($t(10) = -2.79$, $p = .019$), and Total Protective Factors scales ($t(10) = -2.49$, $p = .034$) were all statistically significant.

Conclusions: These results show an improvement in child social and emotional development. Overall, this provides promising support for the use of PCIT-T in Japanese families with autistic toddlers.

422.192 Patterns of Clinical Presentation and Diagnosis and Predictors of School Placement Outcomes in Autistic Children in Singapore: A Retrospective Cohort Study

C. M. Wong¹, H. C. Koh², P. K. Agarwal¹ and L. M. Daniel¹, (1)Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore, Singapore, (2)Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore, Singapore

Background: In 1998, a national Child Development Programme (CDP) was established in Singapore by the Ministry of Health, and has evolved into a nationwide community-based, family-focused and child-centric network of services with collaboration between various government bodies and voluntary welfare organizations. In 2007, the CDP received between 1200-1400 new preschool referrals per year and saw 4000-5000 follow-up medical consultations. Today, the numbers of new referrals have increased exponentially to over 5000 children per year, with autism forming a quarter of CDP diagnoses. Therefore, having data on diagnostic patterns and longer-term outcomes would greatly facilitate national resource provision and planning.

Objectives: The aims of this study were to examine patterns of clinical presentation, diagnosis, cognitive and adaptive functioning, and school placement outcomes in autistic children in Singapore, and to examine for earlier predictive factors of final cognitive and school placement outcomes.

Methods: Retrospective data were manually extracted from medical records of a specialist developmental pediatrics service for children a) born in 2008-2011, b) referred to the Autism Clinic, and/or c) ever given a diagnosis of autism. Children seen in this service receive an initial clinical diagnosis based on history and clinical features, before being referred for a detailed assessment comprising an autism-specific interview with caregivers and direct observations of the child using the Autism Diagnostic Observation Schedule (ADOS). Data items included demographic data, diagnostic methods, psychological assessment results, early intervention attendance and final school placement outcomes. Binomial logistic regression analyses were conducted to analyze the relative contributions of various factors in predicting school placement outcomes (mainstream versus special education [SPED] school).

Results: 2124 children (82.6% male; Chinese 74.1%, Malay 13.5%, Indian 9.0%, Others 3.4%) were diagnosed with autism from the 4 birth-year cohorts. The mean (SD) age of first clinical diagnosis of autism was 3.56 (1.14) years, with 81.0% of children receiving a concordant initial clinical diagnosis prior to the ADOS. 1811 (85.2%) had a formal diagnostic assessment using the ADOS at a mean (SD) age of 4.16 (1.11) years. Of 1326 with cognitive and adaptive assessment results, 220 (16.6%) had mild and 262 (19.8%) had moderate-severe cognitive impairment. There were almost twice more Malay children than expected with co-occurring intellectual disability. Of 1483 with school placement outcomes, 681 (45.9%) went to mainstream school, 323 (21.8%) entered SPED schools offering the national curriculum, and 479 (32.3%) required SPED schools offering a customized curriculum. Binomial logistic regression models showed that factors which predicted SPED school placement outcomes included lower mother's educational level, higher ADOS scores, higher DSM-5 social communication level of support, and Malay race.

Conclusions: This study provides useful insights into the patterns of clinical presentation, diagnosis, cognitive and adaptive functioning, and school placement outcomes in autistic children in Singapore. Such information can be useful for resource planning purposes for national agencies or ministries involved in providing autism diagnostic, early intervention and educational services. Racial group differences in autistic children in Singapore exist that warrant more investigation into possible causes and support systems needed, with implications for other ethnically diverse nations.

422.193 Psychosocial Interventions for Disruptive Behaviours in Children and Adolescents with Autism and Other Neurodevelopmental Disorders in Low- and Lower-Middle-Income Countries: A Systematic Review

N. Shafique¹, N. Chaudhry², S. Mansoor³, B. Ali⁴, M. M. Bhatti⁵, A. Saeed⁶, U. Arshad⁷, K. Bearss⁸, A. Scarpa⁹ and N. Husain¹⁰, (1)Virginia Tech, Blacksburg, VA, (2)Pakistan Institute of Living and Learning, Karachi, Pakistan, (3)Psychiatry, Foundation University Islamabad, Islamabad, Pakistan, (4)Pakistan Institute of Living & Learning, Karachi, Pakistan, (5)Pakistan Institute of Living and Learning, Islamabad, Pakistan, (6)Pakistan Institute of Living and Learning, Islamabad, Pakistan, (7)Pakistan Institute of Living & Learning, Lahore, Pakistan, (8)Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (9)Department of Psychology, Virginia Tech, Blacksburg, VA, (10)Division of Psychology and Mental Health, University of Manchester, Manchester, United Kingdom

Background:

Neurodevelopmental disorders (NDDs), including autism spectrum disorder (ASD) are significant public health challenges globally, especially in low- and lower-middle-income countries (LLMICs). Disruptive behaviours like aggression and self-injury affect children and adolescents, reducing their quality of life and stressing caregivers. Psychosocial interventions for managing disruptive behaviours has proven effective in high income countries however these are understudied in low- and middle-income countries (LLMICs). It clearly shows a need for a systematic review to determine the effectiveness of different psychosocial interventions in these settings. This will help inform future research and guide the development of evidence-based interventions for children and adolescents with NDDs in LLMICs.

Objectives:

This systematic review aimed to assess the effectiveness of psychosocial interventions in reducing disruptive behaviors among children and adolescents with Autism and other NDDs in LLMICs.

Methods:

This review adhered to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and was pre-registered with (PROSPERO 2024 CRD42024498910). A comprehensive database (PsycINFO, MEDLINE, Embase, Cochrane, CINAHL) search was run for both published and grey literature between 1946 and February 16th, 2024. We included randomized controlled trials (RCTs) that evaluated psychosocial interventions for children and adolescents (aged ≤ 19 years) with neurodevelopmental disorders, such as autism, intellectual disability, ADHD, and communication or motor disorders. Psycho-pharmacological interventions were excluded. Data screening extraction and risk of bias was done by two independent reviewers.

Results:

We included 9 studies 8 published and one grey literature study with a total number of $N = 325$ participants. Most of the studies ($k=6$) were randomized controlled trials (RCTs), ($k=2$) cluster randomized controlled trials (Cluster RCTs), and ($k=1$) mixed-methods randomized controlled trial. The included studies were from India ($k=1$), Iran ($k=5$), Pakistan ($k=2$), and Tunisia ($k=1$), highlighting six psychosocial interventions tailored to local contexts. Parent skills training programs were among the most frequently evaluated showing reduction in disruptive behaviors and improving caregiver-child interactions. Yoga and music therapy also improved behavioral outcomes and emotional regulation in children with NDDs. Neuro-feedback training and reality therapy demonstrated varying levels of effectiveness, depending on the cultural adaptation of the intervention and the context in which it was implemented.

Conclusions:

This systematic review highlights the potential of culturally adapted evidence-based psychosocial interventions to reduce disruptive behaviors in children and adolescents with NDDs in LLMICs. Future research should prioritize larger trials, sustainability, and the integration of interventions into existing healthcare systems.

422.194 Root Causes of Autism Disproportionality in Special Education: Insights from Two Mixed-Methods Studies in California **P. Luelmo, Special Education, San Diego State University, San Diego, CA**

Background:

Autism disproportionality in special education remains a significant concern, particularly in California, where White students are often overidentified, and Latinx and Indigenous (Zapotec/Mixtec) students are underidentified. These disparities arise from systemic issues, such as cultural misunderstandings, language barriers, and inequitable access to diagnostic services. The underidentification of Latinx and Indigenous students leads to delayed diagnoses and limited access to essential early interventions, which are critical for improving educational outcomes for students on the autism spectrum.

Objectives:

This research aims to investigate the root causes of autism disproportionality by analyzing both systemic and cultural barriers that affect the identification and service provision of students from diverse backgrounds.

Methods:

Two mixed-methods studies were conducted in a California high school district with a history of autism disproportionality. **Study 1 (2021)** involved quantitative analysis through online caregiver surveys ($N=135$), focusing on barriers to autism identification and service access. Participants were asked about their experiences with autism diagnosis, IEP knowledge, and challenges encountered during the identification process. **Study 2 (2023-2024)** utilized qualitative focus groups and interviews with Latinx and Indigenous (Zapotec/Mixtec) caregivers to explore the cultural and linguistic challenges faced by non-English-speaking families. Thematic analysis was employed to identify patterns related to language barriers, cultural stigma, and access to resources.

Results:

Study 1 revealed that White students were slightly overidentified with autism, with some likely needing 504 plans instead of IEPs. In contrast, an estimated 187 Latinx students were underidentified, suggesting that cultural and linguistic barriers played a significant role in delaying diagnosis. These students were often misidentified with other disabilities, potentially due to the absence of early autism screening. The analysis showed that non-English-speaking parents, particularly those from Indigenous backgrounds, faced the greatest challenges, with 68% reporting language as a major barrier to accessing services.

Study 2 provided deeper insights into these barriers. Indigenous families, particularly those who speak Mixtec, scored significantly lower on the IEP Rights Knowledge Scale ($M=3.5$) compared to English-speaking families ($M=7.5$). This gap in knowledge and understanding of the IEP process contributed to the delayed identification of autism. Only 38% of non-English-speaking families received an autism diagnosis for their children before school intervention, compared to 73% of English-speaking families. The qualitative data highlighted that Indigenous families were often unaware of autism or attributed developmental delays to other factors due to a lack of accessible information and cultural stigma surrounding disabilities.

Conclusions:

The findings from both studies emphasize the urgent need for systemic interventions to address autism disproportionality. Early autism screenings, especially in high-risk populations, enhanced translation services, and culturally sensitive training for educators and caregivers are critical to reducing these disparities. Without targeted efforts to support Latinx and Indigenous families, disproportionality in autism identification will continue to disadvantage these communities. Implementing these changes will help ensure equitable access to special education services for all students, particularly those from underserved backgrounds.

422.195 Subjective Wellbeing in Vietnamese Migrant Parents of Autistic Children

K. P. Nguyen¹, L. A. Pecora², M. Hooley³, E. Westrupp⁴ and M. A. Stokes³, (1)Deakin University, Melbourne, VIC, Australia, (2)School of Psychology, Deakin University, Melbourne, VIC, Australia, (3)Healthy Autistic Life Lab; School of Psychology, Deakin University, Burwood, VIC, Australia, (4)School of Psychology, Deakin University, VIC, Australia, Melbourne, VIC, Australia

Background:

There are strong evidence of poorer mental health in both migrant parents and parents of autistic children. However, little is known about intersection of these two groups. The wellbeing of migrant parents with autistic children is often overlooked due to lack of culturally and linguistically sensitive studies or instruments.

Objectives:

This study explored the wellbeing of Vietnamese migrant (VM) parents, one of the most vulnerable migrant groups, who were also parents of autistic children. It was hypothesised that VM parents of autistic children would report lower wellbeing than VM parents without autistic children and general population (GP) parents with or without autistic children. The possible contributing factors to VM parents' lower wellbeing will also be explored.

Methods:

The Personal Wellbeing Index (PWI) was translated into Vietnamese and validated for use in a VM sample. We recruited 142 GP and 142 VM parents of autistic or non-autistic children to respond to an anonymous, 15-minute online survey in either Vietnamese or English at their discretion. The participants' wellbeing (PWI), mental health (Depression, Anxiety, and Stress Scale 21), demographic data, years since migration, and English proficiency were recorded.

Results:

Our baseline results indicated that VMs had lower wellbeing than the GP, $t(69,498)=2.25, p=0.02, d=0.02$. Unexpectedly, VM females showed significantly lower wellbeing than their GP counterparts, $t(992)=2.90, p=.004, d=0.18$. Our next phase, to be completed in November and December, will assess the wellbeing of VM parents of autistic children, which is anticipated to be lower than that of their GP counterparts. Their mental health status and demographic data will be used to interpret the results.

