[36] Similar approaches are adopted by NGOs, such as the World Bank in order to help the rehabilitation and development of shantytowns. In Great Britain, for example, the movement for the self-building (promoted by Segal) led to the realization of various groups of buildings; while in the United States, is very common to order the project of homes by catalogue. In Italy, we recall some experiences of the cooperative movement.

discipline may continue in design and using innovating devices such as new furnishing systems and architectural subsystems which encourage the adaptability of existing spaces or ones that have to be built *ex novo*. However all these issues must be managed, within an overview attitude, as parts of a unique strategy.

an *IDtool*[37] for the conversion of buildings

The interior designer needs to develop a tool which allows his/her practice, promoting the organisational dimension of the project (developed with a high social involvement) and useful to facilitate communication between stakeholders. **Real-time layouting** is an example of an effective tool developed to answer such needs; in particular, it makes the causal connections between demand and design proposals/outcomes explicit. It is a low-tech tool, that is used by the interior designer (playing the role of technician-facilitator) with the inhabitants; it is an instrument which can promote and sustain a social learning process becoming an adaptable *management tool* in the conversion of building contexts.

Initially, Real-time layouting was conceived for **XS-scale planning**. The specificity of such tool is to match the following variables: time and lifecycle of the building, user's needs and visions about spaces and its meaning, resources of the building in terms of potential space and available structure and stuff. The case study **"Sacra Famiglia"** in Como is an example of how to use the diagram in practice, for this specific goal. It is a reconversion of a 19th century country house (currently a boarding school) into a general's house for the congregation of an order of nuns called "Suore Figlie della Presentazione". The team working on this participated project set up with the religious community was a transversal one: an architecture and engineering studio for the brickwork, decorators and craftsmen[38] for the restoration of the heritage parts, a designer responsible for the interiors and the *Colour Plan*, several suppliers for the realization. In such case study, Real-time layouting has been applied as a valid support in the last two phases of the process, as operational tool to be included in the planning methods kit II; it has been specifically used for a series of design game sessions.

[37] Interior Design tool.
[38] Antique dealers, glaziers and upholsterers for sacred objects and ancient furniture.

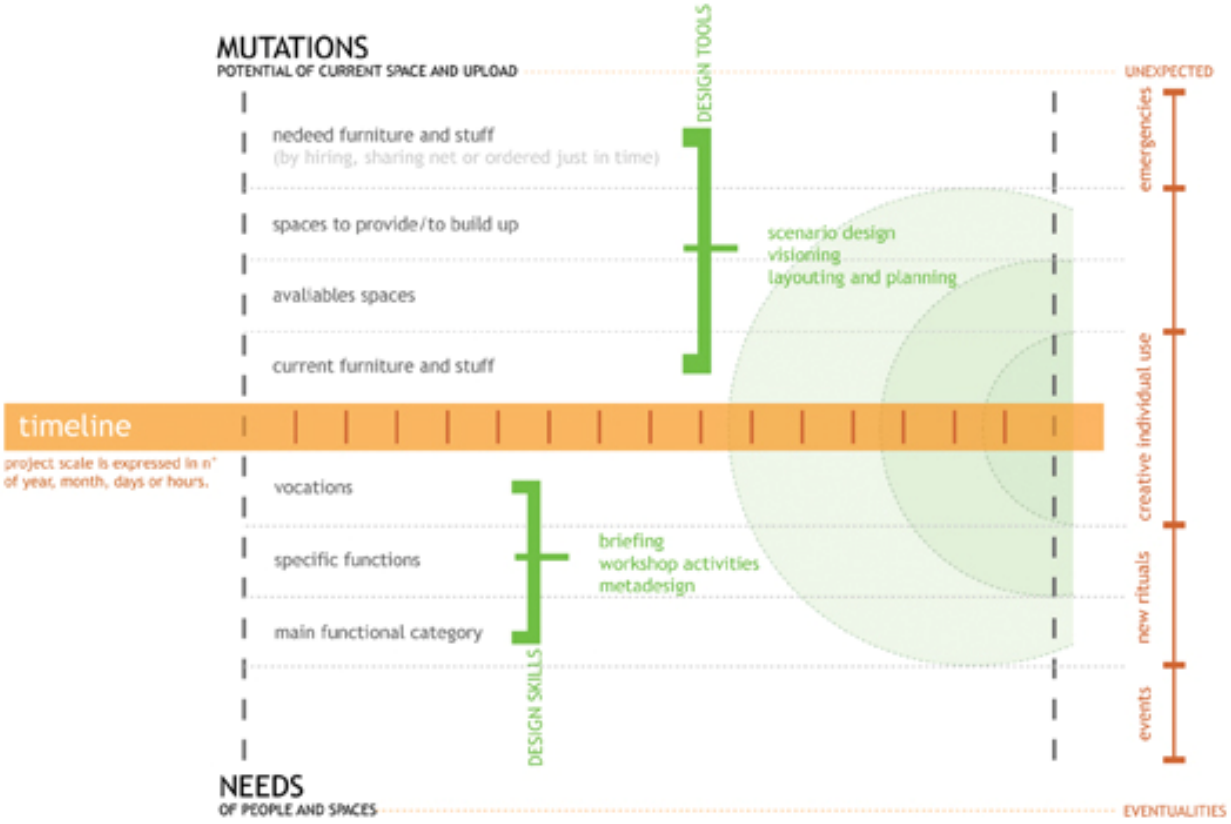

Fig. 2: Example of Real-time layouting diagram (not filled with project data). Design may develop not only a *mindstyle* but also a precise *tool* for the interior designers involved into participatory processes for the conversion of buildings.

Its first strength is the ability to carry out an efficient analysis. The tool is designed to **support the phase of 'listening',** considering various levels of input-data: functional needs, imaginary/representation of a place (object of conversion), shared values and built up visions. Consequently, the outcome in giving priority and evaluating current resources and future design needs would be guided by ideas. Real-time layouting is a tool capable of collecting data deriving from a listening activity which is more careful to interaction with inhabitants (this represents the shift from the quantitative phase, where the assessment of needs takes place, to the qualitative and performing one): this tool has therefore been used to define collective needs. In particular, in order to support this theory, we would like to mention an Outreach[39] experience, which has taken place in Milan, in the **Mazzini neighbourhood;** during the "briefing collection" process, the inclusion of a designer in the team operating in the area has proved to be useful. The regeneration of the Mazzini neighbourhood is part up a wider plan called Five Contracts[40], a process of re-qualification of residential areas. The action potential of the above-mentioned political tool[41] seemed to be adequate for the research topic. The Municipality of Milan, together with Aler are the proposing actors, linked by an agreement protocol signed in 2004. The stakeholders are: an architecture studio and building company, who are responsible for the

[39] This is an investigation technique of the territory which is used for Community Appraisal. Among the "insiders" it is considered with the metaphor of "courting" because this instrument tents, practically, to go directly to people in places where they live and work.
[40] Those that affect the recovery of housing areas in: Gratosoglio, San Siro, Calvairate-Molise, Mazzini and Ponte Lambro. The funds refer to the call " Neighborhoods Contracts II" and concern interventions of building regeneration, infrastructure recovery and public areas (including green ones), social support. Martini Associates Ltd. (http://www.martiniassociati.it/ita/chisiamo.html) is the company charged by the Municipality of Milan for the management of plan.
[41] Or the Neighborhoods Contracts, as complex program. These contexts are privileged occasion for the introduction of innovative factors about local equipment.

realization of re-qualification actions; the inhabitants[42]; social workers that operate in the area (psychologists and educators; cultural mediators and facilitators).

Fig. 3: Photo of the working team, during an Outreach. The AR is part of a process driven by *Laboratorio di Quartiere*, Mazzini district - Milan.

Real-time layouting has a second potential: it is a **global management tool** the designer can use, as it connects the needs and representations of the collective-committing[43] subject to already existing resources (settlement), but above all to what is "new" and must be co-designed; making everything easier to be read and communicated to the non-experts. Such premises allow a wider employment of the tool, in function of the interpretation the community-outsourcer gives of "participation", in regards of available resources. **"*I have a dream:* Cisternino 2020"** is the slogan of a participatory process in Livorno, which has provided the opportunity to check the capabilities of this tool in a different context. The project, proposed by the Livorno[44] Municipality, is a participated design process for the recovery of an historical building located in the city center: the Cisternino in Guerrazzi Square. The process is structured in four phases: the first one foresees the creation of an Organizing Committee, responsible for guiding the launch of the process and guaranteeing positive participation; in the following phases, the city is the main actor of the exploration, proposal and decision-making actions. The administration, the citizens, the facilitators and technicians are involved at different levels of the process. Our focus for this research is on the phase "La città propone" ("the city proposes"), where the younger citizens[45] of Livorno have been invited to take part in a session of Open Space Technology. The goal was to propose and discuss ideas and projects for the re-use of the former Casa della Cultura; the program was called: "*Che Fare nel Cisternino di città dopo la ristrutturazione?"* [46] . The participation of a technician-facilitator in this meeting could be very useful for the interaction itself:

[42] Sometimes organized in Associations.
[43] Or the briefing collected during 'listening' phase and future search; in add, activity 'visioning' (if performed).
[44] Coordinated by Marianella Sclavi, professor of Urban Ethnography at the Politecnico of Milan, and Susan E. George, chairman of degree course in Public Communication and Social Entrepreneurs at the University of Pisa; they are both expert in communication field and experimenting with new forms of participation. For details, see the site about process. (http://cisternino2020.comune.livorno.it/)
[45] Of all ages!
[46] "What to do within the city's Cisternino after its restoration?".

during a collective brainstorming process on the reuse of the building, a professional able to drive popular debate toward a progressive focalization of design trends, combining them with the vision already expressed by citizens, might lead to the definition of *emic* guidelines for the project.

From the interior designer's point of view, Real-time layouting is a tool which can be applied to some **classical metadesign phases** (as cleared in the table below).

	applied use of RT-layouting for:
consultant methods:	
choice catalogue	* *briefing*
field methods	
community appraisal	* *briefing*
Parish maps	
OST	* *trends and potential vision* | *guideline for project*
Priority Search	* *trends*
Future Search	(this technique is already considered in the diagram as a disciplinal tool)
Community Visioning	(this technique is already considered in the diagram as a disciplinal tool)
planning methods I:	
Action Planning Event	
Planning for Real	* *mission and concept* | *guideline for project*
Strategic Choice	
EASW	* *series of concept* | *guideline for project*
microplanning or *CAP*	* *mission and potential concept* | *guideline for project*
planning methods II:	
Pattern Language	
Design Workshop	* *series of concept*
Design Game	* *concept and potential layout*
Building Design & Conversion Kit	* *final layout*

The diagram can be filled out with a variable degree of accuracy; according to a different applicative goal (of data collection, concrete planning and design) in regards of the phase of the process and in function of the methodology behind its use; finally, in relation to the nature of the outsourcer-collective. This will consequently combine with other disciplinary instruments which are typical of a designer, such as: cognitive maps and images/scenarios, moodboard and storyboard, plans and tridimensional models, catalogues and chromatic/material samples. Briefing collection, resource analysis and priority, timeline and mock-up of the process/project: we can say that Real-time layouting is the link with the system of procedures carried out during the participated process and becomes an implicit and explicit tool, i.e. addressed to technician (interior designers) and at the same time functional for the collective decision-making process.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

THE MANAGEMENT OF DESIGN AS A TOOL FOR CULTURAL CHANGE LEADING TO SUSTAINABILITY

A case study in the Industrial Company of Pernambuco, Brazil.

Glenda Cabral, Virgínia Cavalcanti and Ana Maria de Andrade[1]

Abstract

The concern with organizational culture regarding sustainability is justified in relation to industrial production using the binomial: consumption versus market. The issue has also entered the agenda in discussions of design because design is considered an important agent for changes in society's habits of production and consumption. Against this background, we set out from the following premise: because it performs a strategic role in the relationship design-company-market, the management of design has the ability to provoke consistent changes in organizational culture as it uses design tools to optimize productive processes and products. The results of the research study point to transformations in organizational culture in favor of a sustainable relationship with the internal and external environments of the company.

[1] Laboratório O Imaginário, Universidade Federal de Pernambuco - Brasil, Departamento de design, glendagcabral@yahoo.com.br, cavalcanti_virginia@hotmail.com, anamariadeandrade@gmail.com

1. Introduction

The issue of sustainability has entered the agenda in discussions of design in a rather peculiar way, it being considered an important agent for changes in society's habits of production and consumption. This responsibility which is attributed to it is fundamentally anchored on its intimate relationship with material culture.

The concern with the organizational culture of companies as a way of bringing about satisfactory results with regard to sustainability is justifed to the extent that what becomes evident is the relationship between the current forms of capitalist logic which involve the binomial: consumption versus market and its mechanisms, besides the result of astounding progress. Further, in global discussions on the issue, some problematic situations are pointed out such as, among other factors, polluting production processes which equally degrade human life and which are directly associated with the logic of the indiscriminate consumption of industrialised goods by society.

Nevertheless, in order that design may contribute consistently to changes in this scenario what is needed is for there to be an appropriate management methodology for design which will make it possible to raise the awareness of the company to the use of this tool and so to generate a sufficient opening for innovation based on sustainable development[2], states Kiss (2005). Thus we believe that the objective and subjective relations worked on by design can be adequately dealt with in the business environment.

As part of the result obtained in a master's research study which is being undertaken in the Post-Graduation Program in Design at UFPE (Federal University of Pernambuco – Brazil), this article sets out from the following premise: because it performs a strategic role in the relationship design-company-market, the management of design has the ability to provoke consistent changes in organizational culture because it makes full use of design tools in order to optimize productive processes and sustainable results with regard to markets and their consumers.

Along general lines, it is also believed that the management of design should be positioned in a strategic, coehesive and structured way within the organization, since it is charged with coordinating the design actions which occur in and for the company. Thus, it is believed that it will be able to influence the culture of the organization, by directing itself towards stimuli to constant innovation, by making full use of design tools which seek to sensitize and potentialize parameters of sustainability regarding productive processes, the market and consumers (MARTINS, 2004 and TEIXEIRA, 2005).

In searching for evidence that may corroborate this claim, the case study methodology put forward by Yin (2002) will be used and illustrated, in the case of the partnership between the Pernambuco Imaginary (an extension project of the Department of Design of the Federal University of Pernambuco) and the Companhia Industrial de Vidros de Pernambuco (Industrial Glassware Company of Pernambuco) – CIV (in Portuguese).

CIV has been active in the market of glass packaging for food and pharmaceutical products since 1958 and only in the year 2000, did the Company begin to act in the sector of domestic utilities for classes C and D and only from 2003 has it inserted design into its strategic planning.

With the insertion of design directed towards the line of domestic utilities, the challenge was concentrated in adding value to CIV products, by allying the technology used by the company (IS – Individual Seccion[3]) to the needs and wants of its potential consumers.

---

[2] On sustainable development, Kazazían (2006, p. 8) conceives it as being "that which reconciles economic growth, preservation of the environment and improvement of social conditions".

[3] Technology which presupposes the conformation of a superior termination in all products as support to the withdrawal of this from the line of production.

The course of the path of this partnership, with its successes and difficulties evaluated in the interaction of design-company-market, brought about organizational changes, which were instituted so as to facilitate and bring out the potential in the reach of this strategy within and without the environment of the organization.

The results show that, the greater the boost from the management of design to innovation, the greater will be the transformations in the company's organizational culture in favor of its capacity for invention. Therefore, the increase in the company's performance reflects a sustainable relationship in the environments internal and external to CIV.

2. Industrial Production and Sustainability

Consumer goods industries almost always deal in a market of cut-throat competition and demanding consumers. As if it were not enough that this competitve backdrop has been intensified by the state of a globalized world, the historical record of world industrialization has brought the burden of decades of indiscriminate use of the environmental riches and of degrading forms of production. According to Ferreira (2003), this scenario was encouraged by the practice of the market in meeting the needs and wants of the population while the reconstruction was underway of a Europe devastated by the Second World War. This phenomenon gave rise to the then consumer society, avidly seeking new experiences and a fertile field for "justifying" progress. Currently, these and other countries located in the central economies, faced with years of devastation and technologies that pollute, are grappling with the need to contain the levels of production.

As a counter-point to this, the peripheral countries are also causers of large indices of environmental pollution and one of the factors which aggravates the threat to the environment is the fact that they are in the shadow of the technology generated in the central countries and are consuming obsolete productive systems and processes which are moreover very harmful to the eco-system (FERREIRA, ibid.). The sum of all these phenomena leaves us no option other than to change habits and models, not only of production and the use of raw materials of both economies, but also of their attitudes when faced with the market and its consumers.

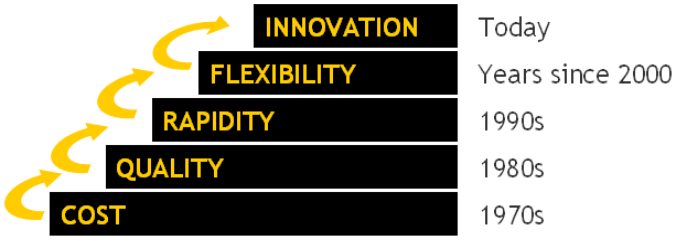
Focus of the Undertakings – a capitalist behavior

At the height of the 60s and 70s, companies' tactics consisted of simply enlarging the offer of products on the market through increasing production. At that time, there was the stimulus to supply the internal market with low-cost products and with little concern for differentiating themselves from each other. At that point in time, when industrial consolidation was starting, the reality of the age was that of low competitivity between companies which, consequently, did not deal with innovation or even did not feel the need to innovate in products for the market. (MORAES, 2006). Even the multinationals set up in Brazil kept their best products for the external market, leaving in this country what was not to the refined taste of European and North American consumers, or what in these markets had already become obsolete.

Now, from the year 2000 to date, companies have been experiencing organizational changes targetting flexibilization of their productive and bureaucratic structure and pursuing constant innovation. It is worth mentioning that the concept of technological innovation to which this article refers also displays changes in the behavioral and methodological paradigm and which, according to Cabral, Tabosa, Tschá and Cavalcanti (2007):

> [...] deals with the set of knowledge and scientific principles which are applied to a given branch of activity that is, their amplitude extrapolates materiality, having the function of giving shape to a specific body of knowledge which accentuates a given ability [...].

Fig. 01: Strategic focus for capturing opportunities by enterprises.



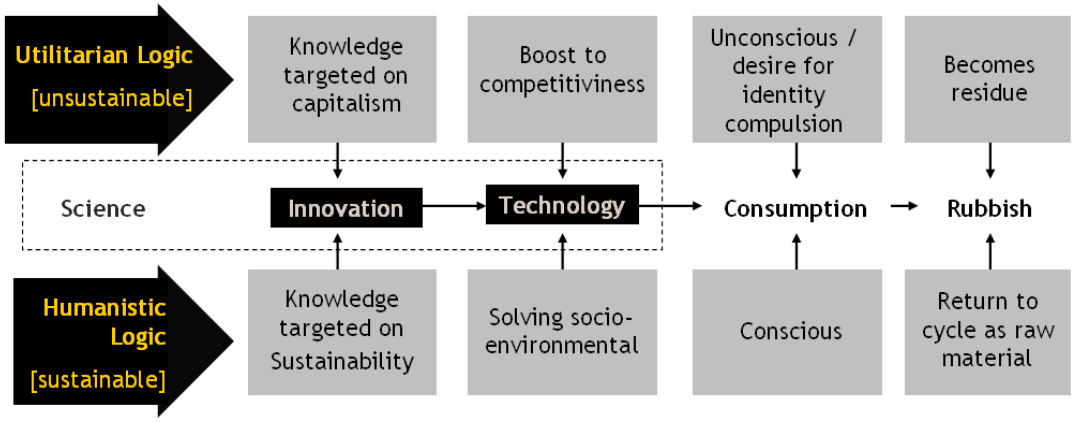
Source: IBIE, 2007.

It is also important to remember that the practice of these companies almost always concentrated on capitalist interests, that is, on the utilitarian logic of increasing profits and without much concern for for environmental and social issues. However, Teixeira (2005) points to the changes in the behavior of consumers, demonstrated by elevating their degree of demand and their level of awareness of issues, and by demanding the restructuring of organizations by means of a development based on sustainability and on a positioning which needs to be more and more innovative, This new level of awareness which is formed has its strength in humanistic logic, which seeks to direct developement which is centred on adding value to socio-economic and environmental matters.

Both forms of logic have innovation and technology as their spring-boards. However, while the former does not display care for socio-environmental aspect, as it incites giving a boost to unconscious consumption and generates residues which become mere rubbish, the latter seeks to raise the awareness in society at large of indiscriminate consumption, as well as of re-using residues as raw material of other or the same produtive processes.

Figure 02 shows the utiltarian and humanist forms of logic, and displays the type of development which each of them assumes as based on technology and innovation.

Fig. 02: Logic of development.



Source: adapted from Kazazian, 2005.

For utiltarian logic, innovation and technology focus on competiveness without much concern for the consequences of production and consumption of all these industrialized goods. While in humanist logic, one sets out to generate a sustainable culture of production, market and consumption, capable of provoking a consistent transformation in the habits inherent in this cycle.

It is worth mentioning, moreover, that the variable of science is presented here as the cradle of the relationship of innovation/technology by the fact of our dealing, in this article, with a case study on the partnership of university/company. However, this same relationship can occur, in other forms, not necessarily containing science as the inductor. It will depend on the modality of the partnerships established for developing new technologies.

3. Organizational Culture as the Port of Entry for Change

For Laraia (2006) and Santos (2006), it is important to bear in mind the power that culture exercises over individuals and groups, since it is one of the reception and transmission channels of visions of the world. It can also be read as one of the motivational factors in the decision-taking and attitudes of individuals, groups or even nations. Therefore, it should be understood as the "*back-cloth*" to changes, conflicts and other forms of behavioral expression.

It is important to understand that culture is not sealed off. On the contrary, it possesses its own dynamism which can be further influenced by various contingent factors, of a political, religious, technological, environmental, economic or social stamp.

For the purposes of study, it is common to observe culture by separating its aspects into material and immaterial. In the first case, we have the symbols, values, beliefs, myths, ceremonies, shared histories, tradition, languages and habits, and so forth. These translate some of the subjective relationships established "between" individuals "and" societies and "from" indivídual "to" society. As to the second, what can be cited are the norms, rules, established procedures, architecture, technology, visble and physical objects, etc, which represent, in the form of artefacts, these same relationships.

When we deal with organizational culture, we speak of the essence of the organization and that it may possess its suas nuances both of material and, above all, immaterial culture This, whatever the changes aimed at for the company may be, it is is necessary, first and foremost, to consider its cultural character.

According to Cardoso and Cunha (2001, p. 91), "*the organizational culture is the phenomenon which most expresses the institutional dimension of the organization: the order, the structuring function which produces subjectivity and models behaviors*". Further, according to

these authors, these structuring functions are responsible for producing "*perceptions, attitudes, values and behaviors, which, for their part, are synthetized into an organizational ideology and into predominant collective behaviors*".

What is is clear, therefore, is the power and influence which organizational culture exercises, not only on the individuals of the organization but also on macro society [4] of which it forms part.

According to Motta and Caldas (2006), the finality of organizational culture is to promote the company's survival, for which it is divided into having two distinct purposes: the first, of adapting itself to the external medium, such as to the market, to the business environment which includes the economy and to the relationships of networks external to the organization; and the second, for its part, aims to provide the organization as a whole with internal coherence.

In an interview with the magazine HSM Management, the buiness leader Jorge Paulo Lemann, one of the partners of InBev, talks of the importance of having organizational culture as his ally for consistent and long-lasting changes in the current globalized market. Lemann speaks of his experience of working on management culture, more precisely, fostering touches that encapsulate Brazil while managing his enterprises, which, so he claims, have shown thmselves to be a good strategy for the prosperity and sustainability of his businesses and the [environmental, social and economic] medium in which it is placed (SALIBI, 2008, p. 14-24).

In the same way, for changes in the marketing context, into which clients and their current habits of consumption are inserted, it is important to work on the culture of the organization by means of actions which target this environment, such as innovation of productive processes and of products, for example. Under this focus, design can be inserted in a direct way, through creative solutions which ally the efficiency and productive effectiveness of products to use and discard of those products last thought about when they were conceived.

4. Management of Design and its Field of Action in an Industrial Environment: stimulating change

Companies currently need to deal with the constant threat of new products and competitors who increasingly set out to meet or even stimulate the needs of consumers. In this dynamnic scenario, it is no longer possible to avoid the process of innovation. On the contrary, the exercise of generating innovations has practically become a *sine qua non* and not only to take advantage of those of others', since reactive postures alone are no longer sufficient for industries to survive in the globalized market. Therefore Brandão and Gonçalves (2006) are hard-hitting when they state that: "*the ability to innovate gains preponderant importance in defining who will prosper or succumb"* in the global business scene.

Nevertheless, to innovate is not only to invent or simply to discover. Innovating, necessarily, ends in a cycle where something is, finally, created, implemented. If referring to innovation through design, and he could well expand the concept to other areas, Teixeira (2005) states that inovating deals with the process where design "*practises a new idea, transforming it into an effective action*".

Therefore, design is positioned in a direct connection with the competitive adaptation of companies to the market in its temporal and physical conetxt, by means of its ability to transform the subjective and objective elements of this context into new products, processes and/or services, it being an important agent for sustainable development, as Mozota (2002) argues.

It is through the movement around innovation that design finds space to insert itself into the company and incites changes in its organizational culture. This relationship can be understood as

[4] Society in which the organization is inserted, such as country, State, town, neighborhood or also, religious and political groups and/or economic segments, and so forth.

one of “projecting for change”, since design (ONO, 2006), through channels, tools and abilities, exercises influence on the macro culture[5] and, consequently, on the trends of consumption.

Nevertheless, it is important to understand that the complexity of design goes beyond differentiating or innovating products or brands and its correct management within the company becomes fundamental for the success of these projects, as Kiss (2005) says when he states that:

> [...] design needs a methodology just as all corporate activities do. Processes should be created to guarantee that design is consistent and meets the standards of quality and innovation, in the same way as effective structures of management are necessary to guarantee that design [...] is integrated correctly with the other corporate activities.

The Management of Design and its Levels

Some authors separate the management of design at the operational, tactical and strategic levels. At the same time, no matter that in some moments it acts with greater intensity on one of these aspects, the three are component parts vof design itself and, consequently, inseparable in practice.

The operational level is reponsible for the conduct of project designs in themselves. However, depending on the opening that the management of design at the operational level has, it may influence the company strategically, when it takes the decision to innovate in raw materials or even in suggestions for changes to productive processes, for example.

The tactical level is answerable for the coordination of the design actions which occur in the company, by mobilizing material and immaterial resources and making them available so that design strategies are fulfilled in an eficient and coherent way and meet the company’s objectives.

As to the strategic level, it can be understood as the highest level in which design participates within the company since its decisions impinge directly on the future paths of the enterprise itself.

Table 1, below, shows these three levels, their respective fields of activity, the creation of value from the management of design in each of them, as well as the influence of design.

Table 01 – Influences of design on the Management of Design

Management of Design			
Levels	Activity	Creation of Value	Influence of design
Operational	Actions targeted on the design project. Considered a task from ‘within to without’ both in style of intellectual conception and functional simplicity (European) as well as so that serves for sales and advertising (American).	Creates value on what the company supplies	On the corporate image and product: gives sense to the discourse and object.

[5] Culture of society in general which can be affected by the actions of the action in a direct or even indirect way,

Tactical	Occurs on the coordinating function of the design project, i.e. the function of control falls to it.	Creates value on the support functions, in particular on the management of innovation and technology.	On people: helps to mobilize and motivate by the facility of circulating information, by drawing close to different actors of the process.
Strategic	Assumes responsibilities for the evaluation of the company's mix of products, by checking its performance and seeking new possibilities regarding products to be produced by the company.	Creates value on the business environment or transforming function of design.	On the company: facilitates the formulation of a project which boosts the vision of the strategic nucleus.

Source: adapted from Martins, 2004, p. 99.

In general, the mangement of design should seek to act at the level closest to the strategic one so that the actions of design in the company can be brought to realise their potential. Thus, it will be possible to influence organizational culture, by targeting ways to stimulate constant innovation and by making full use of design tools which seek to raise the company's awareness of the parameters of sustainability regarding the productive processes, market and consumers (MARTINS, 2004).

According to the CPD - Centro Português de Design (Portuguese Center for Design) (1997), the management of design should be positioned next to the sectors of marketing, engineering and production, thus making it possible that this network may communicate efficiently and effectively during innovation processes.

This position when added to the correct management of communication of these and other sectors in the company confers on the management of design a favorable opening to changes in and breaks of paradigms. Nevertheless, for design, this interaction is made all the more necessary in the departments mentioned, since, according to Ferreira (2003), these are responsible for:

- **Engineering and Production:** working on the technical and technological aspects of the product and productive processes;
- **Marketing:** determining the briefing for creating new products and for decisions of the type: "what is there to be done", i.e. it manages to achieve new possibilities for products and markets.

It is worth underlining that breaks of paradigm of the technological type can also come from marketing stimuli, when this identifies, for example, a new opportunity for a product. In the same way, breaks of paradigm in products and marketing devices can also come from engineering and production.

Emphasizing this need for interaction, in an interview with the magazine AMANHÃ (Müller and Graciano, 2005), Professor Celaschi of the Polytechnic School of Milan points out that it is by the union of forces of all agents and departments involved in the process of innovation, by means of good communication, inter-relationship and awareness of each on their roles and objectives of the projects that the company will manage to attain good results, thus facing less risks and optimizing productive processes.

5. Methodology

In the search for evidence that may corroborate the central premise of this article, the methodology used to develop the research is that of a case study as proposed by Yin (2002). As the main unit of analysis, the experience undergone in the Companhia Industrial de Vidros

(Industrial Glassware Compnay) – CIV – will be presented since this firm has been demonstrating gradable results and since they prove the influence of design and the management of design on its organizational culture.

The partnership with the Pernambuco Imaginary, an Extension Project of the Departament of Design of the Federal University of Pernambuco, in 2003, was one of the company's first experiences in the use of design with the initial objective of differentiating the products of the Company on the market.

The course of this partnership shows, however, that other relationships were established as a way to meet strategies centered on deign. The case sets out to give a succinct report of this experience, and emphasizes phenomena which prove the influence which the mangement of design can exercise on the organizational culture of a company and, thus, obtain more satisfactory results regarding their sustainability.

The data which will be presented in the description of the case were collected from semi-structured interviews, gathering documents, and in conversations with members of the Pernambuco Imaginary project. These results also form part of a a master's degree research study of the Post-Graduate Program in Design at the Federal University of Pernambuco, the theme of which focuses on the management of design for industries producing utilitarian products.

6. The Case of the Companhia Industrial de Vidros (Industrial Glassware Company) - CIV

Founded as a family business, the Companhia Industrial de Vidros - CIV forms part of the enterprises of the Cornélio Brennand Group and has been active in the glass packaging for food and pharmaceutical products since 1958, and has reached the ranking of being among the top three national industries in this sector (CAVALCANTI, 2006).

The company possesses 4 manufacturing units in the Northeast of Brazil, which supply it with the capacity of 07 fully installed kilns and permits the production of 1,000 tonnes of glass a day i.e. 1.5 billion units/ year. In the year 2000, with the aim of expanding its business, the Company entered the market of domestic utilities for social classes C and D, a line which currently responds for 20% of its annual turnover.

Surveys conducted by specilized bodies. Such as IBGE – the Brazilian Institute of Geography and Statistics - reveal that the volume of purchases by CIV's target public (C and D) has been increasing considerably. The results point to scales of advance in the order of 9% only in 2006, almost double the growth of the total consumption of the population. When class E is added, the three bands represent 31 million Brazilian homes, i.e. 72 out of every 100 urban households, and together they detain the purchasing capacity of 372.5 billion *reais*, the equivalent to 42% of national consumption (BLECHER and TEIXEIRA, 2003), that is, the market scenario in which CIV is active demonstrates great opportunities both in the economic sphere and in a fruitful environment for the institution of changes in the habits of consumption.

CIV and Design

It was by gambling on innovation and on incremental and even radical changes in its model of doing business that CIV, in 2003, began to invest heavily in increasing its productive capacity and in differentiating its products through design. From this same period, CIV also began the phase of transition from a family company to a company managed by professionals from the market.

One of the company's first contacts with design came about as the result of an external consultancy, through the Pernambuco Imaginary extension project, of the Department of Design

of UFPE - the Federal University of Pernambuco. In this project, students and teachers began to develop new products for CIV's domestic utilities line such as cups, jars and pots, and had the initial challenge of making the technology used by the Company compatible with the aesthetic and ergonomic requisites, including those of usability, of these products demanded by the consumer.

The greatest obstacle of this challenge is concentrated on the fact of the IS - individual seccion[6] technology, used by CIV, being the proper equipment for the production of glass packaging, which implies, necessarily, conformation of a superior finishing in all the products which it serves as support in order to withdraw these from the production line.

In addition to this finishing interfering visually in the aesthetics of the product, in some cases, it can also interfere in their usability by the end consumer, or even in the productivity of the company, when poorly dimensioned.

Other issues also referring to technology can affect both the usability and the ergonomics and aesthetics of the product, such as, for example, the type of conformation of the glass walls of the product. By the fact of the technology used being of the type blow-blow[7] or press-blow[8], there is no means of having total control on the distribution and quantity of glass on account of the shape of the product. This characteristic can provoke failings in the production process which can be perceived by the end consumer as a factor of the product's low quality.

Design Methodology for Developing CIV Products

Figure 03 shows the methodology used by the Pernambuco Imaginary to develop products for the line of domestic utilities.

[6] Type of pneumatic machines commanded mechanically or electronically. This type of equipment is created for the production of glass packaging in the blow-blow and press-blow processes.

[7] The blow-blow process begins from loading the gob of glass, at a temperature around 1200º, inside the pre-mould which receives an injection of compressed air and forms the neck.

[8] The press-blow process offers more flexibility in the conformation of shapes for the product, thus making a greater variety of glass pieces possible. The drop of glass inside a pre-mold, is now on a pin, which will press the glass against the bottom of the pre-mold. The extraction of the piece is similar to the blow-blow process.

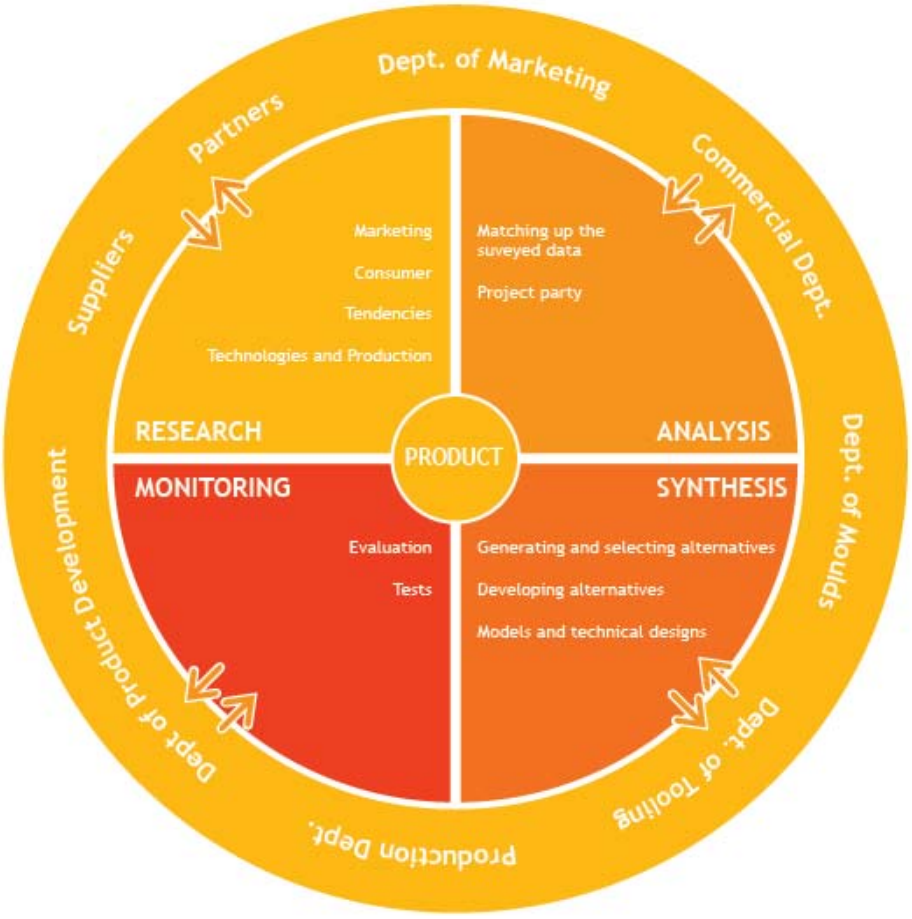


Figure 03: Methodological steps for developing new products.

Source: Cavalcanti, Andrade, et. al, 2007.

In the macro steps which the figure above shows, we can note that the Pernambuco Imaginary Project establishes several relationships with the departments of marketing, production, CEO (directorate), suppliers, consumers and, depending on the complexity of the project, these relations are widened to other agents and also intensify.

In general, the methodology begins with the briefing, formated by the marketing department, in which the background[9] of the product to be developed, and moreover its target [10] appear.

The following steps on receipt are, respectively:

- **Survey:** the phase in which [i] information is collected on the technical project limitations together with the engineering and production departments, [ii] the market surveys are carried out, such as looking for similar ones on the market and the positioning of competitors, in addition to [iii] direct surveys with the potential consumer of these products.

[9] Type of historical record in the company and its relationship with the market; the objective, which involves the characteristics of "utility and significance" of the object and its targeted positioning (CAVALCANTI and ANDRADE, et. al, 2007).

[10] Syntesis of the consumer's profile which includes information on gender, age and social class (CAVALCANTI and ANDRADE, et. al, 2007).

- **Analysis:** step relating to the formulation of the project party based on de-codifying all the information obtained in the previous steps, since the briefing;
- **Synthesis and Ongoing Monitoring: the last step in developing products deals with selecting and enhancing the alternatives chosen, by the company, to be launched on the market. This phase sees the start of the technical detailing of and ongoing monitoring of the project until it is inserted onto the market.**

It is worth mentioning that the management of design which occurs in CIV is still at the operational and tactical level. Nevertheless in certain projects, it was possible to observe that some strategic level solutions started out from design stimuli.