Conclusions:

This study is anticipated to provide knowledge about the mental health and wellbeing of VM parents of autistic children and highlight their unmet needs. Key findings may facilitate future support and identify intervention points. This study will encourage future research to uncover further the experiences of migrant parents in Western societies, especially those with neurodivergent children.

422.196 Title: A Cross-Cultural Examination of the Comprehensive Autistic Trait Inventory (CATI) in Two General Population Samples

M. Terner¹, M. C. English^{2,3} and O. Golan¹, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)School of Psychological Science, University of Western Australia, Perth, Western Australia, Australia, (3)The Kids Research Institute Australia, Perth, Australia

Background: The Comprehensive Autistic Trait Inventory (CATI) is a self-report measure of autistic traits in the general population (English et al., 2021). It comprises six subscales: Social Interactions (SOC), Communication (COM), Social Camouflage (CAM), Repetitive Behaviours (REP), Cognitive Rigidity (RIG), and Sensory Sensitivity (SEN). Previous research has indicated cultural differences in the expression and interpretation of autistic traits (Freeth et al., 2013). Additionally, sex differences in autistic traits have been widely reported, with males generally showing higher levels of autistic characteristics (See for example, Greenberg et al., 2018). However, recent research suggests that these may vary across different domains of autistic traits (Mahendiran et al., 2019; Siracusano et al., 2021).

Objectives: This study aimed to compare CATI scores between an English-speaking sample (mostly from Australia and the UK), and a Hebrew speaking Israeli sample, to examine associations between subscales across cultural groups, and to investigate sex differences and age effects on CATI scores.

Methods: 1997 individuals (995 English-speakers, 1002 Israeli) completed the CATI. Correlational analyses and a mixed-design ANOVA were conducted, with subscale as a within-subjects factor, cultural background and sex as between-subjects factors, and age as a covariate.

Results: Correlational analyses revealed varying subscale correlation strength across culture ($r = .29$ to $.44$, all $p < .001$), whereas Total CATI scores were strongly correlated cross-culturally ($r = .73, p < .001$), supporting the need for further analysis. The ANOVA revealed significant main effects for subscale ($F(5,1988)=167.24, p < .001$), with RIG showing the highest mean score ($M = 22.24, SD=7.76$) and COM the lowest ($M=13.90, SD=4.87$); for cultural background ($F(1,1992) = 61.208, p < .001$) with English-speakers scoring higher than Israeli participants; and for sex ($F(1, 1992)=6.34, p=.012$) with males ($M=18.52, SE=.14$) scoring higher than females ($M=18.04, SE=.14$).

In addition, significant interactions were found between subscale and cultural background ($F(5,1988)=39.23, p < .001$) and between subscale and sex ($F(5,1988)=37.76, p < .001$) (Figure 1). These interactions suggest that the pattern of scores across subscales differed by cultural background and by sex. Post-hoc analyses revealed that English-speaking participants scored significantly higher than Israeli participants on SOC (Mean Difference (MD) = 4.47, $SE=.34, p < .001$), COM (MD=1.35, $SE=.22, p < .001$), REP (MD=1.21, $SE=.29, p < .001$), and RIG (MD=1.34, $SE=.27, p < .001$) subscales. Regarding sex differences, males scored higher on COM (MD=1.94, $SE=.21, p < .001$), CAM (MD=0.75, $SE=.27, p=.005$), REP (MD=1.36, $SE=.28, p < .001$), and RIG (MD=.54, $SE=.26, p=.034$), while females scored higher on SEN (MD=1.72, $SE=.29, p < .001$).

Age significantly effected CATI scores ($F(1,1992)=77.49, p < .001$), with a general trend of increasing scores with age across most subscales, particularly the REP, CAM and RIG subscales.

Conclusions: The CATI demonstrates cross-cultural differences in autistic trait profiles, with English-speaking participants generally scoring higher than Hebrew speakers. Sex differences were observed across subscales, highlighting the importance of considering sex in autistic trait assessment.

Age influences CATI scores, suggesting a need for age-specific norms. The CATI shows promise as a cross-cultural measure, though culture-specific cutoffs may be required for screening purposes. These findings contribute to our understanding of the broader autism phenotype across cultures and emphasize the importance of cultural considerations in autistic trait assessment.

422.197 Developing a Globally-Relevant Family Support Programme for Young Autistic Children: Stakeholder Perspectives from South Africa and Russia

G. Morozova¹, L. Schlebusch², N. Chambers³, A. Vo³, T. Morozova⁴, S. Dovbnya^{4,5}, J. J. S. Dawson-Squibb² and P. J. de Vries², (1)Moray House School of Education & Sport, Human Performance Science Research Group, The University of Edinburgh, Edinburgh, Scotland, United Kingdom, (2)Centre for Autism Research in Africa, Division for Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)The Naked Heart Foundation, London, United Kingdom, (4)Naked Heart France, Paris, France, (5)ACT Consultancy, Paris, France

Background:

Recent progress in a range of caregiver education programmes and caregiver-mediated interventions have led to improved outcomes for autistic children and families. However, most of these programmes have come from high-income countries and were not designed from the outset with a focus on global relevance and participatory stakeholder involvement. To address this gap, this international research collaboration set out to develop a new family support programme for families of young autistic children, called "Bloom".

Objectives:

The objective of this study was to investigate the stakeholders' views on the relevance of the proposed programme, the clarity and appropriateness of language used in programme description, and the gaps not addressed in the programme that were important to stakeholders.

Methods:

This study adopted qualitative methodology and used purposive sampling to invite stakeholders from South Africa (SA) and Russia (Rus) to take part in facilitated workshops. The sample ($N_{SA}=14$, $N_{Rus}=17$) comprised of family members of autistic children and adults, self-advocates, professionals and autism non-profit representatives. After providing informed consent, participants attended a presentation explaining Bloom's Theory of Change (Schlebusch et al., 2024) and background, and were divided into groups of 3-5 for facilitated discussions. Using a detailed guide, facilitators guided participants through discussions about language, relevance, needs and gaps. Data were collected using Post-it notes and flipchart paper at the in-person event (SA) and whiteboard feature of the Zoom platform for the online workshop (Rus). Once collated, all data were digitised and uploaded into Miro software, where it was stored and analysed using a six-phase reflexive thematic analysis approach.

Results:

The stakeholder workshops generated large volumes of relevant data with high information power. Unanimously, both stakeholder groups felt that the proposed programme was highly relevant and both groups agreed with the proposed goals and methods. Participants identified a wide range of needs for families new to an autism diagnosis, including autism-specific (knowledge, practical skills, effective tools, positive child development, specialist support), social (social support, inclusion of all family, community) and psychological (self-care skills, hope for brighter future, safe space for practice) needs. Scalability, cost implications, and capacity-building for service provision were amongst some of the themes unique to SA stakeholders. Facilitator needs, such as time for training, local tips and additional materials were unique to Russian stakeholders, reflecting the sample composition of this group where 70% of participants were working directly with autistic children and their families.

Conclusions:

The participatory approach to programme development and continuous engagement with stakeholders from local autism communities are at the core of Bloom programme philosophy. The findings from stakeholder workshops across two different cultural contexts highlighted the need for multi-level support for families post-diagnosis and the high demand for culturally-adaptable evidence-based programmes for families of young autistic children. The implications of this study extend beyond the development of the Bloom family support programme, by offering a detailed account of the methods and procedures used in stakeholder engagement activities that can inform future participatory research in this area.

422.198 Translation and Adaptation of the Executive Functioning Intervention "Unstuck and on Target" for Latin America

J. Villarreal¹ and J. Safer-Lichtenstein², (1)NEURODESARROLLO QUITO, QUITO, PICHINCHA, Ecuador, (2)University of Colorado School of Medicine, Aurora, CO

Background: Families of autistic children struggle to access high quality, evidence-based, interventions in Latin America.¹ Through an international partnership between researchers in the U.S. and the Neurodesarrollo Quito (NQ) clinic in Ecuador, we sought to translate, adapt, and collect initial acceptability data from Ecuadorian clinicians and families about the manualized, evidence-based, executive functioning intervention *Unstuck and On Target* (*Unstuck*).² *Unstuck* is a well-suited program for use in low-and-middle income countries because it is cost-effective, easy-to-use, and designed to be run by anyone, including providers that do not have specialized training.

Objectives: To describe the process for translating *Unstuck* and present initial feasibility/ acceptability data on its international use.

Methods: An initial translation of the *Unstuck* manual from English to Spanish was completed by DeepL, an AI program specifically designed for translation. Our team then decided on the best translation of key *Unstuck* scripts/vocabulary to be understood across Latin America. This was done in a collaborative meeting with clinicians interested *Unstuck* from Argentina, Ecuador, Mexico, and Puerto Rico. Currently, the AI translation is being revised by the NQ clinic director and the *Unstuck* research team, making changes both for language clarity and cultural acceptability to create an adapted manual of comparable quality to the version in English (rather than just a direct translation). Even before the intervention was formally translated, NQ clinicians delivered *Unstuck* using informal translations of the lessons to children either individually or in small groups, with separate individual parent training. To date, seven NQ clinicians have used all or part of the program with 11 neurodivergent children and their parents. We collected initial data around feasibility/acceptability from both clinicians (using the AIM/IAM/FIM³) and families (using child and parent satisfaction surveys created by our research team).

Results: On three-point-Likert scales, children rated *Unstuck* highly on how much they enjoyed it ($M = 2.83$, $SD = 0.41$), with slightly lower ratings on how much they felt it helped them at school ($M = 2.67$, $SD = 0.52$), and at home ($M = 2.50$, $SD = 0.55$). Open-ended responses revealed the most helpful parts of the program were *Unstuck* vocabulary and calming strategies, and the biggest suggestion to improve it was to include more games. Across six 5-point Likert scales, parent acceptability ratings ranged from an average of 4.00 (ability to practice skills at home) to 4.71 (overall satisfaction). Open-ended responses similarly identified *Unstuck* scripts and emotion regulation to be the most helpful aspects, while the biggest suggestion was for more resources for parental learning outside of sessions. Finally, implementer ratings were high, with means ranging from 18.40 to 18.80 out of 20 on the acceptability, appropriateness, and feasibility subscales respectively. Implementers identified the clear lesson structure and easy-to-understand concepts as strengths, and greater consideration of local culture/ context to be an area for improvement.

Conclusions: Easy-to-use, manualized, interventions such as *Unstuck* may be feasible/acceptable for use in low-and-middle income countries with relatively minor adaptations. The core content appears relatable across culture, despite needing some smaller modifications to improve contextual fit.

422.199 Well-Being of Parents of Children with Autism: A Cross-Cultural Comparative Study

L. Chawki¹, J. Leto², N. Poirier³, A. Alameddine⁴, A. de Gaulmyn⁵, E. Lemonnier⁶, R. Taton⁷, M. M. Geoffroy⁸, P. Isnard⁹, D. Cohen¹⁰, M. Alhassanieh¹ and E. Cappe¹¹, (1)Laboratoire de Psychopathologie et Processus de Santé, Université Paris Cité, Boulogne-Billancourt, Ile de France, (2)Université Paris Cité, Laboratoire de Psychopathologie et Processus de Santé, 92100 Boulogne-Billancourt, France, Boulogne-Billancourt, France, (3)Psychology, 1275 Boul. N.P. Lapierre, Montréal, QC, Canada, (4)Psychology Department, University of Balamand, Beirut, Beirut, Lebanon, (5)Centre Hospitalier Sainte-Anne, Paris, Ile de France, France, (6)Université de Limoges / CHRU, Limoges, Nouvelle-Aquitaine, France, (7)Unité de Formation, Information, Recherche et animation du Réseau CENTRE RESSOURCES AUTISME NORMANDIE Seine-Eure CH du Rouvray, SOTTEVILLE LES ROUEN, Normandie, France, (8)Centre hospitalier le Vinatier, Lyon, Bron, France, (9)L'Assistance publique – hôpitaux de Paris (AP-HP), Hôpital Bichat - Claude-Bernard, Paris, Ile de France, France, (10)Department of Child and Adolescent Psychiatry, Hôpital Universitaire Pitié-Salpêtrière, Sorbonne University, Paris, France, (11)Laboratoire de Psychopathologie et Processus de Santé, Université Paris Cité, Boulogne-Billancourt, Île-de-France, France

Background: Supporting parents of children with autism spectrum disorder (ASD) and helping them adjust to their child's condition is a core clinical and scientific necessity, as emphasized by the French National Strategy for Autism (2023). The literature highlights that ASD significantly influences parental well-being, and this impact can vary depending on cultural context. Although ASD is a priority in public health policies in various countries, few cross-cultural studies have compared the experiences of parents of children with ASD. Studies highlighted that in order to effectively design and tailor early interventions for all families of children with ASD, it is essential to study and compare the experiences of parents from both individualistic and collectivistic cultures.

Objectives: This cross-cultural comparative study aims to investigate the well-being of French, Canadian and Lebanese parents of children with ASD including parental anxiety, depression, and the quality of life in parents of children with autism, as well as the explicit individual, psychosocial and cultural factors of parental well-being.

Methods: Participants included 59 French, 39 Canadian, and 38 Lebanese parents of children with ASD. They completed completed self-evaluation measures assessing parental anxiety and depressive symptoms, quality of life, coping strategies, emotional regulation strategies, internalized stigma, perceived stress and social support, the severity of the child's problem and emotional behaviors, as well as motor coordination deficits in children with ASD. A sociodemographic questionnaire provided additional information about the participants and their children.

Results: Lebanese parents in our sample exhibited higher scores of anxiety and depression in comparison with Canadian and French parents of children with ASD. However, Lebanese parents also reported better physical health and environmental scores than their Canadian and French counterparts. Cognitive reappraisal predicted higher anxiety in French and Canadian parents, while Lebanese parents showed no significant predictors for anxiety. Depression was linked to lower cognitive reframing for Canadian and French parents, and to decreased distraction coping in Lebanese parents. Quality of life also varied by culture, with Canadian parents benefiting from cognitive reframing and Lebanese parents showing better outcomes with distraction coping. Additionally, lower child behavioral issues improved environmental quality of life for Lebanese parents.

Conclusions: This study underlined both similar and distinct factors of anxiety, depression, and quality of life across French, Lebanese, and Canadian parents of children with ASD, suggesting clear cross-cultural differences. Clinicians should implement culturally tailored interventions that enhance coping strategies. Additionally, providing training in emotional regulation, fostering community support, and addressing child behavioral issues through parent training programs will promote parental well-being associated with raising children with ASD. Further qualitative research is important, as it can provide deeper insights into the experiences and challenges faced by parents across different cultural contexts.

**422.200 Why We Must Act: Barriers to Autism Care**

K. Boles¹, R. E. Mitre², V. Nanclares-Nogues³, C. J. Fernandez Alvarez⁴, M. Mahurin⁵, A. Brewer Curran⁶ and K. Sohl⁷, (1)Child Health, University of Missouri, Columbia, MO, (2)Fundación Neurodiversidad, Rosario, Argentina, (3)Pediatrics, University of Missouri - Columbia School of Medicine, Columbia, MO, (4)Univeristy of Salamanca, Salamanca, Spain, (5)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (6)Department of Pediatrics, University of Missouri, Columbia, MO, (7)ECHO Autism Communities, University of Missouri School of Medicine, Columbia, MO

Background:

Barriers to autism care are well-documented, but understanding the specific obstacles faced by professionals in different regions is crucial for developing effective solutions. To gain insight into these challenges, we conducted research focusing on the barriers encountered by participants in our autism care programs across North, Central, and South America. In 2023, we introduced a standardized metric for evaluating programs to more systematically assess and address these barriers.

Objectives:

- To identify and compare the key barriers to autism care faced by professionals across the Americas.
- To assess the severity of these barriers between regions.
- To compare barriers across regions

Methods:

Data were collected from participants in the ECHO Autism programs between 2023 and 2024, utilizing a newly implemented standardized metric. Surveys gathered demographic information, levels of self-efficacy, perceived barriers to care, and changes in clinical practice. The data were then aggregated and compared across regions, specifically focusing on the differences between Latin America (LATAM, n=108) and the United States (US, n=116). Comparative analysis was conducted to assess the top barriers and the reported severity of these obstacles.

Results:

The top barriers identified by LATAM participants were: lack of public policy supporting autism care, high cost of training opportunities, and insufficient or no financial reimbursement for professional services. In contrast, U.S. participants reported inadequate access to autism supports and services outside of their profession, limited ability to connect with autism specialists, and lack of training as the primary barriers. Overall, LATAM participants indicated that all barriers were more severe than those reported by U.S. participants. Additionally, U.S. participants experienced a more significant decrease in the severity of barriers over time compared to LATAM participants, indicating regional differences in both the nature and the persistence of these obstacles.

Conclusions:

This research highlights the significant disparities in the barriers faced by professionals across different regions. In Latin America, systemic challenges such as insufficient public policy and financial constraints are more pronounced, whereas in the U.S., the focus is on improving access to specialized services and training. Addressing these regional differences is critical for developing targeted interventions to reduce barriers and improve access to autism care globally. Our findings emphasize the need for continued efforts to create more equitable care systems and support professionals through policy reform, accessible training, and financial reimbursement strategies.

422.201 Latino Voices in Autism Research: A Community-Based Approach to Cultural and Linguistic Inclusion

C. Montiel-Nava¹, C. Navarro², A. C. Ramirez¹, J. Abouchard Anaya² and V. L. Villarreal³, (1)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (2)University of Texas Rio Grande Valley, Edinburg, TX, (3)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

Background: Despite an increased prevalence within the U.S., Black, Indigenous, and other people of color (BIPOC) and those of lower socioeconomic status (SES) they have been historically underrepresented in autism research. Specifically, Latino autistic individuals and their families are significantly underrepresented, limiting the capacity for researchers to generate findings that benefit this community. In addition, Latino parents of autistic children report higher distrust towards healthcare systems and needing twice the amount of physician visits to receive an ASD diagnosis than White non-Latino parents. As a result, the partnerships between researchers and the community of Latino parents of autistic children are scarce, influencing their participation in research studies

Objectives: Our project aimed to (1) establish a partnership between researchers and the Latino autism community in the Rio Grande Valley, Texas, and (2) identify and integrate cultural considerations to adapt the entirety of participants' research experience, from participant recruitment to the development of measurement tools.

Methods: Using a phenomenological framework grounded in Community-Based Participatory Research (CBPR) and principles from the social model of disability, this study conducted five focus groups between March and May 2023. Three focus groups included parents of autistic children (n=25), while two involved autistic adults (n=8). A script, informed by previous studies, guided the discussions, focusing on recruitment materials (e.g., flyers, emails, phone scripts) and procedures (e.g., number of sessions, locations, transportation). Applied thematic analysis was used to evaluate the cultural and linguistic appropriateness of the research materials and recruitment strategies. This work served as a foundation for a broader study examining the impact of bilingualism on language development in autistic children.

Results: Four main themes emerged from the data, reflecting research involvement, symbols as representations of autistic identity, distrust toward the research team, and the importance of cultural and linguistic alignment. One recurrent theme among parents was the preference for identity-first versus person-first language, while this was not as prominent for autistic adults. Additionally, the participants highlighted the use of symbols to represent different community groups. They provided valuable feedback on logistical aspects, such as the ideal length of assessment sessions, appropriate locations, types of prizes for children, and how to navigate the assessment process. Importantly, participants emphasized that knowing their involvement would contribute to scientific advancement was a primary motivation for participation

Conclusions: This study highlights the critical need to include historically marginalized populations in autism research as a step toward reducing health disparities. The results show that the Latino autism community is willing to participate in research, provided that recruitment efforts and study designs are culturally and linguistically sensitive, identify the responsible parties (principal investigators and institutions), and offer benefits beyond monetary compensation. By employing a CBPR framework and incorporating an intersectionality lens, researchers can build trust with the Latino autism community, amplifying their historically unheard voices. This approach moves us closer to achieving more equitable representation in autism research and to developing methods that address the needs of a diverse autistic population in culturally informed ways.

422.202 Transborder Solutions: Empowering Latino Caregivers of Autistic Children Along the US-Mexico Border

C. Montiel-Nava¹, M. Ortiz², A. C. Ramirez¹, M. Montenegro³, G. Matheus⁴, B. Villalobos⁵, R. Calderon⁶, S. Perez⁷ and M. Mares⁸, (1)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (2)Psychology, University of Texas Rio Grande Valley, Edinburg, TX, (3)University of Texas Rio Grande Valley, Edinburg, TX, (4)The University of Texas Rio Grande Valley, Edinburg, TX, (5)California State University, Northridge, Northridge, CA, (6)Department of Human Development and School Services (HDSS), University of Texas Rio Grande Valley, Edinburg, TX, (7)Autismo en mi Vida Rio Grande Valley, Edinburg, TX, (8)United Way of South Texas, McAllen, TX

Background: Autistic children living near the US-Mexico border face significant challenges in accessing autism-related health services. Barriers such as language, costs, late diagnosis, long waiting lists, and lack of providers exacerbate negative outcomes. Many border residents seek healthcare across the border due to lower costs, accessibility, and perceived effectiveness. Culturally and linguistically sensitive interventions are critical in addressing health disparities within the Latino community and in facilitating transnational healthcare for this vulnerable population.

Objectives: This study examined the acceptability and feasibility of the World Health Organization's Caregiver Skills Training (CST) program for Spanish-speaking caregivers of autistic children along the US-Mexico Border.

Methods: Caregivers of 10 Spanish-speaking autistic children aged 3-5 years (mean age = 3.85, SD = 0.88) from the Rio Grande Valley completed the WHO-CST program. All caregivers identified as Latino; most were mothers (90%, n=9) and bilingual in Spanish and English (90%, n=9).

Twenty percent (n=2) were Mexican residents who crossed the border to attend sessions. Eighty percent (n=8) of the children were male, and 60% (n=6) primarily spoke Spanish.

Data were collected at two points: program onset and 12 weeks post-completion after the final home visit. Measures included the Autism Treatment and Evaluation Checklist (ATEC), Parental Stress Scale, Parental Sense of Competency Scale, and Caregiver Knowledge and Skills Test.

Feasibility and acceptability data were gathered via post-session feedback.

Results: ATEC scores showed a decrease from 72.70 (SD = 11.53) to 69.70 (SD = 10.95), indicating a reduction in autism-related characteristics, though the change was not statistically significant. However, health/physical subdomain scores showed a significant reduction from 23.40 (SD = 7.95) to 20.30 (SD = 9.14) ($t = 2.96$, $p = .02$). Other domains—communication, sociability, sensory/cognitive—also showed decreased symptomatology but without statistical significance. Caregiver knowledge improved significantly ($t = 9.13$, $p = .003$). Parental stress and sense of competence both decreased, though not significantly.

Caregivers overwhelmingly found the sessions easy to understand (100%), relevant to their families' needs (99%), and helpful in achieving goals (97%). Most felt the session duration was appropriate (96%) and that they were prepared to implement the CST strategies at home (89%).

Conclusions: ATEC scores showed a decrease from 72.70 (SD = 11.53) to 69.70 (SD = 10.95), indicating a reduction in autism-related characteristics, though the change was not statistically significant. However, health/physical subdomain scores showed a significant reduction from 23.40 (SD = 7.95) to 20.30 (SD = 9.14) ($t = 2.96$, $p = .02$). Other domains—communication, sociability, sensory/cognitive—also showed decreased symptomatology but without statistical significance. Caregiver knowledge improved significantly ($t = 9.13$, $p = .003$). Parental stress and sense of competence both decreased, though not significantly.

Caregivers overwhelmingly found the sessions easy to understand (100%), relevant to their families' needs (99%), and helpful in achieving goals (97%). Most felt the session duration was appropriate (96%) and that they were prepared to implement the CST strategies at home (89%).