Organizational changes Arising from the Action of Design

Given this model of partnership on account of the innovation in design, the Company has been displaying transformations in its organizational culture with regard to innovation, concern for the needs and wants of the consumer, the search for sustainability in its three parameters, as well to constant adaptation to the market.

Table 02 shows some of these changes and their respective influences on the organizational culture.

Table 02 – Organizational changes and their influence on the company's culture.

Change perceived	How it affected organizational culture
Improvement in communication between the sectors of marketing and engineering	Increase of efficiency in the flow of development of new projects.
Increase in the capacity of innovation, since, currently, the company is allowed to run greater risks because of the better positioning for its product.	Better adaptability to the market and meeting the needs and wants of consumers, in some moments, by behaving in a proactive way in the segment of domestic utilities.
Increase of the stimulus to the creative capacity of its staff. For, in each project, the participation of various stake-holders in the company is encouraged to find solutions to project problems (CABRAL, et. al. 2007).	Sustainability of the society internal to the company and, consequently, of the internal and external economy, since this type of functioning brings greater capacity for generating innovations.
Increase of the perception of value on the product by the end consumer arising from re-structuring the company and its corporate image, with a view to adapting itself to this new perception (CAVALCANTI, 2006).	The change in the company's internal behavior, i.e. in its identity, generated the need for adapting the corporate image so as, once again, to adapt itself to the market.

Source: creation of the authors, 2008.

7. Conclusion

The Pernambuco Imaginary Project has contributed to CIV at the R&D – Research and Development – levels, by prompting innovation in the company and the gradual absorption of design by the organizational culture. Therefore, many changes arising from the actions of design were realized, such as the greater interaction among sectors involved in the devopment process

for new products, thus permitting innovation to meet more efficiently and effectively both needs of the business but also of its consumers.

As the focus is applied research, the risks inherent in innovation are reduced in addition to which it is possible for the company to estimate rapidly the performance of the product on the market. This factor confers a certain degree of reliability in the strategy of innovation centered on design.

It is also perceptible that, despite occurring in a gradual way, and even though management of design at the strategic level in the Company has not yet been instituted, there are signs that these projects indicate a path is being constructed so that this may come about.

Given, therefore, that the influence of the management of design has gained fame, even if at the operational and tactical levels, in the CIV organizational culture, it is possible to state that the greater the opening up and stimulus of the management of design to innovation, the greater will be the inventive capacity of Brazilian companies and, consequently, their performance in the global market.

Management of design and innovation when integrated bring out the potential of actions on organizational culture in order to obtain and propagate satisfactory results in the market with regard to the general sustainabiity of the company and its physical, economic and social surroundings.

DESIGN VISIONS PROPOSALS AND TOOLS

COLLABORATIVE SERVICES AND MOBILE NETWORK

Observation of social innovation and anticipation of sustainable lifestyle in China

Miaosen Gong[1], Shu Feng[2], Chakrapipat Assawaboonyalert[3]

Abstract

The paper reports the observations of some emerging grassroots social innovations in China as collaborative services and the anticipation of Chinese visions of sustainable lifestyle specifically in the perspective of mobile network.

By case studies, the paper starts with a discussion of bottom up initiatives of sustainable lifestyle in China in comparison with European experiences. Moreover, the characteristics of collaborative services in China are identified in the terms of service structures, contents, motivation, social context and so on through a series of research activities like interviews and seminars. In the second part, the relationship between collaborative services and mobile communication is investigated in two aspects: MCTs(Mobile Communication Technologies) supporting contexts and MCTs enabling solutions by case studies of MCTs creative services and applications.

In a word, the paper puts in evidence that mobile communication and networks have specific qualities to enable the collaborative services.

Social Innovation, defined as “innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly developed and diffused through organizations whose primary purposes are social.”(The Young Foundation 2006, 11), has been widely discussed in the field of civil society and is becoming a new wave of human evolution since our environmental and social problems are growing all over the world much larger and faster than what other innovations in technologies and businesses can deal with. Given that, social innovation could be a strong driver towards sustainable society.

Social innovation happens in different domains and by different approaches. What we inquire here is a specific type of social innovations, those grassroots social innovations in everyday life, known as Creative Communities[4] (Meroni 2007) and Diffused Social Enterprises, where the collaborative services are implicated.

Cases of creative communities towards sustainability have been observed in Europe[5] (EMUDE 2006) and worldwide (CCSL 2007). They are bottom-up emerging initiatives that illustrate the real possibility of reorienting the evolution of present society in the direction of a sustainable knowledge and network society (Manzini, Jegou 2003). Therefore, promotion of this kind of social innovation could be a viable strategy for sustainable development and in this transition strategic, design approaches are supposed to play important roles as a social learning process. Furthermore, the collaborative service was abstracted from the observation and study of cases as a new typology of service evolved from diffused social enterprises. Therefore, to promote the creative communities or their initiatives towards sustainability means to promote the collaborative services.

As mentioned above, sustainable society inclines the network society and involves the social network, which have been enhanced and diffused by information and communication technology (ICT). Furthermore, Mobile communication extends and reinforces the technological platform of the network society and diffuses the networking logic of social organization and social practice everywhere, to all contexts - on the condition of being on the mobile Net (Catells et al. 2006, 258). Then the following question is how Mobile Communication Technologies (MCTs)[6] support the promotion of collaborative services.

The aim of this ongoing research is to investigate collaborative services implicated in social innovation in China and the potentialities of MCTs as enabling system in the transition of sustainable society. This paper is an intermediary result of the first stages of the research, which is based on some activities including the promising cases collection and analysis, interviews, a seminar and a design exercises with supports from local partners and research network in China. It consists two parts. First part is to study Chinese cases of creative communities and local contexts of social innovation in comparison with the experiences of Europe; the second part is to have a pilot observation and discussion on the possibility and the way ICTs support collaborative services in the context of China.

[4] Creative communities: groups of innovative citizens organizing themselves to solve a problem or to open a new possibility, and doing so as a positive step in the social learning process towards social and environmental sustainability.

[5] For instance: groups of people who re-organize the way they live their home (as in the co-housing movement) and their neighbourhood (bringing it to life, creating the conditions for children to go to school on foot; fostering mobility on foot or by bike). Communities that set up new participatory social services for the elderly and for parents (such as the young and the elderly living together or micro-nurseries set up and managed by enterprising mothers), or new food networks fostering producers of organic items and the quality and typical characteristics of their products (such as the Slow Food movement, solidarity purchasing and fair trade groups). (For more, and more detailed, examples see: http://www.sustainable-everyday.net/cases).

[6] Also named wireless communication technologies.

Collaborative service, Mobile network and China

Collaborative services and design

Collaborative service is a new typology of service to be distinguished from general service. It is generated by a group of people, creative communities or diffused social enterprises who collaborate in the co-creation of commonly recognized values (Manzini 2008). Most of promising cases indicate a common characteristic: clients and agents of service system are interwoven or totally overlap since the solutions are based on a cooperative approach (Cipolla 2006). In some cases of communities supporting agriculture, the clients are involved into production as co-producers such as “Jardin du Ceres”[7]; or the actors often switch between clients and agents such as the case “Nurse at home”; While in the case of carpooling or car share, the actors could be totally equal.

It could be found that collaborative service has a different fundamental structure from the traditional service system. They are based on the peer-to-peer, collaborative relationship between actors, which needs the high degree of mutual trust and relational quality. And they call for the direct action by the involved people and are based on their willingness and capacity to act. Given that the contexts of collaborative services are highly complex socio-technical system, as a whole, they cannot be “designed”. So how to promote the collaborative services? In the perspective of strategic design, it also could be designed in two perspectives: contexts improvement and enabling solutions development (Manzini 2008). Contexts improvement means to fertilize the ground for creative, bottom-up initiatives and make it more feasible and accessible to grow the collaborative services. For example, tolerant environment is a necessary and important condition since collaborative services are often radical innovation so that they are beyond of the consideration of traditional system. An enabling solution is a system of products, services, communication and whatever else necessary, to improve the accessibility, effectiveness and replicability of a collaborative service (EMUDE 2006), in another word, to enable it to happen easier in different conditions and contexts.

Mobile communication and social network

Mobile communication has been diffused all over the world faster than any other communication technology in last decades. It really began to take off worldwide in the mid of 1990’s and till end of 2007, according to statistics from the market database Wireless Intelligence, the number of subscribers has reach around 3.3 billions, almost half of World population. In China, at the same time, the number of subscribers had reached 547,286,000 (Ministry of Information Industry of P.R. China, 2008). In this radical change, the mobile phone is not only a portable tool for calling, but also a new lifestyle for connections rebuilding with the collapse of traditional social infrastructure.

Mobile communication extends and reinforces the technological platform of the network society, a society whose structure and social practices are organized around microelectronics-based networks of information and communication. So mobile network society is simply the enhancement of the social structure conceptualized as the network society by new, wireless communication technologies (Catells et al. 2006, 6). It provides unprecedented opportunities for organizing, communications, and service and information delivery. The civil societies and research communities have recognized the significance of mobile communication to social innovations in terms of social benefits, social changes and social impacts towards some particular social problems or context like poverty, war, Aids and so on.

China and Harmonious society

China is one of the largest emerging countries. In the last decades, the fast economic growth has transited the ages from agriculture to industry while this process took western world several centuries. However, the rapid industrialization is bringing out pressing environmental and

[7] Those cases as examples here could be found in our website: http://sustainable-everyday.net/cases/

social problems, and changing the social infrastructure much, which has been beyond of the capacity of traditional system of society and call for social innovations.

A new movement oriented by central government of China is expanding in China---Harmonious Society, a harmonious society should feature democracy, the rule of law, equity, justice, sincerity, amity and vitality (Hu Jintao 2005). Harmonious Society is a concept raised by the Chinese government during the 10th Annual meeting of the Chinese National People's Congress in March of 2005. It tells the big decision of central government to shift from fast economic and industrial development to sustainable development and society. Given this top-down policy and governance. Social innovations are expected to contribute for harmonious society.

Research framework and methods

The research starts from the cases that were collected in EMUDE[8] as a paradigm. The research programme includes two stages, in which different research methods were applied, including desk research, case studies, interviews, seminars and also some field researches:

Stage-1[9]: case studies of Chinese creative communities and their local contexts. With supports of local partners[10] in China, more than fifty promising cases of creative communicates were collected and 18 of them were selected for case studies to address the state of art of collaborative services. 8 interviews with experts, social workers, Professors were organized to discuss the general context of social innovation. Then a seminar was organized to discuss those cases and their implications with participants from civil society organizations, social enterprises and academic institutes.

Stage-2: case studies of creative services and applications of mobile communication. Through desk research, another group of cases were collected worldwide. They are not only the cases of MCT-related collaborative services, but also in general sense of social benefits, impacts, changes and innovations, such as mobile election monitors, mobile communities to share the views and daily experiences, mobile emergency system, mobile banking, mobile microfinance, mobile information services, mobile learning and other mobile benefiting social change on global health, humanitarian assistance, environmental conservation and so on.

As presented above, to answer how MCTs support collaborative services means to investigate how they support contexts improvement and enabling solution development. But first of all, we need to understand what and how collaborative services are happening in China. This is exactly the task of stage-1. It has been found easily that among the EMUDE cases, most of them don't address the explicit specific values of mobile communication. Although almost each case involves mobile communication, the ways of involving is not in the sense of creativity but ordinary. Therefore, in the second stage, new case studies were done to observe what and how MCTs have been involved into social benefits, impacts, changes and innovations in terms of creative services or applications in order to investigate the potentialities of mobile communication. In addition, since mobile communication, being technologies, is universal and not much different between different regions, the cases were collected not only from China but also from all over the world.

Collaborative services in China

Same ideas, different stories

[8] EMUDE - Emerging user demands for sustainable solutions: social innovation as a driver for technological and system innovation 2004-2006 (NMP2-CT-2004-505345) End date: 2006-03-31 Duration: 24 months. Instrument: Specific Support Action). The research Consortium was coordinated by IDACO-Politecnico di Milano

[9] Most of research activities in this stage were organized during the research project CCSL.

[10] Institute of Civil Society, Sun Yat-sen University and School of Design, Guangzhou Academy of Fine Arts

It could be found that most of the service ideas indicated by European cases are also addressed by Chinese cases, such as communities support agriculture, carpooling (PINCHE), purchasing group, co-house, mutual elderly services, mutual neighbourhood, time bank, rediscover of bicycle transportation and so on. They are emerging out actively in the urban.

However, those cases with same ideas have different contents from European experiences. For example, carpooling today is very popular in China but in general it is collaboration between an owner of car and others who haven't cars, instead of between car owners, so the motivation, structure of system, the relationship between actors are quite different from European cases. While they are also collaborative services since the car owners don't only provide services for others and all of them have to be collaborative to generate the common solutions by themselves. Taking group purchasing that has been diffused in China as another example, with the same ideas, the contents and expressions have been largely enriched in Chinese practices. Firstly, it is very popular particularly in the young group and in universities; Secondly, the purchased products and services are widely various from food, fashion to cars and houses; Thirdly, the scale of participants of activities are much larger than European cases. In sum, the service ideas often have local stories and expressions in the contexts of China.

Strong economic motivations

Collaborative services happen with different motivations in general. Part of Chinese cases address that economic motivation is stronger than the motivations of environmental benefits, especially in the cases that have been widely diffused, scaled up and successful diffused social enterprises, such as carpooling, group purchasing and flea market. Since China is still a developing country and the GDP per capita is still low, it's normal to put the economy motivation in an important place.

Through the interviews, participants involved into those cases presented interesting feelings: at beginning they participate mainly for economic reasons, but their activeness is enhanced by collaborative experiences so much that they'd like to keep being involved. It means marketing-oriented collaborative services could bring out a social learning process to increase the willingness of participation and collaboration.

Trust rebuilding

Collaborative services need high degree of relational quality between actors. And it's a big challenge since the credit system in China hasn't been established very well after radical and continual change of social infrastructure in the last decades. However, it doesn't mean people don't want to trust each other. One interviewee said:

"... Today people talk much about the inhospitality of people and society. The warm neighbourhood of the past is like a memory left in our mind. With the change of economy and society, also because of the large and fast movement of population, my generation and the younger generation feel that people are not used to take care of each other as before..."

It indicates a contradiction that they would like to trust each other but they haven't security when they offer trust. Actually, all cases of collaborative services have to face the problems of trust and in general there are two kinds of solutions: 1) to decrease the threshold of trust to generate them. For example, some group purchasing is organized depending on the purchasing activities other than purchasing groups so that it's more flexible to involve it or not any longer. 2) to rebuild the trust in the new service system and it could be rebuilt in different ways: Involvements of enterprises or social enterprises, as credits guarantee, are helpful approaches to rebuild the trust, such as carpooling; Closed Identity certification could also increase the trust effectively, such as flea market in university where they use the BBS as a platform which is open only to the students and staff in their university and they need to register with students identities. In some self-organized group purchasing, they have credit system where participants could increase the credits with their performances of participation; Top-down intervention also works in some cases like elderly association and community services. In a word, since credit system of

entire society couldn't be rebuilt in a short time, it has to rebuild the trust case by case to promote the collaborative services in China.

Social infrastructure evolution

As we known, Chinese social infrastructure has been changing so much during social transformation. Before industrialization, it was based on the families and production units[11]. Since "reform and opening"(80's), the original infrastructure was released step by step. The working and living were departed and new residential communities were mainly reorganized by the means of financial conditions: which kind of houses they are able to buy. Consequently, there are no connects between people who buy houses in the same places, local communities[12]. The social fabric based on families and production\working were weakened much and they have no ideas to rebuild the new social fabric in neighbourhood.

However, our study also reports an opportunity as our interviewees addressed: most of people now still have vivid memories of traditional neighbourhood and communities and they have strong need to recover the social fabric and relational quality in new condition after losing them for some time, no doubts, which is very different and complex. But it is still a good moment to have leapfrog from a traditional social infrastructure to a new sustainable one before the memories are totally lost in the next generations.

Top-down and bottom up

Chinese civil society is a typical case of a civil society led by the government (Yu 2006, 82). For historical and political reasons, China has a particular context of civil society. Firstly, the related law and regulars require all NGOs to subordinate the bodies of administrative or government. Secondly, most of the predominant NGOs were founded by government bodies; Thirdly, most of them have leaders with government background. Fortunately, it has been recognized well that this old system couldn't follow the radical change of society or meet the needs of growing the civil society and grassroots innovation. Therefore, Chinese government started to retrieve the intervention in the field of civil society to encourage bottom up initiatives and innovations. Nevertheless, government still is a very effective stakeholder to promote the collaborative services since it has strong resources and experiences in promotion and replication of good ideas, activities and programmes by top-down approaches, as an interviewee said*:*

" As to the promotion, our government has very established approaches and experience to replicate a model all over country once it is convinced."

MCTs supporting context

The question, how MCTs support collaborative services in China, was investigated by two groups of cases studies. The first group is the cases of collaborative services in China for the question of what and how mobile communication supports the services in general cases now. The second group is the cases of creative services and application of mobile communication all over the world, through them to anticipate the potentialities of mobile in two perspectives. The first one is MCTs supporting contexts.

Ubiquitous and permanent connectivity

In the last fifteen years, mobile communication has been diffused all over the world. It enhances and deepens the social network structure and transforms the human communication as

[11] We suppose there are three mainly stages of communities history since last century. Firstly, before Liberation(1949), Families system is infrastructure of society. The power of government only reaches the "Xian" level and below that, people were governanced by families system. Secondly, after liberation, government management reaches the bottom of society, and families system was weakened less or more. With the movement of " Nationalization"(50's), people were organized into collective communities which is comprehensive small society with functions of production, living, education, entertainment, welfare and etc. more vivid description: it provides all kind of services from your born to death. It's also a stable structure oriented by production.

[12] Here the "community" mainly means neighbourhood.

ubiquitous and permanent connectivity, which provides a favourable physical, external and technical context for collaborative network.

Looking at the promising cases from China or Europe in detail, almost no one can work without mobile communication. On one hand, it tells that involved people have and use the same mobile phones and services as others. On the other hand, it means mobile communication is very necessary to services. In terms of technologies, furthermore, mobile communication technologies and services were developed and diffused for other needs instead of social innovations. However, it unintentionally provides technical conditions and opportunities to the concept, development and management of collaborative services as external context improvement. The second group of cases also indicate those large scale MCT-based collaborative and participative behaviours have a precondition of ubiquitous and permanent connectivity.

Participative social learning process

Those emerging cases of collaborative services often happen in particular local context and on particular people who have willingness and are collaborative to participate the communities and the willingness is almost impossible to be designed as well as collaborative services. The second group of cases indicates that mobile social network based participation experiences, as a social learning process, have improved the internal, cognitive, internal and social contexts for collaborative activities.

Mobile communication and social network have enabled many large scaled participative actions from civic engagement, collaborative m-learning, disaster management to TV program interaction, such as Nasamo in Korea, Mobilevoice in Africa and Supergirl tv interaction in China. Super Girl is an annual national singing contest. Viewers are able to participate in the judging process by sending text messages with their mobile phones to vote for their favorite contestants. Over 800 million text messages were sent during the third season (2007) of Super Girl, and fan clubs began to appear throughout the country. It is considered as one of the largest "democratic" voting exercises in the Mainland of China. Given that Chinese civil society is mainly government oriented, the interaction of voting experiences could be a social learning process to increase the willingness of participation and involvement into collaborative initiatives.

MCTs enabling solutions

If MCTs supporting context is an unintentional result of technology development and application, enabling solution is usually the result of intended design process for the specific service idea. Therefore, how mobile communication supports enabling solutions is manageable and could be anticipated in certain sense. The following discussions are about how it does or could support the enabling solutions for collaborative services in China.

A bridge between virtual and physical world

Given recent hardware, platform development, and Internet connectivity gains, mobile devices are quickly becoming key outlets for social software (Counts 2006, 1). The mobile social software and network brings new opportunities to shift Web 2.0 actions into a physical social world.

Collaborative services are often complex and the more people are involved, the higher degree of complexity it is. Having a look at the first group of cases, most of them have Internet-based networks/communities as coordination platforms for the service system. Till today, mobile phones still couldn’t replace computers because of the limitations of interface and computing capacity so that much coordination work is taken up on Internet. However, in the stages of execution in physical spaces, mobile phones are very necessary and easier communication tools as they are personal, potable, pedestrian and instant. For examples, in the case of PINKE (carpooling), they coordinate everything online for plan and preparation. When they start to act in

a real space, they have to use mobile phone as communication and coordination tools. So do the cases of purchasing group, carpooling and flea market.

Based on above discussions, added extension observations of social network and p2p phenomena that are highly diffused in Internet and have huge social impacts, we find that mobile communication and network is an enabling bridge to lead the collaborative initiatives in virtual communities to shift into a physical world.

Different service ideas and democratic groups

Different service ideas have different ways and potentials to use the mobile communication because they have the different system structure and process that generate different technology needs. For example, in the case of the elderly associations, mobile communication is not very necessary for the coordination of services because they have a place to stay together; in the case of carpooling, the location specific services could be very helpful to facilitate the services; in the case of WWF in Finland (Share ideas), the SMS alert system is the core part of services. Therefore, it's important to understand the service ideas and specific needs to anticipate the potentialities of mobile communication in supporting enabling solutions.

Not only services ideas, but also democratic groups of services determine the needs of technologies. Different democratic groups have different experiences in use of mobile phone and services. For example, the young have easier acceptance and greater capacity to adopt, adapt, use and innovate the new communication technologies so they are always at the cutting edge of the cultural and technological innovation. While the elderly users prefer to use mobile phones as simply as possible. Therefore the technologies and services have to balance between the capacities and motivations of participants in involving or learning to involve the services.

Mobile social network and trust

Some mobile social networks are typical MCT-based enabling solutions like Dodgeball, Friendstribe in USA and Bedo in China. Bedo is the first location specific mobile social network (Lomoso) in China including the other services like push-to-talk, Instant messages, M-space,M-blog and so on. It has been launched at the beginning of 2008 and made great success. In this case, a new enabling solution as a complicated system has been developed to generate and scale-up the collaborative services. It enables young people to enhance and increase the social fabric a new and attractive way in immaterial world and also in physical spaces.

The key competitiveness of the service is the balance between un-expectable sense and security. It's not only mysterious and attractive but also reliable and secure. This enhancement of security and trust results from two aspects: firstly, mobile phone is a personal handset and has strong identity not only it's a expression of personality but also it is subscribed with real ID of users; secondly, the location based services provide a physical dimension of connection between them and possible opportunities to interact in physical spaces. Both of them are distinguished characteristics of mobile communication.

Conclusions

Collaborative services, implicated in grassroots social innovations as creative communities and diffused social enterprises, were found in Europe and other emerging countries like China. By case studies, it reports Chinese collaborative services have different characteristics from European experiences in terms of content, motivation, structure, scale, context and so on, which calls different policies and technical supports.

Case studies show that up to now the practices of collaborative services haven't indicated the specific value of mobile communication in service system in general but it has been widely used as creative services or applications for generic social benefits, impacts, changes and innovations, which implicates mobile communication and network are becoming an significant driver for social innovations.

It’s clear that mobile communication has important contributions and potential roles in the promotion of collaborative services in the perspectives of context improvement and enabling solutions development. MCTs supporting context has two aspects including the external condition as ubiquitous and permanent connectivity and the internal condition as participative social learning process. The discussion on MCTs enabling solutions indicates that mobile communication has potential roles in the establishment of the bridge from immaterial world to a real world, the adoption and adaption for different service ideas and demographic groups, the trust increasing by mobile social network and so on.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

A Dialogue on the Future of Design Education

Naomi Gornick [1], Ian Grout [2]

Abstract

The paper investigates two educators' responses to dealing with world uncertainty and change and falls into the conference's general theme of 'Tools'. The authors take their existing programme curricula, philosophy and strategy as a starting point and discuss together their ideas for answering the following questions:

How well are our current programmes responding to our changing world?

How may we change programmes in the near future with the objective of developing best ways for preparing students for the current and emerging local and global contexts?

The authors seek to move design education from discipline specific to holistic, from relative certainty to better best-guessing, from designer as individual to designer as teamworker, from standard of living to quality of life.

Introduction

In this study, we want to, together, examine how we believe design education should evolve in the future. This paper represents an extension of a group seminar we were both involved in last year at the 'Connecting' Conference in San Francisco along with other International design educators and practitioners (ICSID 2007). That discussion confirmed to us that there is an urgency to the development of this subject in expectation of an impending massive change in world conditions, the imperative to take action, the seemingly steady marginalisation of design and its inability to respond quickly to these conditions. Designers appear to have reached an important stage of public and corporate recognition, but at a level that may not adequately reflect their true worth to society. Designers are in a significantly enhanced position to lead with new ideas and yet few are in key decision-making roles or realise the potential and responsibility to be a part of this change. We argue that a major reason for this paradox is the cautious reaction of design education as a whole to the current global issues that form the context for all design activity.

We discovered, in starting to plan this study, that although our academic interests took us in different, but parallel, directions, our attitudes to change in design education are extremely similar. Naomi Gornick began, in London in the late 80s, to develop masters programmes for experienced designers to take up senior roles in manufacturing and service industries, concentrating on designers' roles in, mainly, large organisations, thus developing an interest in organisational behaviour and strategy. Ian Grout and Norman McNally at The Glasgow School of Art transformed a vibrant product design course into a forceful programme highlighting and developing the designer's connection with and responsibility for society's contemporary and rapidly changing needs. What we appear to have in common is a certain 'maverick' side to our personalities and this characteristic has enabled us to develop radical programmes recognised in Gornick's case by the high profile of many of her graduates' career patterns and in Grout's by a new vision of the 21st century product designer concerned with ethics, sustainability and ecological issues in a societal context.

We each have a determined and personal way of taking strategies into action, the departments in which we operate understand that dimension. There were and still are institutional champions of our way of thinking that enabled and still enable our educational experiments to flourish.

This paper represents a dialogue on our main concern – a huge subject, the future of design education. As we began to write out our chapters for this paper, two aspects became clear. First, this study is the start of a much longer conversation and secondly, we approach the investigative process in two very different ways as a result of where we stand today – Ian, experimenting inside the education system and looking out and Naomi, reflectively re-appraising the system and looking at broader contributing factors to its strengths and weaknesses. So, we decided to let the stories run their own course so as to better understand how we both got to this particular crossroad at this point in time and what that meant to each of us. In the summary we will attempt to consolidate what we have communicated here and what, hopefully, may be of future value, each to the other in moving forwards and also to the general debate on design education's future.

.

"The meeting of two personalities is like the contact of two chemical substances; if there is any reaction both are transformed" - Jung

What are our backgrounds and what are we bringing to this dialogue?

Naomi:

Looking back, it's difficult to recall the time in the 80s when a small number of dedicated people were trying to persuade UK industry to integrate design into their organisations for greater economic success, especially today when most international companies recognize the value of design as a major business resource. There was a huge wave of enthusiasm then for the field of design management and this was carried along, in no small way, by the influence of a number of seminal reports on the importance of industrial design for UK manufacturing industries and the future of industrial design education (Carter 1977, Corfield 1979, Hayes 1983 and DTI, Design Council 1984).

I was invited to start a Masters in Design Management at the Royal College of Art in late 80s with David Walker from the Open University. We wanted to create 'new design professionals' who could take up the equivalent of management roles to promote the value of design throughout industrial organisations. From the start, in research projects, we collaborated with large companies that had design management facilities within their organisational structure, such as British Rail, British Airways and London Transport. As educational experiments do, this first attempt floundered. But not without creating some remarkably successful graduate careers. Subsequently, Brunel University Design Department asked us to set up a new programme and in 1994 MA Design, Strategy and Innovation was launched and is still going strong.

Our educational rationale was not to make designers reject their core skills, but to make them contextualise their professional work and give it a new sense of purpose. This new platform of education at Brunel included:

- A core taught syllabus based on case studies and current design and management literature
- An emphasis on team building for investigative research projects
- Links with Brunel University School of Business and Management
- Formal industrial collaboration leading to employment opportunities

Fully one third of the curriculum was devoted to students work with industrial organisations which took the form of a team-based company audit and individual internship. Through these projects students had direct contact with managerial personnel. They had to learn new languages to communicate with their management counterparts. Most of all they had to learn by listening. Many graduates have started their own consultancies such as Engine Group and Plot, several are working inside companies as I originally envisioned such as British Airports Authority and Procter and Gamble, some are educators such as Alison Prendiville, Senior Lecturer in Contextual and Business Studies, Product Design Futures, University of East London

One of the greatest influences on my thinking in developing the RCA and Brunel programmes were Ralph Stacey's ideas on the conversational lives of organisations (Stacey 2002). Design and management have two distinct languages and cultures, so conversations and power relations between designers and managers become paramount. It was obvious that design-trained students needed special skills and Stacey describes these as:

- The capacity for self-reflection and owning one's part in what is

happening
- The ability to facilitate free-flowing conversation
- The ability to articulate what is emerging in conversations
- A sensitivity to group dynamics

Designers do not automatically acquire these skills in their undergraduate years. We always acknowledged that the reasoning behind these graduate programmes was based, in part, on an underlying paradox in undergraduate design education. The ethos of the design academy is that of a hothouse of invention, creativity, and “blue-skies” thinking. The dilemma still is, how much of the outside world should be allowed in while this creative development is taking place? In the years since we started, there is far more inclusion now, in undergraduate programmes, of the key global issues affecting design under ‘design studies’ or ‘cultural studies’. The level of this exposure varies enormously, much depends on the predilection of individual programme leaders and tutors and on the ethos of institutions. In my research I have argued for the inclusion of business and contextual studies in undergraduate design degree programmes (Gornick et al. 1995). Now as I continue my investigation, I begin to look at two new areas: first, how as a consultant rather than course leader, I would further develop Master’s programmes based on design in current organisational life and reflecting today’s key issues of sustainability and ecological dilemmas and second, how the general flow of undergraduate design education should now, most appropriately, be carried out. It was with both these subjects in mind that I wanted to engage in a dialogue with Ian.

Ian:

In 1999 we began a radical overhaul of our courses in Product Design at GSA. We had a gut feeling of the world changing and with it a future change in design education. We had been experimenting with the course, moving towards the humanities. We were interested in social sciences which we saw would enable us to develop a better understanding of:

- designing for society
- our relationship with and the design of artifacts
- how to educate designers for a changing world

I had been developing sustainable design. As most practicing designers at that time I was still trying to make sense of this. Papanek, (Design for the Real World 1972), Schumacher (Small is Beautiful 1973), Pye (The Nature and Art of Workmanship 1968) and Womak and Jones (Lean Thinking 1996) were what we were working with. This was limiting considering our changing world. A more humanities centred design approach seemed a positive opportunity for the development of sustainable design education. At that time I had no idea where it would lead but to take action in this way felt intuitively right. Designers trust their intuition. I trusted mine.

So now we were designing design education. We created 2 courses, both innovative, both new and that, as they say, was where the fun started. Designing them was relatively easy and took just a few weeks. We knew what we wanted to do, why we wanted to do it and how to do it. What took time was to get it through the management systems at GSA. That took a further year and a half.

The first course, a 5 year Master of European Design (MEDes) is a 3+2 integrated masters in partnership with; Konstfack, Taik, Politecnico di Milano, KISD, Kunste Akademie and Les Ateliers. Increasingly, designers were working Internationally so we wanted design education to be truly International. We also

wanted the excellence and diversity of each partner to enable individual pathways for the students. To this end the programme was constructed to allow 2 exchanges of one year each. This results in unique and very individual students who are broadly cultural, mobile and in tune with developments across International boundaries. They work Internationally, naturally. The programme is minimally bureaucratic, the students remain students of the home institution which awards the degree. Within this the students and staff enjoy a culturally rich network to exchange and develop the latest educational thinking.

The second course is a 4 year Bachelor of Design with Honours (BDes(hons). There are distinctions between this and our old BA, namely:

- An integrated first year giving 4 years for the degree allowing us space to teach an expanded skill set
- Sharing the first 2 years with the Medes course
- European language teaching
- An extensive dedicated exchange programme with 15 global partners

We also integrated social sciences into the curriculum firstly with staff from humanities at Glasgow University then, latterly, with dedicated staffing within the department. Currently, Gordon Hush, our acting head of department is a social scientist. This opening up of product design and new relationship with social sciences allowed us to move from “how to design” - problem solving towards “what to design” - a deeper understanding of the issues of living into the future in a changing world. Furthermore, it has created a course that is inherently flexible and adaptable and able to be under continuous development, projecting visions and developing new tools for future education. As I intended, it is a good place to be when considering future issues of sustainable design education.

We took it upon ourselves to develop these programmes, there was no pressure from the school to do so. The motivation came from the feeling that the old BA model had run its course and that something new had to be in place.

When we started out we expected that the MEDes would need the most developmental input and the BDes(hons) would simply be a development of the BA. The MEDes naturally found its own way and is still substantially as it started out. By nature it is more of a network of independently evolving courses rather than a course per se. The BDes(hons) rapidly entered new educational territory and we found ourselves well ahead of the game. Consequently there has been much learning as we grew and this has created a symbiotic relationship between the students and staff. We enjoy a collective pioneering spirit.

What are the current contexts of design education?

Naomi:

We have been describing our own educational experiments but we have to acknowledge that these are part of a number of new radical initiatives that have emerged in Europe and USA during the last two decades. This development is largely driven by academic authors, some of whom we know very well, in design

institutions who have an acute awareness of global changes in industry and society and who recognise the dichotomy between design practice and education. Each programme has its author/s own distinctive aims and objectives. A key characteristic of this phenomenon is the disparate nature of these programmes and their potential institutional vulnerability. There is no overall directive, although in the UK a new government sponsored inquiry (Design Council 2008) is working towards broad educational change.

Certainly, current world affairs are having an effect on many branches of education. The shifts in economic structures, changes in corporate life as well as new thinking on environmental issues reflect global opportunity and upheaval as well as remarkable changes in society norms and work patterns. To examine the future of design education, I think we need to look on the client side as well as the new world of the design practitioner.

There is much discussion on the need for massive corporate organisational change. This has been described (Zuboff and Maxmin 2002) as a current 'transaction crisis' between institutions, companies and consumers and promotes the idea of a new and greater understanding of the needs of all stakeholders. Existing traditional business practices must be humanised. We need to take a meta-view of a new economic system required to deal with fluctuating markets and uncertain business environments. A leading management theorist (Mintzberg 2004),holds MBA programmes in business schools responsible for many of business's ills, as the teaching stresses formal analysis and control rather than much required vision and experience of webs, networks and teams.

Business and management practices have certainly caused many of our current problems, but designers also have to re-examine their own practices. On many levels, designers are expected to understand increasingly rapid and unpredictable changes in corporate life and consumer behaviour and to help their client companies anticipate future trends. Can they do this?

A few leading design consultancies, the Doblin Group, IDEO, Seymour Powell and Ziba Design for example, undertake extensive user research for their clients. Essentially, they are moving into the sphere of management consultancy but with enhanced human-centred tools and techniques. As management consultancy and design consultancy converge, we may see the emergence of a new type of innovation consultancy. Both Richard Seymour of Seymour Powell and Sohrab Vossoughi of Ziba design are adamant about the need for design practice to broaden its sphere of responsibility (Gornick 2006). Seymour believes 'all the boundaries designers are familiar with are dissolving". He wonders whether the design industry is capable of being fast enough to understand what is needed from them to fulfil client needs".

Equally, in-house design teams and design managers have reached an important stage of corporate recognition, at a level that makes many demands on their innate knowledge, interpersonal skills and forecasting strengths. These shifts point the way to an expanded new world opening up for designers to enlarge their range of activity. Whether designers choose to take up new roles or not, the expectations of their knowledge and position in business life have become significantly heightened. Their opinion and advice will be sought after more than ever before. The opportunities exist if they can take up the challenge. Enhanced design education is the key in this respect, and this process, for designers, does not stop at graduation. It is a case of life-long learning.

Ian:

In the intervening period since we began our new programmes much has changed in the world. As sustainable design has become more important there has been both convergence and divergence in both thinking and action. Convergence in the sense that from relatively fragmented approaches there has emerged, broadly, two directions and divergence in that they are diametrically opposed.

(1) Concerned with sustainable designing for the status quo that supports; a growing standard of living, extending status and ownership, continued economic growth and increasing energy needs met through new technology. In this approach sustainable design becomes a quantifiable, bolt on, component typified by cradle to cradle (McDonough and Braungart 2002) and dust to dust design activities.

(2) Engages with the changing attitudes of society and explores design in a more holistic manner, social and cultural in ways of designing for quality of life centred in opportunities for and including: co-designing, designing for society, designing for the experience of living (programme development, product design, GSA 2008), affordance (Gibson, 1977), social innovation, social ecology and social entrepreneurship (Bornstein, 2004). This approach can be typified by the EMUDE project in which we explored, through eight European design schools, people inventing sustainable ways of living (Manzini et al 2007).

Both approaches have their devotees but, in general, action in sustainable design education has been too slow. This may be for several reasons, fixed modular educational programmes, increasing bureaucracy, lower funding and the rise of research in the purely theoretical. All have their effects in slowing down the ability of academics to make experiments and take risks. As I was writing this I was listening to a radio programme on bureaucracy in secondary school teaching. I heard this, *"As I test them more and more I teach them less and less . . . soon I will be absolutely sure that they know nothing at all" (anonymous teacher, Radio 4 UK, 23.05.08, 17.50).* We would all recognise this as a growing issue in higher education and the problem inherent in it as symptomatic of the barriers we face to change.

What do we think are the future contexts for design education?

Naomi

It is mysterious that the education of designers is so entrenched when other areas are adapting to new global conditions rapidly. Admittedly, it is difficult to move a very structured, discipline-specific culture, now bound on many sides by complex funding arrangements, evaluation criteria, assessment requirements and increased research demands. But why is it more ponderous for design than other disciplines going through similar metamorphoses? We need to consider the following aspects:

Most pressing for Western design education is the recognition that the development of design in the Far East will outstrip provision in Europe and USA. It's interesting to compare the numbers of institutions with design departments. The Chinese authorities have decided to establish over 400 design schools. There is no doubt that they see a direct link between design and a successful economy. In

comparison the UK has 190 institutions offering design programmes and in the USA, NASAD lists 248 art and design institutions.