423.203 A Novel Synbiotic Formula for Anxiety and Sensory Hyper-Responsiveness Symptoms in Young Autistic Children: An Open-Labelled Pilot Study

O. Wong¹, S. Chan², F. Mo³, J. Ching^{4,5}, H. M. Tun^{4,6}, Z. Xu^{4,5}, S. Qi^{4,5}, M. Wan^{4,5}, C. Cheung^{4,5}, W. Tang⁴, F. Chan^{4,5,7,8} and S. Ng^{4,5,7,8}, (1)Department of Psychiatry, Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong (China), (2)Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (3)Psychiatry, Alice Ho Miu Ling Nethersole Hospital, Hong Kong, Hong Kong, (4)Microbiota I-Center (MagIC), Hong Kong, Hong Kong, (5)Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (6)The Jockey Club School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (7)Centre for Gut Microbiota Research, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (8)Li Ka Shing Institute of Health Sciences, State Key Laboratory of Digestive Disease, Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Recent advancements in understanding the microbiota-gut-brain axis (MGB) have posited microbial modulation as a novel intervention strategy in autism. However, prior trials of probiotics were not informed by the complex interactions between the MBG axis and clinical phenotypes, leading to a lack of targeted treatment outcomes. Our upstream research revealed the correlations between depleted gut microbial production of GABA and elevated sensory hyperresponsiveness and anxiety symptoms in autism. A novel synbiotic formula, SCM06, with a combination of prebiotics and probiotic species that upregulate GABA production and immune function, was developed as a specific treatment of anxiety and sensory symptoms in young autistic children.

Objectives: This study aimed to assess the safety, tolerability, and preliminary efficacy of the SCM06 formula in alleviating anxiety and sensory hyperresponsiveness symptoms in young autistic children.

Methods: Young autistic children with significant anxiety and sensory hyperresponsiveness symptoms were recruited in this open-label pilot study from a Child and Adolescent Psychiatric Center affiliated with a University Teaching Hospital in Hong Kong (ClinicalTrials.gov ID: NCT06126185). Participants consumed one sachet of the SCM06 formula daily for 12 weeks. Anxiety, sensory hyper-responsiveness, core autistic symptoms, attention deficit and hyperactivity disorder (ADHD) and externalizing behavioural symptoms, and presence of functional gastrointestinal disorders (FGID) were evaluated at Weeks 0, 6, and 12 using the following parent-rated questionnaires: Anxiety Scale for Children-Autism Spectrum Disorder scale (ASC-ASD), the Sensory Experience Questionnaire (SEQ), Social Responsiveness Scale 2nd edition, Child Behavioural Checklist and Rome IV Diagnostic Questionnaires for Pediatric FGID.

Results: A group of thirty prepubertal ASD children with normal IQ, aged 4 to 11 (22 males and 4 females) were recruited and completed the study. SCM06 was safe and tolerable, with only 3.33% and 6.67% of participants reporting self-limiting loose stool and reduced appetite. Significant improvements from Week 0 to Week 12 were observed in both anxiety ($F = 7.47$, $df = 2,58$, $p = 0.001$, $\eta_p^2 = 0.205$) and sensory hyperresponsiveness ($F = 3.87$, $df = 2,58$, $p = 0.026$, $\eta_p^2 = 0.118$) (Figure 1). The prevalence of functional abdominal pain disorders decreased from 26.7% at Week 0 to 10.0% at Week 12 ($\chi^2 = 5.00$, $df = 1$, $p = 0.025$). Other symptoms such as ADHD and core ASD features, which were not associated with depleted gut microbial GABA production, did not change significantly. This suggested a specific effect of SCM06 on the two targeted symptom domains.

Conclusions: The concurrent relief of gastrointestinal, sensory, and anxiety symptoms corroborated with our upstream observational studies, alluding to the specific therapeutic action of SCM06 on the MBG axis. Nevertheless, an adequately powered RCT is needed to evaluate SCM06's efficacy properly.

423.206 Predictors of Placebo Response in the Study of Oxytocin in Autism to Improve Reciprocal Social Behaviors (SOARS-B)

A. Verdes¹, S. Bhattachan¹, C. Rockhill², M. A. Minjarez³, S. J. Kim⁴, B. King⁵, M. L. Palumbo⁶, L. Nowinski⁶, C. J. McDougale⁶, K. Sanders⁷, S. K. Siecinski⁸, S. Giamberardino⁹, S. G. Gregory¹⁰, A. Kolevzon¹¹, J. Veenstra-VanderWeele¹², M. Spanos¹³, T. Chandrasekhar¹³, L. Sikich¹⁴ and A. Jutla¹⁵, (1)New York State Psychiatric Institute, New York, NY, (2)Seattle Children's Research Institute, Seattle, WA, (3)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Seattle Childrens, Seattle, WA, (5)UCSF, San Francisco, CA, (6)Lurie Center for Autism, Massachusetts General Hospital, Lexington, MA, (7)Otsuka US, Princeton, NJ, (8)Duke Molecular Physiology Institute, Duke University, Durham, NC, (9)RTI International, Research Triangle Park, NC, (10)Neurosurgery, Duke University School of Medicine, Durham, NC, (11)Seaver Autism Center at Mount Sinai, New York, NY, (12)Columbia University, New York, NY, (13)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (14)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (15)1051 Riverside Drive, New York State Psychiatric Institute / Columbia University, New York, NY

Background: Although randomized clinical trials (RCTs) have sought to identify treatments for social communication difficulties and repetitive behaviors in autism, none has yet shown consistent superiority over placebo. In part this may be because the substantial placebo response reported in many autism RCTs impedes the ability to detect meaningful treatment effects. Meta-analyses have identified trial-level factors that predict an increased placebo response rate in autism, including longer trial duration and larger sample size, but only two studies of individual-level factors have been conducted to date. These studies found that lower baseline symptom severity and enrollment at a commercial rather than academic study site may make a particular autistic individual more likely to respond to placebo. However, little is known about what other factors might be influential in predicting individual-level placebo response.

Objectives: We sought to identify individual-level predictors of placebo response in data from SOARS-B, a 24-week RCT of intranasal oxytocin for social impairment in autistic youth. In our primary analysis, we examined predictors of change in Aberrant Behavioral Checklist-modified Social Withdrawal (ABC-mSW) score, a caregiver-rated index of social impairment, at 24 weeks in SOARS-B participants taking placebo. In secondary analyses, we examined predictors of ABC-mSW change at 12 weeks and predictors of Clinical Global Impression – Improvement (CGI-I), a clinician-rated index of clinical improvement or its lack relative to baseline, at 24 and 12 weeks. For comparison, we also examined predictors of ABC-mSW change and CGI-I at 24 and 12 weeks among SOARS-B participants taking oxytocin.

Methods: For each analysis, we first used lasso regression to identify potentially influential predictors from among a large group that included demographic factors, rating scale data, study site, and prescribed medications. We then estimated an unpenalized linear regression model for the outcome of interest that included only those variables retained by the optimal lasso. We considered any variables with statistically significant coefficients to be influential predictors.

Results: We found that a higher baseline ABC-mSW score was the only influential predictor of ABC-mSW change in the placebo group at 24 and at 12 weeks. Regarding CGI-I, we found no influential predictors at 24 weeks, but at 12 weeks found that age, IQ and study site were influential. In our comparative analysis, we found that ABC-mSW was also an influential predictor of ABC-mSW change at 24 and 12 weeks in the oxytocin group. Predictors of CGI-I, however, were inconsistent with those in the placebo group, suggesting that random variability explained the observed effects.

Conclusions: In this analysis of SOARS-B data, higher baseline severity on an index of social impairment (the ABC-mSW) predicted greater placebo response. This contrasts with a prior analysis of data from a trial of citalopram for repetitive behaviors in autism, in which lower baseline severity of a composite measure that included core autism features and mood symptoms predicted greater placebo response. This may indicate that different factors contribute to placebo response in different symptom domains. Further analyses of individual-level RCT data are necessary to better understand predictors of placebo response in autism.

423.207 Psychoactive Medication Use and Polypharmacy Among Children with Autism Spectrum Disorder in New Jersey: A Population-Based Study

K. Sidwell¹, L. Gomez Bustamante², D. Rahama², T. Modla², J. Shenouda¹ and W. Zahorodny³, (1)Department of Pediatrics, Rutgers University, Newark, NJ, (2)Rutgers University, Newark, NJ, (3)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ

Background: While there are no pharmacological treatments for the core symptoms of Autism Spectrum Disorder (ASD), psychoactive drugs are commonly used to manage associated symptoms or comorbid conditions. Two antipsychotic medications, risperidone and aripiprazole, are FDA-approved to treat maladaptive behaviors such as irritability and aggression in individuals with ASD. Other psychoactive drugs are frequently used to address additional psychiatric comorbidities. However, most previous studies on psychoactive medication use in children with ASD have relied on convenience samples or administrative data, which may introduce bias or limit generalizability.

Objectives: This study aims to estimate the proportion of children with ASD who are prescribed psychoactive drugs, assess polypharmacy rates, and examine whether psychoactive drug use varies by sex, race/ethnicity, and socioeconomic status (SES) in a large, diverse population.

Methods: Data were obtained from the New Jersey Autism Study (NJAS), part of the Autism and Developmental Disabilities Monitoring (ADDM) Network, which conducts population-based ASD surveillance. The findings represent children (age 8-years) born in 2012 and identified with ASD in study year 2020, residing in Essex and Union Counties. ASD cases were identified through active, multi-source review and analysis of health and education data. Information on prescribed psychoactive medications was collected from these records, along with demographic and case-specific data. The Social Vulnerability Index (SVI) was used as an additional measure of socioeconomic status (SES). Chi-square tests were used to test associations.

Results: The study identified 544 children with ASD, yielding an estimated prevalence of 28.7 per 1,000 (95% CI: 26.4-31.2) for the 2020 surveillance cycle. Among these, 137 (25%) had indication of receipt of psychoactive drugs and 91 (17%) had indication of multiple psychoactive drugs (polypharmacy). Medications targeting ADHD symptoms, including both stimulants and non-stimulants, were the most commonly prescribed (91%), with non-stimulants used most frequently (67%) followed by stimulants (55%). Antipsychotics (26%) and anti-seizure medications (13%) were the next most frequently used categories. Psychoactive medication use differed significantly by race/ethnicity, with 43% of children receiving pharmacotherapy being Hispanic, 30% Black, 18% White, and 9% from other racial/ethnic groups ($p=.01$). This variation was driven largely by ADHD medications, where 44% of children prescribed these medications were Hispanic, compared to 27% Black, 19% White, and 10% from other racial/ethnic groups ($p=.01$). Antipsychotic use was significantly associated with higher social vulnerability, with 83% of children prescribed antipsychotics falling into the high-vulnerability category ($p=.04$). There were no significant differences by sex. In cases of polypharmacy, the number of medications used ranged from 2 to 9, spanning 1 to 6 different drug categories.

Conclusions: Approximately 1 in 4 8-year-old children with ASD in metropolitan New Jersey are prescribed psychoactive medications, with two-thirds of these children receiving multiple medications. These findings align with other studies showing an increase in psychoactive drug prescriptions for children with ASD. The high rate of polypharmacy may indicate a greater prevalence of comorbid conditions among children with ASD. Further research is necessary to understand the long-term effects of psychoactive medications on individuals with ASD.

**423.208 Randomized Placebo-Controlled Crossover Trial of Diphenhydramine for Sleep in Youth with Autism**

I. C. Reyes, E. Gropman, I. Cotto, J. McGrath, R. Libove, M. Kawai, P. T. Taweedsed, T. Ishii, J. M. Phillips, R. O'Hara, B. Jo, Z. Li, B. Kim, J. F. Hallmayer, E. K. Baker and A. Y. Hardan, Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA

Background: Disrupted sleep is one of the most burdensome symptoms reported by parents of children and adolescents with autism spectrum disorder (ASD). Pharmacological treatments targeting specific neurotransmitters and/or hormones are available to better regulate sleep, but there is a lack of investigations assessing the biological effects of these agents in ASD. Diphenhydramine is an over the counter, FDA approved treatment of insomnia for children aged 12 years and older. It is an ethanolamine and first-generation H1 antagonist that acts as a reversible, competitive inhibitor of histamine binding to the H1 receptor. H1 antagonists, especially ethanolamine, have significant antihistaminic and antimuscarinic activities and concurrent sedative properties. The efficacy of diphenhydramine on sleep has been investigated in several studies of children and adults with a wide range of psychopathology, but is yet to be systematically investigated in individuals with ASD.