As the recent British official commission chaired by Sir Nicholas Stern (Stern 2006) stated, climate change "is the greatest and widest-ranging market failure ever seen". IHT (Lieven 2006) comments on this widely-publicised report: "The question now facing us is whether global capitalism and Western democracy can follow the Stern report's recommendations, and make the limited economic adjustments necessary to keep global warming within bounds that will allow us to preserve our system in a recognisable form; or whether our system is so dependent on unlimited consumption that it is by its nature incapable of demanding even small sacrifices from its present elites and populations." It is in this area of current high-profile concern that many designers are now making a choice of the direction they wish to pursue

Recently discussion has turned to the nature of the traditional design brief and the necessity for designers "to find" the problem for the client's organisation. In conversation with Garry van Patter (van Patter 2007), Min Basadur quotes research indicating that successful leaders of the 21st century "be they designers or politicians or managers or concerned persons of any type, are going to have to do more than just get important problems properly defined. They are going to have to generate such problems first and excite others about taking them on." Problem finding "means continuously and deliberately discovering new and useful problems to be formulated, solved and implemented."

One of the difficulties here is that most often people involved in problem formulation fear failure in the implementation process and especially current media attention to applying blame. It takes a certain kind of courage to undertake a different pathway.

There is considerable urgency in this discussion. When design graduates leave college they will be representing 'design' to the people they deal with outside their design world. They will need to communicate ideas of meta-design, not simply the discipline – graphic, product, interior, fashion – in which they've been trained. This idea is echoed (ICOGRADA web-based newsletter) by Richard Grefe, Executive Director of AIGA He wrote (Grefe 2006). 'Clients seek "designers", broadly defined, and the highest and best use of a designer's talent depends on the way he or she solves complex problems, not bounded by the medium of the outcomes'.

Educational experiments will continue to flourish inside those academic institutions interested in broadening out design education. But if we are concerned about future generations of designers and the slow pace of change in design education generally, then we have to conclude that that the numbers of graduates emerging from new, innovative programmes are too low, at present, to make a substantial difference overall. A critical mass is required for a significant change to be recognised and time is of the essence.

Ian:

We face a future that is increasingly unstable and less easy to predict. We all know that we are rapidly accelerating towards many new challenges, that this is unavoidable and that we are, to a large extent, in denial. We need to take urgent action for and in the education of our students.

I would make a positive comment here that, right here right now, this is the best opportunity for design that we have had since the Industrial Revolution. *"The*

great thing about the dilemma we're in is that we get to re-imagine every single thing we do . . there isn't a single thing that doesn't require a complete remake. There are two ways of looking at that. One is: Oh my gosh, what a big burden. The other way, which I prefer, is: What a great time to be born! What a great time to be alive! Because this generation gets to essentially completely change this world" (Hawken 2007)

What I have learnt in developing sustainable design at GSA is that the approach expressed in (2) above affords a positive way forward for the future. We can see great potential in designing for; real issues, real users, real situations and real life. It can offer tangible outcomes in being able to work across specialist disciplines including ecology, economy and society. It works in a virtuous cycle of philosophy and action. With this adaptive and flexible methodology we may find ways for design to help tackle global warming, reduction in biodiversity and the ethical issues surrounding the exploitation of other cultures to prop up our consumerist addiction.

I have found designing in this way with students has been very successful in social entrepreneurship including community based projects on the south side of Glasgow concerned with social issues surrounding waste and in Drumchapel with a wood recycling company strategically developing a bid for new funding.

One issue seems central here and this is peak oil (Bently 2002) and energy descent (Abdullah S, 1999). From this has grown the transition town movement (Hopkins, 2008). There is potentiality here for future design education in that this movement expresses a view of a positive ecological aware society that is actually in formation. Its views, actions and development forms a real opportunity for taking action in designing and testing new pathways for future sustainable design.

What do we think are the potential future pathways for design education?

Naomi:

I believe designers are natural pathfinders if they put their minds to it. Larry Keeley, Doblin Group in Chicago says (van Patter 2004) "In a world with far more designers, designing far more artefacts, there is a cadre of individuals who want to think deeply about what life could be, what it should be, and what our role is in closing the gap with our daily reality. Thoughtful designers must find one another, and continue to ask the tough questions"

My colleagues and I know that design management must move with the times. We must re-visit and re-examine the emphases of our educational models. With educators from London College of Communication and University of Dundee I have organised three symposia in the last year designed specifically to bring together practitioners, educators and researchers (who do not normally meet together) under the title of 'Metamorphosis of Design Management'. Key themes have emerged from this continuing discourse that include the changing contexts within which design management practice operates and the need to explore the changing roles of design management practitioners to help inform the process of new academic programme

development.

The ds21 project also provides a direct examination of future pathways for design education. In the report 'Tools for Metadesigning' (Wood 2006) initial questions were raised with regard to this subject:

> - Ecological design as a discipline is still too over-specialised, politically confused and emergent to make a sufficient impact. Our economic system encourages consumers (and designers) to live (and design for) a scale and pace of consumption that can make Eco-design counterproductive.

Arguably, designing a 'total living style' is too complex for traditional modes of design because it would require the cultivation of a discourse of synergy that goes far beyond what conventional designers are trained to accomplish. Such a high level of complexity calls for the development of an appropriate mode of 'metadesign' that will incorporate synergistic methods within whole systems.'

In the same report, I asked (Gornick 2006) 'How do we teach 'metadesign' to design students and to practising designers? Should traditional design education transform itself into metadesign education? Could traditional design education transform itself into metadesign education (bearing in mind an equally traditional reluctance among design educators to countenance change)? Should there be a separate discipline of metadesign education, alongside traditional design education? Or should design education remain as it is, highly discipline-based, and other related professional disciplines ie sociology, anthropology, media, move into metadesign education?

In the global economy there is now a wider range of career paths for designers. From RCA and Brunel the numbers are small, but there are steady career development patterns. Here's an example of a 'new design professional'.

Jake McLaren was an excellent industrial designer who graduated from Brunel University MA Design, Strategy and Innovation in 1996 with distinction. As a result of his specialist thesis on recycling electronic hardware he worked with Nokia for 8 years at their HQ in the UK as Environmental Specialist, Design for Environment. His role was to embed and manage environmental issues within the R&D function of Nokia. The scope of his work was development of mobile phone products, within the Multimedia Business Group. This is very much about operating in an influencing mode to make sure all the disciplines involved in R&D take care of various environmental issues. In short, he was acting as a environmental design champion within the company.

His tasks in Nokia included, defining and managing environmental requirements, managing research and internal implementation projects, supporting and training R&D programmes during product development and representing Nokia UK regarding environmental issues to suppliers, customers, media & government.

Learning from Jake's and other graduates' career experience a new educational model for design begins to take shape for discussion:

<u>Traditional design education</u>	<u>Towards Metadesign education</u>
Design discipline pathways	Understanding design holistically
Individual projects	Working in Teams

Designers relating only to design	Designers and synergistic context
Starting from Zero	Value of Constraints
Technical skills	Analysis and Synthesis
Design in Theory	Design in Practice

Ian:

The Glasgow School of Art, Plymouth University and HDK Göteborg are constructing a joint project with Transition Town Totnes for the spring of 2009. This project, based on eco sufficiency and resilience will concern itself with the pragmatic growth of knowledge in the expectation of discovering new ways in which design may work within an ecologically aware society and how an ecologically aware society may work with an expanded social view of design. The two key philosophies mentioned above can be expressed thus:

Eco-sufficiency:

- Requires a reduction of the level of production and consumption.
- Has potential to reduce substantially use of natural resources without compromising human wealth.
- Is closely related to issues of quality of life and life-balance
- Wide spread eco-sufficiency will only occur when less material wealth brings increased well being or happiness to individuals and societies.

(Wuppertal Institute 2005/2006 & SERI's 2007)

Resilience

A resilient system:

- Is adaptable and diverse.
- Has some redundancy built in.
- Acknowledges that change is constant and prediction difficult in a complex, dynamic world.
- Understands that in manipulating individual pieces of a system, it changes it in unintended ways.

In a resilient system:

- People, companies, communities and countries draw on support and resources from elsewhere.
- Components are self-sufficient enough to provide for essential needs in emergencies.

(Ward 2007 & Dixon, 2007)

In this project we will look at how one supports the other, affects the other and transforms the other as a way of building new design vocabulary and tools for designing in the service of society.

This will also aid in the designing of a new set of masters programmes currently under development at GSA. As with the MEDes and BDes(hons) these new programmes will have an open architecture able to be flexible and adaptive in their future development. At its core is the idea of designing for the experience of living. In that I see design as a proactive agent in a transforming society. It builds on current experience and develops, amongst others, these tools: Social sciences methods, Co

designing, Scenario building and story telling. Design activity will be based in the understanding of human activity through which we may afford service, system, object, interface and interaction design to symbiotically work better in the service of humanity. Embedded in this is designing in context where the activity (for instance brushing your teeth) and the players involved (say eight year old children) are explored thoroughly from which the design opportunities can be revealed (centred within the activity) and then the service system, product combination can be enhanced, altered prototyped and tested to improve the situation you are designing for.

One further opportunity is to learn from your students. Recently I saw a draft PHD thesis in HDK entitled Fashion-able (Heretic Journeys in Engaged Fashion Design) by Otto Von Busch. Here is his summary: Coming back once again to a designer practice, I think it would be something like this:

- Accessing technology
- Promoting transparency
- Empowering users
- Decentralising control
- Creating beauty and exceeding limitations
- Using the intelligence of many for innovation
- Making constructive assemblies
- Creating interfaces and sharing the knowledge
- Keeping the power on

Or to put this in a more metaphorical way:

- Explore the everyday
- Use tools at hand
- Start where you stand
- Be practical
- Leave the door open
- Colour outside the lines
- Multiply

The only thing that I would add to this is, accelerate.

The overarching driver here is that design can't of itself change the world but can be a significant part of a word that is changing. Designers must work in this world rather than about or upon it. (Wodiczco. 1999) In recent years I have had the good fortune to work with wonderful people from outside the traditional disciplines of design. All have openly expressed that most of what we are discussing in our changing world is, to a large extent, a design issue and a frustration that there seems little that design is doing in these issues. It is my ambition that future designing will be concerned with designing for, and here I purposefully repeat myself; real issues, real users, real situations and real life. In pursuit of this, design education will seek deeper relationships with disciplines able to transform society. This is an exciting prospect and one from which there is much to learn and opportunity to take action.

Summary

In drawing this dialogue to a close for the time being, we decided that the title 'conclusions' would be misleading. In essence, we feel that the conversations must

and will continue until such time as relevant progress in design education is actively pursued by many, rather than just a few.

We have structured this paper to give an overall view of our own pathways and our joint concerns. Building on our own experience we can see common characteristics in ourselves, as well as the colleagues with whom we work and the institutions that enable our work to develop and grow. But more than that we and many of our colleagues seem to have developed antennae for the remarkable changes in economics, technology and society which are not only making traditional design roles outdated but also generating a rich field of opportunities. We seem to be able to convey to our graduates a strong belief in our programmes while not simply filling up the demand for student quotas. We aim for graduate employment but also send out a strong message for long-term ambitions for world-wide economic and social improvement. We represent part of revolutionary global changes that carry designers towards new and meaningful roles.

In examining the current and future contexts of design education we wanted to investigate the predilection for change and the barriers to change. Our dialogue presents not only our thoughts but also the people who are influencing our thinking. If there is a message coming out of this paper it is this; there is a pressing need for a transformation of design education in general. Our society is in transition, new markets are emerging and the economy is finding new routes. We can and must be in the vanguard as proactive contributors, as this transition has much to offer designers. If we don't engage, our profession runs the risk of being further marginalised and irrelevant.

It is also imperative that we achieve a critical mass for change in design education. As we see more mass movement emerging in our society towards change so design should follow. There is a need to accelerate our activities. In respect of critical mass it's worth reflecting on the 80/20 rule (Juran 1951). The rule asserts that approximately 80% of the effects generated by any system are caused by 20% of the variables in that system. So, in our society, markets and economies we could say that 80% of the change comes from 20% of the people.

This initial dialogue has been valuable. We see also that there are many more design practitioners and educators wishing to engage in this type of debate, many of whom are willing to take ideas into action. We had an indication of this, last year, in San Francisco. We believe that there are a number of new educational and design practice initiatives world-wide that would benefit from being connected. A comprehensive survey needs to be carried out at the earliest opportunity to determine the rationale of these programmes and where they are taking place. This research should explore, at an International level, those advanced practices with which we could have a deeper more prolonged dialogue on these pressing issues.

Finally, we put forward this familiar quote as encouragement to educators contemplating taking innovative leaps in pursuit of change towards a better world through the education of their students who are, after all is said and done, our future society.

"First they laugh at you, then they ignore you, then they fight you and then you win"
- Ghandi

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

productive friction:

a case study of design research between practice, education and community in rural australia

Fiona Harrisson [1]

Abstract

This paper offers the process of working between three divergent perspectives of practice, education and community as a vehicle for changing the change. These ideas will be explored through a case study of a design project in two remote rural towns in regional Australia where RMIT University entered a practice relationship with the local Government. The project was also run simultaneously as architecture and landscape architecture design studios. Students, practitioners, academics, local Government and community came together to towards developing design possibilities. This meeting of diverse experience and different perspectives (practice, education and community) inevitably involved conflict but these tensions are described as productive friction. Rather than see this tension as something to avoid, this paper argues that it is the very tension that produces an outcomes beyond the sum of its parts. This paper will track the process and outcomes of this project.

[1] Lecturer, RMIT University, Landscape Architecture Program, Architecture and Design,fiona.harrisson@rmit.edu.au

1. Introduction

This paper offers the process of working between three divergent perspectives of practice, education and community as a vehicle for changing the change. These ideas will be explored through a case study of a design project in two remote rural towns in regional Australia where RMIT University entered a practice relationship with the local Government. The project was also run simultaneously as architecture and landscape architecture design studios. Students, practitioners, academics, local Government and community came together to towards developing design possibilities. This meeting of diverse experience and different perspectives (practice, education and community) inevitably involved conflict but these tensions are described as productive friction. Rather than see this tension as something to avoid, this paper argues that it is the very tension that produces an outcomes beyond the sum of its parts. This paper will track the process and outcomes of this project.

2. scenario

The project focuses the processes and outcomes of a project in remote rural Victoria. Rainbow and Jeparit are two small agricultural towns in rural Australia located either side of the 39th latitude; approximately five hours drive from Melbourne, the University location. Both towns are remote in location and historically have been agricultural centers but more recently have seen steady population losses and reduced services as a result of the trend toward larger farms run by fewer people. This is a microcosm of larger global trends affecting rural towns across the globe.

This phenomenon of declining population is called 'Shrinking cities'. The reorganization of production and consumption across the global has resulted in both population expansion and, the less discussed, population contraction. Shrinkage is defined as "cities that have temporarily or permanently lost a significant number of their inhabitants." (Oswalt & Rieniets, 2006:156) The problematic of shrinking cities has received design attention though these have focused on postindustrial cities of more than 100 000 inhabitants rather than small towns in rural contexts such as occur in Australia. While these small towns share issues such as increased vacancy and loss of services, there are issues specific to small rural towns in Australia. For example unlike industrial cities, rural towns in Australia are low density and decline means that the towns become even less dense. Some large de-instrialised cities such as Detroit have decommissioned parts of its city to maintain density in other parts. This is not feasible in small towns with populations of less than 1000. Some protagonists in Australia argue that small towns should be actively decommissioned as Rogers notes, "the traditional economic enterprises are no longer viable, that both public and private services have withdrawn and that many communities are faced with environmental problems. Increasing population homogeneity, with very little to attract new people." (Rogers, 2001:135)

There is a possibility that the population demographic may increase in Rainbow and Jeparit, but it is more likely that the net population will remain the same or continue to decline. As Bourke and Lockie suggest that "the rapid and profound change which rural Australia is undergoing is at time exciting as it is worrying". (Bourke and Lockie, 2001: 1) It is evident in the towns that there is great flexibility within the community to adapt. Many shops within the towns take on a multiplicity of roles. The museum in Jeparit is open seven days a week on volunteer labour alone. It also plays the role of informal drop in centre. Some farmers volunteer to do shifts within the museum as a break from the isolation on the farm. Many of the students were impressed with the level of social capital in the towns, something less apparent in big cities. The student projects

drew on this social capital to inform their re-imaginings for the future.

Some local governments have been proactive in seeking ideas for rethinking these towns in response. The Hindmarsh Council, responsible for Rainbow and Jeparit, were keen to invest in the towns to support the remaining inhabitants and to consider how these towns might be developed from a landscape and marketing perspective. They selected a consultant team lead by NMBW Architects on the grounds that the project was also part of a design studio at RMIT University and included extensive consultation. The consultant team was made up predominantly of architects, I was the consultant landscape architect on the team. Myself and another member of the consultant team were also lecturers at the University and led an architecture and landscape architecture design studio. This decision was a risky one on behalf of Council as the team, at that stage, had limited experience working in this context and the process definitely didn't follow the convention or aspire to known outcomes. The Council was obviously satisfied with the outcome as they engaged the team again to work on another larger town within the Shire.

3. productive frictions

This project was simultaneously run as a consultancy and as a design studio between landscape architecture and architecture within RMIT University. This hybrid approach to the project enabled more time to understand the town and also to investigate other roles for design in situations of decline. Rather than see education and practice as separate, students, along with the consultant team were involved in extensive community engagement including a series of public and individual community meetings designed to solicit local knowledge prior to the commencement of design. During the design phase feedback was sought through presentation at public meetings and also the final work was exhibited where locals were invited. This level of consultation would have been impossible on the fees allowed for towns in decline. The dual pressures of academic scrutiny, responding to the Council brief and also taking on board the community comments pushed the final outcomes further than would have been possible for consultants alone or had the project remained within the walls of the University. For RMIT University, working with community is part of the University brief. This project achieved the strategic aspiration of working with community as well as with Government partners, as students were offered the opportunity to work in close relation to community. The theory that often remains within the walls of the academy became practice.

Following is an account of the project organized around a number of tensions that have arisen as a consequence of the hybrid between practice, academia and education. This paper argues that proposals are both more challenging and more possible as a consequence of working between three divergent perspectives of practice, education and local community. It is the friction between divergent paradigms that offers the potential to both think and act differently.

Between academia and practice

The straddling of practice, teaching and academia enabled more time and more heads to understand the specific dynamics of these towns and to consider the possibilities of design. Students were obliged to straddle the academic requirements of design research, to explore and innovate design scenarios that are not already existent. The hybrid consultancy/design studio brings another pressure to bear, as it obliges that the design ideas are relevant to the community and is also able to be built. It is this seemingly contradictory pressure that enables outcomes not impossible but often not achieved in academia or consultancy alone. It also allowed an engagement with the broader research agenda of shrinking cities and the role of design in declining communities rather than expanding ones. This project became a vehicle to imagine other possible futures where design is embraced as a catalyst for change rather than something that should or could be turned around.

The focus of the design projects was not to try and reverse the population loss rather it asked for an exploration of the potential of decline. This required a rethink of the role of design because design is often premised on growth and future redevelopment. Tourism is the conventional way in which small towns have been developed throughout the region. Whilst there is potential for tourism it is highly unlikely that all towns will succeed in becoming tourist towns. Tourism therefore was not accepted as a valid driver of the project, though it could be a by-product of an idea. It was clear that the towns were in competition so it was also agreed that whilst the consultation process and design ideas were specific to each town, the towns would not be set in further competition where possible. They were considered as a collection in terms of their contribution to the facilities in a larger regional context, thus the strengths of each town would be identified and built upon and services would not be duplicated. The project was premised on the assumption that decline was likely to continue. The task was to speculate on other possible futures whilst also working in relation to what was already evident in the town and region. Could the increasing vacancy provide an opportunity for something else? Could perceptions of decline change? How could it be an impetus of transformation into an unknown future?

Doubling as teachers and consultants

The studio teachers operated simultaneously as consultants. This doubling of roles allowed the project to be explored and developed more thoroughly than would have been allowable for a consultant required to fit the budget. The studio component of the project occurred at the front end of the project to align with the design exploration and community engagement part of the process. The students and the consultant team were involved in extensive community engagement and in the production of design. There were a series of public meetings and an exhibition of student work to solicit feedback from the community who were considered as integral to the outcomes of the project, though not necessarily the final determinants of the outcomes.

The process was structured over a period of four months, we visited the towns once a month over this time and four times as a collective. There were three community consultation meetings and an exhibition, these were timed to be in sync with the University semester. The assessment milestones were tied into the community presentations, which allowed the students to be active participants in this process and also intertwined the academic and the community requirements. All of the meetings occurred in the towns rather than in the University to emphasize the ‘live’ nature of the project for the students. The process of consultation was paralleled in each town. Each time we visited we would go for intensive weekends where we would spend time in each of the towns. If you imagine 30 – 40 students descending on a town for a long weekend, our presence was conspicuous and the businesses appreciated the influx. This number of people allowed a thorough investigation of the town as a whole including consideration of how this town operates in relationship to the broader context. The consultant team shadowed the community process. At the completion of the consultation process, the consultant team was responsible for pulling together a final set of proposals for the town. The final proposals included some of the student work, though not all projects were included in the final recommendations. As mentioned all student work, however, was included in the appendix of the final report, which acknowledged the student contribution to the process and design ideas.

The consultant fee was thus dedicated to the production of a comprehensive report which provided a series of packages of work that was limited to $10 000 to be built over a period of ten years. It also documented the process including the community interviews and provided an appendix of all of the student work, so that this was not lost. Parts of the student projects were

included in the final recommendation, so by including the student proposals in the appendix, it acknowledged their work and also allowed the community or Council to revisit the ideas at a later if they so desired.

Between participation and design

The extensive design community meetings were set up to enable a participatory process whereby the inhabitants could be involved in the process of re imagining a future that is not necessarily a direct reflection of the past. Rogers suggests, "To survive and prosper, small communities, must find new ways to define themselves-to recreate a future of their own choosing." (Rogers, 2001: 135) These meetings played a role in the community imagining another future, though this process didn't just unfold without conflict. As with all communities, this community wasn't a singular community it was many communities and thus wasn't collected by a singular voice. Conflict thus arose between the various communities within the town community in relation to what they wanted for the design. This conflict was embraced as an important part of the process not something that needed to be minimized.

The conflict about the future direction of the town became apparent through the community interviews and meeting. For example many people mentioned that more trees would improve the amenity of the town but numerously it was mentioned that many of the mature trees had been chopped down in the past few years. The issue came up in another interview, "lots [of trees] have been cut down and I just think why." They continue later in the interview saying that, "In a small town like Jeparit, the mostly older people have been brain washed to think we cant have these sorts of trees because they're going to effect drainage and crack the houses. We need then to have an open forum where people like yourself can come in and talk to these people and try and educate them." (NMBW Consultant Team: Jeparit interview 3)

Clearly there is not a consensus in the community around the issue of trees and part of our job was to wade into the issues and to find a way forward. We were answerable to all parties but we were also independent. Ultimately our job was to provide professional advice within the scope of the project. We saw our role as being in dialogue with the community through the community meetings and to put forward design proposals that were relevant to the lives of the people living in these towns. This role involved listening and finding out about the town from a range of perspectives as well as stretching each other beyond preconception. It also involved brokering between the different and often conflicting voices of community.

Operating between education and community

The 'live' model of studio teaching that this project undertook enabled students to have an insight into the implications of their design ideas in the world. The users of their project become an active force in the design process rather than passive recipients. For the students the stakes were high in this project as it was possible that their project might be built but also their work was scrutinized by the client (Hindmarsh Shire) and the users of the project (the community). Through the community process it was apparent that the outcomes of their work mattered, it wasn't just theory in preparation for the real world. The academic demands on the project meant that the students couldn't default to just keeping the community happy by giving them what they wanted and doing what was done in other towns. It required thinking in other ways about towns in decline, responding to community concerns and building on local knowledge.

The community was aware that the students were asked to be exploratory and the community brought openness to the work presented. They appeared to appreciate the effort put

into the ideas and they also provided feedback and direction. This was a critical moment of readjusting and redefining projects in response to the comments and surprising things came out of this stage of the process because the student work was not constrained by past limitation. For example, many students proposed development including the vacant blocks which once had houses and others suggested developing part of the large blocks where people still live. Through the community consultation it was revealed that unlike the situation in the cities the privately owned property would be more easily negotiated to develop that the land owned by public Authorities.

Between the event and the design outcome

During the community interviews many people mentioned that “its nice to know that somebody is interested in our town. It was just good to feel that somebody was interested” (NMBW Consultant Team: Rainbow interview 1) This came up a few times in the interviews which indicated that the process itself was important. In many ways it is shift in thinking for the community that is the real outcome of these projects. The design proposals provide a vehicle for these imaginings. As Kilpatrick observes “learning has a transformative aspect, which has to do with understanding values, ideas and pressure from peers that constrain the way we think and act.”(Kilpatrick: 115) This process of learning is a multidimensional process and in this project is included the students, the consultants, the community and Council.

Whilst the locals have an invaluable insight into their towns they can tend to focus on what is lost rather than what they actually have. Kilpatrick describes a phenomenon called ‘regional lock-in’ “when social and cultural institutions cling to yesterday’s way of doing things” thus looking backward at what is lost rather than what might be. Kilpatrick suggests “Unlearning old ways is as important as learning new ones when it comes to adjusting to change.” (Kilpatrick, 2001: 118) One of outcomes of the design and consultation process was that other ways of seeing the town were offered.

The RMIT cohort were excited by these towns and thought that each town had distinct qualities that should be built on to use as the foundation of the design project. It was proposed that the project would build on the strengths rather than try to remedy the perceived problems. It was a useful exercise as it shifted the focus away from what was missing to what was possible with what was already there. This was an advantage of having people from outside of the town. It was the dialogue between the local knowledge and the outsider knowledge that enabled another way of seeing, thinking and making.

The process of design and consultation became an event in itself. More importantly perhaps is the role that the process has in shifting the community and the Council’s perception of the town itself, even without any physical changes.

4. possible futures

Following are two examples of student work, one a landscape architect and the other is an architect. One example of this was the proposal of a new walking track within the town.

The landscape architecture student responded to the existing network of walking tracks along the river. Whilst a walking track is conventional in and of itself, this project used the walking track as a vehicle to re envision the landscape of the whole town. It extended the flora and fauna rich river landscape into the township through planting both public space and the vacant housing blocks. Whilst planting on private property seems naive, the community suggested that this was a

viable option, in some cases more viable than using space owned by public authorities. The planting on vacant blocks tended to avoid the root problems raised in the meetings, as they would be away from public infrastructures. This is not how things tend to work in more urban environments but this the value of bringing in fresh eyes. Eyes that is willing to propose the absurd.

It was proposed that this project would be constructed over time. This slowly another vegetated pedestrian network would offer relief from the extreme heat of the summers. It would also extend the wild life corridors within the town. If the vacancy did continue then increasing the vegetation could expand. The issue of tree selection was addressed based on plants that had proved to survive the drought conditions in the town. A combination of indigenous and remnant exotics were used.

To realize a project like this would require close community consultation, as it is likely that the survival of any planting would rely of the care of locals. Whilst this might sound far fetched in the city, this is already happening in Jeparit as came out in the interviews.

Another student reconfigured the museum to redefine the entrance to the Jeparit. Rethinking the entrance was one of the explicit requests in the Council brief. Whilst the museum in Jeparit is located on the road at entrance to Jeparit, it is easy to miss as it is set back from the road and contained behind a cyclone fence. From the street the museum appears smaller than it actually is. It appears that the museum consists of the small timber building at the front where visitors enter when one enters it becomes apparent that the museum is vast in scale, made of up of many small buildings, sheds and extensive historic farming equipment. The design was simple; it proposed to remove the cyclone fence from the front and to relocate some of the museum equipment and a small building to the other side of the road opposite the museum, so that when one entered Jeparit, they actually drove through the museum. This approach to rethinking the entrance uses the town itself to redefine the entrance. This is an alternative to the redevelopment of signage as a logo which is a common approach to small town re-development and particularly so as a way of identifying the entrances. This proposal emphasized the entrance through exposing a very significant asset of the town, the museum.

The entrance to Jeparit was identified in the report as a priority area for development and one that would provide an immediate impact. Aspects of both of the above projects were brought together as one of the proposed packages of work in the final report and the museum entrance has already been redeveloped. The idea of the river walk and the museum drive through was hybridized at the town entrance. The final built outcome of the ideas as proposed were adjusted in response to budget and community concerns over security. Rather than move a building, large pieces of less precious but antique farm equipment was moved to the other side of the road and the fence that was removed was replaced with another more visitor friendly fence and as lower one that exposed the museum to the road. The planting aspect of the project was carried out but by planting small sized plants to maximize their chance for survival.

5. conclusion

This project offers the opportunity for researching the potential of design and this is something that would ideally happen in practice but is difficult because of the economic realities of small business. If, however, these explorations remain within the walls of the academy their potential is limited. This project offered working between practice, education and community as one way of bridging the gap between explorations that occur within the academy and the built

world. The remains how can there increasingly be dialogue between design research and practice.

Investigating the sustainability of mundane activities using theories of everyday practice and human/ object interactions

Dr Tom Fisher[1], Sabine Hielscher[2]

Abstract

This paper discusses two processes of everyday life – hair care and the disposal of household goods. Both are aspects of our 'ordinary' daily routines which impact on resource consumption and therefore are implicated in environmental sustainability. Particular 'material interactions' (Dant 1999) that are part of hair care routines and which influence consumers' actions when disposing of goods are here considered. Both relate strongly to the emotional dimension of routine practices and draw from empirical research. The paper highlights that the consumption of resources in hair care and by replacing household goods are influenced by the integrative nature of the practices of which they are part rather than the degree to which individuals are dedicated to sustainability, though both may be influenced by Design. What is considered a 'normal' standard of greasy and unruly hair care (Hand et al 2005) or an acceptable plastic surface could be re-conceptualised and could in turn affect practices to conserve resources.

1. Introduction

The environmental impact of consumption depends partly on consumers' habits; our everyday routines – our practices – consume resources. These habits are patterns of behaviour that have 'evolved' and therefore they are in principle open to change in the future. This paper discusses some aspects of everyday routines around hair-care[3] and the disposal of plastic goods that relate to how we feel about our material surroundings; it discusses the emotional component of those everyday routines for the insights this can provide into ways these routines might change to reduce resource consumption. Day to day interactions with hair and hair care products create and draw on standards that govern what is an acceptable feel, smell and look for hair. They often determine when to deal with one's hair or not and the nature of the actions that feel 'correct'. Equivalent 'feeling rules' (Hochschild 2003, Lupton 1998) are implicated in many decisions to dispose of plastic items where surfaces have degraded and become dirty.

Because we are surrounded with plastic products, some of which have visible effects on our environment as litter, the environmental impacts of plastic seem obvious. The plastic bags fluttering in the branches of winter trees, or other packaging littering our streets offends us aesthetically, but it is only the visible part of our large scale consumption and disposal of plastics. While packaging does account for 60% of the three million tons of plastic that the UK consumes per annum, a million tons is made into goods (FOE 2008). The lifespan of these goods is determined by more than just their material (Cooper and Christer 2005), but it is clear that in a 'throwaway' society all the factors that affect the decision to throw away an item are significant to its lifespan. These factors include the feelings that we have about the plastic materials that products are often made from which may prompt us to discard them.

Hair care routines also have a significant environmental impact. Showering and bathing accounts for 17%-18% of UK daily domestic water consumption - on average we spend seven to eight minutes under a power shower that pumps out between twenty and fifty litres a minute. These figures account for only part of the environmental impact of hair care as they omit the energy consumed to heat the water or to power hair care appliances and the waste produced from used packaging and unwanted appliances. Just as the rate at which products are thrown away has environmental impacts, so does the nature of our hair care routines. However the amount of resources used in hair care is not a 'given'; historical studies show that only recently has our current daily showering habit displaced the British tradition of less frequent bathing (Shove 2003).

While it may seem a little ambitious to claim that attending to the ways consumers' actions are reproduced in practices by concentrating on emotions may make it possible to move towards sustainable consumption, this attention to the details of everyday interactions with the material world does seem overdue. As highlighted by Sherwin and Bhamra (1998) in particular manufacturers often disregard the significant environmental and social implications of products in the use phase, concentrating instead on technical innovations. Such design strategies for sustainability emphasise improving the environmental profile of products through, for instance, design for disassembly and enhanced efficiency, but as Demi notes, these should not be the only focus as they ignore the more slippery phase of use (Fletcher et al 2001). Where designers have started to engage with the use phase by considering consumer behaviour, approaches are often solution-based; designers interpret and develop a design strategy and try to apply it to a certain context instead of being more explorative and considering if the strategy is actually appropriate for the context. These solution-based strategies apply so called product focused or result focused

[3] This paper draws on research with Boots the Chemist UK to understand relationships between the elements that constitute the practice of hair care at home in order to develop opportunities for design. The study is based on depth interviews with 24 women between the ages of eighteen and sixty-nine and interviews with hair care experts.

approaches (Fletcher et al 2001). While they sometimes address ways of satisfying needs these are often questioned in relation to lifestyles and behaviours understood through values and attitudes rather than through the patterns and assumptions that determine habits and routines.

Product focused approaches to promote sustainable behaviour may disregard the fact that products are not used on their own but are part of everyday practices – they have a cultural and physical setting. Shove cites studies of technology to highlight the limitations inherent in analysing objects, their acquisition, use and disposal in isolation, without investigating the 'reconfiguration of ideas, actions and habits' connected with their use and appropriation (2006). Everyday activities and products can be distinctly unspectacular. These mundane parts of our everyday life can consist of taken-for-granted routines that are often so 'built-in' that we hardly ever reflect upon them. What people do with their hair, or how they interact with plastic goods are determined by competences, knowledge, past experiences and the temporal, sensual, contextual and emotional arrangements of everyday life; they constitute 'practices'. The paper concentrates on 'practice' in the sense found in the sociological study of culture in the work of Bourdieu (1977) and others. Andreas Reckwitz suggests that such 'practice theory' offers a view of human actions where cultural practice is the 'site of the social' and distinguishes it from theories of culture that emphasise mind, discourse and interaction (Reckwitz 2002: 241). For Reckwitz a 'practice' is

> 'A routinised type of behaviour which consists of several elements, interconnected to one another: forms of bodily activities, forms of mental activities, 'things' and their use, a background knowledge in the form of understanding, know-how, states of emotion and motivational knowledge.' (Reckwitz 2002: 251)

These elements of a practice are 'carried' by individuals and they are sustained, not by norms or rational choices (2002:p252), but by routines.

To think in terms of one of the examples considered here, an individual might use their appointments during a particular week as the basis for choosing to shampoo their hair or these choices could be determined by rationalising whether it would be most 'beneficial' to shampoo hair in the evening when going on a date rather than in the morning after going to the gym. However from the perspective of practices, instead of depending on rationalisations these actions would be seen to depend on everyday routines that draw on various sorts of 'knowledge' that includes emotions. The emotional dimensions of day to day interactions with hair and hair care products discussed below both create and draw on standards that are inherent in routinised actions in the practice of hair care and govern what is an acceptable feel, smell and look for hair. These standards influence when it is appropriate to deal with one's hair and what are appropriate things to do with it; they create 'normal' standards of behaviour. Although these are more or less abstract standards, they influence us to take actions by operating through routinised ways of feeling, which accompany explicit 'reasons', and may replace them.

Both the practice of hair care and the consumption of plastic goods use up resources and therefore have environmental impacts. Given that emotions are one factor that constitutes practices, the rate of this resource use might vary depending on the intensity and nature of the emotions that accompany them. 'Practices' reproduce and change through time (Shove 2006). Reckwitz notes that practices can change through 'ruptures' in the routines that sustain them (2002) and in principle such ruptures could include changes in the emotions that are part of practices – if we feel differently about what we do, what we do might be different. Also, and importantly from the perspective of design, practices and our material surroundings constitute each other, so changing our material surroundings through design as well as what we feel about them, might also accompany changes to practices as a whole.

The discussion below focuses particularly on feelings about dirt, contamination and the margins of the body, which are prominent in hair care routines, and in decisions to dispose of plastic items. A notable emotion that prompts the disposal of plastic goods is disquiet that can border on disgust; a significant aspect of the practice of hair care is devoted to allaying the negative emotions that can be felt at substances that ooze from our bodies (Fisher 2004). The

aspects of hair care and our interactions with plastic goods that have environmental consequences are strongly affected by the emotions that are elicited by encounters with dirt.

Mary Douglas' famous definition of dirt as 'matter out of place', which she retrieves from a time before our modern knowledge of pathogens, is accompanied by her observation that 'where there is dirt there is system'. She suggests that 'as we know it, dirt is essentially disorder. There is no such thing as absolute dirt: it exists in the eye of the beholder' (Douglas 1966: 36). So when people wash and clean their bodies or their living spaces they are making their bodies and their environment conform to a societal pattern. Douglas illustrates this with the way that in cleaning the house we create out of a material house a home that conforms to acceptable every day practice (1984:69). The decisions we make on the basis of whether our bodies or our possessions conform to such practices are not only the 'visible statements' about ourselves that Douglas refers to. To emphasise vision and 'display' gives the impression that such decisions are restricted to a symbolic, cultural plane, when they often involve routinised sensual experiences of the materiality of our bodies and of objects which we encounter through emotions that are configured by a practice. We feel more or less good about our bodies and our possessions by physically appraising whether they fit the 'system', to use Douglas' frame, or the practice, to use Reckwitz'.

To move closer to the examples discussed below, our appraisal of the smell, touch and sight of our hair, or of the plastic objects we use, indicates to us how we should deal with them. How 'dirt' is detected and what is considered 'dirty' reveals a configuration, a system that is dynamic and changes through time, but it is important not to reduce dirt to the systems that define it – it has its specific materiality. Dant argues against reducing the appraisal of dirt to its cultural determinants, noting that as well as taking place within a cultural system, our relationship to dirt is pragmatic. When it comes to dirt, 'if [people] can see it, it is dirt or if they can smell it, it is dirt' (2004). We use our senses to make decisions on what has to be done to remove the 'dirt' and Dant (2003) warns that we should be 'cautious of any reduction to culture that overlooks prior bodily and material concerns'. Although Dant is correct to warn against such a 'reduction to culture', dirt is not limited to things which can be touched, which can be physically sensed. To perform routines in everyday practices we draw on knowledge and competences as well as being influenced by emotions. Knowledge about invisible pathogens and potentially harmful 'chemical' substances has generated a class of dirt that is invisible and cannot be directly detected with the senses – a sort of 'immaterial' dirt.

This type of dirt has no necessary connection to a particular head of hair, or a particular plastic object, drawing as it does on concepts that come from science as well as from everyday life experience. Ideas involved may be quite abstract and draw from systems of thought that have no necessary connection to the spheres of activity, the practices, in which they are influential. 'Hair that needs washing', or 'a plastic object is too dirty to be used and should be thrown away', are categories that some theoretical approaches might say are constructed in discourse (Potter 1996, Edwards et al 1995). However, for a person to experience the feelings that can accompany such things a particular head of greasy hair or a particular dirty plastic object must have existed.

These two elements, an object and a discursive formation that constructs it as 'dirty' or not, have equivalents in ways of thinking about emotions themselves. Lupton identifies a spectrum of theoretical approaches to emotions that ranges from the 'biologic' to the 'constructed'. At one extreme of this spectrum emotions are reduced to qualities of our physical make-up; at the other they are taken to exist entirely in discourse. From the former perspective, emotions 'are' in our biology, the latter takes them to be things that we 'do' in our embodied social and discursive relationships with others. Lupton argues that the discursive dimension of emotion is what defines 'bodily experience', or 'feelings', *as* emotions (1998: 24).

This dichotomy between the 'biologic'/ 'material' and the 'constructed' echoes others in the social sciences that Halkier (2006) notes are unproductive, such as 'body versus mind', 'doings versus saying' and 'individual versus context'. Highlighting the routinised performance of activities through practices, stressing their multirelational elements, makes it possible to avoid the

sterility of such dichotomies. Social practices are not reduced to discursive practices. Practices are not only forms of sayings but also forms of doing and display themselves in regular bodily and mental activities (Schatzki 2001). As Reckwitz (2002:254) points out 'discursive practices are one type of practices among others'. These discursive practices also include their own routinised arrangement of body/know-how/emotion. In this view, meanings do not necessarily depend on intersubjective agreements but are built on routinised ways of understanding and feeling. This is not to say that routine understandings and feelings are permanent, because they can change through 'ruptures' in the routines that sustain them and in principle such ruptures could include changes in the emotions associated with them.

Embodied, routinely performed interactions with palpable dirt often lead to actions with things – washing dirty hair or discarding worn objects. Where 'dirt' requires 'matter' and it's identification within practices, emotions require a bodily 'index' – the catch in the throat, the sweaty palms – as well as the routine ways of understanding them that allows us to name these physical feelings as emotions (Lutz 1985). The cases discussed below identify these feelings and the resulting emotions that lead to objects being classified as dirty with consequent use of resources as they are washed or disposed of.

2. Dirty' hair[4]

At the beginning of the 21st Century washing the hair requires synthetic detergent shampoos and hot water from either a shower or bath. Shampooing consists of a sequence of distinct steps and stages – experiencing the state of the hair, appraising it (tacitly or explicitly) as being 'dirty', wetting it, squeezing shampoo into hands, rubbing it in the hands, massaging it into the scalp, rinsing it off with water and experiencing the 'clean' hair. Depending on the person these steps might be part of the routine of evening bathing morning showering - according to Mintel (2007), 25% of women wash their hair everyday, 59% every two-three times a week, 16.5% once a week or less. Shampooing means women interact with a range of tools, facilities and fluids whilst carrying out a variety of activities in relationship to particular parts of the body, all of which involve some resource use. In interviews women mentioned three main motives for shampooing or not shampooing their hair: 'cleansing', 'pressures of time' and 'creating a new canvas'. This discussion concentrates on ideas of 'dirty' hair that lead to the cleansing i.e. shampooing of hair.

From inside the practice of hair care 'clean' may simply be the absence of palpable dirt but as the discussion above demonstrated defining what constitutes dirt is not simple. The substances that may be considered to be 'dirt' in the hair include dust and pollution but the category is particularly related to the body's own production of sebum[5]. Women refer to this oily substance either as 'grease' or 'natural oils'. It is odourless but its bacterial breakdown can produce smells. It removes static electricity, protects and waterproofs the hair and keeps it from becoming dry and brittle. Like sweat and the fungi and bacteria that live on the skin sebum is close to us, almost 'internal' as it is produced by our bodies (Draelos 2005).

Women interact with their hair with eyes, fingers and nose; seeing feeling and smelling their hair to determine when it needs dealing with. Smell, touch and sight were mentioned during the interviews when women evaluated the states of their hair and they were associated with the frequency of shampooing it. Alongside 'caring for' hair in a routine of shampooing, conditioning, drying, styling, combing and checking the style, women interact with it in an unstructured way – moving it out of the face, seeing it by chance when passing a mirror, smelling it when laid upon it and played with it when feeling bored. Women are affected by these interactions as their hair

[4] This section is based on a series of depth interviews with 25 women about their hair care routines and consequently, it refers to 'women' rather than 'people'. Some of the points suggested may not be gender specific but this would need to be further explored in a study of both men and women.

[5] Sebum is produced by the sebaceous glands and is made of fat and debris from dead fat-producing cells.

touches the skin, produces grease, changes its surface, absorbs and gives off smells. These states of hair are the standards to judge whether the look, touch and smell of hair is acceptable. Hair was described as being too 'flaky' and 'straw like' but predominantly it is 'dirty' i.e. 'greasy' hair is shampooed on a regular basis.

Women connected 'greasy' hair with other states using words like 'shiny', 'clumped', 'dark', 'sticks together', 'separate', 'messy', 'lank', 'damp', 'wet', 'flat', 'limp', 'heavy', 'plastered', which already indicate the range of sensual interactions women have with their hair. Although, smell does not seem to be used in the determination of grease, hair can absorb smells such as smoke but it does not seem to create its own noticeable smell. Although of the participants said 'it doesn't smell or you haven't got the sensation that you feel when you need to wash your armpits or your feet' but over history this was not always the case. In the mid-eighteenth century most people considered frequent washing as unhealthy therefore hair was damped with a sponge dipped in scented water to cover up smells (Trasko 1994). A convention of frequent shampooing means we seem to have lost our sense of what 'dirty' hair actually smells like - women shampoo to wash out 'immaterial' rather than material dirt.

'Greasy' hair may not smell, but it can be seen. Grease shows at the roots, changing the colour, texture and shape of the hair. This is visible not only in the mirror but also to others and is a meaningful state of hair that relates to standards that are culturally framed by ideas, routines and products. Women manipulate hair to show others who they are and to make themselves socially distinct or at least acceptable. 'Greasy' hair influences women's self-image and confidence when coming in contact with other people. As one participant put it 'if it was totally horribly greasy, then I wouldn't feel comfortable or confident with other people in the office'. Further, it is not only the look of the grease in itself that is unacceptable as it also affects the hairstyle and therefore the self-image. The only way to rescue this image is to shampoo and blow-dry the hair using the appropriate styling products to restore the feeling of 'me-ness' temporarily stolen by palpable grease.

This is not so say that women only shampoo their hair to make themselves socially acceptable. 'Greasy' hair touches the skin of our body. It becomes 'plastered to the head', 'sticks together on your face' and 'clings around your face'. Furthermore, this plastered, sticky, clingy hair is 'wet' and 'damp'; it is coated with something that can be transmitted to the skin of the face and other surfaces. There might be something about the feeling of greasy hair that touches us more fundamentally, via an emotional reaction. As one of the participants said

> *'it's not that it [hair] looks greasy or anything. It's just because I know myself that I've not took that time in the morning to wash it… Somebody else might not know that I've not washed it that morning. It's just me. I am aware of it'.*

This awareness leads to a coping mechanism that women described of tying up their hair in a ponytail – sensually 'distancing' themselves from their hair so that they don't notice the grease. This puts hair 'under control', as it is distant from the skin and the person is only aware of it when they touches it. This only seems to be a temporary solution though. During the interviews women suggested that if their hair was not shampooed they would still feel 'dirty' even having washed their body – they wouldn't feel right in their skin because the 'grease' somehow disembodies their hair.

3. Degraded plastics[6]

To relate feelings about dirty hair to feelings about degraded plastic surfaces may be counter-intuitive, but they are related by more than the fact that they both invoke categories that define what is dirty. From many of their everyday manifestations in products and packaging we

[6] This discussion derives from an interview-based study of 22 UK consumers and an online questionnaire conducted among a community of plastic mackintosh enthusiasts between 1999 and 2003.

know plastics to be useful but also highly mutable; clean but also 'chemical'; solid but also ephemeral; impervious but also somewhat absorbent. Our feelings about them are as ambivalent as is their materiality (Meikle 1995, Fisher 2003, 2004). They can perform what almost amounts to a work of purification in the form of food packaging - they contain the sticky mushiness of some raw foods functioning as a barrier to polluting substances that might contaminate food, including human effluvia. Very soon the same materials may elicit disgust as they are re-classified as rubbish.

Whether we want to keep an object depends on how it makes us feel. At the extreme an object which may once have delighted us disgusts us; we no longer want it around and have to get rid of it, voiding it from our spatial 'body' as we might spit up a piece of food we find disgusting. This disgust may be at the material qualities of the object, it may be a visceral reaction to potential contagion. Many times however, objects commit 'sociomoral' violations of the system in which they fit - we know them to be wrong not because of their materiality but because of what they are; ugly, tasteless, unfashionable (Rozin, Lowery, Haidt and Imada 1999: 374). The negative emotions that objects elicit have a material 'ground' in the person - bodily feelings of disgust that have their equivalent in the material qualities of the object - as well as a discursive element, a 'sociomoral' aspect. This paper is opening a discussion of the relationship between this 'sociomoral' aspect of an emotion about an object, the discursive formation which is necessary to turn a 'feeling' into an emotion, and the social practices in which objects exist.

Among the objective qualities of plastics that can indicate potential contagion are the evidence of dirt, wear and the palpable porosity of some plastic surfaces. The inevitable, permanent and often rapid deterioration of plastic surfaces from their initially pristine and 'ordered' state means that very soon after they are new, they begin to become 'disorderly' through wear. Plastic surfaces that are particularly porous visibly absorb dirt. Plastic electronic products attract fine dust from static and grime from our bodies as we use them, which often cannot be removed without damaging the surface of the plastic. Plastic objects show scuffs, scratches and wear in a way that is different to the quirky 'distressing' of wood or leather, which reveals the texture of the material. Because plastic is homogenous, it is only the agent of wear that defines the marks that spoil it – and wear makes evident the fact that plastic lacks its own texture. Shocks will bruise plastic objects and they may break but most do not shatter with the spectacular excitement of glass or china.

Out of these ways that plastic objects become 'disorderly', those that highlight their porosity seem to elicit particularly strong feelings. A female participant in the plastics research referred to the 'traumatised' surfaces of plastic forks and other participants referred to the way that 'Tupperware' absorbs smells and colours. This porosity is something we are aware of as we use plastic objects; just as they absorb stains we suspect that they will exude 'chemicals' that may harm us. While staining is visible, we also fear contagion by invisible chemicals – an invisible essence that inhabits plastic influences our feelings about its materiality in the manner described by Rozin and Nemeroff (1990) in the context of Hindu culture. Our fear of contagion is activated not by religious belief, but by an awareness of the porosity of plastic in the context of a system in which we believe 'chemical' substances might harm us.

4. Discussion and Conclusions

These examples are intended to show the role of emotions in actions that have consequences for resource use. They have concentrated particularly on the negative emotions that an individual feels when their unwashed hair brushes against their skin or when they run their fingers through it; when they consider whether their computer keyboard is too dirty to continue to use it; when they decide whether to reuse a 'disposable' plastic cup; when they decide whether to store some food in a reused plastic container. Mild in intensity though they maybe, everyday experience and the empirical work on which this paper draws suggests that feelings bordering on disgust are present in these encounters with hair and plastic.

The discussion at the start of this paper presented some theoretical perspectives on emotions and evaluations of dirt and offered a practice theory approach as a way to resolve the apparent conflict between approaches to emotion that emphasise either their embodied origin or their construction in discourse. Practice theory highlights the performative aspects of everyday life and the material aspects of its routinised mental and bodily activities rather than intersubjective experience and discursive repertoires. Considering the negative emotions that are part of the everyday practices of hair care or the use of plastic it seems that the 'systems' that define dirt and disorder in those practices are the routinised bodily and mental activities that transform a feeling of embodied disquiet into the emotion of disgust. From this perspective, an approach to emotions that mainly stresses their biological dimension seems inappropriate. Since practices are reproduced and change through time, then so must the 'emotional states' which we experience in performing them. Changes in these emotional states must therefore reflect changes in the routinised bodily and mental activities that define bodily feelings as emotions proper to the practice in which we feel them.

To the extent that some formulations of plastic have physical properties that are similar to the greasiness of dirty hair – the oily wet-look of pvc fabric comes to mind – there may be a degree of equivalence in the negative emotional reactions to them sketched out above. The materiality of greasy and slimy surfaces has not escaped attention as a prime disgust elicitor. Sartre associates a sense of vertigo, dizziness, with the materiality of slimy things which call the margins of our bodies into doubt. Greasy hair certainly does this by disembodying us from part of our physical self and the dubious surface of some plastics may do it too, if only by analogy. It is the palpable porosity of plastics that seems to elicit disgust – if Sartre is to be believed our feelings about the dubious margins of plastic objects mirror an uncomfortable sense that the margins of our bodies are similarly porous[7]. For Sartre (1957) this discomfort is brought to awareness by 'Slimy'[8] substances that blur the determinate boundary between our body and the outside world. In Mary Douglas words, stickiness "…is a trap, it clings like a leech; it attacks the boundary between myself and it." (1966: 38). The 'slimy' threatens a horrific dissolution of the self into the matter of the world.

From the point of view of this discussion of how it is appropriate to treat the emotions that are part of practices it is the theoretical point that Sartre makes about 'the slimy' that is relevant. He suggests that the 'psychic meaning' of its materiality *'is identical with'* its symbolic value; in other words for this emotion he allows no distinction between materiality and system, materiality and socio-moral context, materiality and discursive formation, materiality and practice (Sartre 1957: 606). There is an echo here of Dant's warning against a reduction of dirt to culture, but in a rather more extreme form, which is in direct conflict with the principle that emotional states operate as part of historically specific practices. Sartre is not wrong to point to the power of disgust at substances, sensations and ideas which compromise our sense of the boundaries of our bodies to affect us, but the limits of this power are indicated by his abstract formulation of the cause of such feelings. His use of an abstracted 'slimy' artificially divorces such feelings from any particular slimy object or experience.

Such feelings are never so divorced. We are always disgusted at something and our feelings of disgust do reflect the cultural patterns which that 'something' inhabits. So while our readiness to clean, to order, to discard, to renew does certainly depend on our reactions to the materiality of our surroundings, or even parts of our own bodies, these reactions are more than their 'psychic meaning'. They are embedded in the practices that give them the meanings on which we act – practices operate in what Raymond Williams (1961) called 'structures of feeling' – and they depend in turn on the materiality of the technical components of practices; the particular formulations of hair care products and of plastics.

The impact of this insight on resource consumption is that it dislodges the emotions from the biological sphere into the cultural – emotions are things we do and they can change along

[7] Historically, this belief influenced bathing practices (Shove 2003).
[8] Translated from 'visqueus'

with practices. 'Systems' that define dirt and disorder in practices are rooted in routine structures of mental and bodily activities that can break and shift through what Reckwitz (2002) calls 'everyday crises of routines'. In hair care ruptures in routines occur frequently through for example a new haircut however they hardly ever influence our shampooing frequencies. The sensations of not feeling right in your skin seem deeply rooted in our emotions and therefore difficult to change. On the other hand, over history our washing behaviour has not always been as frequent as it is today. Various haircuts in the past were so time-intensive to create that women slept in uncomfortable positions in order to be able to 'wear' them for a few days therefore washing the hair was not considered and grease tolerated. Further, the life of a 'disposable' cup could become part of our routine of having summer barbeques and not be regarded as 'rubbish' after once being handled but be washed and used in the future – it becomes part of an altered practice. So how we feel about the state of our hair, of our bodies, of our possessions can change.

Future work would needed to be conducted to make it possible to suggest more specifically if ruptures in emotional states that lead to changes in everyday routines can actually be 'steered' towards less resource intensive practices. Emotions are only one element of a practice next to for example knowledge. These elements cannot be reduced to each other, as the change of one element influences the practice of a whole. Therefore a multi-relational understanding of practices is needed. Overall, what is considered 'normal' would need to be re-conceptualised. This could be based on the encouragements of a multitude of meanings and standards for what it is to have 'clean' or 'dirty' hair or when plastic goods are too 'distressed' to use, which could be induced by design.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Surrounded by high-tech environmental persuasion

Possibilities for new expressive surfaces

Joana Hipólito[1], António Câmara[2]

Abstract

The role of design as the link between products and consumers with rising public environmental concern, has given it a central position towards the development of new environmentally conscious tools for motivating behaviour changes.

Designing persuasive tools and interfaces that positively motivate consumers' environmental behaviour change is the goal of our research.

A case study illustrates the use of new expressive surfaces to support energy conservation. An environmentally friendly wall illuminated light switcher tool for providing sensorial feedback on energy consumption was designed.

Potential adult consumers were involved in a concept perception study.

Obtained results are encouraging and support future research that includes prototype user studies and the exploration of more expressive surfaces for environmental persuasion.

1. Introduction

Nowadays, governments and other social and economic partners strive to demonstrate their environmental credits. On the other hand environmental problems attract high levels of popular concern. Although there is a consensus that environmental problems cannot be ignored and that a new sense of involvement emerged it is not always easy to individuals to change behaviours towards sustainability.

The transition towards sustainability involves social learning within communities. Improving healthy life styles (e.g. active day life, healthy food, not smoking) and, at the same time, consuming less environmental resources (e.g. energy, water) are some major contemporary goals to be reached.

In the energy sector there are significant changes around the world, in Europe and also in Portugal. Governments set goals for reducing energy consumption until 2015. For this, stimulating the use of new technologies, improving organizational processes and also changing behaviours and values towards more sustainable consumption patterns are some of the social and economic topics in the agenda. The energy challenge requires acting in several fronts, such as promoting energy efficiency, and the public must be aware, involved and prepared to participate.

This is an important message that must reach the public and consumers. In the last decade many efforts for communicating appropriate environmental behaviour were made. Still at the present time, information is communicated face-to-face in schools but also through community flyers, media campaigns or ads. Actually, we live in a world overflowing with sensorial information that, by claiming consumers' attention, tries to change their behaviours.

However, although environmental information is already available, a step forward must be taken to reach sustainability. This step leads to the promotion of environmental positive behaviour changes and to sustain the positive environmental behaviours achieved for instance in the area of everyday life resources sustainable consumption.

To accomplish this, new tools can be designed to support increased environmental awareness. These new tools are designed as environmentally- conscious tools and embody the high importance given to environmental matters such as reducing resources consumption. Their designs focus on multi-purpose adaptability. Interactive sensorial feedback is added as a response of resources consumption with minimal use of materials to increase simplicity. The designed sensorial argumentation becomes products added intelligence and intends to promote sustainable consumption augmenting consumers' awareness, involvement and participation.

A design research framework that addresses the challenges of motivating environmental behaviour changes and, at the same time, explores the opportunities that arise from the present technological and cultural evolution is needed. The creation of such framework requires addressing the following questions:

- How to motivate behaviour changes in order to become more environmentally responsible? Can new expressive surfaces contribute to increase environmental social behaviour learning?

- How can objects surfaces accumulate new performance qualities and become privileged interfaces for dynamic sensorial visualizations with aesthetic, emotional and persuasive qualities towards sustainability?

We foresee a sustainable reality scenario as a research territory in which new technologies are applied to create innovative sustainable meaningful solutions that allow motivating positive behaviour changes. In this future scenario, individuals are surrounded by

high-tech environmental persuasion argumentation that is embedded in objects surfaces, making them expressive, sensitive and communicative.

Our ongoing design research framework focuses on the development of original Environmental Persuasive Interfaces (EPI). These interfaces provide just-in-time environmental persuasive argumentation in the form of sensorial visualizations (e.g. visual and sonic) helping consumers and families to achieve friendly environmental behaviours.

As a strategy to sustainability we intend to reinvent, re-use or upgrade existing products. We illustrate potential future applications through the rapid fabrication of prototypes.

In this paper, a wall illuminated light switcher tool designed to provide sensorial feedback on energy consumption is presented. Additionally, potential adult consumers were involved on a concept perception study and results are summarized.

2. New expressive surfaces for environmental persuasion

Advancing successful and innovative sustainable tools and solutions for motivating environmental behaviours changes is based on technological and cultural research.

Before presenting sustainable alternatives to consumers, profound conceptual and applied research must be undertaken. Consumers want to participate in the sustainability challenge and they will accept solutions that help them to achieve sustainable results.

In order to build a design research framework to support environmental behaviour changes, finding what peer research groups around the world are developing is fundamental.

In this paper, due to its proximity to our research, we have selected three peer research approaches: 1) Sensorial interfaces; 2) Persuasive technology; and 3) Ambient information displays:

- *Sensorial interfaces*: augmenting objects surfaces with information makes them go beyond their physical constraints and creates sensorial mappings (Chang and Ishii, 2006) enabling new ways for interactivity. These authors propose sensorial activity theory to relate multi-sensorial mappings to the context of device physicality and rituals of use. They define a new class of interfaces, called sensorial interfaces, which articulate information expression across modalities. They advance that designers of these interfaces are less concerned with designing new physical forms for manipulation of digital information, but rather, are concerned with expanding the expressive capability of familiar artefacts.

- *Persuasive technology*: if the added information has persuasive quality the expressive surfaces also contribute to the persuasive technology (Fogg, 2003) research area. In the nineties, Fogg coined the term “captology” which refers to the study of computers as persuasive technologies < http://captology.stanford.edu/>. This includes the design, research and analysis of interactive computing products created for the purpose of changing people’s attitudes and behaviours. This is a research area that continues to grow quickly. More computing products are designed to change what users think and do, and persuasive technology applies to many areas of life. Whenever there is a need to change what people believe in or how they behave, persuasive technology may very well play a role.

- *Ambient information displays*: within an environmental framework, an inspiring example is The Power-Aware Cord (Gustafson and Gyllensward, 2005) that is a redesigned power strip that acts as an ambient information display for increasing energy awareness by showing with light the energy that is passing through it in a given moment. This is done by dynamic glowing patterns produced by

electroluminescent wires molded into a transparent electrical cord. They argue that using light is a more natural and intuitive way of symbolizing energy than Watts on a numerical display. In this paper, they present the use of information technology and design in an electric product with an ambient interface that is both simple and intuitive for everyday use and learning in a domestic context. The authors have been involved in developing new ways of representing and interacting with energy in electric products intended for domestic environments. Their prototypes are used to investigate how such ambient displays can be used to increase energy awareness.

Tools for giving feedback on social behaviour that intend to motivate positive behaviour changes are in tangible development. This supports the research on new expressive surfaces and sensorial feedback tools design that, once welcomed in the real world, intend to persuade to take sustainable environmental behaviours.

Our research territory includes a sustainable reality scenario in which new technologies are applied to create innovative sustainable solutions to motivate positive environmental behaviour changes. In this scenario, consumers are surrounded by high-tech environmental persuasion that is embedded in objects surfaces, making them expressive, sensitive and communicative.

3. A design research framework to support environmental behaviour changes

Our ongoing design research framework focuses on the development of sustainable solutions for motivating environmental behaviour changes. We propose the development of original Environmental Persuasive Interfaces (EPI) contributing both conceptually and practically for the development of new human-computing interactions.

The proposal of a design research framework that explores the development of EPI comprises four major steps: 1) Analyse the issues involved in environmental behaviours, namely individual actions and motivations; 2) Propose new concepts to explore the potential of innovative EPI; 3) Evaluate prototype fabrication feasibility; and 4) Reflect on the requirements of EPI to be developed:

- *Analyse the issues involved in environmental behaviours, namely individual actions and motivations*: this refers to principles related to individuals' relationship with nature and environment (e.g. resources conservation, recycling actions) and to further social and economic issues (e.g. education, community promotion, people involvement).

- *Propose new concepts to explore the potential of innovative EPI*: being aware of our peer research groups work (see Chapter 2), this refers to advancing innovative sustainable concepts such as *environmental behaviour sensorial feedback tools* (Hipólito, 2008). These tools intend to positively motivate consumers' environmental behaviour change. In our research approach we design sensorial argumentation that becomes products' added intelligence and intend to promote sustainable consumption by augmenting consumers' awareness, involvement and participation. It is relevant to stress that consumers' reaction to the sensorial feedback is directly supported by their senses. Sensations are absorbed and used to interpret the sensorial message. This is an intuitive approach that possibly motivates reflection upon resources consumption leading to positive behaviour changes.

- *Evaluate prototype fabrication feasibility*: this refers to analytical information regarding systems and tools specifications, planning and modelling, prototypes development and finally testing. The use of non-traditional pervasive computing (e.g. LED,

electrochemical, photochemical) that enables visualizations embedded on common surfaces such as textiles, boards or paper is encouraged. Testing is an essential phase and must include end users from the conceptual perception initial studies to final hands-on prototype testing approaches.

- *Reflect on the requirements of EPI to be developed*: this refers to resources selection (e.g. water, energy), contextual information (e.g. domestic, public) and user targeting characterization (e.g. age, education). It also includes reflections on the technological development side such as visualization options for the expressive sensorial persuasive argumentation (e.g. visual, sonic).

These four sets of interrelated steps constitute the basis of our development of EPI supporting the promotion of environmental behaviour changes.

We research, experiment and develop new concepts and techniques in non-traditional pervasive computing (Câmara, 2005), together with other research partners, to create distinctive interactive products for inspiring people to become more environmentally responsible and to learn how new interactive techniques motivate behaviour changes.

As a strategy to sustainability we intend to reinvent, re-use or upgrade existing products, focusing on multi-purpose adaptability, with minimal use of materials to increase simplicity. We then illustrate potential future applications through the rapid fabrication of prototypes.

Perceiving new ways of motivating environmental attitude and behaviour changes based on human-computing interactions increases the ability to develop new environmental persuasive interfaces.

Advancing novel techniques that support the design of new user experiences and innovative products and interfaces is fundamental to the overall success of our proposed research.

4. The use of technology to create expressive surfaces

A case study illustrates the use of new expressive surfaces to support environmental persuasion for promoting energy conservation: Wall Illuminated Light Switcher Tool (Hipólito, 2008).

Illuminated apparatus for enabling persons to readily locate a wall mounted light switch when entering a dark room are not new. Additionally, visual dynamics such as automatically emitting light when the room is dark and ceasing emitting light when the room is well lit or flashing in the dark to provide eye catching signals are already available.

However, creating an illuminated light switcher tool for enabling consumers to become aware of the energy consumption when lights are lit is novel and represents its adaptability to a different purpose.

Wall light switchers are used everyday, their face plate act as displays and incorporate the needed electricity to activate sensorial and expressive visualizations. Expressing on the apparatus surface consumption time or energy quantity in an intuitive way (visual or sonic) may contribute to augment energy awareness and possibly change behaviours.

The first prototype design simulates energy consumption sensorial feedback using commercially available green-yellow-red LED as actuators forming a ring display. It intends to express consumption time by starting to emit light, clockwise, when the room light is on and after a period of time.

The added sensorial feedback expression is disabled once the room light is turned off. In order to experiment LED functionality a 9V battery activates LED embodied in a common light switcher (Figure 1).

The light switcher adopts a revitalized look, communicating sustainability just-in-time with simplicity. By representing the consumption time in a sensorial way it makes consumers react inviting them to reflect upon energy consumption. This may promote sustainable consumption behaviour.

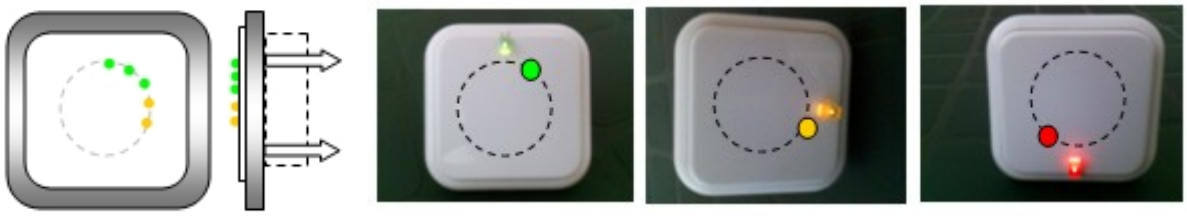

Fig. 1: Wall illuminated light switcher prototype: drawing and LED functionality experimentation.

Further prototype developments include electronics design for adjusting adequate voltage in real settings (batteries are not the best solution) and feedback design for expressing, for instance, energy consumption quantity depending on the light bulb.

An informal research was run involving 15 potential adult consumers (4 female, 11 male) in group meetings. This research intended to answer three questions: Are environmental behaviour feedback tools welcomed? Is the concept of expressing interactive sensorial arguments understood? Are ring displays a convenient visual option? To promote the discussion, PowerPoint slides with the research framework and examples of sensorial feedback tools were presented. Material for hand exploration was available supporting the discussion. The meetings took place in a relaxed way and everyone was encouraged to interrupt with questions or comments.

The following results were obtained. Overall, sensorial feedback tools were welcomed and referred to be helpful (and possibly also playful) within family environments with children. Consumers demonstrated adequate perception of the proposed behaviour feedback expression. The ring form was recognized as to be related with consumption over time as intended. Colours availability and contextual visual communication (e.g. using rings, bars, or lines) are topics for further research.

Concept perception studies results suggest that these innovative tools are powerful sources for environmental persuasion contributing to augment environmental awareness, participation and involvement. However, sensorial visualizations design should be highly considered, once such data is crucial to the application success. Beyond concept perception, prototype user studies are being implemented to find out how useful and informative users find the feedback.

5. Conclusions

The role of design as the link between products and consumers with rising public environmental concern, has given it a central position towards the development of new environmentally-conscious tools for motivating environmental behaviour changes.

In this paper we have proposed the development of sustainable tools that intend to help communities in their transition towards sustainability. The use of new technologies applied to this aim and the creation of multidisciplinary (environmental-electronic-design) research partnerships is part of our current work. In our approach, involving academia, both professors and students, and industrial partners enable us to define our research territory and the sustainable reality scenario that guide our everyday research.

We expect then that our common research results will contribute to change and improve life styles and to promote reduction of environmental resources consumption. We are now focusing on contributing to design tools that converge to energy efficiency goals.

However, in order to address the challenges of motivating environmental behaviour changes, the creation of a design framework is required. The aims of such a framework include researching on how new expressive surfaces can contribute to increase environmental social behaviour learning or how can objects become privileged interfaces for dynamic sensorial visualizations with aesthetic, emotional and persuasive qualities towards sustainability.

In our research territory we have invented a sustainable reality scenario in which individuals are surrounded by high-tech environmental persuasion that is embedded in objects surfaces, making them expressive, sensitive and communicative. We apply new technologies to create innovative sustainable meaningful solutions that allow motivating positive behaviour changes.

Finding what peer research groups around the world are developing is fundamental and in this paper we have selected and presented three research approaches that are connected to our own research: 1) Sensorial interfaces; Persuasive Technology; and Ambient Information Displays.

The analysis of their research together with our own idea for contributing to the sustainable worldwide challenge make our ongoing design research advance the development of Environmental Persuasive Interfaces (EPI) as sustainable solutions for motivating environmental behaviour changes. We particularly design innovative sensorial feedback tools that positively motivate consumers' environmental behaviour change.

To achieve our research goals, we propose a design framework that explores the development of EPI and that comprises four major steps: 1) Analyse the issues involved in environmental behaviours, namely individual actions and motivations; 2) Propose new concepts to explore the potential of innovative EPI; 3) Evaluate prototype fabrication feasibility; and 4) Reflect on the requirements of EPI to be developed.

In this paper, the wall illuminated light switcher tool was presented to illustrate new Environmental Persuasive Interfaces and particularly innovative consumers' environmental behaviour sensorial feedback tools. The light switcher was redesigned to communicate sustainability just-in-time with simplicity. It represents the consumption time in a sensorial way (using LED) making consumers react and reflect upon energy consumption.

These kinds of intuitive expressions may promote awareness and maintain sustainable consumption behaviour.

The changes that are needed in consumers' environmental behaviour clearly support the research on new "hi-tech-design" associations in order to create innovative environmental behaviour feedback tools.

A key factor to the design of these tools for the real world is that individuals capture its purpose and react to given sensorial feedback positively, understanding its meaning.

The implementation of systematic prototype studies is part of future research as well as advancing other functional environmental sensorial feedback tools.

As a final point, the development of new expressive surfaces for environmental persuasion may create real future opportunities in the social and business domains.

The following issues should be addressed 1) Explore the potential of new expressive surfaces used as tools to support families to reduce resources consumption (e.g. water, electricity) and associated costs; 2) Evaluate the role of the design to contribute to more wider social learning processes; and 3) Suggestion of design research frameworks for augmenting environmental volunteer activities.

Acknowledgments

Co-Designing a Sustainable Culture of Life

Design tools: designing research methods for sustainable change

Viveka Turnbull Hocking[1],

Abstract

This paper is a reflection on research into a methodological tool for change towards a sustainable future. The paper's purpose is to communicate this metadesign project in order to open up the ideas for discussion. The project's sustainable context will be explored, as well as the role of design and in particular design research within this context by setting up the system in which design operated and the need for developing a co-design model. The paper will then outline the design-led method developed for fieldwork in Tumut ,which initiated the process of developing the method for the co-design model. The paper will conclude by considering how the model might be further developed into a comprehensive design research method.

1. Introduction

Our *culture of life* has become un-sustainable; humanity (especially of developed nations) has formed interconnecting systems - natural, artificial and un-natural (thought, theory and concept) – supporting our everyday practices which now jeopardizes our future and the habitability of our world. We need tools for change, methods for co-designing a sustainable *culture of life*. The discipline of Design has an important role to play in developing sustainable change.

The word 'sustainability' is distinctly ambiguous; it has come to mean a kind of change (or transformation) for the better. When considering sustainability in terms of *a kind of change for the better* ambiguity is revealed in a series of question arising from contemplation of this statement; what kind of change?, what is better?, for whom?, who chooses?, how can it be achieved?. These are the questions the research community involved in sustainability is trying to determine. This contemporary struggle to determine the nature of the sustainability question is fundamentally a question about our design for the future; what do we want our future to look like and how do we transform our current present into a changed present? It is a question not just for the specialists, but for all people, since it requires a fundamental change in all of our everyday practices towards a sustainable *culture of life*. The why part of this question has been well documented; why do we need fundamental change for the better? Prominent scientific pieces from Rachel Carson's 'Silent Spring' to the Brundland report on 'Our Common Future' and a myriad of others (scientists, social scientists, design theorists, etc) have outlined why we need to *change towards a sustainable future*. They warn of a looming environmental and social crisis; climate change, food security, water wars, to name a few. The discipline of Design had a part to play in the creation of the materialistic culture of *more* which has contributed to the looming crisis we now face. The discipline of design now has a role to play in transforming our culture of life towards something more sustainable. Design's role in this transformation should not only be in developing sustainable artifacts but also in providing tools for developing sustainable change. Design can revise its practices to change the way it constructs our artificial environment of *making ecologically friendly stuff*; doing more with less, lowering energy and material intensity, recycling, reusing, multiple uses, multiple users and so on. Perhaps Design research can also offer the wider research community aid in grappling with the question of '*what kind of sustainable future?'* by sharing the design process's aptitude for *what next*.

If we see design as a kind of research (Frayling 1993, Glanville 1999, Downton 2004) "concerned with how things ought to be" (Simon 1969, 4) then from the methodology of design I propose we can develop tools for a sustainable kind of change for the better. The ensuing method form both *design-led research* and *research-led design*. In designing this method I am using what already exists within the discipline of design; a design methodology, a design process and instances of design methods. By putting them together in a coherent fashion that articulates design as a kind of research we should be able to grapple with the systemic messiness of sustainability. The development of a design guide for research, I believe, is important in terms of our own field's ability to see design as a legitimate form of research and for other fields to gain access to methods that generate a different perspective particularly equipped to deal with questions about the future.

Design for sustainable change requires a fundamental shift in the practice of everyday life. This kind of change has not yet gained the momentum needed to divert our socio-environmental crisis. We need new models of designing for change that enables *co-design* by all actors in the system of the everyday. In order to develop such a model for co-designing sustainable everyday practices we need tools that '*enable design to operate within change and influence its direction*'[2]. Such tools are already emerging from within the design field in the form of design-led methods

[2] This is a core statement in the 'Change the Change' conference outline.

such as cultural probes (examples of which include projects by Gaver et.al., 1999, Ivey et.al, 2007 and Hielsher et.al, 2007), game format (such as the Interactive Institute project *Underdogs & Superheroes*, Mazé and Jacobs, 2003) and scenario building (such as the *Sustainable Everyday: Scenarios of Urban Life* project, Manzini and Jégou, 2003). These existing design-led methods form the foundation from which the method for a *co-design* model can be developed.

2. Culture of Life[3]

Our world; in which we human beings live and enact our lives, is made up of an interconnected network of systems; *natural*, *artificial* and *un-natural*, that support our everyday practices. We live within a *natural* physicality by *natural* processes which exist despite us. We construct skins of the *artificial* (2D, 3D and 4D artifacts, from gardens to lamps to cityscapes) which re-pattern our physical world and our everyday processes that exist because of us. We construct patterns of understanding to form our *un-natural* world, of thought, theory and concept which has no physicality, existing in our minds. Our human ecology is characterized by our biological and cultural adaptations (Schutkowski, 2006), however in looking at our everyday practices the one cannot be separated from the other. Though *life* may be a biological process, there is no way of separating these biological processes from our *cultural* system. For example, a basic biological process such as eating is an extremely cultural activity and as such describing eating solely in *natural* terms "would make no sense, it would be description without meaning – as if you described a Beethoven symphony as a variation in wave pressure" (Einstein as in Suzuki et. al. 1997, 19). Thus our *culture of life* is the interconnecting system of natural, artificial and un-natural that support our everyday practices.