Objectives: The aim of this study was to examine the efficacy of diphenhydramine for improving sleep difficulties in children and adolescents (age 8-17 years) with ASD and examine target engagement as measured by standardized questionnaires, polysomnography (PSG) and actigraphy.

Methods: In an ongoing randomized double-blind crossover placebo-controlled 8-week trial (Autism Centre of Excellence for sleep), seven male children with ASD (8-17 years) have completed all assessments so far. Diagnosis of ASD was confirmed using the Autism Diagnostic Observation Schedule and the Autism Diagnostic Interview-Revised. Children were included if they had a baseline Children's Sleep Habits Questionnaire (CSHQ) score of ≥ 41 and had completed at least one night of PSG. Participants had a starting dose of 25mg which was titrated to 50mg in week 2 of each arm if there were no significant improvements in sleep and no adverse events. The CSHQ and one night of PSG were collected at week 4 (end of treatment arm 1) and week 8 (end of treatment arm 2). Actigraphy (at least one week) was recorded at baseline, week 4, and week 8.

Results: Linear mixed effect modeling was used to estimate mean differences between study groups (placebo versus active) utilizing all repeated measures (baseline, week 4 and week 8). For CSHQ variables, statistically significant intervention effects were found for both the sleep onset delay (Placebo mean = 1.87 [95% CI 1.43, 2.31]; Active mean = 1.13 [95% CI 0.69, 1.57]) and sleep duration (Placebo mean = 5.59 [95% CI 4.52, 6.65]; Active mean = 3.42 [95% CI 2.35, 4.48]) subscales. No other statistically significant intervention effects were found on other CSHQ subscales. In contrast, no statistically significant effects were detected for sleep efficiency and sleep onset latency assessed via PSG ($p > .05$). Analysis of actigraphy data is ongoing.

Conclusions: While anti-histamines are common over-the-counter medications for treating sleep problems in youth, their effectiveness for treating sleep problems in children and young people with ASD is unknown. Our preliminary results from this ongoing trial are promising, suggesting positive results for diphenhydramine on parent-reported sleep parameters. Further analyses with a larger sample size of participants who complete the trial will confirm these preliminary findings.

423.209 Role of Gluten-Free-Casein-Free (GFCF) Diet in Children with Autism Spectrum Disorder: A Randomized Controlled Trial
S. Gulati¹, K. L. Gupta², S. Ojha³, A. Agarwala², S. Khan⁴, G. Kamila³, P. Bhat⁵, S. S. Kumaran⁶ and S. Pandey⁷, (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, Ansari Nagar, New Delhi, India, (2)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (3)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (4)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (5)Department of NMR, All India Institute of Medical Sciences, New Delhi, Delhi, India, (6)Department of NMR, All India Institute of Medical Sciences, New Delhi, India, (7)Department of Biostatistics, All India Institute of Medical Sciences, New Delhi, India

Background: Gluten-free casein-free (GFCF) diet is believed to work through the gut-brain axis by reducing the impact of peptides on neurochemical pathways. Although several studies suggest that GFCF diet may improve behavior in children with Autism Spectrum Disorder (ASD), conclusive evidence remains insufficient.

Objectives:

To evaluate the efficacy of add on GFCF diet compared to standard treatment in improving the core symptoms of ASD.

Methods:

In this single-blinded (assessor), randomized controlled trial, children aged 3-12 years fulfilling Diagnostic and Statistical Manual of Mental Disorders-5th edition, for ASD were screened and those on standard treatment for atleast 12 weeks were included. Children on standard treatment for ≥ 12 weeks, those who received alternate therapy, with chronic systemic illness and allergic to dietary components were excluded. Control group included children with a similar profile on standard treatment. GFCF diet was given for 24 weeks. Childhood autism rating scale (CARS-2), Applied Behaviour Checklist (ABC), Child Behaviour Checklist (CBCL), Children's Sleep Habits Questionnaire (CSHQ), Development Quotient (DQ) were assessed on baseline and 24-weeks. Resting state functional MRI (fMRI) and structural imaging data were acquired in 15 children in each group at baseline and at 24 $\pm$ 2 weeks on a 3T scanner (Ingenia 3.0T M/s. Philips Medical Systems, Netherlands) with a 32-channel head coil.

Results:

Total of 104 children were enrolled [54-Diet group (83% males); 50-control group (86% males)]. Five children were lost to follow-up in diet group. Mean ($\pm$ SD) age was 68.2 $\pm$ 29.6 and 67.1 $\pm$ 29.7 months in diet and control group respectively. The baseline average CARS-2, ABC and CSHQ score in the diet group was 35.66 $\pm$ 3.62, 74.75 $\pm$ 13.0 and 21(8-33) whereas in the control group was 35.25 $\pm$ 3.5, 77.12 $\pm$ 11.67 and 26(10-35) [P $\geq$ 0.05]. On CBCL at baseline, hyperactivity, attention problems and sleep issues in diet group vs control group were seen in 17/54 (31.5%) [32/54(59.2%), 5/54(9%) and 19/50(38%),27/50(54%) ,7/50(14%)[P>0.05] respectively. Intellectual disability (DQ<70) was seen in 47/54(87%) in diet and 43/50(86%) in control group.

At 24 weeks, per protocol analysis showed average CARS-2, ABC, and CSHQ scores of 32.72 $\pm$ 2.76, 66.38 $\pm$ 11.92, and 10(5-25) in the diet group, and 34.33 $\pm$ 3.3, 71.26 $\pm$ 9.9, and 25(7-31) in the control group (P=0.009, 0.029, 0.012) respectively. Additionally, 7/49 (14.2%) in the diet group and 2/50 (4%) in the control group achieved remission (CARS<30) [P=0.04]. In diet group, 9/49(18.3%) children in comparison with 2/50 (4%) in control group showed clinically meaningful change in CARS (defined as ≥ 4.5 point change) at follow-up [P=0.023]. At 24 weeks, hyperactivity, attention problems, and sleep issues in the diet group versus the control group were observed in 13/49 (26.5%), 12/49 (24.4%), 0/49, and 20/50 (40%), 20/50 (40%), 7/50 (14%) respectively [P=0.08, P=0.05, P<0.01].

On Intention-To-Treat Analysis, average CARS-2, ABC, and CSHQ scores of 32.99 $\pm$ 3.2, 67.2 $\pm$ 12.53, and 13.5(5-25) in the diet group were seen (P=0.03, 0.07, 0.04) respectively. No adverse events were reported. The data for fMRI is under process and the results will be analysed shortly.

Conclusions:

The study shows promising results of gluten and casein elimination from diet in children with ASD showing significant improvement in behavioural profile and sleep issues.

423.210 Risperidone for the Treatment of Autism Spectrum Disorder: A Systematic Review and Meta-Analysis of Efficacy and Safety

I. Serag, Faculty Of Medicine Mansoura University, Mansoura, Dakahlia, Egypt

Background:

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition characterized by difficulties in communication, social interaction, and behavior. Risperidone, an atypical antipsychotic, is one of the few FDA-approved medications for managing irritability and challenging behaviors in individuals with ASD. This systematic review and meta-analysis aim to evaluate the efficacy and safety of risperidone in the treatment of ASD

Objectives:

To systematically analyze the current evidence on the effectiveness and safety of risperidone in managing core and associated symptoms of ASD

Methods:

A comprehensive literature search was conducted in PubMed, Cochrane Library, Scopus, and Web of Science, up to September 2024. Randomized controlled trials (RCTs) comparing risperidone with placebo or other interventions for treating ASD were included. The primary outcomes assessed were irritability and behavioral improvement, measured by scales such as the Aberrant Behavior Checklist-Irritability Subscale (ABC-I) and Clinical Global Impressions (CGI). Secondary outcomes included changes in social functioning, repetitive behaviors, and adverse events. A random-effects model was used to pool data, and the results were expressed as mean differences (MD) and risk ratios (RR) with 95% confidence intervals (CI).

Results:

A total of 8 RCTs involving 1,032 participants were included. Risperidone demonstrated a significant reduction in irritability scores compared to placebo (MD = -8.95, 95% CI: -10.30 to -7.60, p < 0.001). Behavioral improvement, as measured by CGI, was also significantly greater in the risperidone group (RR = 2.10, 95% CI: 1.50 to 2.80, p < 0.001). However, risperidone use was associated with increased risks of weight gain and sedation (RR = 3.85, 95% CI: 2.10 to 5.60, p < 0.001).

Conclusions: Risperidone is effective in reducing irritability and improving behavior in individuals with ASD. However, clinicians should carefully weigh its benefits against potential side effects such as weight gain and sedation. Further long-term studies are warranted to assess its prolonged safety profile.

423.211 Aripiprazole in the Treatment of Autism Spectrum Disorder: A Systematic Review and Meta-Analysis of Efficacy and Safety**I. Serag**, Faculty Of Medicine Mansoura University, Mansoura, Dakahlia, Egypt

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by persistent deficits in social communication and restricted, repetitive behaviors. Pharmacological treatment options are limited, and antipsychotics such as aripiprazole are commonly used to manage associated symptoms like irritability, hyperactivity, and repetitive behaviors. This systematic review and meta-analysis aimed to evaluate the efficacy and safety of aripiprazole in the treatment of ASD.

Objectives: To systematically review and quantitatively synthesize evidence from randomized controlled trials (RCTs) assessing the effects of aripiprazole on core and associated symptoms of ASD in children and adolescents.

Methods: We conducted a comprehensive search of PubMed, Cochrane Library, Scopus, and Web of Science databases up to September 2024. Eligible studies included RCTs comparing aripiprazole with placebo in participants diagnosed with ASD. The primary outcome was the reduction in irritability, measured by the Aberrant Behavior Checklist (ABC-I). Secondary outcomes included changes in hyperactivity, stereotypic behavior, and overall clinical improvement. Safety outcomes, including adverse events, were also analyzed. A random-effects model was used to calculate pooled effect sizes, expressed as mean differences (MD) for continuous outcomes and risk ratios (RR) for dichotomous outcomes.

Results: A total of 8 RCTs involving 1,247 participants were included. Aripiprazole was significantly more effective than placebo in reducing irritability (MD = -8.34, 95% CI: -9.12 to -7.56, $p < 0.001$) and hyperactivity (MD = -4.75, 95% CI: -5.32 to -4.18, $p < 0.001$). However, adverse events such as weight gain and sedation were significantly more common in the aripiprazole group (RR = 1.84, 95% CI: 1.56 to 2.11, $p < 0.001$).

Conclusions: Aripiprazole is effective in reducing irritability and hyperactivity in children with ASD, but its use is associated with increased risk of adverse events. Clinicians should weigh the benefits against potential side effects when prescribing aripiprazole for ASD.

Poster Session**424 - Interventions - Social, Cognitive, Behavioral and Educational - School-Age, Adolescent, Adult II**

May 2nd, 2025, 12:30 PM - 1:30 PM - Hall 4A

424.212 Impact of a Culturally Adapted and Translated Intervention Program on the Mental Health of Autistic Latino Young Adults

A. C. Ramirez¹, A. F. Pagán², C. Montiel-Nava¹, K. A. Loveland³ and R. Acierno⁴, (1)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (2)University of Texas Health Science Center, Houston, TX, (3)Louis A Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical School, University of Texas McGovern Medical School, Houston, TX, (4)McGovern Medical School at UTHHealth Houston, Houston, TX

Background: The transition to adulthood for autistic young adults can be complex and challenging, as it often involves navigating changes in education, employment, independent living, and social relationships. This transition is even more complex for autistic Latinos, as they may encounter additional barriers related to cultural differences, socioeconomic challenges, and a lack of culturally and linguistically appropriate therapy to manage co-occurring mental health difficulties. The neurodiversity-affirming, culturally and linguistically adapted *¡Iniciando! la Aduldez* therapy program is tailored for Latino autistic individuals. *¡Iniciando! la Aduldez* not only helps develop skills in social cognition and executive functioning but also provides key skills to manage mental health.

Objectives: The purpose of the present study was to evaluate changes in the mental health of autistic Latino young adults participating in the *¡Iniciando! la Aduldez* program.

Methods: A total of 26 autistic Latino young adults (ages 18-25) and their parents ($n=38$) participated in *¡Iniciando! la Aduldez*, a 12-week intervention program which consists of telehealth-group therapy sessions for both parents and young adults, weekly coaching therapy sessions to work on goals and family therapy sessions. The mental health of autistic young adults was assessed by the Adult Self Report (ASR) questionnaire and the Adult Behavior Checklist (ABCL) at baseline and post-treatment. A paired sample t-test was conducted to examine changes in both measures.

Results: Findings revealed significant improvements in several areas on the ASR. Notably, participants reported reduced anxiety and depression symptoms and thought problems with large effect sizes ($d = 0.77-0.99$). Significant reductions were also observed in attention problems ($d = 0.49$) and sluggish cognitive tempo problems ($d = 0.69$). There were significant decreases in overall internalizing problems ($d = 0.48$) and total problems ($d = 0.52$). On the ABCL, parents reported significant reductions in anxiety and depression problems ($d = 0.58$), somatic complaints ($d = 0.53$), thought problems ($d = 0.77$), and attention problems ($d = 0.60$). Similarly to young adults, parents reported significant decreases in depression problems ($d = 0.70$), anxiety problems ($d = 0.51$), avoidant behavior ($d = 0.65$), ADHD symptoms ($d = 0.53$), and hyperactivity impulsivity symptoms ($d = 0.91$). Additionally, parents reported significant decreases in sluggish cognitive tempo ($d = 0.65$) and obsessive-compulsive problems ($d = 0.67$).

Conclusions: Culturally sensitive and affirming interventions that support a successful transition to adulthood and independence for autistic individuals not only address immediate needs but also have the potential to significantly enhance overall well-being in important areas of co-occurring mental health. By aligning interventions with the individual's cultural values and neurodivergent identity, these programs foster a sense of belonging, self-confidence, and empowerment, which are deeply connected to improved mental health and life satisfaction.

424.213 Impact of a Supportive STEM-Focused Pre-College Internship on Autistic Adolescents and Their Mentors

A. R. Arista¹, W. Martin², A. Grillo-Hill³, J. Valcarcel³, K. Melchior³, K. Nguyen³, L. Peticolas⁴ and L. Cominsky⁴, (1)Center for Children and Technology, Education Development Center, New York, NY, (2)Education Development Center, New York, NY, (3)WestEd, Redwood City, CA, (4)EdEon STEM Learning, Sonoma State University, Rohnert Park, CA

Background: [Program blinded], a multi-institution collaboration between [blinded], was developed to provide a pathway to STEM employment for autistic learners. [Program] provides authentic experiences to neurodiverse youth, including a high school internship program wherein select students from across the US are paired with Subject Matter Experts (SMEs) based on their skills and interests. Key components of this program to ensure success include a neurodiversity-affirming approach to mentor training and onboarding, consistent ongoing support for intern/mentor pairs, and individualized check-ins.

Objectives: To assess the success of our program model and prepare for iteration, we investigated interns' STEM Identity, STEM, research, socioemotional, and executive functioning skills, and SME mentor feedback on program structure and support through external evaluation.

Methods: A mixed-methods survey was administered and completed by all 21 interns and mentors from the 2024 cohort. Surveys included a single-item pictorial measure for assessing STEM identity, the STEM Professional Identity Overlap (STEM PIO) and a series of Likert scale questions to retrospectively assess skill gains in key areas.

Results: Analysis of STEM PIO responses indicate that interns' STEM identity after the internship ($M = 4.8$, $SD = 1.4$) was significantly greater than before ($M = 3.3$, $SD = 1.3$), $t(19) = 8.8$, $p < .01$ with a Cohen's d effect size of 0.68.

Retrospective responses measuring growth in research, socioemotional, and executive functioning skills showed that interns reported a statistically significant increase in their confidence on all assessed STEM research skills and all eight assessed executive functioning and socioemotional skills (Table 1). Interns felt more confident in their ability to be polite and kind to peers, use their time effectively, organize information, track progress towards goals, and communicate information clearly, concisely, and logically.

SMEs were asked how satisfied they were with the initial welcome meeting with mentees, their family, and staff. Almost all were very or extremely satisfied with the ongoing support from the staff (94%) and the internship matching process (95%). Similarly, all SMEs were very or extremely satisfied with the program onboarding process and 94% with the training webinar. Almost all mentors felt the program prepared them for their role as a mentor moderately (33%) or greatly (56%) (Figure 1a).

Similarly, most SMEs felt the program moderately or greatly changed how they engaged with neurodiverse individuals (61%) and increased their capacity to work with neurodiverse individuals (78%, Figure 1b).

Conclusions: These findings demonstrate how a pre-college internship program rooted in allowing autistic students to deepen their existing interests and knowledge helps interns to achieve both STEM and executive functioning skills, that are key components of success in post-secondary and workplace settings. Programmatic effects on SMEs also illustrate how neurodiversity-affirming training and support led to a more intentional and inclusive mentorship experience for our autistic youth.

424.214 Implementation of Classroom Pivotal Response Teaching (CPRT) for Autistic Students in India

A. Nagpal¹, G. Divan², A. Chopra³, J. Chan⁴ and M. Pellicchia⁵, (1)Child Development Group, Center for Autism Research, Children's Hospital of Philadelphia, Bardez, Goa, (2)Child Development Group, Sangath India, New Delhi, India, (3)La Trobe University, New Delhi, Delhi, Australia, (4)Early Childhood Department of Special Education, San Diego State University, San Diego, CA, (5)Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA

Background: India, home to 430 million children, has an autism prevalence of 1 in every 68 children aged 2 to 9 years. The school, where children spend between 800 to 1000 hours annually, is an accessible setting for sustained autism intervention delivery at scale. However, autistic students in India often lack access to evidence-based practices in school. Classroom Pivotal Response Teaching (CPRT) is an evidence-based teaching framework for autistic students. Research has demonstrated that teachers can be trained to implement CPRT with high fidelity, producing greater gains on students' focal IEP goals in comparison to students not receiving CPRT. Specifically, CPRT has been shown to help students learn new language, social, play, and academic skills. Additionally, CPRT training for teachers has predicted improved student engagement and decreased withdrawal behaviors.

Objectives: the goals of this study were to evaluate the acceptability, feasibility, and implementation fidelity of CPRT in a special education school in Bangalore, India. The study sought to answer the following research questions:

1. Can teachers in India achieve and maintain CPRT fidelity?
2. What are the barriers to CPRT implementation?
3. Is CPRT acceptable and beneficial compared to usual practice?
4. Are the CPRT training protocol and trainer acceptable?

Methods: This mixed-methods study included 8 teachers in a special education school in India. Over 12 weeks, teachers were trained to implement CPRT following the manualized CPRT approach by a certified CPRT trainer. Teacher fidelity of implementation was assessed via direct observation of teachers implementing CPRT lessons. Inter-observer agreement was calculated for 20% of observations. Following training, qualitative interviews were conducted with all teachers to gain in-depth information about the feasibility, acceptability, and perceived fit of CPRT. Qualitative analyses were conducted using an integrated approach that included both inductive and deductive features.

Results: Seven of eight teachers achieved CPRT fidelity during the 12-week training. Inter-rater agreement for all coded observations was high (mean = 80%, range = 41-94%). Data regarding CPRT sustainment are ongoing. Teachers described many aspects of the approach as highly acceptable and beneficial in comparison to current teaching practices. Teachers replaced repetitive, structured materials with play-based, creative activities using preference assessments. They felt more connected to students, reported that students exceeded their expectations, and found CPRT applicable to any student. Video feedback was deemed the most valuable tool for improving implementation. Teachers also described aspects of the intervention that were viewed as challenging. They found CPRT planning for all learning goals overwhelming and CPRT implementation challenging for group classes. Teachers also provided valuable information about aspects of CPRT that could be adapted to better fit the Indian context.

Conclusions: CPRT is acceptable and feasible for delivery in special education settings in India, and teachers can be successfully trained to fidelity in 12 weeks with high rates of fidelity. Adaptations to the current training protocol to account for the needs of the Indian special education context are warranted.

424.215 Improving the Fit of Behavioral Interventions for Autism in Schools: Lessons Learned from Paraeducator Feedback on the Rubies Program

D. M. Tagavi¹, C. Dick², A. V. Dahiya³, K. Bearss⁴ and J. Locke¹, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Seattle Children's Autism Center, Seattle Children's, Seattle, WA, (3)Department of Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background: The need for effective, school-based behavioral interventions for autistic students with challenging behaviors is increasingly evident as the number of autistic children in mainstream classrooms grows (Cardinal et al., 2021). Evidence-based interventions, such as Research Units on Behavioral Intervention (RUBI), have shown significant success in reducing challenging behaviors when implemented by parents in home settings (Bearss et al., 2015). However, translating such interventions to school environments requires careful adaptation to ensure feasibility and effectiveness within the unique context of public education (Chambers & Norton, 2016). RUBIES (RUBI for Educational Settings) was developed as a systematic adaptation of RUBI (Bearss et al., 2022) and was specifically designed to meet the needs of educators serving autistic youth in schools.

Objectives: The objective of this study was to analyze feedback from paraeducators who were trained in and implemented RUBIES. Specifically, we aimed to identify modifications that could further improve the program's fit and feasibility in public schools.

Methods: This study was part of a larger pilot randomized controlled trial comparing RUBIES to psychoeducation in public elementary schools across the United States. Sixteen paraeducators, who participated in the trial and implemented RUBIES with an autistic student, were interviewed after completing the study. Semi-structured qualitative interviews were conducted to gather feedback on the RUBIES training, the implementation process, and the generalizability of RUBIES to other students and educators. Interviews were recorded, transcribed, and analyzed using a Rapid Analysis Procedure (Hamilton, 2013), allowing for quick and efficient coding of themes in a time-sensitive context. Two PhD-level researchers independently coded the transcripts and achieved high inter-rater reliability (>90%).

Results: Although RUBIES had already undergone systematic adaptation for school settings, paraeducators identified several additional modifications to RUBIES content and implementation strategies that could enhance the program's utility and fit within schools. Key themes surrounding RUBIES content included: (1) a desire for content that addresses self-regulation and self-care for educators managing challenging behaviors. Themes surrounding implementation strategies included: (1) the importance of RUBIES coaches coordinating training and support with the broader educational team, (2) a preference for more individualized coaching schedules, allowing for flexible pacing based on the paraeducator's needs, (3) the creation of a digital, portable tool, such as a mobile app, that could serve as a quick reference for RUBIES strategies, (4) access to asynchronous, recorded coaching sessions, allowing paraeducators to revisit training materials at their convenience, and (5) the inclusion of instructional videos demonstrating RUBIES strategies being used in real-time classroom scenarios to enhance understanding and confidence in implementation.

Conclusions: The feedback provided by paraeducators underscores the need for continued refinement of RUBIES to better align with the realities of public schools. These suggested adaptations—such as enhancing collaboration with other educators, increasing flexibility in coaching, and providing additional resources for self-care and strategy reinforcement—will guide future iterations of RUBIES. Implementing these changes will likely increase RUBIES' acceptability, feasibility, and effectiveness. Future trials will incorporate these modifications and evaluate the impact of RUBIES in supporting paraeducators to improve outcomes for autistic students in diverse school environments.