Our *culture of life* has become un-sustainable. Our system of living in the world, the dominant narratives of our contemporary life, are based on the notion of constant growth - '*more*'. In a finite world this culture of '*more*' can only exist until there is no more – then what? - "nothing comes of nothing" (Shakespeare's *King Lear*) so we become nothing; we fail, sink, will not last, we will not be sustained[4]. Our status anxiety (Alain De Botton 2004) is driving us to consume more, our everyday systems disconnected and wasteful, our practices dislocating our sense of being and degrading our landscapes, our semiotic pollution (Manzini 1992) deafens us and we are numbly disempowered by our *culture of life*. We need to change, to transform our system of the everyday into a sustainable *culture of life.*

The *quest for sustainability* to date seems to rely largely on education for the transformation required, such that if you educate people they will be able to perform sustainably (Hobson 2006). If we ask people to re-think each action they perform, as sustainability currently seems to necessitate, then this very quickly becomes overwhelming. This is not normally how human beings achieve their everyday activities; these practices for the most part are placed beyond conscious thought by being embedded in culture[5]. Hence instead of seeing *popular culture* as the enemy (demonized for proliferating an un-sustainable culture of excess) we perhaps need to see it as the kind of pathway that can lead to sustainable change.

---

[3] The phrase '*Culture of life*' comes from my search for an appropriate metaphor of a systems approach for Design to tackle the complex messiness of sustainability. In following Ulrich's argument that "the systems concept remains an empty abstraction so long as it is not linked to some root metaphor" (1983, p.317), then Design needs a 'root metaphor' in which to align its systems approach; one which includes motivation and purposefulness inherent in the social systems of design. In choosing a systems metaphor more appropriate than 'ecology' (such as in 'ecology of the artificial' previously used by design theorists like Manzini to initiate a systems approach to design) we could borrowed from Moscovici's phrase '*culture of life*' (as in Whiteside 2002, 17). In this way 'culture' could be used as the metaphor of a network of interconnecting systems that forms patterns inherent in the practices of humanity. The '*culture of life*' then, implies the network of interconnecting systems that characterise a way of life, an interplay of natural, artificial and un-natural systems enacted to form our everyday lives.

[4] The Concise Oxford Dictionary tells us that *sustain* is to "1. Bear weight of, hold up, keep from falling or sinking…2.Enable to last out, keep from failing" (1964, 1303) hence if we are not able to change to a more sustainable culture of life we will no longer be able to do any of these things *sustain* describes.

[5] This statement is an anecdotal assertion on my behalf which needs further work.

Design is particularly apt in seeking methods for *pop-cultural* transformation; using transgression, luminal notions, play, imagination, translation and integration. At their best these designerly abilities can be innovative, culturally rich and sophisticated or at their worst banal, superficial and trivial[6]. Hence a guide for design-led research which incorporates research-led design; each and both at once, could maximize the designerly abilities of the methodology.

3. Design-led Research and Research-led Design

The word 'design' is used in a variety of ways to mean multiple things; a profession, a discipline, a process and even an artifact. I will refer to the profession/discipline as 'Design' and the process as 'design', I will avoid the meaning of design as an artifact, apart from noting that its use in this way highlights a primary misconseption and preoccuption of the field. Design often serves to accelerate unsustainable processes through its preoccupation with 'stuff'. Like an 'object fetish' of beautiful photogenic artifacts placed on a pedestal against a white background, as apparitions without any socio-environmental context (Jones 1990)[7]. Design's move towards a sustainable practice was documented in the Munich Design Charter of 1991 which initiated this shift through the notion of 'the ecology of the artificial'. This caused the re-orienting of design away from the object and towards a systems approach; of everyday practices which the artefacts of design facilitate.

Non-object oriented design, focuses on design as a process that facilitates our *culture of life* instead of concentrating our attention on the artifacts created. In order to reflect on the systemic nature of design I have attempted to consider where the design system sits with in our human ecology (see *Figure 1* below). Human ecology can be characterised as human society, cultural systems, biophysical systems, the rest of the biosphere (Boyden 2004, 30), including our social activities, institutions, artifacts and so on. Our *culture of life* looks at the particular way we live within our human ecology (as the interconected natural, artificial and un-natural systems that makes up our way of being in time and space). Our *culture of life* is both the context of social activity and facilitated by social activity, where design is one part of our social activity. The design act of 'doing' could be seen as an element in a *social activity* process within the *culture of life* acting to intergrate the natural, artificial and un-natural systems. This could be described as a cyclic process were we understand and act in our natural world through pattern recognition, forming our un-natural world of thought, theory and concept, we use our un-natural world for doing; of designing and making, which forms our artificial world which in turn re-patterns our natural world.

[6] Characterised by Manzini as "superficial, 'photogenic' styling" (as in Jones 1990, 17) and by Frayling as "style obsessed" and "trendy" (1993, 3).
[7] These ideas are raised by Manzini in an interview with Jones for the *Design* journal article (1990).

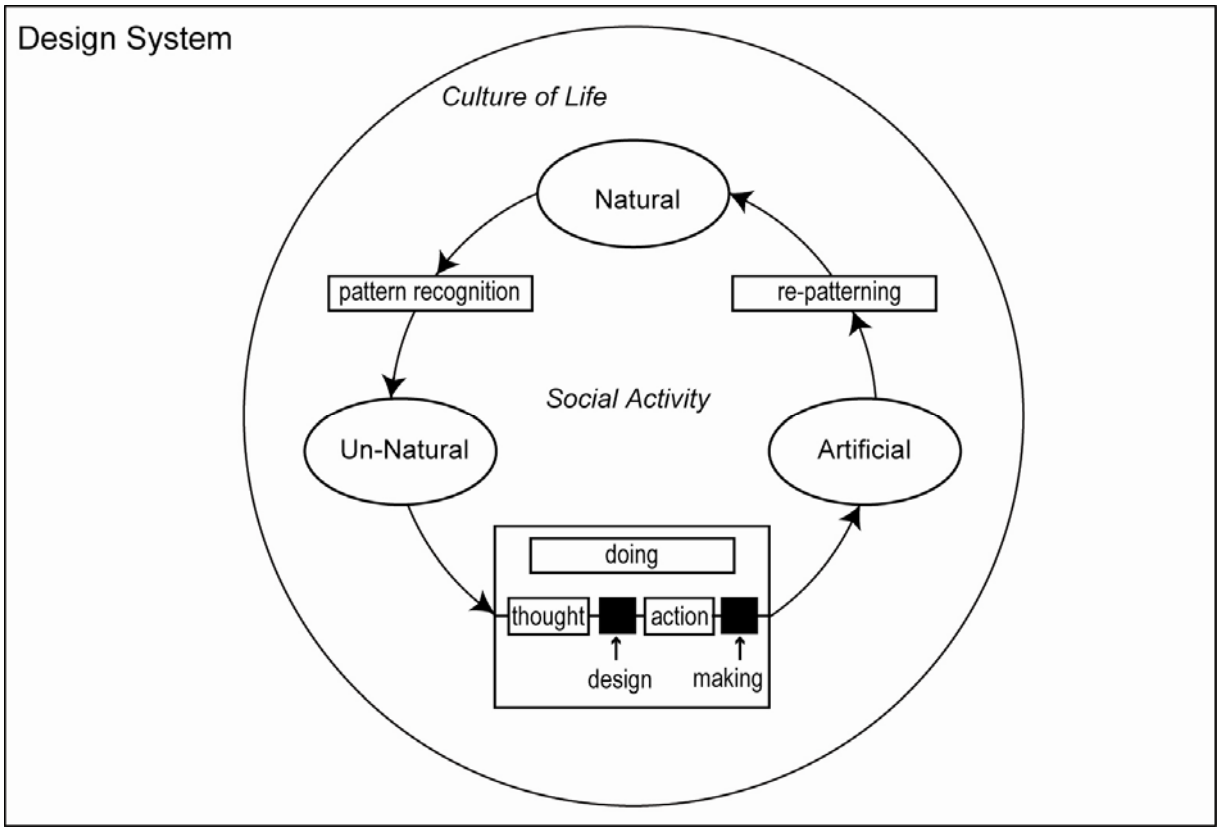

Fig. 1: The Design System - design exists within the system of the culture of life and performs a vital function in bridging the gap between thought and action which not only directly produces artifacts but also enables the system as a whole.

By concentrating our attention on Design artifacts only looks at a small fragment of the system that forms the bridge bettween thought and action. Although artifacts are a direct product of converting thought into action this brindge is also a vital link in the overall system, playing an important part in how we re-pattern our world and thus how we exist in it – *our culture of life*. Although their is a need for sustainable artifacts, their is a greator need for a sustainable *culture of life*. From this need arises an oportunity for Design to contribute to research into the whole system - to grapple with the question of '*what kind of sustainable future?'* - by sharing the aptitude of design for forming a bridge bettween thought and action. If we see design as a kind of research then the methods of design can be used as a tool for sustainability research.

Theorists such as Glanville and Downton (influenced by Frayling) propose design as a methodology and the design process as a method of research; they frame this sentiment 'design as research'. Design-led methods have the potential to offer new perspectives on sustainability research due to the nature of design thinking. Design thinking (both within the discipline and the activity) focuses on a process concerned primarily with generating 'what could be' rather than 'what is'. For the Design field, knowledge is enacted through a process characterised by identity, praxis, playfulness, constructivism, a fluidity of meaning and dynamic variability. The practice of design could be described as an iterative process flowing through phases which can be loosely defined as brief, background research, concept, concept development, design outcome and presentation. The creative process of translating one phase into the next is unique to each designer (Downton, 2004). The identity of the designer is embedded in the design process hence repetition of the process by a different designer yields variability. For the designer the process of thinking through a design is enacted, 'thinking by doing'. I believe this is an important element

shared by many creative practices where the thinking happens in the process of construction. It is about submersing oneself in the process, not pre-empting the outcome. It is a conversational[8] process between knowledge and practice – praxis. For example the process of sketching could be thought of as a conversation; in a sketch you may have an idea of what you might like to draw, you make a mark on the page, you look at that mark, it tells you something which you respond to by putting another mark on the page in relation to the first, you look at these marks which tells you something about their relationship to each other and the page, so you add another mark and so on (the final sketch may or may not turn out how you thought at the start depending on the decisions you made a long the way in response to how the conversation went). The design process can also be described as 'playfulness' with many things tried, not out of an expectation of their success instead to see if they bring something unexpectedly fruitful. Design can be considered a 'quintessentially constructive activity' (Glanville, 2006, p.62). If, in simple terms, constructivism is about constructing meaning in the world then Design is more interested in the construction than the meaning generated and hence Design generates 'knowledge for acting' rather than 'knowledge of what is' (Glanville, 2006, p.66). The aim of design is not to uncover 'the truth' but to propose 'what next'. If design is a kind of research (as Frayling 1993, Glanville 1999 and Downton 2004 suggest) then how can we articulate this?

To articulate design as a research methodology for sustainability I have engaged in a metadesign project to develop design methods within the design process to form a coherent guide. Such a design guide will outline not only *design-led research* but also *research-led design*. Hence design is being used for research and research is being used for design. If we are to develop a model of design research for sustainability we need to consider the specifications rising from the sustainability questions; what kind of change?, what is better?, for who?, who chooses? and how can it be achieved? These sustainability questions are not just for the specialists but for all peoples since it requires a fundamental change in all of our everyday practices towards a sustainable *culture of life*. Hence we need a co-design model of design research.

4. In Search of a Co-Design model

Recent models of designing for sustainable change have not gained the momentum required to generate a fundamental shift in the practice of everyday life. Currently the process of designing for change often follows a model (see *Figure 2A*) where the 'expert' is employed to insert innovation into current practice. This frequently leads to a disordering process culminating either in changed practice or in cycling back to either re-designing the innovation or reverting to current practice.

[8] The idea of the conversation comes from Glanville, although I like to explain design as a conversational process in a slightly different way.

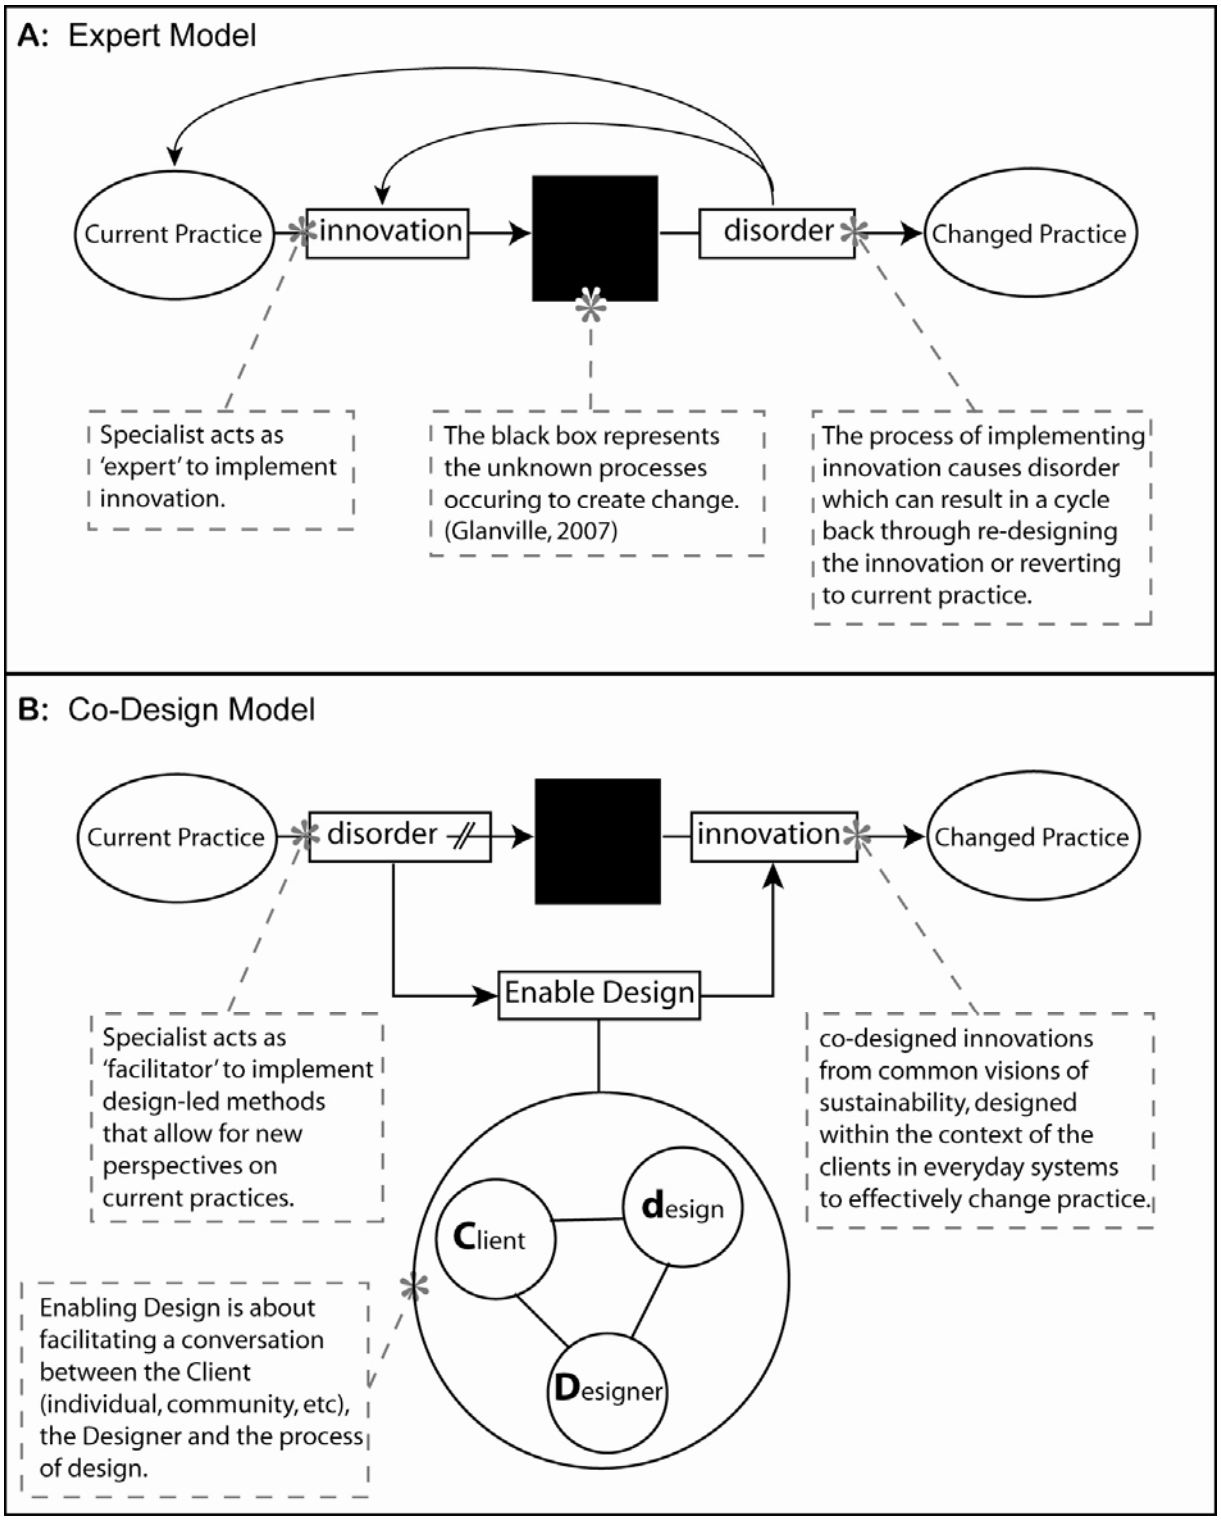

Fig. 2 – A: The 'expert' model for implementing change. In this model the specialist acts as expert to design for innovation towards change. This model has not been effective in creating the momentum needed for fundamental changes towards a sustainable '*culture of life*'.

– B: The 'co-design' model for enabling design towards sustainable change. This is an example of a model that may have potential for engaging all in the design of changes in everyday practice towards a sustainable 'culture of life'.

Designing for sustainable change requires a fundamental shift in the practice of everyday life. This kind of change has not yet gained the momentum needed to divert our socio-environmental crisis. We need new models of designing for change that enables 'co-design' by all actors in the system of the everyday. One such model could be created through the manipulation of the above 'expert' model, transforming it into a 'co-design' model (See *Figure 2B*) by swapping 'disorder' and 'innovation'. In this case the specialist becomes a facilitator (rather than expert) in enabling design towards changed practice that would engage all (community, business, specialist and so on)[9] in the process of sustainable change. The purpose of starting with 'disorder' is to implement a break with current practice allowing people to see their everyday practices from a new perspective and thus able to imagine change. Then, through harnessing the creative energy of the community in imagining change, people can be enabled within the design process to develop innovations (Maase & Dorst, 2006) leading to changed practice towards a sustainable 'culture of life'. These ideas are already emerging from a systems approach to design research as explored in a variety of different design projects based in Europe.

A systems approach to design has focused on bottom-up initiatives that explore the idea of open-source design through co-creation approaches to participation (Maase & Dorst, 2006). Methods for such an approach have been developed from the creative process of design and are considered as design-led research methods. Examples of design-led research methods include; cultural probes (examples of which include projects by Gaver et.al., 1999, Ivey et.al, 2007 and Hielsher et.al, 2007), game format (such as the Interactive Institute project *Underdogs & Superheroes*, Mazé and Jacobs, 2003) and scenario building (such as the *Sustainable Everyday: Scenarios of Urban Life* project, Manzini and Jégou, 2003). Cultural probes are creative stimuli (kits of maps, postcards, digital camera, mp3 recorder and other highly visual prompts asking you to respond in a creative way), aiming to disorientate participants into looking at their everyday practices from a different perspective when responding to the visual prompts. Game formats use game play to explore hopes, dreams and aspirations from a creative context with which participants are familiar (for example in *underdogs and superheroes* participants engaged in the game play through the context of the superhero character). Scenario building uses visualisations of more sustainable everyday practices in order to allow people to imagine possible futures (the project *sustainable everyday: scenarios of urban life* used general principles such as promoting variety, use what already exists, bring people and things together and share tools and equipment, to develop visualisations of possible sustainable everyday practices such as commuting or food preparation). Such design approaches have the potential not only for developing innovative methods for the field of design but also for generating methods that give a unique perspective to sustainability research. These existing design-led methods form the foundation from which the method for a 'co-design' model can be developed.

Taking the co-design model described in *Fig. 2B* the question emerges - how do you immerse the client and the designer alike in the design process and thereby enabling everyone in the system to design the innovation that can lead to changed practice? Design-led methods, such as the ones described above, have been developed to immerse participants in the design process. It would seem that these design-led methods explore instances in the design process (defining particular parts of the design method). If we think of the design process like a song map 'song lines'[10] guiding us through our design landscape with each part of the design process as a verse in the design song. Verses in the design process might be described as:

Brief-> Background-research-> Concept-> Concept-development-> Design-outcome-> Presentation

Perhaps design-led methods could be seen as verse fragments and hence could be put together to articulate the design process. Cultural probes could be an initial step of generating a concept, then game format could be the next step of further developing that concept, and finally scenario

[9] Brown identifies different knowledges associated with these various actors as individual, local, specialist, strategic and holistic (2007, p.31).Each of which have a part to play in sustainability projects.

[10] Indigenous Australians traditionally travelled through country using what we have come to call song lines; an oral map. The verses of the song lead the indigenous people through their traditional routes, with each verse designated for each location.

building could be a way of formulating the design outcomes for presentation. To engage in this metadesign project of developing a co-design method I used fieldwork in Tumut (a town in rural south-east New South Wales) to aid in the process of designing the method; of '*thinking by doing*'. I called the fieldwork 'Project Designing Tumut' and planned to implement 5 phases. By the time of writing this paper I have implemented phases 1 & 2 and designed Phase 3. Even though the process this is only half completed strong results are emerging in terms of how to re-asses the model and re-design the method. Below I will describe each phase and the outcomes obtained so far, leaving further detail about the results and reflections to the next section.

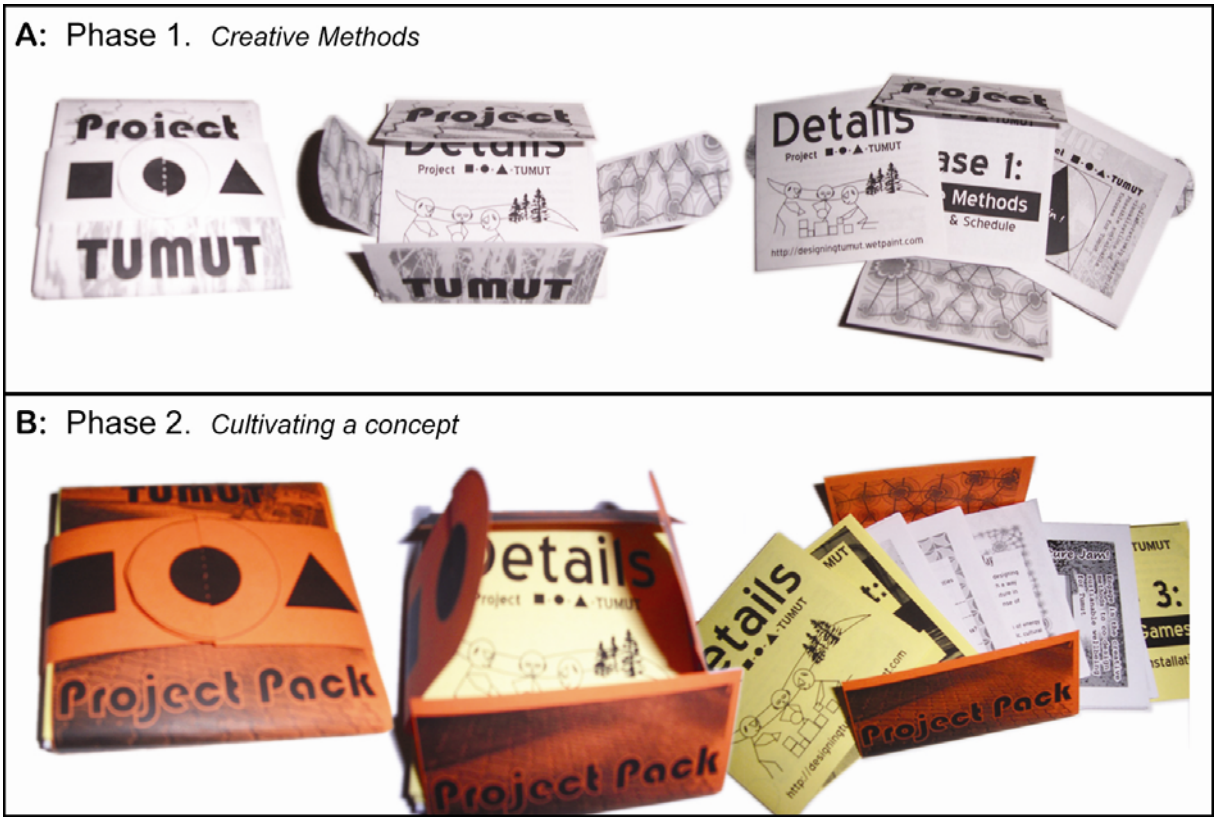

Fig. 3 – A: Phase 1. Creative Methods: Images of the gift pack given out to members of the Tumut Community in phase 1 of 'Project Designing Tumut'.

– B: Phase 2. Cultivating a Concept: Images of the project pack given out in phase 2.

Phase 1: Creative Methods

A gift pack was designed to give to Tumut community members (see *Figure 3A)* with information about the project and a creative questionnaire using cultural probe like techniques. This phase was intended to get some background information on community members. To get to know them and their ideas about Tumut and get their feedback on the different kinds of creative methods so I could design the next phase tailor made for the community of Tumut.

Phase 2: Cultivating a Concept

A project pack was designed to give to Tumut community members (see *Figure 3B)* with information on the project and cultural probe like activities. This phase was intended to harness community members creative energy in working towards a concept of sustainable wellbeing for Tumut. The project package consisted of creative activities which asked participants to look at their everyday happenings in a new way. The activities in the Project Pack were designed to extract ideas in a creative way such that participants engaging in the activities could contribute to the process of cultivating a concept for the next phase of the project. The concept cultivated from this phase was '*diversify cohesively*'. The participant responses suggested that for the community

of Tumut to sustain themselves into the future they needed to diversify their enterprises, they needed to find a balance between industry and culture in the life of the town (being primarily an industrial forestry town) and with an aging population they needed to encourage a diversity of age groups and form relationships between these groups to improve the town's vibrancy. From this concept of '*diversify cohesively*' playful interactive designs were produced for phase 3.

Phase 3 : All Fun and Games

This phase is about engaging in game play. It is about playing with the ideas that came out of phase 2 and developing them into possible sustainable scenarios. This phase aims to further develop the concepts uncovered in phase 2, '*diversify cohesively*', into a game design that enables participants to play with this concept. To do this playful interactive designs will be produced in the form of a 3D interactive object and game to be placed in one or more Tumut locations/venues. The 3D interactive object will take the form of a 1 meter tall beanbag like Tree-creature with paperclips attached to its branches. People will be asked to write stories about Tumut on green leaf shaped paper and attach it with the paperclips to the Tree-creature. These leaves will then form one set of cards in the story game. The story game has a board of butchers paper to construct the story-scape (like a mind-map) and 4 sets of cards to aid in the development of the story-scape; Tree-creature cards, link cards, new story cards and game play cards. Player use the cards to create and link stories on the board. These playful designs will engage people in the creative process of developing up the concepts from phase 2 into Visualising Futures for phase 4.

Phase 4: Visualising Futures

Phase 4 will show the visions from the communities input of sustainable wellbeing for Tumuts future. The different ideas on possible sustainable futures from phase 3 will be worked up into visualisations to be displayed in the exhibition. Community members will be asked to give feedback on these visualisations. From these visualisations one viable vision will be developed up into a final work.

Phase 5: Our Future Vision

The final phase presents the one viable vision worked up from phase 4. Key representatives from the community of Tumut will be asked to assess the viability of this sustainable visualisation for the future of Tumut.

Each phase helps to design the next phase and in this way is part of a dynamic iterative process of design. In implementing this design project also initiates the larger metadesign project of design-led research and research-led design. In initiating this process I am starting to explore the kinds of paths that can be taken, which ones take you somewhere interesting, which ones lead to a deeper understanding and which ones are easy to get lost along, in so doing I am starting to formulate how to articulate a comprehensive design research method.

5. A Design Research Method

I instigated the Tumut fieldwork to aid in the design of a method by entering into a process of 'thinking by doing'. It was not until I started implementing my design research method that I was able to determine how it needed to be designed and how the model needed to be developed. This section will outline the results from the fieldwork so far and my reflection on the process described above.

At the beginning of the fieldwork I thought about what kinds of people would choose to engage in these kinds of activities, whether it would be mainly people who saw themselves as creative or whether it would appeal to a younger generation more used to multimedia than those of the older generations who are more familiar with traditional forms of communication (this may be something I need to explore further). The main factor coming from the fieldwork and conversations with people in Tumut was the educational level required to engage in the phase1

and 2 activities. The educational bias of the method is something I need to redevelop by perhaps making the activities much more visual and much less reliant on reading and writing.

The results from phase 1 suggested the method was missing a motivational factor. I thought there might be a common concern in the community they were eager to change for the future, such as water. The Tumut river in the Murray-Darling basin, is heavily dammed and its flow is highly controlled for irrigation and hydro-electricity and has been in drought for several years. However this did not seem to be the case from the responses received, phase 1 uncovered a range of concerns none of which were drought related:

- A need to create a better balance bettween industry and culture in an industry dominated town[11] (mainly forestry with hydro-electricity, orchards and national parks).
- A need to maintain a diversity of ages in the demographics (Tumut has an aging population).
- A general appreciation of the seasonal weather expressed through four distinct seasons in the region[12] (uncommon in other areas of Australia).
- A significant commitment of time to family and sporting activities

Hence I could not rely on one socio-environmental issue as the motivating factor in my project. I needed to find a way to engage people in a project of developing ideas for Tumut's wellbeing and a sustainable future for the town. In phase 1 I tried inviting Tumut community members to a workshop and found that most people where disinclined to turn up to a workshop. In phase 2 I changed this to coffee at the local café (with only marginal improvement). I considered that perhaps there is a need to re-work the co-design model to engage more knowledge groups which may help to uncover motivations earlier on. I should also note here that this was a very small scale project only intended to initiate the process of designing the method and to shed more light on how to build the model. The project had next to no budget so I was not able to set up incentives like morning tea or lunch which could also have aided motivation. By the end of phase 1 I thought the motivational problems might be solved by a redevelopment of the model to better uncover the sustainable needs of the region. By the end of phase 2 I realized there was a need to develop the methods to open up the design conversation to all the knowledge groups and to develop the method in a more collaborative way. It became obvious that the project would have been aided by collaboration. I propose, because I do not have community consultation skills and I did not learn them in the process of becoming a designer then perhaps as a designer I need to either learn these skills or collaborate with someone who has them.

The results from phase 2 suggested that those people who participated in the phase did so in the spirit the activities where intended. Even though only a small number of responses where returned a concept was still able to be cultivated out of the replies 'diversify cohesively'[13]. I realized that because these methods where quite different from anything else most members of the Tumut community had experienced they needed more support while engaging with the activities. This meant I could not just distribute the packs and let people try and fill them out in their own time. I needed to be able to set up situations where people could ask me questions and work in groups or get ideas and suggestions from others. Having said this I was very pleased with the responses I received and I'm confident the method works in the dynamic iterative way I intended it to. Such that the concept derived from phase 2 enabled me to design the game format

[11] The main industry in Tumut is forestry with plantations and mills. There is also hydro-electricity with Tumut 1, 2 & 3 hydroelectric power stations located in the shire, the north part of Kosciusko National Park as well as apple orchards and other agriculture being a feature of the landscape (including lots of weeds like blackberries)

[12] Four distinct seasons are not common in other places of Australia like Sydney that gets only very minor variations in the seasons, usually described as only two; hot and mild. Whereas Tumut makes a feature of its autumn leaves and spring blossoms and may even get a bit of snow drifting off the main range in winter, summer needless to say is hot and dry.

[13] This concept was generated from phase 2 with some help from phase 1 as well as the conversations and observations I made along the way in Tumut.

for phase 3. At the point of writing this paper I have designed the game ready to take to Tumut for phase 3 so do not as yet have the results.

By the end of phase 2 it seemed that the process in Tumut was uncovering 'the brief'. I am keen to implement phase 3 and develop a story-scape that will work up the Tumut community's ideas. I would then like to introduce other knowledges to the model, like specialist knowledge. Perhaps develop a workshop for interested academics working on issues relating to the Tumut region and engage them in the Tumut story-scapes. I felt it was important not to bring in specialist knowledge too soon; I wanted to see what the community of Tumut thought before asking the experts for thoughts on Tumut's sustainable future. This was partly in avoidance of the expert model I described earlier and to enable design from within the Tumut system of the everyday. However in doing so I realize I had focused the model mainly on local knowledge and it needed to be open up to include specialist and organizational knowledge[14].

Design is an activity not exclusive to the Design discipline. It is a process that the wider research community enters into whenever considering questions about the future of 'what next' or 'what ought to be'. Hence I believe the design research method I am attempting to articulate gives the discipline of Design a chance to share its aptitude for design. In this way I am concerned the process described in the Tumut fieldwork above still relies too heavily on my ability to translate the participant's responses into the outcome for that phase, eg. responses to phase 1 cultivating a concept I translated the responses into the concept of 'diversify cohesively', and feed that back into the design for the next phase, eg. The concept of 'diversify cohesively' I designed into a game about making and linking stories to form a story-scape, (which also might be considered as a reliance on the cult of personality's notion of artistic genius). I still think there is a way of articulating this process so it can be of use not only to those trained as Designers who already have the skills to perform these translations. However, perhaps the answer will come in the need for collaborative sustainability projects to include a designer (or another kind of creative practitioner) in the project team to perform these kinds of translations and transformations (creative practitioners and Designers in particular are specifically equipped with these kinds of abilities and thus can effectively perform this kind of role in the project team).

The dynamically iterative nature of the design research method where each phase designs the next phase of the project proved challenging to those with more traditional notions of research. The University Ethics Committee who did not have any concerns about the project in terms of its potential risk to participants, did have some trouble fitting this iterative process into their framework. Seminars I gave at the ANU's[15] Fenner School of Environment and Society uncovered questions about what I was going to do with the data I received from each phase in terms of quantitative or qualitative analysis. I explained that I was not treating the responses as data in the traditional way, that the results of each phase would be used to design the next phase until the design outcome was achieved; in this case a visualization of sustainable wellbeing for Tumut's future to be exhibited. Design research is a different kind of research; it does seem to challenge more traditional conceptions of what research is. Through this fieldwork I am closer to being able to show that the design process can be articulated as design-led research and research-led design and is useful for brining a different kind of tool to sustainability research, although I have more work to do.

6. Conclusion

[14] Although I have focused on local knowledge the methods have also encouraged individual and holistic knowledge, the ones I feel are most missing from this project so far are specialist and organizational knowledge. Though building the inclusion of all the knowledges within the model will need to be reviewed further.

[15] The Fenner School at the Australian National University is predominantly a social science school although has a multidisciplinary agenda so is populated with a variety of other disciplines, like myself representing design. The seminar I am referring to here is the Human Ecology Forum.

The aim of this paper was to reflect on my research into a methodological tool for change towards a sustainable future and by doing so open this metadesign project up for discussion. The project's sustainable context lies with in the questions arising from *a kind of change for the better*. This is fundamentaly a design question about what kind of future we want. In this way design has something to offer not only in creating more sustainable artifacts but also in sharing the design procces's aptitude for *what next*. *Non-object orientated* design focuses on design's part in the social activity of enabling our *culture of life*. This is a systems approach to design which has been explored in a variety of European design projects utilising design-led methods. These projects have focused on bottom up initiatives and highlight the need for a co-design model of design research. I have proposed a co-design model that may have potential as a frame work for an overall design method. The method ustilises the iterative phases in the design process, the emergent design-led methods and the need for opening up the design conversation to all knowledge groups in the system of the everyday. I initiated the Tumut fieldwork in a process of 'thinking by doing' to further develop the method's design.

The Tumut fieldwork has helped to uncover how the model might be further developed into a comprehensive design research method. In re-building my co-design model I need to consider motivation, brief generation, bringing different knowledge groups into the process and developing a collaborative framework all of which I felt were lacking in the Tumut fieldwork. Perhaps the creative activities in phase 1, 2 & 3 will be worked together into the brief generation phase. Local knowledge then needs to be supplemented with specialist and organizational knowledge to better pick up on motivational factors in the local system, generate more comprehensive notions to support the creative energy of the participants and establish the context of sustainability in the region. Collaboration could also make use of different knowledges, skills and expertise, such as adding project members with community consultation and creative translation skills. The co-design model needs to consider all aspects of the system of the every day and thus needs to build in the different knowledge groups not just in the participation but also in the facilitation. In articulating the Design research method I hope to show its usefulness for dealing with *messy* questions about the future like *what kind of change for the better?* as an additional tool for sustainability research.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

ETHICS BECOME SEXY!

A critical approach to Design for the right to access to aesthetics and technology in the knowledge society

Lorenzo Imbesi1

Abstract

If environmental issues have had a prevalence to delineate what sustainable design is, we are facing the rising of further social topics somehow dealing with ethics matters, while rehabilitating to design that 90% of the people which are out of the profits of production.

If the culture of the “limit” as principle of responsibility have marked the ecological culture for a long time, giving an aesthetics for project and at the same time rejecting technology as the primary cause for environmental failure, our analysis should consider the paradigmatic shift towards knowledge society and the social role of consumption beyond need as a form of knowledge and production of culture.

Therefore, the power of access to technologies and the right to aesthetics are the challenges of design facing ethics while producing political statements. Desire and intelligence become a framework for new scenarios of development: very sexy!