424.216 Increasing Utilization of a Digital Health Therapeutic for Caregivers of Children with Autism and Other Developmental Disabilities: Attend|Behavior and Project Echo

K. G. Stephenson^{1,2}, W. J. Leevers^{1,2}, S. Pisecco³, B. Mackinaw-Koons^{1,2}, A. Hess⁴, C. M. Albright^{1,2}, S. Long⁴ and E. M. Butter^{2,4}, (1)Nationwide Children's Hospital, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)Attend|Behavior, Nashville, TN, (4)Nationwide Children's Hospital/Ohio State University, Columbus, OH

Background: Digital therapeutics are a promising way to increase the availability of evidence-based treatments. Attend|Behavior is an app based on the evidence-based RUBI parent management training program. It includes video training modules and behavioral tracking and management tools. Caregivers can use the app independently or can be supported by a clinician. When used in conjunction with ongoing in-person therapy, Attend|Behavior is associated with increased engagement in therapy and more caregivers reaching treatment goals. However, more information is needed on the use of Attend|Behavior as a standalone intervention. One barrier to this goal is low rates of utilization. In a previous clinical implementation, of families who were provided with a free tablet for clinical use and access to a free Attend|Behavior account, only 20% installed the app and only 4% actively used Attend|Behavior. Similar struggles have been found with other digital therapeutics. Training existing service coordinators who have frequent contact with families as digital coaches is one promising way to support families in using Attend|Behavior.

Objectives: Compare differences in utilization of a caregiver coaching digital health therapeutic (Attend|Behavior) for children with developmental disabilities from two non-randomized pilot implementation programs from either a self-directed or coaching framework.

Methods: The first pilot program ("Self-directed") included offering Attend|Behavior subscriptions to caregivers for self-directed use following developmental evaluations of their child. The second, ongoing, pilot program ("Coaching") involves training service coordinators through a state county board of developmental disabilities program as digital coaches to support caregiver engagement. Training was completed using the Project ECHO (Extension for Community Healthcare Outcomes) framework which is a telementoring paradigm that has been widely used to disseminate evidence-based knowledge into communities using didactics and case-based applied learning, including evidence-based care for autism and RUBI parent training. Digital coaches provide free Attend|Behavior subscriptions to the caregivers. The Self-directed pilot project had a total of 42 caregivers and the Coaching pilot project currently has 12 caregivers. Utilization metrics include number of completed didactic lessons (through the app), completion of behavior rating *check-ins*, and behavior tracking (*incidents*). Due to the presence of outliers and non-normal distributions, nonparametric (Mann-Whitney U) tests were used to compare groups.

Results: The Coaching group had significantly greater number of completed sessions ($Mdn=13$, $M=14.08$, $SD=10.11$) than the Self-directed group ($Mdn=3$, $M=8.36$, $SD=11.29$), $Z=-2.20$, $p=.03$, $r=0.30$. The Coaching group also had a greater number of completed *check-in* ratings ($Mdn=5.5$, $M=14.33$, $SD=16.76$) than the Self-directed group ($Mdn=0$, $M=2.07$, $SD=6.40$), $Z=-2.20$, $p=.03$, $r=0.35$. There were no differences in *incident* ratings (Coaching: $Mdn=0$, $M=2.92$, $SD=5.23$; Self-directed: $Mdn=0$, $M=1.05$, $SD=1.99$), $Z=-1.06$, $p=.29$, $r=0.14$.

Conclusions: Exploratory data from two pilot programs provide initial evidence that training community-based providers can support caregivers and potentially lead to greater utilization of therapeutic technology tools. Additional work is needed to confirm and expand our findings including randomized-controlled experimental designs and evaluation of behavioral outcomes of Attend|Behavior. However, our results provide an example of increasing engagement and utilization using a community-focused training program.

424.217 Initial Outcomes of a Community-Informed Driving Program with Cognitive Strategies Curriculum and AI-Based Driving Simulator

M. J. Baker-Ericzen^{1,2,3}, J. Meehan⁴, R. Caldwell⁵, A. Ferrell⁶, A. Plunk⁷, D. Wilson⁷, D. Caudel^{7,8}, K. Stassun^{7,8} and N. Sarkar⁹, (1)Administration, Rehabilitation and Post-Secondary Education, San Diego State University, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego State University, San Diego, CA, (3)Interwork Institute, San Diego, CA, (4)San Diego State University, San Diego, CA, (5)San Diego State University Research Foundation, San Diego, CA, (6)Child and Adolescent Services Research Center, San Diego, CA, (7)Vanderbilt University, Nashville, TN, (8)Frist Center for Autism and Innovation, Nashville, TN, (9)Mechanical Engineering; Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN

Background: Many autistic individuals face challenges in successfully launching into independence. While a driver's license can facilitate self-sufficiency, there are low rates of driving among autistic individuals. Many factors, including concerns regarding motor coordination, executive functioning skills, and anxiety, contribute to autistic individuals' decision not to pursue driving. Thus, there is a great and immediate need for driving interventions that are based in the community targeting these concerns.

Objectives: This study addresses the transportation challenges faced by autistic individuals using a novel curriculum and AI-based virtual driving instruction platform. This open trial reports on cohort 1 data, from a larger study, testing the feasibility, usability and outcomes within 3 community sites across 3 states in the United States.

Methods: A total of 24 autistic teen/adults ($\mu=22$ yrs; 15-36 yrs) with 75% ≥ 18 years participated. Sample demographics: male (70%), race/ethnicity-21% Hispanic, 10% black/AA, 10% Native, 67% white, 21% intentionally blank, 38% in High School, 33% taking medication, 8% receiving SSI, 50% in vocational rehabilitation and 92% living with parents/family. One person had a driver's license and 17% had a driver's permit. Participants completed 8 group curriculum sessions (1.5 hrs per week) learning executive functioning and emotional regulation skills for driving and completed 5 driving simulator sessions using an artificial intelligence-based driving simulator that incorporates eye tracking and physiological sensors (45min weekly) providing feedback. Pre and post assessments included standardized assessments on anxious driving cognitions, driving avoidance, driving attitude, post changes in thoughts, emotions, behaviors and attitude towards driving, pursuit of driver's license and program satisfaction.

Results: Analyses included paired sample t-test on informant outcomes of driving cognitions, anxiety and attitude. According to teens/adults significant differences between pre and post were found for driving attitude total score ($p<.01$; $d=1.06$) and negative attitude ($p<.001$; $d=1.49$) demonstrating improvements in attitudes towards driving. Caregivers reported significant improvements in both positive ($p<.05$; $d=.67$) and negative ($p<.001$; $d=1.14$) attitudes towards driving. Driving cognitions were significant for social ($p<.05$; $d=.943$) and trended towards significance for driving cognitions total score ($p=.06$; $d=.850$) indicating decreases in problematic and anxiety-related thoughts about driving for participants. Caregivers did not report changes on this measure. (Refer to Table 1). No significant differences were found for panic-related thoughts and accident-related thoughts but there were medium effect sizes for both. No significant changes and small effect sizes were evident for driving and riding avoidance for both informants. Both informants reported the majority of participants demonstrating positive changes overall (96% self, 88% caregiver) and in positive thoughts (92% self), emotions (96% self, 81% caregivers), behaviors (67% self, 63% caregivers) and attitude (83% self, 78% caregiver) towards driving. Almost all participants reported activities towards obtaining license at post 92% compared to only 42% at baseline. All informants (participants, caregivers and providers) rated high satisfaction and indicated positive feasibility and accessibility.

Conclusions: There are currently few interventions targeting executive functioning and emotional regulation barriers to driving. The current study provides preliminary evidence for the meaningful ways a driving program could help autistic individuals pursue a driver's license.

424.218 Internalizing and Resilience-Related Symptom Changes Following the Resilience Builder Program® Group Therapy Intervention within Autistic School Aged Children

N. G. Herman¹, M. K. Alvord² and B. A. Rich³, (1)*Catholic University of America, New Haven, CT*, (2)*Alvord, Baker & Associates. LLC, Rockville, MD*, (3)*Psychology, Catholic University of America, Washington, DC*

Background: There is a high co-occurrence of internalizing symptoms among children with autism spectrum disorder (ASD). Interventions aimed at increasing resilience among children with anxiety have been shown to be especially effective. Limited research, however, has been conducted to examine how resilience-focused interventions can impact internalizing symptoms among school-age autistic children.

Objectives: The current study aimed to evaluate the effectiveness of the Resilience Builder Program® group therapy intervention for autistic school-aged children by investigating pre-to-post-intervention symptom changes.

Methods: Thirty-one children with ASD (22.6% female; $M=10.09$ years, $SD=1.76$ years) completed the Resilience Builder Program® (RBP) in a large private practice. The 12-week intervention consisted of weekly hour-long sessions focused on adaptability, emotion and behavioral regulation, and social cognition. The participant's parents completed demographic questionnaires and the Behavior Assessment System for Children Parent Rating Scale, Second Edition (BASC-2 PRS) before and after the treatment was implemented. Paired sample t-tests assessed within-subject symptom changes.

Results: Following the Resilience Builder Program®, participants showed no significant differences in Anxiety, Depression, Somatic, or overall Internalizing symptoms. There were significant improvements, however, in adaptability ($t=-2.51$, $p<.05$) and resiliency ($t=-3.42$, $p<.005$).

Significant results were not moderated by participant age or gender.

Conclusions: The findings suggest that although the Resilience Builder Program® did not result in significant reductions in internalizing symptoms, it did produce significant improvement in adaptability and resilience. Results highlight the validity of the intervention for broader resilience-based skills, the main focus of the intervention. Future research could investigate the long-term effects of RBP to assess if internalizing symptoms are affected several months after the program. Additional research could also aim to develop a version of the Resilience Builder Program that explicitly targets internalizing symptomatology.

424.219 Key Stakeholder Voices on Designing and Developing Social Robots for Autistic Students

G. Y. Kim¹, U. Lee², H. Kim³, J. Eom⁴, H. Jeong⁵, S. Lee⁶, G. Byun⁶, Y. Lee⁷, M. Kang⁸, J. Na⁹ and J. Moon¹⁰, (1)*Educational Psychology, Baylor University, Waco, TX*, (2)*Korea University, Seoul, Seoul, Korea, Republic of (South)*, (3)*SK Telecom, Seoul, Seoul, Korea, Republic of (South)*, (4)*Seoul Chihyeon Elementary School, Seoul, Seoul, Korea, Republic of (South)*, (5)*Chung-Ang University, Seoul, Seoul, Korea, Republic of (South)*, (6)*Seoul National University, Seoul, Seoul, Korea, Republic of (South)*, (7)*Seoul Poongnap Elementary School, Seoul, Seoul, Korea, Republic of (South)*, (8)*Daegu National University of Education, Daegu, Daegu, Korea, Republic of (South)*, (9)*Special Education, Ewha Womans University, Seoul, Korea, Republic of (South)*, (10)*The University of Alabama, Tuscaloosa, AL*

Background: Sustainable implementation and dissemination rely on strong research-community partnerships. Without collaboration from stakeholders, practices may not be adopted or used with fidelity. In autism intervention, engaging self-advocates, families, service providers, and researchers is crucial for increasing acceptability, feasibility, and usability. Their input is critical in shaping interventions through an iterative process to ensure relevance to their lives and needs. Autistic students often require additional language and communication support to succeed academically, socially, and in future employment. Given the rapid advancements in technology-based interventions (e.g., AI-embedded instruction), we proposed developing social robots in collaboration with key stakeholders to address these needs (see Figure 1).

Objectives:

The interview aimed to gain key stakeholders' perspectives on affordance, usability, instructional design, and instructional usefulness in designing and developing a large language model-based social robot for autistic students.

RQ1: How do key stakeholders perceive the affordance, usability, and instructional usefulness of the initial model of the large language model-based social robot for autistic students after observing the demonstration?

RQ2: What recommendations do key stakeholders offer to enhance the design and instructional integration of the social robot to increase the likelihood of its successful translation into community and school settings?

Methods: Semi-structured interviews are ongoing with key stakeholders (e.g., autism researchers, special educators, family advocates, autistic individuals, and non-autistic students). These 50-60-minute interviews focused on evaluating social robots for language and communication interventions for autistic students, addressing both technical and educational aspects. Audio recordings were transcribed, and the transcripts were reviewed by a note-taker, followed by member checks with each participant to ensure accuracy. The constant comparative method (Glaser & Strauss, 1967) was used to identify themes, allowing comparisons across groups and detecting emerging trends or patterns.

Results:

Preliminary findings revealed six themes:

1. Clarity in Language and Communication Goals: Participants emphasized the need for clear instructional goals to guide intervention design and adaptation.
2. Social Validity of Intervention: Educators noted the importance of peer perceptions and age-appropriateness of tools used in classrooms.
3. Diversity within the Autism Spectrum: All participants highlighted the need for interventions that accommodate a broad range of strengths and needs or are focus on specific needs, with room for expansion.
4. Contextual Fit in Specific Settings: Stakeholders reported interventions should incorporate environmental factors relevant to different settings like home or classroom, to ensure effective implementation.
5. Improved, Cost-Effective Technology: Recommendations included reducing response latency while keeping the technology cost-effective for future dissemination.
6. Integration of Verbal and Nonverbal Communication: Participants emphasized the importance of supporting both verbal and nonverbal aspects, as these are often intertwined in natural conversations and should be modeled in teaching.

Conclusions: Engaging key stakeholders in the design and development of social robots for autistic students is essential to ensure the technology is relevant, feasible, and effective. While stakeholders shared both similarities and differences in their perspectives, the themes identified above will guide the iterative refinement process. By collecting and incorporating these insights throughout development, the intervention's potential for successful implementation and dissemination in educational and community settings will be significantly enhanced.

424.220 Listening to Autistic Voices: A Community-Partnered Approach to Adapting PEERS for College Students

J. Albright¹, A. Baxter², V. Chassin¹, M. Robeson¹, C. Lewis¹ and K. Zlomke¹, (1)Psychology, University of South Alabama, Mobile, AL, (2)Leadership and Teacher Education, University of South Alabama, Mobile, AL

Background:

Autistic college students complete postsecondary education at significantly lower rates than neurotypical students. Identifying ways to support these students is of critical importance. The Program for the Education and Enrichment of Relationship Skills © for Young Adults (PEERS-YA) is an evidence-based, manualized 16-week social skills group for autistic young adults, making it a promising option for social support on college campuses.

Although several studies have adapted the PEERS-YA for use on college campuses, none of these adaptations were informed by the perspectives of autistic college students or other stakeholders beyond the research teams. Adapting interventions with an established evidence-base for implementation in new contexts is an efficient and viable strategy; however, involving target end users in the adaptation process is critical to ensuring the feasibility and acceptability of the adapted intervention.

Objectives:

Study 1 - Examine the perspectives of autistic college students and parents of autistic college students regarding the feasibility/acceptability of the PEERS-YA program; use the perspectives to inform adaptations to the PEERS-YA intervention for implementation on a college campus.

Study 2 - Evaluate the preliminary effectiveness of the adapted PEERS-YA intervention in a quasi-experimental pilot study.

Methods:

Study 1 - Qualitative interviews were conducted with 10 autistic college students and two parents of autistic college students. Rapid qualitative analysis was used to ensure timely analysis and identification of adaptations. The Framework for Reporting Adaptations and Modifications – Expanded (FRAME) was used to organize final adaptations.

Study 2 - Knowledge of social skills, perceived social and empathic self-efficacy, quality of life, and college belongingness were measured pre- and post-intervention for six autistic college students and six non-autistic college students serving as social partners. Paired-sample *t*-tests were used to assess changes in outcome measures. A modified Cohen's *d* was calculated to indicate effect size. Reliable change indices (RCIs) were calculated to illustrate clinically significant changes in individual participant outcomes.

Results:

Study 1 – Autistic college students (30% male, 60% female) and parents (100% female) expressed satisfaction with PEERS-YA content but suggested shortening session length and adding sessions on handling microaggressions, appropriate emotional responding, and emotion regulation. Most autistic participants did not state a preference for an autistic or non-autistic social partners.

Study 2 – Six social partners (ages $M=20.59$, $SD=1.05$; 33.3% male, 50% female, 16.7% non-binary) and six autistic college students (ages $M=22.01$, $SD=2.48$; 33.3% male, 33.3% female, 33.33% non-binary) participated in the adapted PEERS-YA intervention. Significant improvements were observed in empathic self-efficacy for autistic participants ($p = 0.043$; Cohen's $d = 0.92$) and social skills knowledge for both autistic participants ($p = 0.006$; Cohen's $d = 2.86$), and social partners ($p = 0.011$; Cohen's $d = 2.73$). RCIs indicated that autistic participants showed meaningful improvements on measures of perceived social and empathic self-efficacy.

Conclusions:

These findings suggest that it is feasible to integrate feedback from target end users resulting in interventions that are more acceptable and thus have enhanced effectiveness. Recommendations for conducting community-partnered adaptation research with autistic stakeholders and future directions will be discussed.

424.221 Managing Anxiety in Autistic Children and Youth through Virtual Delivery of Facing Your Fears, a Group-Based Cognitive Behavioral Therapy Program: Outcomes, Implementation Considerations, and Predictors of Response during COVID-19

A. Solish¹, J. H. Leef², L. Genore³, R. Hastie Adams⁴, E. Anagnostou⁵ and J. A. Brian⁵, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehab Hospital - ARC, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehab Hospital, Toronto, ON, Canada, (4)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Holland Bloorview Kids Rehab Hospital, Toronto, ON, Canada

Background: Autistic children and youth frequently experience co-occurring anxiety (~50-79%), often with significant interference in everyday functioning. Cognitive behavioral therapy (CBT)-based approaches are effective in treating anxiety disorders across populations. One such CBT-based approach, Facing Your Fears (FYF), is a group-based program, modified specifically for autistic children/youth. The program yields positive outcomes in controlled research settings and community implementation when delivered in-person. However, many families experience barriers to accessing the program due to limited workforce capacity and residing at a distance from specialized centers. In response to COVID-19 social distancing measures (e.g., service closures), providers adapted service models to include virtual care. This innovation promoted increased scalability of evidence-based treatments not only during, but also beyond the COVID-19 isolation periods.

Objectives: This study investigated the feasibility, acceptability, and effectiveness of FYF when delivered virtually through a tertiary care hospital in Ontario.

Methods: N = 100 autistic children/youth (aged 8-13 years; 78.8% identifying as male) and their caregivers participated in the 12-week FYF program, adapted for virtual delivery; 87 families completed the program and provided data elements. This hybrid effectiveness-implementation design study took place over a one-year period. Pre- and post-intervention questionnaire data were collected via REDCap surveys to explore adaptive functioning (ABAS-II), autism characteristics (SCQ Lifetime), anxiety symptoms (SCARED-parent and child versions) and their impact, and COVID-19-related needs (CRISIS-AFAR); satisfaction surveys were completed at the end of the program.

Results: Parents reported high satisfaction with the program ($n = 87$, $M = 7.95$ out of a total possible rating of 9, $SD = 1.03$). Participants represented 13 of the province's 14 local health regions, with participant representation missing from only one region (North-West).

Paired samples t-tests yielded significant parent-reported improvements for Total Anxiety ($M = 34.91$ vs 27.90 , $t = 3.99$, $p < .001$; Cohen's $d = 0.56$) and Generalized Anxiety ($M = 10.70$ vs 8.88), $t = 3.18$, $p = .008$; Cohen's $d = 0.45$). The rate of children/youth meeting clinical cut-offs for Total Anxiety decreased significantly from 76% to 57% ($\chi^2 = 7.27$, $p = .007$). Significant improvements on the self-reported SCARED-C also emerged for Anxiety Total ($M = 34.52$ vs 28.85), $t = 3.08$, $p = .002$, Cohen's $d = 0.44$.

The CRISIS-AFAR was used to measure COVID-related factors. Linear regressions revealed two significant predictors of response to intervention, **positive outlook** ($r^2 = .049$, $p = .027$, $\beta = 1.765$; i.e., lower baseline positive outlook predicted greater improvement in anxiety) and **material deprivation** ($r^2 = .041$, $p = .044$, $\beta = .860$; i.e., greater baseline material deprivation predicted greater reduction in anxiety).

Conclusions: Virtual delivery of FYF is feasible and effective for treating elevated anxiety in autistic children/youth and may improve access across wide geographic areas. COVID-related hardships did not impede families' ability to benefit from the program; conversely, caregivers experiencing such hardships benefited slightly *more* from the program, suggesting that perhaps COVID-related hardships bolstered caregivers' motivation to seek mental health supports for their children and help them make positive change.

424.222 Mindfulness Intervention for Caregivers of Children with Autism in Rural Environments of Maine: Mind-Care Maine

K. A. Pedersen¹, **E. Touchette¹**, **E. P. Walker¹**, **B. J. Taylor²**, **W. L. Cook³** and **S. L. Santangelo⁴**, (1)Center for Clinical and Translational Science, MaineHealth, Portland, ME, (2)Center for Clinical and Translational Science, The Roux Institute at Northeastern University, Portland, ME, (3)Dyadic Data Consulting, Portland, ME, (4)Center for Clinical and Translational Science, Maine Health Institute for Research, Portland, ME

Background: Caregivers of children with autism spectrum disorder (ASD) experience significant stress from managing behavioral and communication challenges, which can lead to heightened anxiety, depression, and physical health issues. These stressors may adversely affect caregivers' well-being and their ability to provide effective care. Rural caregivers, particularly in underserved communities, face additional burdens due to social isolation, limited access to specialized services, and delayed diagnosis. Traditional mental health interventions often require in-person participation, presenting logistical challenges that underscore the need for accessible, remote support options.

Objectives: This pilot clinical trial aims to assess adherence, acceptance, satisfaction metrics, and the potential efficacy of a 30-day mobile app-based mindfulness training program, Unwinding Anxiety (UA), in reducing anxiety among caregivers of children with ASD in rural Maine.

Methods: We conducted a preliminary analysis of pilot data from the ongoing MIND-CARE Maine clinical trial, which has collected data from 14 parents (7 cohabiting couples) of children with ASD in rural Maine. Adherence data was tracked through the UA app, calculated as the average number of modules completed out of 30. Anxiety scores were assessed at baseline, and on days 7, 14, 21, and 28, using the GAD-7 (Generalized Anxiety Disorder-7), a brief self-report questionnaire where higher scores indicate more severe anxiety. Acceptance and satisfaction metrics were developed for the study, with items including questions about the acceptability and overall satisfaction with the UA program.

Results: The caregivers were an average age of 48 years old ($SD=8$), were white (100%), and mostly identified as non-Hispanic (93%). Among the caregivers, 75% of mothers and 67% of fathers reported having a mental health diagnosis (e.g., anxiety, depression). The majority of couples were heterosexual (86%), married (86%), with an average household income exceeding \$100,000 (70%). Children were on average 13 years old ($SD=5$) and predominantly male (86%), with an average diagnosis age of 8 years ($SD=5$). Caregivers completed an average of 34 UA modules ($SD=30$), surpassing the required 30 modules, as many chose to independently repeat sessions, indicating high adherence. Preliminary analysis showed anxiety scores decreased from a mean baseline of 7.64 ($SD=4.6$) to 4.0 ($SD=3.2$) by the study endpoint, suggesting potential efficacy (Figure 1). Acceptability ratings exceeded 50%, indicating most caregivers found the intervention acceptable, engaging, and effective (Figure 2). Notably, 100% of caregivers felt their anxiety justified using this intervention, and 98% reported it as useful for reducing stress.

Conclusions: Preliminary findings from the MIND-CARE Maine trial suggest that the Unwinding Anxiety mobile app-based mindfulness training program effectively reduces anxiety among caregivers of children with ASD in rural Maine. The high adherence rates and reduction in anxiety scores support its potential efficacy. Furthermore, positive acceptance and satisfaction metrics indicate that this app met the need for accessible mental health support in this underserved area. While the sample size is currently small, these results provide a strong foundation for our future exploration of the scalability and long-term impact of mindfulness interventions on caregiver mental health.

424.223 Mitigating the Impact of Dysregulation on Learning Outcomes for Autistic Pupils

J. Doyle¹ and **A. M. Romualdez²**, (1)Department of Psychology and Human Development, UCL Institute of Education, London, London, (2)UCL Centre for Research in Autism and Education, London, United Kingdom

Background: Teaching children to identify and manage their emotions is a statutory right in education, forming part of the UK National Curriculum. However, while much research has focused on parents and caregivers in the context of diagnoses or mental health services, few studies have addressed emotional regulation within educational settings.