1. Introduction: a Design for the urgent majority

There's a percentage in the world which is out of any statistics, which has no weight in the numbers of marketing and production. It's a proportion of men and women which are invisible for the commercial balances and the exportations. They are people which are indifferent to any form of target and even to commercial battages. It's a society which is far away from iperconsumption and which brand is not able to place any mark but the one of need. But however it has necessities, urgencies, also desires, which "mainstream" design is not able to give answers because they are out of the numbers of consumption. It is a humanity living among the limits of survival, crowding the slums of the cities, filling the refugee camps of the old and new wars, dwelling the temporary centers of migration. They are victims escaping from natural disasters, such as hurricanes, floods or hearthwakes and arranging the favelas and the ghettos emerging in-between the interstices all over the world. It's an exceeding humanity without project and excluded from any form of project.

However, someone has evaluated this multitude amounting as the 90% of men and women dwelling the earth: they come to be an overwhelming and invisible majority resulting of nearly 1.300 million of people surviving with less than one dollar a day. One billion are without drinking water; 800 million, among which 200 million children, are malnourished; 2,4 billions are living without basic sanitary services; 36 million are affected by HIV/AIDS, among which the 92% are living in developing countries. 325 million of children cannot go to school; 46 million are victims of floods every year. These are proportions which summed together reach the big majority of the global population estimated around 6.400 million of people dwelling the earth and which live without access to everything we regard as normal, as having a repair, water and food, instruction, sanitary protection. It's the real world, as Victor Papanek would call it, which doesn't even take advantage of the attention of design research.

Design actions can have important outcomes for this invisible but real part of the word and a growing contemporary design movement is exploring new matters highly affecting social issues which the design professionals usually don't pay attention, while being interested to the 10% richer part of the world. As it can be testified by the recent exhibition "Design for the Other 90%" displayed at the Cooper-Hewitt, National Design Museum in New York, while gathering design solutions on the big issues such as water, health, energy, education, dwelling, infrastructures, which are distressing the greater part of the world population.

More than elaborating typologies of products which are already existing, as design often acts while encountering experiences of styling, they seem to be real inventions with innovative and original features and which involve together low tech technologies with industrial processes and low cost materials through design intelligence. It is often the expression of an anonymous design which isn't able to be news and whose designers usually do not appear in the glossy pages of international magazines. Even if no one will remember the name of its designers, those projects demonstrate how design can have the power to change and improve the lives of men and women, while being interested in their real needs.

2. Aims: social awareness, aesthetic responsability

The consideration of the social responsibilities of design suggests the relationship with its ethical value and impact on daily life of people, both reconsidering with a critical eye some of the categories related to sustainability which have based for a long time the ecological thinking while developing a sort of morality for the project.

The research starts from the consideration of the shift brought by the third industrial revolution, knowledge society and information technology in the forms of organization of

contemporary societies and the spaces we live and dwell. The change is modifying at the same time the global geography of development which was once cut between north and south. The rise of the global cities in every part of the world is a brand new phenomenon for bigness and density while displaying at the same time new and original critical situations which should be examined with innovative tools.

At the same time, the diffusion of new technologies spreading in the world, opens again a reflection for analysing what can be considered a sustainable technology towards which development. If helping the once called third world for a sustainable growth meant just downgrading or giving away the last but one innovation in technology or industry; the rise of new technologies, mostly connected with communication and knowledge, releases chances for development and for playing new leading roles in a sustainable way which should be investigated.

Also, one of the products of globalization is a form of culture of responsibility which generates the awareness of the local and global effects of consumption. Therefore, consumption cannot anymore be considered just as a passive act, but moreover an action which can be aware of its active role in producing skills, knowledge, as well as redirecting production itself towards more sustainable strategies for environment and society. The progressive market politization may open to new schemes and experiences of enterprise to be explored.

Sustainability has been shaped through time as a form of strict castigatory project instructed by the morality of need where desire is banned. The “culture of the limit”, which has produced a form of aesthetics to sustainability through time, should be reconsidered according to the penetration of media around the world and the diffusion of global lifestyles producing a form of aesthetic awareness and education among social strata and places. Therefore, the strict limit between need and desire should be reviewed in order to claim “the right to aesthetics” together with the basic needs for every men and women. This is one of the challenges for contemporary design: shaping an aesthetic for ethic in order to make good choices be recognized and accepted also as beautiful choices.

The research faces the conceptual relationship between ethics and design through different aspects (organization, production, distribution, consumption, …). Through an interdisciplinary theory-based and design-based approach, linking design, productive consumption, cultural studies, anthropology, the contribution will be based on the experiences of two exhibitions and a conference on the topic, while it will provide images related to product design projects which will illustrate the subject matter.

3. A question of ethics

Any good designer sustains that a likewise good project, any good project, cannot be called like that without assuming a number of features that attains to its ethical measure connected with the society and the environment where being inserted. But in addition to professional deontology, which binds individually every good professional as active actor of a society to right practices and values of general etiquette, design has a responsibility in creating the material landscape where we live, which is to say the raw material of the world, and consequently the social scenarios been shaped, while drawing the network of relationships mediating our behaviours. Then, design has to do with our material culture, meaning as a mix of men and things, matter and behaviours, living and inert, visible and invisible.

Close connected with technology, design is the way we try to solve problems, fill needs, satisfy desires, shape our world and change the future, as well as create new problems. Design is primarily an iterative and complex process which important decisions are being made related with society. As a result, design can build many important consequences on the cultural and ethical issues related to hypothetical future scenarios that somehow arise and involve actors and heterogeneous contexts. The project does not stop with the design of a shape, rather continue in

the choice of materials, as in production, distribution, consumption, even dismission, while implying an endless network of subjects, often with contradictory interests.

4. Responsible, fair and solidal

If environmental issues have had a prevalence to delineate what sustainable design is, while ecodesign approach has been developing products with low environmental impact; nowadays we are facing the rising of further social topics somehow dealing with ethics matters. Above all, the ethics dimension, which belongs philosophically to the sphere of behaviours, while setting together design and production, makes a contradiction to be solved while expecting a form of responsibility after economic profit. Specifically, the ethics of production doesn't necessarily relate itself with the social and the environmental one, while assessing only the economic factor as the only engine and principle of profitability in calculating cost-benefit of enterprises. But the growing critical conscience in consumption and its impacts on environment as on the exploitation of labour, or developing countries, on planet pollution, or the mistreatment of animals, has given the chance to emerge new opportunities for companies to work beyond the logic of instrumental rationality and economic profit, while discovering a competitive advantage in a form of ethics and social responsibility.

At the same time, the recent conscience to live in a smaller world, if on one side it awakens us regarding the limited resources available, as the social costs connected, on the other side while connecting smoothly cultures, goods, technologies, information, it gives the chance to discover new potentials for creating experiences while including entrepreneurship, production, but also widespread creativity. These can be considered opportunities that make solidarity and sustainability not just a philanthropic value, but a principle of entrepreneurial policy opening at the same time a new area of research for the project in a cultural perspective. The experiences of Corporate Social Responsibility were born in this connection in order to respond to a request for aware consumption by creating competitive advantage also with criteria which aren't directly monetary.

Design proved to be able to develop enterprises of cooperation between project and production related to sustainability and solidarity, between local and global in the direction of developing countries. Therefore, for example, North South Project involves small enterprise and local producers between Guyana, South Africa and Botswana in creating products based on the vocabulary of forms and materials of the place, but at that time direct for other and high global markets, or else the experience accomplished between research and didactic by IUAV Venice for the realization of bamboo prototypes designed by students and implemented in Vietnam by the artisans of CraftLink. While welding knowledge and manual skills, capabilities and cultures, new chances for research and creativity come out, while crossing at the same time industry and handicrafts, improving old and new materials, embedding local traditions and global cultures, ethics and techniques. The development of new product lines, designed with special attention to the outcomes for a compatible and responsible development, at the same time can be an opportunity to discover new markets while structuring systems not only for production, but also for distribution, marketing and consumption, thus appraising each section of the line, also through design, and thus constituting third forms of aggregation.

5. Post-production products

Along with the transition to the postfordist economy, the reconsideration of the limits of production, where small production increasingly varied and customizable is privileged to mass quantity, releases areas for new business practices, as for project, capable of bridging the gap between production and ethics, among the objectives of profit and those of social progress. Therefore, it can be taken as an interesting case study the experience of Cyrille Varet, a French designer who works with Wola Nani, an association of South African women infected with HIV,

which together design and work on standard incandescent light bulbs of Edisonian memory, while bringing together hand made with machine made. Almost as a metaphor of the serial product created by the Fordist mass industry, the classic light bulbs are taken as object trouveé and manipulated with innovative materials and technologies, such as colored silicones and metals, in order to elaborate special tactile, visual or colour performances. The final products are all unique pieces and at the same time serial mass-products; but moreover they mainly employ new technologies for marketing and distribution while being sold only online on the web and basically facing a global market.

This can be considered the expression of a widespread and varied projectuality, which is not just the representation of local cultures of craft, nor those of the big global multinational industry, but the result of powerful and fertile hybridizations. Those experiences have the power to invalidate every barrier established between north and south, developed and developing countries, in order to design the new scenarios of post-production products while involving a profound rethinking of the concept and modalities for enterprise and market research. They can open new systems of relations and organization while cracking common established processes of design, production and consumption and launching unexpected possibilities for creativity, as well as new markets that do not recognize the accepted principles of profitability, while introducing ethical and social criteria. Therefore, profit happens to be the result not just of strictly financial viability and economic gain, but also of quantifiable values in terms of improvement of the environmental quality, solidarity, human development or social security.

5. Mapping post-colonial scenarios of marginality

At the same time, the critical thinking on the role of design, as well of production and consumption in contemporaneity, cannot ignore the historical epistemological turn from the fordist-taylorist paradigm of mass and serial production into the post-industrial development which draws a new economic and productive geography. In a world where the industry of the chain assembly leaves space to new and more flexible forms of labour, allowing production to untie and decentralise itself from territory, the binary paradigms of centre-periphery or north-south, which have painted the maps of marginality and colonialism, cannot tell anymore the complexity of contemporaneity.

Then, a net of connected hubs designs a fluid horizontal structure without centre, delocalizing and autonomizing the activities. At the same time, a new geography of global cities is emerging while crossing and connecting the transnational market. It’s a new map which is including, after the renown London, New York and Tokyo, also places as São Paulo, New Delhi, Hong Kong, Cape Town, before considered as peripherical. Here, finance, technologies, fluxes and strategical decisions, but also an extraordinary quantity of humanity produced by migrations, are concentrating in such special places. As stressed by Saskia Sassen, those incredibly extended global cities display themselves as iperconcentrations of infrastructures and define the new scenarios where centrality and marginality are now concentrating while increasing inequalities.

If the world could be cut in two along the classic dichotomy between north and south, centre and periphery, developed and underdeveloped, colonizers and colonies, the new post-industrial geography of networks and fluxes maps a rather complex new form of development where many centres come forward as hubs in the peripherical marginal regions and at the same time on the contrary lots of peripheries can be drawn within the central key places. Thus, while squeezing dramatically together more than half of the global population, at the same time contemporary cities have the power to incrementally condensate inequalities, contrasts and conflicts, which can be seen in the concentrated depots of human multitudes which live reduced in suburbs, as well in favelas, or in refugee camps.

The issue of new technologies can therefore suggest new forms of development, beyond the fordist industry, capable to break down the classic dichotomy between north and south,

developed and underdeveloped. Besides, if global has become the way to be local, is it still relevant to make any difference between the north and the south of the world? Rather, isn't it that we can now locate as many south in the north and north in the south?

6. Power of access

If the big majority of the inhabitants of the planet will soon live in big global cities, and the trend does not seem to be near to reduce, these will be the scenarios where production and project should focus. Here, the problem doesn't seem to be just the transfer of technologies into the developing countries, moreover the risk is just to build a form of "peripheral Fordism" connected to the decentralization of the most polluting productions in the emerging industrialized countries. Moreover, it is important to build new models of development able to cross together technological innovation with intelligences and capabilities of process management. Thus, the immaterial capital in terms of scientific and technical knowledge would be involved as an important competitive factor as our contemporary society of knowledge displays. As a proof of this, it should be highlighted the progresses in technological innovation for managing immaterial information flows, attained by important investments in human resources, which have meant a chance for redemption in many emerging countries as it can be displayed by the industry of software in India. This is a recurring topic of contemporary design research which should be focused, while reflecting on new models of development connected to knowledge society. Thus, design research should aim at developing that immaterial capital as knowledge taken into account as an important factor for competition.

The technological question certainly is one of the most relevant contemporary issues at the global level which we should face: as Jeremy Rifkin stressed, poverty cannot anymore be measured just by the satisfaction of primary needs, but on access and inclusion to technologies and communication which can give a chance to societies to develop autonomously. The power of access can build the differences and inequalities while opening holes in the net: being disconnected means being excluded to the educative, cultural, informative chances which communication technologies mean, while broadening the economic and social disparity. Therefore, many projects are working to ensure digital inclusion in vast underdeveloped areas often even lacking of electricity, where breaking down technological barriers and the allocation of wireless networks may stand for the only possibility of communication and at the same time the only chance for developing programs for education, for enterprising for small companies, for the progress of small communities. As a well renown and celebrated example, the project OLPC - One Laptop for Child, which has been developed by MIT in Boston and designed by Continuum and Fuseproject from an idea of Nicholas Negroponte, is launching a challenge in order to break the technological gap while realizing a laptop powered by a hand crank and not exceeding the cost of $ 100 and to be distributed to children between 5 and 15 years old.

While drawing the new development and technological scenarios, such design experiences could have interesting outcomes back to the richer societies, while signalling new paradigms and models which can be socially and ethically alternative back also to the richer societies, while matching wellbeing and sustainability. Just imagine if suddenly millions of computers like that were distributed while being equipped with technology of the latest generation, but with open-source software and very cost-effective hardware. Just imagine if an important slice of the world was educated, would communicate and create projects, enterprises and development with such technologies. What would it be of the technological monopolies, or the exclusive software, or multinational digital services? And moreover, if spreading those new formats and digital languages take the capacity of critical mass, then shouldn't the most developed society have to adapt for once?

As well, the history of Freeplay crank radio displays a similar model which can have a meaning also for developed countries, apart from design and technology. While been developed

for African countries, for those many people who have lived the famous blackout in New York, it meant the only vehicle of information about what was happening around them.

7. Sexy, smart and profitable

Moreover, the relationship between ethics and design focuses and crosses over the issue of the aesthetics of ethics, while simply asking: is it possible for design for/of sustainability to exceed somehow the “pauperistic” aesthetics which has been historically connected with?

Hans Jonas’ culture of the “limit” and principle of responsibility have marked the ecological culture for a long time, giving at the same time an extraordinary metaphor for the design imaginary, while pointing to technology to be in charge tout court of the environmental calamities and at the same time dreaming a sort of romantic restoration to a natural condition in order to bring life back to the ecosphere. Therefore, responsibility towards future generations and the globe survival from the emergence bring towards a sort of morality of the sacrifice as the only cure which seems to be possible for the destiny of the planet.

Its related aesthetic answer is a sort of Calvinist programmatic minimalism combined with a prudence for project, the refuse of technology in favour of local handicrafts and a minimal aesthetics for reuse of thrash, both physical and moral. At the same time, the caution for project takes sometimes the risk of flowing towards a policy of “not doing” and an absence of project: as a reflex of the liven and open debate, the 7th International Venice Biennale of Architecture was heading the title “Less Aesthetics More Ethics” in the 2000.

As a result, to give evidence of a civilization of consumption and amplified glamour, as Ave Appiano stressed, the rediscovery of the "aesthetics of wreck" has been rediscovered through poor and minimal, even trash shapes, as the art already taught, which are always connected with a sort of physical and moral recovery, in order to save the refusal to new life. The desire becomes a threat to exorcise due to be unproductive waste beyond the preservation of life: *la part maudite* described by Georges Bataille through the concept of *dépense* is related to the unproductive waste matter of consumption, which is lived as an act of sacrifice and loss, but which also plays an key part as a social function in cultural rites.

But, if we cannot ignore the centrality of consumption of goods and services phenomena, beyond the utilitaristic theories of need, consumption itself cannot be anymore identified as a secondary activity from production and market, moreover able to produce meanings and knowledge. The growing awareness of the role of this activity in everyday life make take it into consideration as a form of production relating relational, technological, creative and cognitive skills. Productive consumption or “prosumerism” are the new categories which are emerging in the convergence between production and consumption leading to new forms of participation, responsibility, self-brand, lifestyles.

The boundary between users and producers of a service is blurred: it is often impossible to differentiate between those who are creating the service and those who are the consumers or users of the output. Furthermore, productive consumption and the critical awareness of the values that goods concentrate, open to new queries to be debated: what is the shape of ethics? Hence, the right to aesthetics namely employs solidarity and ethical values in order not to sentence to a structural outstanding underdevelopment for all those men and women who live excluded and indigent. Thus, aesthetics comes in the political sphere.

Quoting Bob Willard, which is an expert of company’s strategies, design should be “sexy, smart and profitable” while connecting ethics with the intelligence of new technologies, competitiveness of production and being sexy for consumption. That is to say, the future of the ethically aware project should embrace the intelligence of new technologies, the competitiveness for production and being sexy, namely assuming a persuasive aesthetics for consumption. And it is just aesthetics to play a critical role for next future for fair and sustainable project which design should give an answer. Every, any upcoming and new model of development cannot leave out of

consideration the scenarios of everyday life where they are located. Those common scenarios also employ images and shapes which are perceptible and can be recalled into mind: the aesthetic vision will give a more or less cognitive and cultural interpretation to be shared collectively or individually through metaphors and mental images. This is another issue to be queried to design project: which aesthetic expression is able to play and moreover communicate the values of equity, solidarity and respect for environment, while drawing at the same time our scenario of life for the next future?

Then, new technologies and the materials of last generation can give and interesting answer to the ethical and aesthetic scenarios which our future environments will have, while including together factors as ecology, high performances, economy, innovation, ergonomy, without renouncing to seduction. Therefore, productive consumption and the critical awareness of the values of goods ask for a right to aesthetics which can assume at the same time ethics and solidarity values in order to give a shape to the desires of “the other 90%”. Thus, aesthetics become politic. Very sexy!

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Looking for Likely Alternatives (LOLA)

A didactic tool to approach sustainability by investigating social innovation.

Victoria W. Thoresen[1], François Jegou[2], Sara Girardi[3]

Abstract

LOLA is a pedagogical tool for teachers and students which core activity is based on scouting for promising cases towards sustainability. The paper presents LOLA tools and its theoretical background, analysing is potential in shifting our society in a more sustainable direction through didactic activities.

Our conclusion is that LOLA is developing a “designerly way of knowing”. Students are stimulated to describe for each case collected: “how the initiative start”, “who are the users”, “which user need does it answer”, “what works well in the solution”, and other questions that implicitly induce students to recognize initiatives in a “solution-focused way”. LOLA promotes in students the idea that people are able to “design” for themselves, to solve problems and to live in a sustainable way.

1. Introduction

The Looking for Likely Alternatives (LOLA) project is a pedagogical tool for teachers and students, which assists them in the process of identifying, evaluating and documenting cases of social innovation for sustainable lifestyles.

The LOLA project's goal is to help teachers and their class to discover, approach and give visibility to new sustainable lifestyles in their surroundings.

In the complexity of contemporary society, new forms of sustainable users behaviours and promising bottom up innovations are appearing. These initiatives have been carried out by communities of people who organize themselves and develop new solutions based on mutual help, collaboration, sharing, etc. On top of facing their own everyday problems, these solutions can be seen as potential seeds of new sustainable lifestyles. ***LOLA's core activity is based on scouting for promising cases towards sustainability***. ***Giving light to this kind of grass-root innovation, the pupils share knowledge developing a vision about the future and how to change our society in a positive way shifting it in a new and more sustainable direction.***

LOLA goes beyond the common pedagogical use of case studies and project work which tend to be limited to the immediate classroom context. The process brings the students into direct face-to-face contact with groups of people who question their current lifestyles.

The project aims to reach the following goals:

_ develop, as a didactic tool to raise sustainability awareness, the process of searching for cases of social innovation;

_ strengthen the processes of identifying social innovation, evaluating promising cases, clarifying the conditions requiring such innovations and reflecting on the consequences of such initiatives;

_ improve the use of ICT and multimedia by teachers and students/pupils in their work of documenting relevant cases of social innovation;

facilitate bottom-up social learning as a complement to traditional expert-driven learning;

_ motivate teachers to involve students in learning to learn from real life situations.

2. Background

The CONSUMER CITIZENSHIP NETWORK launched the LOLA project in 2005.

The CONSUMER CITIZENSHIP NETWORK - coordinated at Hedmark University College, Norway – is an interdisciplinary network of educators, researchers and civil-society organisations, (including UNESCO, UNEP and Consumers International) who recognize the pressing need for constructive action by individuals in order to achieve sustainable consumption and global solidarity[4]. The CONSUMER CITIZENSHIP NETWORK brings together expertise in the fields of citizenship, environmental and consumer education to further develop research and good practice for teaching and accessing consumer citizenship education. The Network consists of 125 institutions in 37 countries. The project targets lecturers, researchers and teacher trainers in higher education; students, professionals working with children and young people, public authorities, and associations dealing with citizenship training, sustainable development and consumer issues.

[4] Internet address: http//www.hihm.no/concit

Accordingly with CONSUMER CITIZENSHIP NETWORK goals, the LOLA project was started to adapt the needs and ways of the process of case collection by higher education initiated in the EMUDE-European research project[5], co-ordinated by Politecnico di Milano, INDACO Department. EMUDE was a programme of activities which aim was to explore the potential of social innovation as a driver for technological and production innovation, in view of sustainability. Towards this end, it looked for cases where subjects and communities use existing resources in an original way to bring about systemic innovation. In order to identify a collection of promising cases it had set up a network of observers, known as *Antenna*s, encompassing teams of researchers and students from 8 European design schools.

The EMUDE case studies – and progressively other cases collected by some research activities and workshops – compose the **"catalogue of cases of sustainable daily life solutions"** on the Sustainable Everyday Project [6] web platform.

SEP - Sustainable Everyday Project - coordinated by Milan Polytechnic University, Italy and Strategic Design Scenarios, Belgium - started in 2002 and intends to raise awareness about sustainable social innovation through various diffusion channels: a web platform

(www.sustainable-everyday.net), publications, and a series of exhibitions and local events. Most of SEP activities are based on a "catalogue of cases" which's purpose is to empower the promoters of such initiatives giving them the possibility to exchange ideas and experiences; facilitating citizens to participate to such initiatives, to involve a wider audience in a discussion on new ideas of well-being and on how it is possible to promote it starting form now.

Therefore LOLA project inherits EMUDE's didactic methodology and its participants "learn from" and "contribute to" SEP 's catalogue of cases.

3. Tools

Specific tools were designed to reach these goals. The main toolkit was called LOLA ***Teaching Pack***, which contains:

1. ***Student Reporter Book***: supports the collection of cases by the students which consists in an easy to construct booklet supporting the kids in making the interviews, taking pictures and where they are invited to write down and draw all their observations;
2. ***Step by Step Cards***: facilitate the organisation and presentation of the learning process. It consists of 5 preparation cards describing what can be done to prepare each didactic session, and 20 session cards that present alternative ways of organising each session of the investigation with the pupils:

    a) the teachers and students prepare the didactic process in order to help the students in identifying promising initiatives;

[5] EMUDE (Emerging Users Demands for Sustainable Solutions) is a Specific Support Actions (SSA) funded within the Priority 3 – NMP research area: Increasing the "user awareness" of the 6th framework. EMUDE was promoted and developed by a Consortium of European universities and research centres, like National Institute for Consumer Research (Sifo), Netherlands Organisation for Applied Scientific Research (TNO), Philips Design (Philips International), Joint Research Centre - Institute for Prospective Technological Studies (JRC-IPTS), Consumers International (CI), United Nations Environment Programme (UNEP DTIE), Strategic Design Scenarios (SDS) and others. The scientific coordinator was Ezio Manzini (Politecnico di Milano)

[6] The Sustainable Everyday Project (SEP) proposes an open web platform to stimulate social conversation on possible sustainable futures. It is organized around 3 core activities: the constitution of a Catalogue of cases showing examples of social innovation from all other the world developing original solutions promising in terms of sustainability; the organization of a traveling exhibition to meet public events, confront with close scientific communities and give visibility to new visions of sustainable daily living; the promotion of a Scenarios laboratory where new visions of sustainable everyday life are proposed and discussed. The SEP platform hosts several research activities and didactic workshops. The Platform is an organization and communication tool providing an open web space and visibility for activities relating to the fields of design and sustainability in the everyday context. SEP is an independent network funded by public research projects and organization of events. Editorial activities are based on a voluntary participation. SEP events are placed under the patronage of UNEP United Nations Environment Program.

b) the teachers organise the content of the *Reporter Book*[7] in order for the students to have guidelines for searching promising initiatives;

c) the students present potential cases in order to altogether select most promising initiatives;

d) the class prepares for the interviews in order to investigate promising initiatives;

e) the class share the investigation results in order to discuss and share what they have learned.

3. ***Guide Book***, ***Tips & Notes***: to help teachers in organizing the activity in the class a step-by-step guide showing the LOLA process was created to be used both as a reference guide by kids and a didactic guide for teachers;
4. ***Documentation form***: a form to help teachers to document the process and for the LOLA team to get feedback in order to improve and finalize the LOLA work package.

The use of ready-made formats offers information in an easily accessible and adaptable way. However, each class decide its own combination between the steps of the project for pupils to investigate their own neighbourhood, interview people experiencing more sustainable ways of living and come back with a critical view challenging their own living patterns.

A ***Tips & Notes*** booklet is being further developed to be included in the ***Teaching Pack*** in order to help teachers address issues related to sustainability. Vocabulary, some references to existing cases and links to find information about sustainability are simple but effective ways to help teachers better prepare themselves on the subject.

Currently, the LOLA project is promoting its implementation in secondary schools in and also outside Europe. For ensuring direct and clear communication paths with participating schools around the world, the role of “ambassador” was created per region or country, to simplify relations and facilitate feedback to the project. The process of recruiting ambassador’s has already begun. The first task of LOLA Ambassador’s is to communicate and disseminate the project. The second task is supporting interested teachers/headmaster in this participation, showing them the LOLA website where they can subscribe and download the ***Teaching Pack***. The last task is to report back on the participation of the different schools in your country to the LOLA team (to improve and fine tune the *Teaching Pack*) sustainable development.

For such aspects, an ***Ambassador Franchising Kit*** has been created in order to facilitate and prepare their responsibilities. The kit includes:

1. a personal letter for the Ambassador describing the contents of the kit
2. a participation certificate for the Ambassador himself.
3. a set of LOLA brochures;
4. a set of A4 prints to an easy-to-install ***LOLA exhibition***
   (this exhibition is also downloadable in the LOLA website)
5. a complete ***Teaching Pack*** sample;
6. a Participation Certificate for each school volunteering;
7. some reporting formats;
8. all material in digital form on a CD.

[7]

The documentation and evaluation of this process can be seen in two levels: as a teacher using the ***Teaching Pack*** or as an ambassador reporting a general overview of the activities in their countries/regions. This process is useful for giving visibility to the project, connecting teachers, teacher trainers and schools; generating a global perspective of what is actually happening in different contexts or society in terms of initiatives for responsible lifestyles.

In this matter, LOLA intends to connect the work of teachers from several schools through an ICT platform in a collective search for examples of universal value. The objective is to use middle level communication tools aiming to connect ambassadors, teacher trainers, teachers and its students. For this purpose, an easy to use ***Web*** *platform* in the shape of blogs is being designed to connect participating schools, respond to questions, display the found cases, capture the discussion, leave comments, download information and so on[8].

4. Phases

The first phase of LOLA was the pilot project (2005-06) as a follow up of the EMUDE research that involved the SEP actors (see section 1.3 Background). It was then organized in two parts: first generating the contents of the ***Teaching Pack*** in order to organize a method for finding and disseminating more sustainable lifestyle solutions, and a second phase involving four teachers training schools in the process of collecting these cases of social innovation, documenting the didactic process and maintaining an open discussion on the experience amongst the CONSUMER CITIZENSHIP NETWORK members.

The second part involved teacher training colleges in four countries: Belgium (KATHO-RENO, Teacher training college, Torhout); Norway (HIHM, Hedmark University College, Hamar); Lithuania (VPU, Vilnius Pedagogical University, Vilnius); and Portugal (IPBEJA, Politechnical School of teacher education, Beja) in the process of collecting cases of social innovation, documenting the didactic process and participating in discussion on the experience. The pilot project resulted in the development of the ***Teaching Pack*** which has been translated into English, French, Flemmish, Lithuanian, Norwegian, Portuguese, and Slovakian. Separate blogs were opened to collect the work of the students in each school while a main LOLA process blog was created as a reference point for coordinating the activities. The main process blog hosted communication of shared interest and, by providing the possibility of leaving comments to every single posted article, it was thought of as a trigger to exchange experiences between the pilot project's teams. Comments collected on the LOLA process blog represented the seeds for discussion about the project's further development.

An extensive exhibition of the pilot project was made for the CONSUMER CITIZENSHIP NETWORK Conference in Hamar 2006, and in Sophia 2007. An exhibition was also present in Genova 2007 for the meeting of the Italian Task Force on Sustainable Education within the Marrakech Process.

Currently, the LOLA project has started its second phase, the ***implementation phase*** (2006-09). After the successful Pilot Process, the aim is to fine-tune and complete the material by testing it with secondary schools in Europe – possibly further - and re-evaluating through the observation and analysis of those experiences. Many actions are taking place in order to complete this task. Specifically the development of the ***ambassador*** role to help organizational and dissemination purposes; the ***Tips & Notes*** booklet to assist teachers in the usage of the ***Teaching Pack***; and a complete the ***LOLA Web Platform*** to communicate, inform and obtain feedback from participant schools. This process is coordinated by the CONSUMER CITIZENSHIP NETWORK and SEP; and it is also supported by the team of voluntary LOLA Ambassadors (who are active members of CONSUMER CITIZENSHIP NETWORK).

5. Social innovation for sustainability

LOLA project intends to contribute through education and awareness to a change in the currently dominant models of living, production and consumption, in particular giving visibility to new possibilities, through the examples of groups living their everyday life in a more sustainable way:

> *So, contrary to the most common clichés, in social and political terms seeking sustainability is the opposite of conservation or, to be more precise, the conservation and regeneration of environmental and social capital means breaking with the currently dominant models of living, production and consumption, and experimenting new ones*.[9]

This quote refers to the concept of creative communities: "grass-roots organisations of citizens and other actors who have, or could have, the ability and will to re-orient themselves towards sustainable ways of living and producing".[10]

In the LOLA process, students are invited to look for new models around them, promoting a social conversation about possible sustainable futures, or better saying, about the hidden "seeds" of this future.

Considering that, as we will see in the next lines, LOLA is taking part in the movement now discovering "social innovation" as a relevant phenomena to be taken into account if we want to find "new ideas that work to meet pressing unmet needs"[11], here particularly considering the "need" for more sustainable ways of living.

The key point of social innovation theories is how to move social innovations from the margins to the mainstream, considering that social innovations are sometimes understood as a result from the work of heroic individuals, or as a result from much broader movements of change such as feminism and environmentalism. They analyse how social innovations progress through a series of common stages: from the generation of ideas through prototyping and piloting, to scaling up and learning.[12]

"Learning" is keyword in social innovation processes:

> *"The transition towards a sustainable society is a massive social learning process. The radical nature of the objective (learning to live better leaving a light ecological footprint) requires vast experimentation, a vast capacity for listening and just as great a degree of flexibility in order to change when it becomes evident that a road embarked on does not in fact lead in the desired direction"[13].*

> *(…) all processes of innovation can be understood as types of learning, rather than as 'eureka' moments of scarce geniuses. Instead, ideas start off as possibilities that are only incompletely understood by their inventors. They evolve by becoming more explicit and more formalised, as best practice is worked out, and as organisations develop experience about how to make them work. This phase involves consolidation around a few core principles which can be easily communicated. Then as the idea is implemented in new contexts it evolves further, and in new combinations, with the learning once again more tacit, held within organisations, until another set of simplex syntheses emerge*[14]

Types of learning that take place inside organizations, as well as a broader communicational process, are able to promote the transfer of these innovations from one context to another. The replication of social innovation is a key issue that is also being considered by businesses[15] as well as designers[16], these last ones specifically interested in how to replicate innovative solutions maintaining their original qualities[17].

[16] Manzini, 2005.
[17] Jegou, 2006; Cipolla, 2007.

These theories of social innovation for sustainability are particularly related to communicational activities, targeted to give visibility to these spontaneous initiatives that are "seeds" or "signs" of a potential future. This activity is considered as a way to promote a change in the current unsustainable lifestyle trends.

Picture 5: This scheme shows how LOLA uses the Social innovation theories to generate a shift towards a more sustainable mainstream behaiviour

One possibility– as done by EMUDE for example – is use scenario building as a strategy to stimulate social conversation; i.e., design a series of visualisations about how a sustainable future could be lived. These visualisations, based on examples of solutions developed by "creative communities", propose a mosaic of solutions of a "sustainable everyday"[18]

The LOLA project – as a didactic project – acts in a similar way. It does not propose to build scenarios, but stimulates students, teachers and eventually their parents to participate in a "virtuous circle"[19]: initially as "antennas"- detecting promising cases of social innovation for sustainability but also reinforcing these signals through the discussion with their neighbours, schoolmates and parents and interviewing people who are living differently in the reality around them. These conversations insert participants in a broader leaning process, able not only to "transfer" social innovations for sustainability from a extended context to a more near and personal one, but stimulating changes in students (and teachers!), personal attitudes and views about the way they can live everyday life. It's also necessary to add that extra material as the ***LOLA Exhibition***, ***Web Platform*** and SEP's "catalogue of cases" share the role of communicating best practices outside the project's domain, i.e., make them accessible to a broader audience.

6. Collecting cases: qualitative criteria

As we have learned, LOLA project is based on a process of collecting case studies. Which kind of cases studies does LOLA encourage students to look for?

This question indicates the qualitative criteria that form the basis of LOLA didactics and can be described as follows:

1. innovative solutions;
2. bottom-up organizations;
3. socially positive;
4. 4. environmentally friendly.

These criteria were also used in the EMUDE research project, during the phase on which students were invited to observe and collect cases in their own countries. Therefore, these indicate the common ground of SEP's catalogue of cases, the same catalogue that invites to integrate the cases collected by LOLA project, exemplifying promising solutions in terms of sustainability.

2.2.1 innovative solutions

Students are invited to collect cases presenting organizations of different social actors (local-social actors, see next point), which organize themselves to get a result or to open a new opportunity in organizing daily life. The solutions have to be innovative in relation to main stream thinking and action - for what regards places observed per se are not solutions in the sense we are using here, for example: an interesting ecological building, a place with beautiful monuments or a medical therapy.

2.2.2 bottom-up organizations

The promoters of the solutions have to be "local": the same with final users, local entrepreneurs, local NGOs, local institutions. However, the notion of what can be considered as "local" is relative: a regional initiative is local in relation to the national scale, a city initiative in relation to the regions, the neighbourhoods in relation to the city, and so on. In our case, we will consider an initiative as "local" when the promoters operate at the scale of the neighbourhoods and/or of a little city, although they may be linked with larger organizations.

2.2.3 socially positive

The solutions, getting a result or opening a new opportunity (see section 2.2.1), regenerate the social capital and strength the social fabric. They have a socially regenerative effect that takes place directly (it is a formal goal of the initiative) or indirectly (it is not a formal goal of the imitative but, nevertheless, it happens).

However the social aim should not be the main and only one: a case is promising because it is possible to imagine as "a model for new ways of being and doing". Charity and/or social improvement programs are very good initiatives, but they don't insert themselves in everyday life as models of new ways of living for the whole of society. In some cases, few charity initiatives organized bottom-up by the same in need can propose objectives and organizational models that could be valuable also for other people, becoming a more general model of doing.

2.2.4 environmentally friendly

The initiatives - that get a result or open a new opportunity (see section 2.2.1) - reduce previous average environmental foot-print. They should have an environmentally regenerative effect that takes place directly (a formal goal of the initiative) or indirectly (not a formal goal of the initative, but, nevertheless, it happens).

However, the environmental aim doesn't have to be the main and only one. They do not need to be initiatives directed only towards solving some environmental problems as recycling wastes, renewable energy generation, pollution prevention, etc. They should be activities attempting to achieve a positive result or to open a new opportunity and, while doing that, solving some environmental problems (as recycling wastes, using renewable energies, etc.).

To resume, the cases targeted should have an embedded balance between these four elements, accepting that one or more of them can be predominant due to the aims established that motivate the participants to join and persevere in their practice.

7. A "designerly way of knowing"

The LOLA project was presented and analysed here in terms of issues of social innovation for sustainability, pedagogical theories and ICT. LOLA's core activity is based on the process of collecting cases of social innovation. The key pedagogical activity is the definition of the qualitative criteria used to discuss the value of these cases in light of sustainability. Four criteria were examined: *innovative solutions, bottom-up organizations, socially positive* and *environmentally friendly*. These criteria are "initial filters", or "guidelines", because teachers are themselves involved in the learning process with their students during the collection. Here LOLA adopts a phenomenological approach: the value of each case needs to be particularly examined and discussed, and teachers are considered "facilitators" of this process. Students are invited to "discover" the "hidden seeds" of a sustainable future in their surroundings, not only "observing" cases but also arriving to have interpersonal interactions with its promoters. This entire process is targeted to promote changes as to how students interpret "reality", promoting the emergence of new meanings that, hopefully, will be more sustainable.

The importance of adopting ICT in LOLA goes beyond operational issues strictly related to the development of the project itself. Specifically, bearing in mind the fundamental themes of sustainability (environmental and social), connectivity and globalisation, we will have to learn to live better consuming less and regenerating our physical and social environment in an ever more closely and extensively interconnected world. Therefore, efforts to use ICT in LOLA project – now and in the future – can be considered also targeted to create communities of "sustainable" practices that could hopefully evolve in innovative and promising forms of collaboration.

Last but not least, the LOLA project develops also a "designerly way of knowing"[20]. Students are stimulated to understand "how the project start", "who are the users", "which user need does it answer", "what are the aims", "what works well in the solution", and other questions that implicitly induce students to recognize initiatives in a "solution-focused way", or as a result of the arts of planning, inventing, making and doing. So LOLA is more than an "observation" of what is happening around, or a *learning-with-good-examples* practice. It intends to promote in students – so far as possible – the idea that people are able to "design" for themselves, to solve problems and to live in a sustainable way. So the question that each student is being invited to do is: can't I do the same?

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design Activism as a Tool for Creating New Urban Narratives

Guy Julier[1]

Abstract

This paper reports on the activities of an alliance of artists, designers, architects and community activists in the development of a campaign to open up the imagination of how a large, complex city might act on its present and view its future. This is broadly dedicated to the development and diffusion of a counter-narrative of urban identity that provides new models for the everyday life of the city. It highlights the ordinary processes in the maintenance of collective endeavour. It also reviews the ways by which shared visions are fostered and the political challenges this poses. By focusing on processual measures across a community, the possibilities of design activism, both as practical action but also as political agency, are discussed.

[1] Guy Julier, Leeds Metropolitan University, UK, School of Architecture, Landscape and Design, Professor of Design, Contact: g.julier@leedsmet.ac.uk

Introduction

This paper is concerned with design activism both as social action and political agency. It reports on a number of initiatives undertaken within a defined locality that bring together otherwise quite fragmented activities. These activities involve groups or individuals engaged in various forms of creative practice for social and environmental benefit. They are largely working in the third sector, that is in the voluntary or non-government sector, often funded by national, regional or local government grants or charitable support. In bringing them together, a sense of shared identity and purpose is defined as well as the opportunity for mutual support. At the same time, this networking takes place in a larger discursive field regarding the promotion of certain values as to what an urban agglomeration might be – in stark contrast to what it is. This new 'discursive field' itself is more self-consciously created by an alliance of interests.

Design activism itself broadly encompasses a wide range of real-life processes from greening neighbourhoods to transforming communities through participatory design action. Anne Thorpe takes activism to involve intentional action to bring about change, adding that her concern is with the actions that are visibly public in nature, rather than the 'day-to-day, behind the scenes administration of groups' (Thorpe 2008). The ground presented in this paper is indeed highly public. It concerns a city-wide debate on its future in terms of governance, planning and identity. While many of the activities that are reported on exist very much within the 'day-to-day', they therefore also connect to large questions. Necessarily, there is a degree of discussion of 'behind the scenes' activities that reveal some of the dilemmas and solutions in mobilizing design activism.

The Codification of Place

The context for this paper exists at two interrelated levels. One is in the wider practices of urban design and place-marketing in the UK over the last 10 years. The second exists more precisely in the particular conditions of economics, planning and governance of the city of Leeds that has produced an urban problematic. Leeds is a city of some 700,000 inhabitants in the north of England – 150,000 of them are in the bottom 10% of income levels. Some 140,000 of this population live in its inner suburbs (Unsworth and Nathan: 2006). This latter problematic to be found in Leeds is most probably transferable to other UK cities, although its generalizability to other countries may be debateable.

The post-industrialisation of modern cities and their slippage into knowledge economies has produced a seemingly unending requirement to compete with each other. Within this perceived imperative, new systems of governance are created, strategies are formulated and slogans are written.

For example, in 1990, the Leeds Initiative was founded. This strategic partnership brings together the public, private, community, voluntary and faith sectors to create policy and its implementation with regards to economic and social development. At one level this is typical of the 'agentification' has emerged in neo-liberal governance (Whitfield 2001). Through the Leeds Initiative and other local government strategic bodies, large amounts of policy have been turned over to so-called ALMOs (Arms' Length Management Organisations). Social and economic policy, previously formulated and carried through by the state, is formulated and played out by a partnership between national, regional or local government and a wide and sometimes fragmented range of NG0s and other interests.

At another level, such systems of governance are driven by target-setting and attainment that is promoted through rhetorical boosterism. For example, the first of the Leeds Initiative's aims is, 'Going up a League', 'making Leeds an internationally competitive city, the best place in the country to live, work and learn, with a high quality of life for everyone' (Leeds Initiative 2004).

This policy of boosterism has also given way to the emergent discipline of place-branding. In their efforts to distinguish themselves, many authorities of urban agglomerations have developed marketing strategies that identify and roll-out their unique selling propositions, encapsulated in a slogan and graphic applications. Thus, 'vibrant', 'cultural', 'diverse', 'cosmopolitan' and 'sophisticated' are frequently used descriptors that seem to almost come straight out of the Richard Florida (2002) textbook on how to lever a Floridean version of the creative city into a marketing campaign (see Julier 2005). In 2005, MarketingLeeds, a body set up to promote the city, launched its own city brand at a celebrity filled launch in the city's famous shopping quarter. Conceived by a local branding and communications group entitled An Agency Called England, it featured the slogan, 'Leeds. Live It. Love It.'. In developing this identity, the agency undertook a survey of Leeds residents to discern if the city was a person, what kind of person would that be. The research that came back was that Leeds would be, '..a young male, friendly, your best friend, a reall nice person to know, an ambitious person, living in a trendy apartment, driving a Volkswagen Golf GTi' (Scott 2005). This would be used to articulate the new Leeds brand.

Such initiatives imply a codification of urban experience. How a city is, how it is lived, what aspirations one might have within it are set out, almost literally, by the brand strategy handbook.

Another level of codification has also emerged within the practice of urban design and planning over the past 10 years. The UK government's Urban Task Force, founded soon after New Labour's election to power in 1997, published its highly influential policy statement *Towards An Urban Renaissance* (Urban Task Force 1999). This and the subsequent Urban White Paper (2000) came amongst a plethora of government policy that attempted to address urban living in the postindustrial era. For the first time, design was placed as a key component in the revitalisation of urban areas.

Its trickle-down effect to regional and local governments has led to the production of numerous design guides, compendia and statements. The Urban Task Force document made linkages between design, the sustainability of communities, demographic change and economic activities (UTF 1998: 27-34). None the less, its translation into government policy and thence into application at local level has tended to focus largely on a narrow interpretation of design as engaging its purely formal rather than processual features. Implicit in this is a behaviouristic model of urban design that is deeply embedded in its theoretical backgrounds (see Cuthbert 2006). In brief, this approach is firmly rooted in a purview of space as the assemblage of typologies that are based entirely on their material, contextual delineation rather than on practices of everyday life. Thus, for example, we hear of 'settlement pattern', 'urban form', 'urban space' and 'built form' (eg. DCLG 2006: 65) rather than the human infrastructure of, say, 'kinship', 'mobility', 'social networks' or 'labour'. Whether it be the guides on 'best practice' in developing design codes or the design codes themselves, the emphasis is on design that *produces* attitudes and behaviours in and toward places. Put the other way around, despite the recurrent reminders that public consultation is generally a good thing in the development of design guidelines, the end result is a particular, specifically cast narrative of what urban living should be. This narrative is, in turn, served up as something to be consumed, adhered to and adopted as a disposition or, as Bourdieu (1984) would have had it, an urban *habitus*.

As with any marketing strategy or masterplan, this is all well and fine when there is consensual buy-in on the part of the internal audience of an urban agglomeration – citizens, in other ways. This is most likely to happen in the context of economic success, social cohesion and environmental stability. However, even in the most ideal of circumstances, this doesn't' go uncontested. The Urban Task Force vigorously championed Barcelona as a city that had achieved this. Resistances and debates concerning its 2004 Forum swiftly showed how easily this perception can be destabilised (see Degen 2003).

Trouble in Leeds

Where the traditional economic, social and environmental order is in crisis, or is, at least, challenged, so the dominant narrative of what that place is may also come be contested. This seems to be the case in Leeds.

Over the past 20 years, Leeds and its city-centre in particular has undergone significant change. Key features include:

- re-imagining of the city as 24 Hour City with 'European' allusions to being the 'Barcelona of the North', 24 hour café society and city centre living from the early 1990s (Haughton and Williams 1996);
- employment in manufacturing dropped from 33 per cent to 17 per cent 1977-1993 (Leeds City Council 1998);
- growth of its city centre population from a few hundred to a projected 20,000 by 2015 (Knight Frank 2005) (NB. this will only account for 2% for the city's population (Fox and Unsworth 2003));
- £1.4b. worth of office and apartment schemes under construction at the end of 2006 and a further £5.8b. proposed – a total of £10.4b since 1997 (Leeds City Council cited in Chatterton and Hodkinson 2007);
- reduction of social housing stock by 40,000 over the past 25 years with a further reduction of 10,000 by 2016 (Leeds City Council cited in Hodkinson and Chatterton 2007).

Leeds has been marked by a rapid growth of service industries in the city centre, particularly in the financial sector and a related growth of private city-centre dwellings, almost entirely directed at younger upper-income owners with little ambition to long-term settlement there. Hand-in-hand with this development has been a vigorous dedication to the hard landscaping of the city centre, in line with many other city centres.

Without, 'a Masterplan for the city, nor tall buildings policy, nor energy strategy, nor integrated transport strategy nor public realm strategy', this has led to a situation where city planning has ignored, 'the notion of unlimited demand for deep plan air-conditioned commercial space and constantly refused to acknowledge that sustainable design may have a commercial value' (Bauman 2008). Equally, on a recent visit, Wayne Hemingway branded the city as, 'the most unsustainable' (Waite 2008).

In recent months, this strategy, or lack of strategy, has led to something of a planning crisis. As the city's river Aire burst its banks – the second major flooding of the city centre inside a year – so this gave visible evidence to the need to build a more sustainable approach to urban planning and design. In the background, the development boom has passed its zenith. The credit crunch of early 2008 and loss in demand, has led to many schemes being put on hold, including the £160m. Spiracle tower, a building for which the city's only city centre public swimming pool was closed to make way for.

This concentration on the city-centre as a capital intense, transaction rich and design and development dense hub contrasts with Leeds's inner suburbs. This city 'rim' is characterised by high levels of deprivation, a run-down housing stock and low levels of 'official' economic activity. Added to this is are topographical and planning issues which have caused these areas to be relatively cut-off from the city centre. Thus the benefits enjoyed by high investment in the city centre urban realm are not transferred to the rim, in terms of regeneration, by a 'ripple effect'. If there has been a strong narrative of 'going up a league', of Leeds as the international, 24-hour city to do business in, of retail-fuelled loving-it-while-you-live-it, then 2008 may be the year in which this version of the city gets re-coded.

Design Activism Re-Awakens

Set against this context of city-centre growth ‘at all costs’, 2007-8 has seen the emergence, or I should say, re-emergence, of design activism as a practice where a constructive counter-narrative is taking place.

Leeds has a strong history of counter-political action connected to creative practice. For example, it is home to the Leeds Animation Workshop. This was founded in 1976 as a group of women who came together to make a film about the need for pre-school childcare. Since then they have produced numerous titles on social issues. Leeds is the home of Leeds Postcards. Founded in 1979, this group set the standard for activist stationery in the 1980s. Leeds is also where, via a slow process of community participation, steps were made in the 1990s to the establishment of Britain’s first Home Zone, turning residential streets into mixed use civic spaces (see Julier 2007: 204-8). This history certainly acts as inspiration. But many of the people who have been actors in this history have brought their experience to bear in the current situation. This isn’t student protest. It is action carried by many people with considerable experience of carrying forward complex projects and in different contexts of urban governance. In addition to this, recent years has seen the rise of a number of ‘design activist’ social enterprises. Examples of these include:

- Hyde Park Source, who create gardens and play areas out of derelict areas;
- Ketchup Clothes who create new fashionware by recycling existing garments;
- East Leeds FM, a radio station that incorporates community discussion fora on sustainability and the neighbourhood design issues.

From 2005, there has been a considerable re-birth of activism in Leeds that is centred on sustainability, urban form and governance. Thus environmental, design and political (with a lower-case ‘p’) questions are linked (summarised in Fig.1).

This impulse toward activism is held within particular special interest groups within civil society, university academic departments and some professional creative practices. While several fora and groups constitute a broad alliance of activists, movement between them is fluid in terms of ideas, action and people. Such porosity maintains an open sense of participation and inclusion while each group is coordinated or driven by key activists. Also noteable is the close relationship between public lecture events, workshops and symposia, and their leading to the foundation of action groups. Indeed, the call for papers for the Changing the Change itself acted as a catalyst toward the concretization of further design activist initiatives.

Within this micro-history, a key moment were protests regarding the city’s Corn Exchange. At the end of 2007, the Leeds City Council allowed its leaseholders, Zurich, to evict all of the building’s independent stallholders in order to usher in greater turnover and higher rent-paying businesses that belonged to multiples. As this building was a favourite haunt of teenagers on Saturday afternoons, this drew a vociferous and concerted protest. This may seem like a banal affair. However, it was an important watershed in citizen participation in protest as to the governance of Leeds. The notion that there would be consensual buy-in to a vision of city development as embodied in relentless retail development and gentrification is presumptuous.

This event led to a discussion event in early 2008, attended by 250 citizens, as to the direction of the Leeds city centre – its management, governance, form and planning. It was entitled ‘Leeds: Are We Going In The Right Direction?’ and was hosted by the School of Geography at Leeds University. While overtly critical of local authority approaches, it also fostered a sense of positive contribution to planning processes and a willingness to engage local government. Many of the broader wishes of these citizens coincided with stated local authority policy – the development of more green space, better public transport, more affordable housing, better cultural resource. But the development of such fora shows a will on the part of many citizens to see such developments realised. It plays an alternative form of political pressure to the four yearly and underused ballot box.

LoveIt.ShareIt.

The new landscape of peak oil, climate change and of the crisis of many financialisation and property initiatives, and with it of the naïve belief in continuous growth model, requires new understandings and an ability to think laterally and holistically (Bauman 2008). The scale of participation in events such as 'Leeds: are we going in the right direction?', reported above, is evidence of a lack of confidence in the leadership of the city to deliver the requisite new thinking for these challenges. This condition has given rise to the emergence of a strong radical movement in the city under the slogan of 'LoveIt. ShareIt', a play on the Leeds brand, 'LiveIt.LoveIt.

This initiative is made up of individuals and groups, networking creative practitioners, academics and activists. Its steering group currently comprises Irena Bauman (Bauman Lyons Architects), Sue Ball (Media And Arts Partnerships), Rachael Unsworth and Paul Chatterton (School of Geography, Leeds University), Andy Edwards (independent graphic designer), Andy Goldring (Permaculture Association) and myself. As such it comprises an alliance of creative practitioners and members of the academic community.

So far it has identified two aims for the coming months. The first is to undertake a mapping of the inner suburbs of Leeds, paying attention to three aspects:

- social institutions – eg. sporting or leisure clubs, faith groups, support groups;
- green space use – eg. gardens, allotments, left-over spaces, derelict space;
- grey economy – eg. informal childcare networks, vehicle repair activities.

By doing this it is hoped that attention is drawn to the resources that are available but invariably overlooked in these areas and that provide important infrastructures for the sustainability of these communities. It brings this, largely shadow, rim back into the wider picture of the city. It also begins to counter the notion that urban regeneration can take place from the centre outwards by helping to develop resilience of localities. It is intended that this action is both scaled up and down. It has started with a pilot project in the city's Richmond Hill area to test mapping processes and its forms of representation. This prototyping will then contribute to a toolbox which can then be rolled out into other areas of the inner suburbs. At the same time, it is expected that this toolbox can be used and adapted by communities themselves, thus scaling the process down and allowing for greater participation and less concentration in the hands of 'experts'.

The second mid-term aim of LoveIt.ShareIt is the development of an alternative vision for Leeds, counter to the already mentioned Leeds Initiative's official one. This will be guided by three aspirations for the city that are stated in the group's manifesto. These are:

- conviviality: supporting a diversity of forms of living;
- resilience: consolidating economic and social patterns that are tolerant of external change;
- beauty: nurturing a cityscape that exhibits a compelling material and human infrastructure.

The group is planning toward a document that will identify promising scenarios, existing and future tools as well as impact assessments that recognize the interlocking potential of design and/or communitarian activism and urban regeneration. Ultimately, it is envisioned that within 5 years, neither LoveItShareIt nor the 'Leeds. LiveIt. LoveIt' slogan need exist. It is hoped that the city may by then have adopted a new urban disposition.

Leading on from this, and also a number of other initiatives in the city, efforts are underway to create a wider, more inclusive and representative network of creative practitioners who are engaged in environmentally and socially committed activities. Around LiveItShareIt is also the Design Activism Group that has sprung from Leeds Metropolitan University's School of Architecture, Landscape and Design. The latter hosted the first national symposium 'Mapping

Design Activism' in 2007. This event instigated a discussion as to the history, topography and identity of design activism. In 2008 it also hosted a 'Gala Awards Evening' that mixed carnival (eg. cabaret acts, live bands) with an opportunity for various practitioners to meet and form closer contacts. Citywide design activism initiatives were mapped and future collaborations discussed. This was facilitated by a 'do-it-yourself' awards process, where participants made awards to each other in recognition of their respective achievements.

Discussion

The aims of LoveItShareIt and design activism in Leeds are unashamedly ambitious. They demand:

— the creation of new scenarios and visions for Leeds;
— a radical reappraisal of city-wide planning that embraces space use, social arrangements, local economies, mobility and connectivity;
— a reinvigoration of citizen participations in urban governance;
— new roles for creative practitioners within these aims.

These probably also seem rather utopian, touched by the enthusiasms that accompany the early imagineering of a project before the reality pinrciple of delivery sets in.

In terms of the initial mapping project, it is difficult at this stage to predict what the outcome of this initiative might be. At one level, it is about creating information systems through which localised social enterprise and everyday practices may be supported or support themselves. At another level it also carries a potential to broker new relationships between local government policy (and its partner organisations) and citizens. For example, within Leeds City Council, its Local Enterprise Generation Initiative (LEGI) is dedicated to developing entpreneurial activitiy in deprived areas. So far this has gone mostly toward supporting enterprise centres that provide advice and training for new businesses. The LoveItShareIt mapping may help as a catalyst to recognising the social connections required to stimulate local and sustainable enterprise. Implicit in this is an orientation away from a traditional, economically-led growth model of enterprise that is currently embedded in LEGI thinking.

In such ways LoveItShareIt may work to match up local government policy that is delivered through a fragmented range of agents and the disparate landscape of social enterprise and design activism (see Fig 2). At the same time, with its emphasis on socially and environmentally committed practices, LoveItShareIt demands a different story to be told in terms of city aspirations.

The classic and implicit dilemma here is the extent to which design activism practitioners are prepared to adjust to local government policy or, conversely, the extent to which local government is prepared to adopt new frameworks of practice. In terms of the latter, the demands for more sustainable forms of urban living combined with the challenges to current orthodoxies in city centre property development might orientate local government toward a new attitude. That said, a counter argument put forward by Buck (2007) is that ultimately, capital and neo-liberalism (which, ideologically is at the heart of city council policy) will always prevail through constantly propelling itself into new technological frameworks. Corporations, it is argued, will always find a way to install themselves at the head of whatever pile.

In the meantime, design activism in Leeds draws sustenance in two ways. One is in developing an internal sense of identity, a shared language and knowledge as to how to overcome everyday challenges. This is partly achieved through the use of events to bring such activists together. The other is by looking outwards to other sources of inspiration. Thus, for example, Demos's 'City Dreaming' project that sought to engage citizens in defining future visions for Glasgow is one touchpoint. Another is David Barrie's production of the Middlesborough's urban agriculture project.

Meanwhile, urban agglomerations consider their next step as to what experiencing urban

life is. The stories that have been offered in place-branding and in design-led regeneration have so far been limited. Design activism, such as that offered by this paper, may open up new texts and textures for urban existence.

DESIGN VISIONS PROPOSALS AND TOOLS

Other Design at Sulukule:

A Local Development Project in a Degenerated Historical Area of Istanbul under the Threat of Demolition

Cigdem Kaya[1], Burcu Yancatarol[2], Asli Kiyak Ingin[3]

Abstract

The new policy of urban generation in historical Istanbul includes areas with significant cultural heritage. The perspective of this renovation policy lacks the social dimension of sustainability and tends to replace the mature and colorful fragmentary texture with shiny shopping centers and chain hotels while ignoring the unique cultural establishment of communities.

One of these areas are two neighborhoods (Neslisah and Hatice Sultan) known as Sulukule, an old Romani settlement famous for its music and entertainment culture. This study is going to reveal the process of intervening to the area by design for a healthy social transformation. The results of this project shows the potential of valorizing local production and draws a framework for using design as a tool for socio-economic resistance in Istanbul neighborhoods.

The aims of this project are to help the habitants stay in their native land, to institutionalize their material culture (which is being rejected by the local government), to help them gain self-confidence via learning the production culture, and finally to equip them with social and economic toolkits of community empowerment.

Design's Capacities

It can be suggested that the tools taught in industrial design education can be used efficiently to assist the local community with fostering and sustaining local production. If an industrial designer can see his/her practice as the process of creating an entity as opposed to the finalized mass produced item, s/he can appreciate the outcome of a process that is not necessarily produced in a factory. This ability of appreciation will stretch how this production can be placed in the world: introduced, communicated and sold. This could also be regarded as a stance of the designer between the world of factory production and one of a kind sculpting. The industrial designer's toolbox, equipped with skills geared towards mass production, can be reshaped by the contexts where design vision needs to take different forms, and may even be formless.

In his lecture 'Culture as Our Chance, of Finally, Being Human' at Parsons the New School for Design, Dilnot (2007) noted several capacities regarding *'the role of design in relation to cultural work.'* by *'….identifying, even if very loosely, the capacities that design entails which might allow design to engage, even if symbolically, in making a humane world.'* Dilnot (2007) aims to illuminate the ways that design can be a part of everyday life in a more humane, responsible and responsive manner. Grouping these capacities in five areas also indicate the roles that design; thus the designer can take on in their practices apart from focusing on the end-product:

1. Design capacities as capacities to do with organizing and planning (organization, planning, programming, scenarios, schematics)
2. Those to do with mediating and attuning our relationships (negotiation, mediation, attunement, resonance, reciprocity)
3. Capacities of moving from existing to preferred situations /capacities of intervention (translation, intervention, transfiguration, (re-)configuration, disposition)
4. Natalic capacities, those involved in bringing something new into the world (possibilities, propositions, origination, invention, innovation)
5. Transfigurative and poetic capacities (transformation, revelation, transfiguration, poetic gauging of existence, aesthetic discovery)

These capacities are also processes. Every process requires a certain investment of technical, social and communicative skills that can be adapted to new contexts. Therefore, a designer's skills in her toolkits are re-configurable and adaptable to utilize design's capacities as processes that are not always linear but emergent, organic and semi-organized (Dilnot, 2007).

In the following sections, first, the necessity of social transformation and its dynamics will be explained. Then, the case of the Romani neighbourhood of Sulukule in Istanbul will be introduced as an example of gentrification as opposed to a zone of healthy rehabilitation as a result of the global dynamics that are active in the city. The outcome after two years of field work at Sulukule can suggest a guideline for designers who would like to place themselves as agents of valorising the potency of a community in means of cultural production.

The Grand Narrative of the Spectacle

Representing a city in a global network means not only branding it but also re-evaluating its assets: '….*Hard assets include natural beauty and features; shopping facilities; cultural attractions; and buildings, museums, monuments and the like. Soft assets are all about people and culture: skills, traditions, festivals, events and occasions, situations,*

settings, social ties, civic loyalty, memories, and the capacity to facilitate learning of various kinds.' (Thackara 2005, 79) These assets need to be abstracted from their local meanings to a form of exchange and/or symbolic value so that they can be utilized for the city's desired level of integration with the global economy. This process of re-evaluation requires the identification of the city's 'functioning' and 'non-functioning' parts to better operate the grand mechanism of turning the city into a 'spectacle'. In Debord's words, '*for what the spectacle expresses is the total practice of one of the particular economic and social formation; it is, so to speak, that formation's agenda.*' (Debord 1967, 15)

Architect Teddy Cruz (2004) states that after 9/11, the Pentagon '*re-conceptualized the perennial division of the world into northern and southern hemispheres, first and third worlds.*' (Cruz 2004) As Pentagon strategist Thomas Barnett (2004) points out, this new categorization of the world re-identified the parts of the new polarization directed by globalization as the **functioning core** and the **non-integrating gap** according to their development levels. The functioning core is characterized with '*those parts of the world that are actively integrating their national economies into a global economy' s*uch as North America, Europe, China, Australia and New Zealand, South Africa, Argentina, Brazil, and Chile (Barnett 2004). On the other hand, '*regions of the world that are largely disconnected from the global economy and the rule sets that define its stability*' such as Caribbean Rim, Africa, the Balkans, the Caucasus, Central Asia and the Middle East are classified as the non-integrating gap (Barnett 2004). The imaginary borders drawn between these functioning and non-functioning parts constitute the '*thresholds of the current global socio-political geography*' (Cruz 2004) and are re-formed constantly. The tensions emerging across these imaginary borders between the poles of development show how ' the functioning core' insistently approaches 'the non-integrating gaps' as the execution sites of its global economic and political agenda that aims to control the global flow of capital through revised strategies of colonization, assimilation and marginalization.

It is crucial to recognize that the global dynamics and their social, economic and political workings are active not only between nations or continents but also in smaller contexts since the fundamental act is to create centres of power by dividing while uniting. That's why; it is possible to scale the concepts of 'the functioning core' and 'the non-integrating gaps' down to an urban context to better understand the relationships and their consequences. By decreasing the size of the field, the flows of global dynamics become traceable with their tangible side effects.

To be a significant node in the global economy (metropolis) the city has to go through strategic transformations that are led by political, economic and cultural actors in the scene. The grand agenda of turning the city into a spectacle and commoditization of everyday modes of production involves the spread of spectaclist aesthetics through urban transformation in a manipulative way. With this agenda, the functioning cores and non-integrating gaps of the city are identified and the polarizations are emphasized in order to better strategize urban transformation as an aesthetic project and to generate projects for the spread of the 'preferred' aesthetic from the metropolitan centers to non-functioning peripheries. It can be said that the hegemony of glorification disguised as development spreads with regard to the application methods of the grand spectaclist narrative.

The grand mechanism works in two ways: 1.The local, the non-integrating gap is commodified and exotisized with its social-economic struggles so that it appears to be an asset (a touristic one just like the Brazilian favelas) that can be promoted with an emphasis on cultural diversity. 2. The periphery which projects shadows on the city's bright face is 'cleansed' from its current struggle by filtering the useful assets (such as valuable land, historical monuments etc.) and revitalizing the area: gentrifying simultaneously.

According to Cruz (2004) the grand mechanism's focus '*on the extreme areas of development in many cities around the world shows the urgency for many metropolitan*

centers to engage in the relevancy of new economic models of revitalization through privatization'. (Cruz 2004) However, non-integrating gaps are constantly subject to the functioning core's pressures to either transform them according to the aesthetic agenda or to marginalize them to the degree that socio-economic degradation splits the communities apart.

When the production of the spectacle via globalization is scaled down to the city, partial consequences of colonization in the non-integrating localities (the land, the residents and the material culture) can be observed. The colonialist approach of the city's globally functioning parts defines these localities as disempowered non-globals by '*progressive spatial segregation, separation and exclusion*.' (Bauman 1998, 3) This is the reason it is worrisome that the communicational breakdown between the globalizing communities and the traumatized localities help sharpen the gaps (Bauman 1998,3).

In 'The Society of Spectacle', Debord (1967) states that the city as a spectacle *'brings in negation and consumption in the cultural sphere.'(*Debord 1967, 129) In the cultural spheres of the city, the great agenda of aesthetization applied on the material culture of localities through consumption negates the nature of the local everyday production. The organic and cohesive production in the locality is interrupted and '*dissipation of communal networks and forceful individualization of destiny*' traumatize the communities (Bauman 1998, 100). On the other hand, aesthetization of everyday production as a local initiative with the residents-defined not as 'the receivers' but 'the participants'- has the potential to get around the grand strategy and counter-direct the global dynamics in the city. This is why aesthetization of everyday through consumption and commodification of cultural production in the localities can be a tool for people with design training to assist the non-integrating gap to be visible. This involves re-designing the residents into the local production and solidifying the *'the territorial capital into a policy or a design program.'* (Thackara 2005, 79)

The focus of this study is to understand how tactical aesthetization of everyday life through design by re-evaluating the modes of local production in degenerated neighborhoods and turning their exploited relationships with the functioning core to a negotiation of authorship, resources, labor and money can empower the non-integrating gap.

The Commoditization of the Local in Cultural Production

The consequences of globalization with its ties embedded in modernity have defined new polarities discussed above. In a designer's point of view, 'global' connotates unification, being all identical, spheres: economical, political, cultural... 'local', however connotates difference, multiplicity, micro practices, minority and accent. Physically explaining, the global is indifferent to location. It is not site-specific.

What then are the properties of the vanishing local? Locality recalls the word 'vernacular' for an industrial designer. For a sociologist it can be an issue of minority, for an economist a field of poverty. From a broader perspective it may even correspond what opposed the nowadays understanding of 'innovation' and 'development'. For Hardt and Negri (2000), local is the key generator of multiplicities. In their book *Empire* and *Multitude,* Hardt *and* Negri (2000), optimistically point out that globalization have formed unusual practices and perspectives: unregistered economies, black markets, fake brand production and localized sit-coms (Hardt &Negri, 2004).

Overlooked by the centre of globalization, these practices are identified to have started in underdeveloped countries. However, their existence indicates a symptom of a disease: the automatic reaction of the immunity system of the society. It is not designed. It is not planned. It emerged as a back door solution. What can our society learn from the genuine solutions of the poorer? It can be discussed that these motives are good for sustainment, since these movements are emergent bodies as opposed to being top to down.

Also, the variety and the density of unregistered trade of information, items, technology and culture are related to the density of the globalization. The more severe globalization spreads, the more severe the reactions will respond. Locality mirrors the global back unto itself as a replica which validates the aesthetics of the cheap through accessibility.

The local, resembling the content of the vernacular, has been made 'contemporary' by the dominant actors of the market. The global economy adopts local forms to create local accents for global production, still having the say to choose or leave when necessary.There is two applications of this: 1) The famous Ottoman motif 'cintemani' appeared in several haute couture collections in the 90's. This elegant, niche and expensive quotation was regarded as an exquisite interpretation of Turkish culture. It was an outside-global- signal that broke the internal- local- stigma. 2) In the 2000's these local motives are used in all sorts of unregistered design and production in its cheapest way. They are appropriated as a design stance by some designers and some designers keep referring them as the exotic other. From this argument, it can be said that the belief that there is a novel methodology to borrow local designs is not true. They are collective property: heritage, in a sense.

Sticking to local values and negotiating in between ways as opposed to high modernism created hybrid modernities, hybrid forms and hybrid practices. However, in the current value system of aesthetics, these hybrids are overlooked and underestimated. While, powerful designers love to use locality's exotic face, the local is rapidly being dislocated from everyday life and washed away by leaving its objects as history in museums.

Gentrification Becoming an Epidemic

One common method of dislocation in the city is gentrification. As discussed in the first section, the non-integrating gap has to be cleansed for its useful assets: the valuable land. (Yardimci 2005, 38-39). Gentrification, particularly in Istanbul, has direct effects on the dislocation of marginal cultures. The enactment of dislocating these communities means to rip off their cultural bonds with the localities and to erase their culture from the cultural memory of the city.

In his talk about his focus on Istanbul, Cabannes states that Istanbul right now experiences all the problems that all metropolitans will experience. The city as the economic and cultural capital of Turkey receives massive amount of migration and is a place where approximately 13 million people (city records, Istanbul Metroplolitan Municipality, 2008) from many different places and backgrounds live. Due to the tremendously high rate of migration and income difference, new neighborhoods are formed as the size of the city grows day by day. These bring many sensitive issues about how to use design knowledge to construct the local within the city in a healthy way: in a neighborhood scale. Quoting Cabannes: *'If Istanbul succeeds, we will all succeed.'* (Cabannes, 2008) Sustainable construction of localities with the help of design will show that localities are indeed the building stones of a socially just and culturally diverse city.

Looking closer at the city, the two 800 year-old Romani neighborhoods, by the ancient city walls of Istanbul, known as Sulukule (Neslisah and Hatice Sultan Neighborhoods) is the first field to observe the applications of cultural dislocation under the name 'rehabilitation'.

Figure 01. The Sulukule area

The field

The word ‘Sulukule’ can literally be translated as ‘Water Tower’ after the water distribution system during the Roman Empire. The abundance of the baths, fountains and Byzantian cisterns indicate that this water channel enters the city from Sulukule, diverge into three across the historical peninsula (Cecen 1934).

The Romani community has been living in Sulukule since they were located in this area about 800 years ago. Sulukule area, which was only a place for settlement in the beginning, has turned into a symbol of the Romani culture due to the integration of Romani traditions with the features of the land. In 1960’s the then Ministery of Tourism supported the establishment of the Tourism Society of Sulukule. The society organized a month-long Romani festival. This support indicates the intangible heritage.

Sulukule is next to the city walls of Istanbul in UNESCO’s world heritage list. The area is within the preservation zone of UNESCO. According to UNESCO criteria preservation does not only cover physical buildings but also the cultural capital around it: the intangible heritage (UNESCO 2008). In this regard, the city wall cannot be seen as a mere texture of stone and be restored accordingly. It should be considered as a whole with its relationship to its environment to show its real value.

Sulukule is one of the first Romani settlements and Romani music in Sulukule is an ecole in Romani music worldwide. Until the Turkish government’s prohibition of music houses in 1990’s, musical production was the main source of income in the neighborhood which was also one of the points of attraction in Istanbul guides. When the music houses were closed down, the field faced unemployment and lost its income from its entertainment production. More importantly, the communal ties empowered by collective production have been weakened by individual efforts to find alternative sources of income.

Therefore, reducing Sulukule area down to the land's monetary value and location would mean ignoring the Romani rituals, traditions, modes of everyday production and community interaction that are embedded in the streets of the neighborhood. Romani communities, which are famous for their natural talents in performance and music, have transformed the everyday in Sulukule into a performance with their daily exchange on the streets, at the festivals and events, in local squares, conversations on doorsteps and communal cookings. Collective production of music, dance and performance as a common part of everyday also identifies the major source of income for Sulukule residents.

The second and major loss is due to Code 5366[4] developed for two main aims (1) rehabilitate areas that is under threat of earthquake and (2) to rehabilitate physically worn out and degenerated areas which are defined as old and unsafe. Sulukule was selected to be rehabilitated according to this law.

According to the project of the Istanbul Metropolitan Municipality, 85%-90% of the residences are going to be torn down. The land will be made into an empty field and large suburban type residencies are to be built. The solution that is suggested, if not generated from the valid facts of the area, has the potential to sharpen the social and economic gaps between communities.

Taking into consideration that 80% percent of the residents were born in Sulukule, it can be said that living in single storey houses with a quad and having many pets is a pattern of their culture. The second problem is that none of the residents can afford to re-buy the new houses to be built. That is why their return to their homeland does not seem possible. Dislocating the non-integrating gap to remove the unwanted aesthetics for aesthethics of the spectacle can be a reason when the increasing value of the land in central Istanbul is considered (Oral, 2007; Turmen, 2006; Turker, 2007). Neighbourhood's being old, unsafe; and the residents' being associated with thievery as the justification behind the spread of the city's spectaclist aesthetics, create acute issues of social well-being. Even if this rehabilitation builds a safer neighborhood, it washes away material culture of a unique community. If rehabilitation does not protect local production, the diversity and differences in the culture of the globe will rapidly disappear. On the other hand, if local production is protected and supported, the globe can benefit from each community's way of living as a practical knowledge that passes on to the coming generations. It is once more important to indicate that these actions in a local scale are directly connected with the entire city and many other metropols of the globe.

The involvement of industrial designers to the project was in 2007, when a chain of actions were organized to create a foundation of a local development center. These forty day long urban action named '40 days 40 nights Sulukule' started forty days before the demolition. The aim was to make the local problems visible by gaining as much public attention as possible. This action created a think tank and a platform of creativity with the involvement of several experts (musicians, dancers, performers, histiroans, movie makers, artists, architects, industrial designers and sociologists to excavate the potency of the region. The actions were widely exposed to public by media (Ingin, 2007).

---

[4] "The majority of the settlements in Istanbul are unsafe, unstable and under the threat of the earthquake. It has been observed and scientifically proved that several urban problems were identified because some regions are degenerated, some house illegal settlements which caused irregular urbanization.

The most appropriate solution to these problems in Istanbul is to apply sustainable urban transformation with improvement, adondoning, renovation, regeneration, project development etc. for cultural, physically safe, good quality and social and economical development in the areas under risk, degenerated areas and areas without proper infrastructure for common good.
(translated from Reason chapter of the Code 5366 accepted in the Turkish Parliament on May 16th, 2005)

The workshops focused on music, painting, fanzine production and weaving on the theme of daily life in the neighborhood. It has been observed that the creative potency of the region can be used as a lever for socio-economic rehabilitation of the field. Two outstanding exhibitions (Turkcell Hall and International Ulis Photography Festival, 2007) were held after the workshop of Istanbul-based photographer Tansel Atasagun with kids on the question of belonging: 'Why do I love it here?'

The creative practices on the field are tied to rigorous sociological analysis to know who these people really are. After actions and workshops, it has been discussed to explain it methodologically so that the experiences of this process can help other cities that are experiencing similar problems of poverty and gentrification.

In Making Cities Work for All: Global Action Plan for City Development Strategies by Cities Alliance the method suggested for making healthy decisions in a city has several consecutive steps from gathering existing knowledge to a monitored assistance program as opposed to a linear action of demolition and building something completely disconnected with the nature of the field. The design issue in Sulukule is not the architectural transformation of the land by demolishing the community's living spaces and building new villas, but a question of how to monitor a healthy cultural integration of the locality to the city's scene with its colourful life, cultural memory and local production. Instead of imposing design solutions from outside to a neighbourhood with unique communal assets, the territorial capital of the neighbourhood, especially soft assets such as '*skills, traditions, festivals, events and occasions, situations, settings, social ties, civic loyalty, memories, and the capacity to facilitate learning of various kinds*' (Thackara, 2005: 79) need to be identified. Soft assets are the organic bonds that tie the community to their living spaces. Therefore, sustaining everyday production can happen only if these organic bonds are turned into a design program that facilitates local production by utilizing the inherent skills, social ties and traditions.

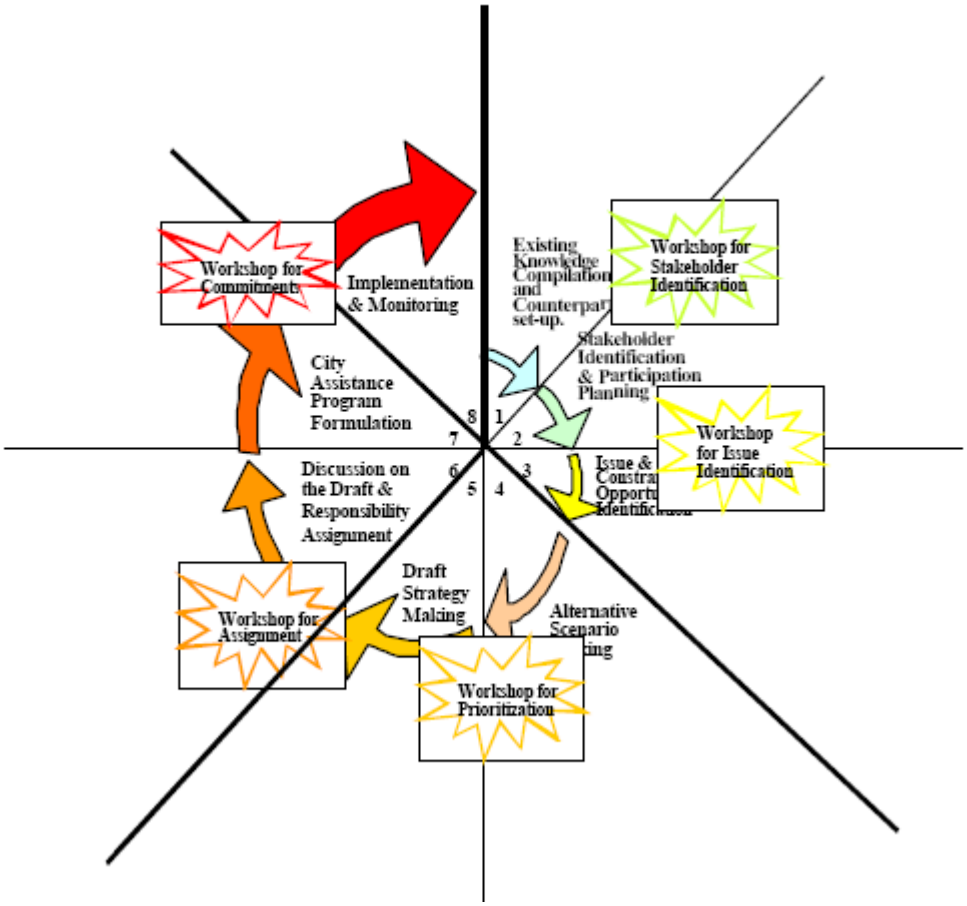

Figure 02. Schematic View: Process in Typical CDS, from 'Making Cities Work For All: Global Action Plan for City Development Strategies', Cities Alliance Draft, June 2002.

The potency of the region

In the case of Sulukule, design needs to identify the existing state (including the facts, the potentials) and to engage itself with the situation in an everyday context to be able to move towards a preferred state of social, economic and cultural well-being. Therefore; the major question to focus on is to define capacity of the area to be a territorial capital. For the last two years, the designers have been working in Neslisah and Hatice Sultan neighborhoods, interacting with the community and participating in their everyday production in order to identify the unrealized/unregistered or well-known capacities all of which carry unique features of Romani culture. The capacity of the region -the potency- can be studied in two groups. One is the intangible heritage in everyday rituals. The other is the tangible opportunities of production that can be created.

1. Music

The famous brass band from the region called Sulukule Romani Orchestra performs at some of the most prestigious venues in Istanbul such as Garage Istanbul, Hilton, Gemi and Tierra. The band released an album in 2007. The region has many musicians who can teach Romani music and dances who would like to study this.

Figure 03. Various Graffiti from the field

2. The wall

The ancient city wall of Istanbul is a landmark that borders the field. The meaning of the wall and its relationship with the city has been discussed before and during the demolition. Although, the neighboorhood has been identified with the wall, prior research could not really explain it.

The relationship of the wall to the neighborhood is more than saying that they are just next to each other. The authors, after a broad field work of two years, suggest the existence of an intangible connection. According to one of the folk stories, a Romani folk opened the "Pempton Gate" to Fatih Sultan Mehmet and let him in the city. It is said that the key to the field was thus given to the Romanis and they have lived there since then. Besides this, Hidrellez (A nocturnal celebration of the arrival of the spring where bonfires are started and young people jump on fire. Wishes are written on pieces of paper and are tied to rose bushes.) has been celebrated by that wall for a thousand years. The wall also has a memory. It can be said that the wall will carry these stories about the inhabitants' lives for thousands of years more. Thus, the city wall by the neighboorhood can sustain the culture of the community and serve as an invaluable landmark for the community if a better design system is created with the local government instead of the current one.

3. The name

The capacity of the region, the potency can be summarised in two groups. 1) The liquidized accumulation of everyday rituals. 2) The tangible opportunities of production that can be created. The liquid potency lies in the name :'Sulukule'.

It is vital to understand that geographical Sulukule and cultural Sulukule as a community is not the same. Even though the city's rehabilitation campaign focuses on the physical negativities in the area as a justification, it is important to understand that what constitute 'Sulukule' is not only two neighboorhoods but also the Romani oral history and the rituals that has been preserved by Romanis for centuries. That is why, after understanding the potential of the area the designers shifted their focus to non tangible cultural production. For instance, debates in the streets by women is a sort of unique performance in the area. Besides this, weddings in the area are spectacular celebrations in the street. As the bride leaves her house, the gifts sent by the groom's family are unpacked and placed along the path she walks. The streets of Sulukule have been a constant stage of performance. The everyday communication of the Romanis embody outstandingly rich gestures and expressions with spontaneous music and dances. Another example are the pleuthera of graffitis in the neighboorhood. These grafittis are brutal in the way that they don't contain artistic credit but they are very strong channels of self-expression on concepts of love, friendship, ownership and fantasy on a daily basis of communication. As a reaction to the present rehabilition project a grafitti saying 'welcome to hell.' was observed in the neighboorhood.

Having seen this natural richess of form, color and sound it can be suggested to designers who would like work in the area to find ways of pointing at, guiding and communicating what is already there. This is a proactive strategy to make the oral cultural heritage, particular to the ares, as visible as possible. Making the 'liquid assets' of the neighborhood become visible involves a tactical use of design to communicate the neighborhood's potential as a cultural heritage both to the public and to the community itself. In this case, design can take on a type of formlessness that can be directed by the dynamics of everyday. Creating not finalized products but platforms of interaction and communication can prepare the groundwork for tangible projects of local production. This can also utilize design's capacities of translation, attunement and negotiation in creating flexible bonds between the stakeholders.

The other side of the project can be valorizing the production potential in the area by assisting already existing production. Apart from the skills of musical production, other skills in the neighborhood should be brought forward and emphasized as the alternative supporters of local production. These modes of production can support already existing patterns such as sewing, beadwork, patchwork and similar crafts widely done by women. Design agendas for these 'alternative' ways of production should be created with the participation of designers, residents, local charities, local manufacturers, NGOs, researchers and academicians. In this case, existing everyday practices and small ways of income can be turned into a production program in an organized manner. For example, neighborhood women who produce food for sale individually can be supported and organized with the help of an agenda for production. In Sulukule, some women experiment with coloring traditional food which has a unique taste and look unknown to the rest of the city. These lines of production can be supported by micro credit on an individual basis or they can be turned into an open community platform by starting a craft house or cooking shop.

Conclusion

Sulukule at its current state illustrates all the tensions that generate from the imposition of spectaclist aesthetics of the 'functioning parts' of the city on the 'non-integrating, localized gaps.' However, Sulukule also renders a microcosm that can benefit from design interventions on an everyday basis and utilize the capacities of design to organize its territorial capital according to the following observation.

1. The region has a reputation with its music worldwide.
2. Many women are experienced in the textile industry.
3. It is within the UNESCO protection zone of tangible and intangible world heritage.
4. It is by the city wall of Istanbul which is protected by UNESCO world heritage.
5. A Romani music and dances research center can be established.
6. Residencies at the center can be offered.
7. Food design can be promoted.
8. Handcrafts can be introduced with the stories of the region.
9. Instead of tearing single storey houses down, some can be rehabilitated.
10. Collective spaces of collective rituals can be kept.
11. The new plan should keep quads for collective activities.

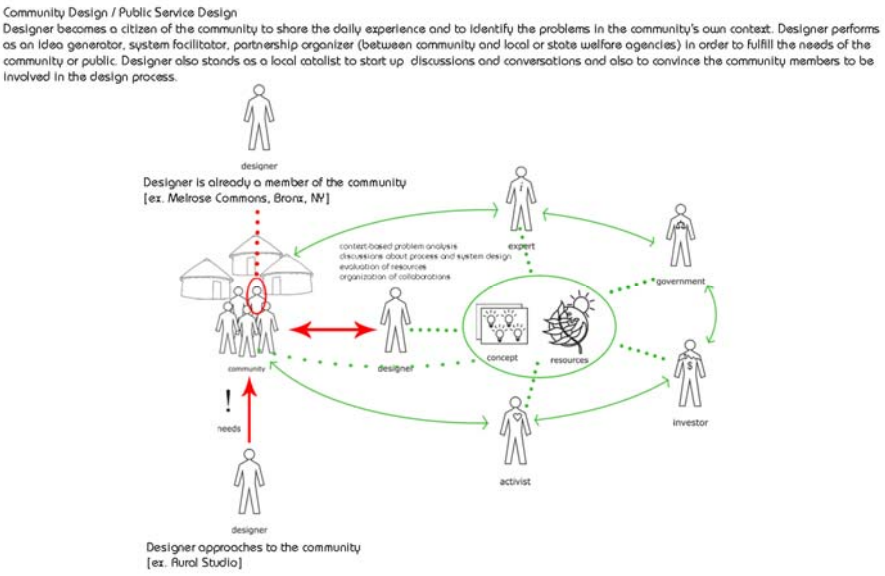

Figure 04. Public Service Design Model

The working methods of a designer for this aim involve collaboration with a web of artists, activists, sociologists and a facilitator for communication matters such as an NGO. After a two-year observation it can be said that these designers as creative agents in a community should have a strong background in psychology, sociology and strategic planning to grasp the situation first. The second quality is being able to develop projects as 'shots' that has been developed with prior experience foreshadowing the results. It should as well be stated that these projects, Sulukule as a case, require patience and ability to work under political stress. Unlike the examples from 'the functioning core', the projects in the 'non-integrating gap' are held with scarce resources, facing poverty. Thus, the designer should be experienced in feasibility and efficiency. It can be said that design education in the 'non-integrating gap' introduces these concepts to future designers as a reality of their context. This awareness, taking its roots from being 'non-integrated', can bring a new sensitivity about the profession of industrial design in the functioning core as well about how to pick what to design, the relationship between the designer and the designed.

Sulukule is not only a symbol of the Romani music and its lifestyle in Istanbul, but also is a case of resistance to the increasing urban rehabilitation processes. Genuine collective rituals such as the street and quad weddings, depiction of chest of hope of young girls and funerals are valuable resources to be introduced to the world from the perspective of a designer in a rapidly fragmenting and privatized world.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Proposals for A Good Life:

Senior Thesis Projects from Parsons Product Design 2003-08

Robert Kirkbride, Ph.D.[1]

Abstract

For the past five years, the Parsons Product Design Department has reconsidered a practice-oriented education through the question of what constitutes “A Good Life,” and for whom. As of July 2008, 169 seniors have developed personal thesis missions in collaboration with non-profit organizations in New York City and around the world, sharpening their professional and entrepreneurial skills with a critical awareness of the design process as a powerful agency for change. Across thesis year, each student identifies a specific problem, explores its local and global influences, and develops a comprehensive design strategy accountable for the impact of his or her product/system, from user scenarios through full life cycle analysis. The following paper and related “visualization” offer examples of the evolution in design research methodology through *A Good Life 1 - 5*.

[1] Parsons The New School for Design (USA). Associate Professor, kirkbrir@newschool.edu

Introduction: Not *The* Good Life, but *A* Good Life

What is *A Good Life*? Where is it? Is it found in a world of bliss and plenty, or somewhere more fleeting and bittersweet? Is it guaranteed by agreement and uniformity, or through debate and difference? Is it produced in a melting pot, as a mosaic, or by some other not-yet-determined cultural, political or economic metaphor? Is it a destination or a distant memory? Is it aesthetically or ethically centered, or somehow both together? And who shapes this world: the haves, the have-nots, or the "have-mores?" How does our world make for A Good Life, and how might the pursuit of A Good Life make, or transform, our world?

To engage and transform the increasingly non-linear and socially complex "wicked problems" that face humanity, *we must re-design how we think*. Ben Lee, Provost of The New School, notes: "Problems such as environmental degradation, sustainability, poverty, financial crises, even democracy, cannot be handled within traditional disciplinary frameworks or national research paradigms."[2] To propose sustainable solutions to these problems *we must also re-think how we design*, working across disciplines and vocations to refocus the mutual influences of design research and practice. Pursuit of "A Good Life" raises questions of personal and cultural identity as well as issues of responsibility and sensuality, addressing the complex weave of forces engaged in developing any given product or system, locally and globally. The following paper reflects on the challenges and benefits of implementing new methods of sustainable design research in thesis year during the first five years of *A Good Life*. Several of the proposals featured in this paper and its "visualization" – including a global project for removing landmines and fashion for mastectomy survivors – have already garnered recognition and are formalizing as real-world endeavors, demonstrating that design can no longer be viewed as the production of discreet, fetishized objects, assembled by linear thinking in isolation of their extended influences.

Why *A Good Life*? Changing the Pedagogical Objectives

Béla Bartók famously declared that musical composition cannot be taught: musical knowledge and analytical skills can be acquired, but the imagination to synthesize the parts into an innovative whole emerges uniquely from an unfathomed talent within. If this is true, can sustainable design be taught? One might respond with another question: how can sustainability *not* be taught as the centerpiece – the assumed basis – of any self-respecting design curriculum? We may choose to attend a concert or not, purchase a recording of a given composition or not, but we cannot avoid the proliferation of *stuff*, tangible and intangible, that inundates everyday life. Due to the crushing ubiquity of design there is an imperative to approach design in a way that considers innovation from a different vantage, changing pedagogical objectives from the traditional barometer of producing students with marketable skills.

And yet, as a tuition-driven program could we risk *not* preparing students to survive in one of the most competitive (and expensive) design centers in the world? Our students arrive from all parts of the world; most hope to stay in New York City, at least for several years to gather working experience. How could we expect them to think and behave differently without jeopardizing their professional opportunities? Furthermore, since graduate study in Product Design is not yet a standard option,[3] most of our students enter directly into the work force and contribute to the cycle of producing yet more *stuff*. True, graduates from Parsons could produce this stuff *very well* – the history of the department is steeped in a craft-based curriculum that fuels an obsessive passion for detail – but could they participate in a broader, more critical dialogue about global issues? Would they have the fortitude to ask themselves – *is a physical object the most appropriate solution for this problem*? How would we responsibly equip our students with the thinking and making skills, and above all the confidence, to enable *them* to equip employers,

[2] Benjamin Lee. "Provost's Convocation Remarks." The New School. www.newschool.edu/admin/convocation/2007/ben_lee_remarks.html (September 6, 2007).

[3] Parsons is currently developing an MFA in Product Design.

clients, manufacturers and consumers with a more nuanced appreciation of the impact of their decisions on the world?

At a career services event with several leading design houses, we received feedback that revealed an opportunity to imagine a convergence of sustainability and marketable skills. *We know your students can assemble attractive portfolios, but to hire them we need to know they will be able to answer the phone*. At first blush, this comment might seem condescending, but it was illuminating: answering the phone is not a demeaning task but a critical skill, reflecting an ability to interpret a new circumstance and direct energies promptly and effectively. The remark signified a need for designers to be agile in *all* analytical modes, whether directing a phone call to the correct person or channeling the respective concerns and efforts of client, consultants and other collaborators. If we are to embrace the range of opportunities for design intervention in world problems, then there are meaningful encounters on all scales in daily experience, all of which factor into the contemporary experience of being a designer.

Since sustainability is systemic and poetic – a mindset – and not merely a new professional skill or accreditation standard to "add-on" to a curriculum, we were compelled to imagine new learning habits for our faculty and students, and reconsider the pedagogical structures to foster them. At the beginning of the first year of *A Good Life* (2003-04), the entire Product Design faculty gathered for a day-long sustainability workshop organized by chair Tony Whitfield. While the most obvious initial step might have been to concentrate on the two "legs" of sustainability already familiar to designers, material and economic sustainability, Whitfield placed special emphasis on examining notions of *social sustainability*, which at the time was a path far less traveled. To focus students' explorations of *A Good Life*, as summarized in a handout, "the department [would] work in collaboration with New York's not-for-profit community to develop design projects that specifically address their missions." In thesis studio, each senior would be required to partner with a not-for-profit group, a real-world component for which there were few references.

In the five years following this initiative, the learning curve has been steep. Early on, the relationships were hit-or-miss, with success relying heavily on a student's personal gumption and good fortune in finding the right group (or more importantly, finding an empathetic person at the right group). Few of the non-profit groups had ever considered working with a designer, and at first many of the students were conscripted as volunteers. With time we grew to realize that this was not a negative but in fact a valuable part of the design research, providing a point of entry to examine user scenarios. It was indeed a real-world test of students' resourcefulness and endurance, but could we build on their enthusiasm and the good will of non-profit participants to strengthen these relationships from year-to-year? After each year we wonder how this aspect of thesis could run more "smoothly." We have held symposia and roundtable discussions early in the fall to facilitate and accelerate the early stages of this process, and developed partnerships with such outreach groups as *Design21*. And yet, reflecting on the recently completed fifth installment of *A Good Life*, perhaps a degree of slowness and uncertainty is inherent, even healthy, due to the fact that each student is searching to identify his or her *own* thesis mission, let alone attempting to match it with someone else's. In fact, for many students each year the search for a not-for-profit group – or *groups* – is a central ingredient, the x factor of their thesis development, tantamount to identifying the essence of their unique personal mission.

To assist with this facet of thesis, a not-for-profit instructor works with the seniors,[4] providing tactical advice and helping them negotiate productive roles with their chosen groups. With time, this role has increased in relevance and complexity, given that the distinction between for-profit and not-for-profit endeavors has become increasingly blurred,[5] generating a hybrid

[4] Since Fall 2007, the non-profit instructor has been Rise Wilson. From experience we have found that this position is best served by a non-designer, to help students appreciate the relationship from the perspective of a non-designer.

[5] Historically, funding from for-profit corporate sponsorships has supported programs through project-based studios – these relationships continue to be important to the balanced growth of the department. With time, however, these partnerships have become more nuanced in their goals, reflecting changing views toward the mutual benefits of sustainability and quality design.

category of “social entrepreneurship” popularly described as “doing well by doing good.” While there are many beneficial aspects to this convergence, the need for critical thinking is highlighted, since there are numerous “wolves in sheep’s clothing” – for-profit entities (such as petrochemical companies) that jump on the bandwagon of sustainability and social consciousness, simply by spinning their public relations campaigns.

To prepare students for the broadened scope of design, we have structured the thesis year to help students recognize and cultivate their aptitudes while earnestly addressing their weaknesses, challenging them to think broadly by forming incisive questions. Specialist skills may be updated or acquired as needed – knowledge of a software program is outmoded even as one graduates – but associative and critical thinking is the foundation of imaginative and sustainable action. Engagement with non-profit groups at the various stages of design development, from researching user scenarios through user testing of prototypes, challenges students to sharpen their communication and listening skills. The project-based learning of thesis year, it is hoped, offers a catalyst to a life-long habitude of problem-solving with design, and a good life, in mind. Based on the first two years of *A Good Life*, we rewrote the department’s mission: *Through an immersion in materials, processes, aesthetic consideration and proactive social engagement, Parsons Product Design Department cultivates the intellectual habits and technical skills essential to imaginatively explore and responsibly integrate the swiftly expanding roles of a successful, professional product designer.*

Is there an “I” in *we*?

At the outset of *A Good Life*, some students, faculty and administration voiced concern that personal expression might be sacrificed by the increased emphasis on social engagement and worldly concerns. Could aesthetic style coexist with ethical pursuits? Would formal inquiry be compelled to play second fiddle to “doing-good”? Would there be enough room for an *I* in *we*? Recalling the ungainliness of solar panels in the 1970’s, it has been often argued that one of the major barriers to earlier, wider adoption of ecological design was its ugliness. How might designers assist humans to aspire to sustainable design for reasons other than “it is good for us” – even when that should reason be enough? Might sensuality be the teaspoon of sugar that helps us absorb our medicine? Perhaps “doing good” could benefit from “doing better.”

In a parallel track, skeptics initially viewed the intensified research necessary to fuel a more comprehensive approach as a *separate* or *additional* scholastic requirement, often placing it in opposition to the more immediately visible products of the design process, such as sketches, mechanical drawings and prototyping. “Too much research” was at times blamed for hindering the design process, slowing the appearance of the familiar evidence of design development. Reflecting on the first two years of *A Good Life*, the increased research did indeed slow this production, precisely because it problematized the way the students had been learning to approach design. Leading up to their senior year, students had been handed a design brief by instructors who framed the problem and outlined the schedule and expected deliverables. Now thesis students were required to identify a problem, clarify a personal mission in tandem with the mission of a non-profit group (and negotiate that relationship), devise sustainable design solutions, realize several prototypes informed by user testing, design packaging and marketing (including on-line components) along with cost analysis and life cycle analysis…all within the final nine months of an undergraduate program. It is no surprise that one of the most important lessons that seniors learn, for better or worse, is *time management*, for the simple reason that they may be facing it for the first time.

The dilemma was circular – in raising our expectations of student performance, how could we as instructors equip ourselves to behave differently in order to equip others to behave differently? To overcome the binary mindset toward *design* and *research* we deliberately merged the two words into *Design Research* and more firmly established the *Thesis Book* as a requirement of thesis completion and graduation. Complemented by a prototype and a final public

defense, this document would articulate each student's thesis argument, summarizing their personal mission, design research and proposed solution, physical and/or systemic, of a specific problem. Since this required students to document their progress in new ways, the position of the "External Critic" was transformed into "Design Research Instructor"[6]; this person serves as a liaison to the thesis-related courses of "Information Design" and oversees assignments geared to stimulate and integrate the various aspects of thesis development. The students' design research is organized and submitted for formal approval at two points during thesis year: at mid-year (December) as a thesis proposal/design, and at year's end (May) as the final *Thesis Book*.

This document proves invaluable in at least two ways. First, it records the conceptual development of a single in-depth, long-term project, providing a comprehensive demonstration of a student's skills and character. Since it far outreaches the standard portfolio (recalling the sentiments of the design houses), the thesis document has been extremely useful to students seeking employment. Second, copies of the book remain with the department, where they serve as irreplaceable reference books for new, incoming seniors. As such, several lineages of projects have emerged over the first five years of *A Good Life*, categorized loosely under the headings of education, ecology, health and well-being, identity and sexuality, disability, safety, politics and poverty: *all* of the projects are evaluated with regard to their extended influences and sustainability. Many projects address several categories.

Another early concern was the likelihood of "repeat" projects from year to year. What has resulted could not have been predicted. There have indeed been many projects that address the same or similar topics, however, each one has been unique precisely because of the singular challenges faced by each student and his or her non-profit relationship, which is irreproduceable. There is also an ethical byproduct: students (especially of recent years) recognize that their work benefits from the hard work of previous students, and that they in turn prepare the way for future students. It is a lesson in humility, grace and responsibility: if they mishandle a relationship with their non-profit it may preclude a future opportunity for someone else. Furthermore, each class of students creates a different chemistry. Although similar topics and categories may emerge, they are manifest differently. Where *A Good Life 4* offered a striking preponderance of Do-It-Yourself projects, much of *A Good Life 5* centered on associational interactivity. Why? Was it something in the air or water? Or was there perhaps an imaginative exchange of I with we?

In any event, in fall 2007, instead of "forgetting" previous student achievements, we embraced them by launching the thesis year with the intensive design charrette "Decomposing a Thesis," for which students selected thesis projects from previous years, quickly analyzed and re-designed them. It was a way of plunging students into the design research mode and avoiding the often-paralyzing question of *what is your thesis mission?* In Fall 2008 we will begin *A Good Life 6* with the same exercise: based on our learning curve, the anticipated results should be familiar yet *different*. The legacy of proposals for *A Good Life* is testament to the understanding that project-based learning is an egalitarian process where students learn from one another, and the instructor facilitates rather than imparts ideas. To further the Parsons Product Design mission, the following learning objectives have been set for thesis year:

- **stimulate lateral thinking** to form unexpected links and identify necessary skill development;
- **encourage social intelligence** in a world and profession where teamwork is in growing demand to address complex problems;
- **challenge individual development of multiple intelligences** in a group dynamic, fortifying personal confidence in what one is "good" at by teaching others, while reducing fear of one's own "weaknesses" by learning from peers and "the task at hand."

[6] Patricia Beirne was hired as the first "Design Research Instructor," a position she has maintained from *A Good Life 3-5*.

Concluding proposal…

Returning for a moment to Bartók's argument, there is another implicit lesson offered by our experience with the question of "repeat" projects. It is more effective and enduring to unleash an imagination rather than require it. This happens most naturally when we are fully invested in an endeavor. The more deeply we care about an issue, a project, the more we seek its continued growth and prepare for its ultimate success by trying to imagine all of its parts, its strengths and failings. Through the thesis inquiry of *A Good Life* our seniors are compelled to build on their strengths and diagnose their personal demons, proposing a vision for the world that is also a renewed vision of themselves, each as a prototype of an argument that is familiar, yet different.

As traditional boundaries between industry and the academy realign at the ethical and economic stimulus of sustainability, a lateral approach to design research is increasingly in demand. Designers are called on to conceive and orchestrate problem solving for complex, non-linear issues, often in interdisciplinary teams. In this context, the design process offers analytical and synthetic methods to appreciate the global impact of local conditions and the local impact of global conditions. The academy offers an ideal, multi-faceted and self-reflective engine to generate sustainable solutions. For this reason, we cannot any longer afford to separate between "industry" and "academy," or "academy" and "real-world." The academy *is* real-world. This is my proposal.

…and links to two others

Regarding Hilary Boyajian's project *Chikara* (from *A Good Life 2*), which set an early standard for thorough design research:

"The outgrowth of Hilary's original thesis is her recently launched clothing line, Chikara, which, implementing the findings of her thesis research, produces high-fashion, flattering, comfortable clothes designed to accommodate women whose post-surgery bodies reflect the changes—including shifting and asymmetry—that a lumpectomy, mastectomy, or double mastectomy will create… The answer to the dissatisfaction these survivors were experiencing [in existing clothing options], Hilary felt, lay in creating a fresh, modern clothing line that 'created the notion of prosthesis externally rather than internally.'"

Fig. 1: Hideaki Matsui's "Cleanup," completed in 2006 for *A Good Life 3*, received the "Best of Category" in I.D. Magazine's 2007 Student Review. In his thesis documentation he writes: "I chose soap as the product to promote the eradication of landmines because people use soap everyday. As someone cleans their hands with the soap, they can help clean the world of landmines."

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design-Oriented Futures Wheels

Using Foresight Methodologies in our Design Schools

Cindy Kohtala[1]

Abstract

This paper explores two specific futures studies methods, with the aim of adapting them particularly for design students at the post-secondary level. It describes in detail the steps a workshop facilitator can take to guide students through the process of a Design-Oriented Futures Wheel and a Design Causal Layered Analysis workshop, the former also using a Futures Table as a tool. The objective of these workshop models is to promote systems thinking, impact analysis thinking, and scenario visioning skills. The topic of this activity has been motivated by the author's personal interest in foresight methodologies and how they may promote a positive combination of design thinking and sustainable solution development.

[1] University of Art & Design Helsinki (FINLAND) – School of Design. Lecturer, cindy.kohtala@welho.com

1. Introduction

This paper introduces a simple workshop model(s) for design students based on futures and foresight methods. The aim of the workshop is to familiarise design students with certain futures methodologies in general, and thereby systems thinking, as well as to provide them with conceptual tools for scenario building; to illustrate how issues are socially constructed by various groups with differing worldviews; and to direct their attention to the long-term impact of their activities. The author assumes that focus on the latter two issues is rather weak in many design programmes even today, and students can only benefit from a more thorough discussion on long-term technology impact assessment, trend impact analysis, stakeholder analysis and ethics in design practise in general. It is therefore plausible to see this workshop as operating in a BA or MA programme as project or course introductory material and/or as forming part of a curriculum module under the theme of systems thinking, design ethics or similar. The workshop platform is basic, flexible, and discussion-based and can thus be adapted to local needs and themes. It can be seen as a step towards encouraging a ‘macroscope’ view of the world, as opposed to, or preferably in combination with, the ‘microscope’ view and micro-level knowledge traditionally required by product design activities (see Thackara 2006, 6).

The workshop focuses on the use of the Futures Wheel and Causal Layered Analysis as methods and the Futures Table as a supplementary tool. The first method is especially simple to understand and implement but leading the activity does require some experience or careful facilitation, as it may easily result in “intellectual spaghetti” (Glenn 2003, 10). It is a brainstorming approach, but a structured and systematic one. It can stand alone as a discussion tool or be combined with the Futures Table or other matrix tool in order to develop scenario parameters. A further application could move towards eco-innovative product/service development brainstorming.

The second method, Causal Layered Analysis (CLA), is far more conceptual and requires sensitive facilitation. It too can stand alone as a discussion and thinking tool or can be used as a platform for the development of various kinds of scenarios or vignettes. If the purpose of the Futures Wheel tends more towards mental mapping, the aim of the CLA method is to eventually propose measures: in essence, to design how the future could unfold and change/be changed for the better.

While the Futures Wheel considers horizontal linear-time-based impacts, CLA explores the vertical layers of (as a likely example) sustainable development issues before moving horizontally forward to future speculation. Each method requires a certain type of analytical thinking and benefits from, ideally, incorporating certain scientific or other expertise that neither design students nor design lecturers necessarily have. For these reasons, the workshop template(s) developed for this paper suggests a set of design-relevant questions and structure proposals. The goal is that with this simple set of instructions and leading questions, any lecturer anywhere can conduct Design Futures Wheel and Design CLA exercises with only paper and pen.

This paper will thereby concentrate on the practical details of conducting workshops based on these two methods specifically. A more general discussion and evaluation on how futures and foresight methods in general are adaptable to the design education context will be left for future study. This paper is a preliminary study in preparation for future doctoral studies for the author. The workshop template(s) is thus undergoing continuous testing and improvement.

2. The Futures Wheel

The Futures Wheel was developed in 1971 by Jerome C. Glenn as a method to identify and organize the primary, secondary and tertiary consequences of events, in a structured brainstorming approach that intends to create a mental map of the future (Glenn 2003, 3-4). It is related to mind-mapping but more clearly sets out the various levels of impacts as they occur in time and is thus useful in further forecasting and scenario work. In Glenn's own words, the "Futures Wheel also helps move the mind from linear, hierarchical, and simplistic thinking to more network-oriented, organic, and complex thinking" (Glenn 2003, 9).

A Design-Oriented Futures Wheel as proposed in this paper is one in which a design proposal, social trend, design-relevant event, technological development, or similar, is defined verbally and placed in an oval in the centre of the paper. The immediate consequences of this event are then discussed; they may range in scale from micro to macro, and may, or should, cover a range of sectors. (There is no need at this point to limit the discussion to the design field and its implications.) Each effect is put in its own oval and all are drawn going around the central topic in a circle. Each primary effect in turn will trigger a secondary effect or effects, and these subsequently a third, tertiary effect. The primary, secondary, and then tertiary impacts (or first order, second order and third order) are thus placed in the wheel in their respective circles radiating outwards. Arrows or spokes indicate connections between the impacts. Colours or differing line weights may also be used to differentiate the impact levels and clarify the cause-effect relationships.

The facilitator may pose questions in order to structure thinking and identify likely (not too far-fetched) impacts. These questions can address, for example, sector-based issues, according to Glenn's Version 2 Futures Wheel (see Glenn 2003, 11). Sample questions would ask: what is the cultural impact of this event? What impact will this have on the natural environment? What are the political consequences? In the author's experience, following this kind of STEEP or PESTEC framework is extremely helpful in advancing the discussion, and in the workshop slideshow the image of the sectoral wheel by Glenn has been used by the students as a constant reference point (see Fig. 1). (A STEEP analysis considers the sectors of Social, Technological, Economic, Environmental or Ecological, and Political. PESTEC adds the sector of Cultural.) Students should consider what areas are important to their topic and add them accordingly. In Glenn's example of a Version 2 Futures Wheel (Fig. 1) he adds the areas of Educational, Psychological and Public Welfare Impacts to the PESTEC sectors in his consideration of 'African economic integration'. A Design-Oriented Futures Wheel will have design-relevant sectors – one could even suggest Aesthetic Impacts. This leads to the point that it is likely the students will hover around the general or the specific: if they are concentrating too heavily on only design-based issues, the facilitator may broaden the scope by introducing a PESTEC consideration. On the other hand, if the discussion remains at the wider macro level, the facilitator may ask about design-related details (such as aesthetics, consumer behaviour, or other, even more specific, considerations).

Facilitator questions can also be related to normative evaluation: if the impact is considered to be positive, negative, or neutral. It should be remembered that the wheel does not represent one particular future but many possible future corollary chains; positive impacts as well as their antithetical negative possibilities can appear on the same wheel. As will be explained below, this could in fact indicate a useful element for the later Futures Table and scenario space work.

The Futures Wheel may incorporate time-based elements (the dimension of past time and how a trend evolved), if it is clearly marked which event leads to which. (See comment below on Cmap Tools and labelling connectors.) This can also be accomplished by creating a more complex 'Version 3 Futures Wheel', which looks rather like an hourglass (see Glenn 2003, 12) and includes the dimensions of historic forces, the current situation, and future implications. Here the main Trend or Event remains in the centre of its wheel of 'current impacts', but the spokes also extend from the central Trend up the 'hourglass' to 'future consequences' and down the 'hourglass' to 'historic forces', in a kind of isometric projection.

No matter the form of the wheel, as the discussion continues, the complexity of the interactions will increase and may become overwhelming, resulting in the conceptual spaghetti mentioned above. The facilitator should heed where there are clear gaps in the wheel, un- or under-considered issues, and when it is time to move to the next step. (In some cases blocks in the brainstorming process or conceptual lock-ins can be unblocked by working on the Futures Table at the same time. See Fig. 2.)

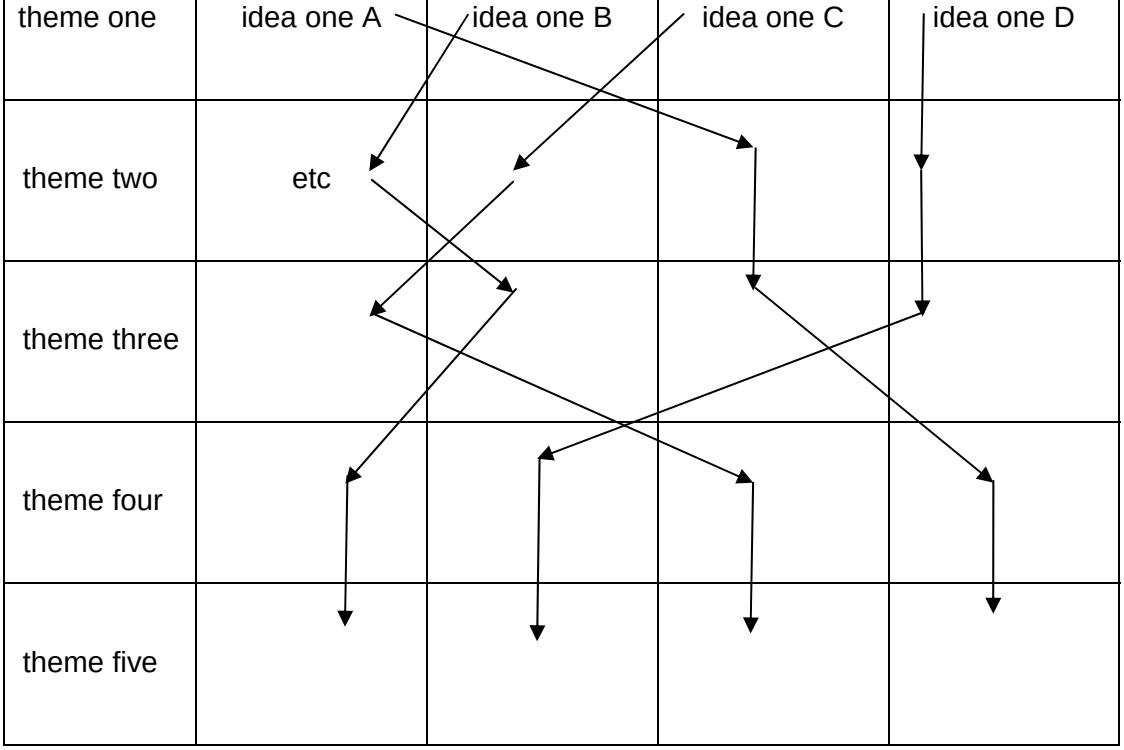
Moreover, it can be problematic for students to determine if an impact is truly primary or in fact the result of an intermediary event that is not immediately evident. (There can be some surprising, even disturbing, cause-effect chains that are not visible in our day-to-day existence.) It is furthermore possible to mistakenly connect events that are correlated but not necessarily causally related (Glenn 2003, 9). These are points considered useful to be kept in mind; there is however no need to over-intervene in the students' thinking processes.

The Futures Table. After sufficient consideration (the author suggests at least two hours for the entire workshop) the facilitator introduces the Futures Table exercise, in which the students begin to classify and organise the outcomes of the Futures Wheel discussion. The Futures Table is a way to structure futures information that lends itself nicely to scenario development. The left vertical axis of the table lists the key themes or variables that the participants believe are most crucial to the topic to hand. In this workshop, these themes may accord directly with the sectors (for example, PESTEC), some sectors may be divided into sub-themes or defined more specifically (for example, health, design education), and some megathemes may be included (for example, values in a STEEPV framework).

On the top horizontal axis are listed four (or at least three) choices of 'vision': A, B, C, D. These will represent four alternative visions of the future. For each vertical theme, the students imagine four different alternatives, four realities, based on their Future Wheel discussion (for example, health: A – totally privatised health care for the wealthy; B – extensive public health care system funded by taxes; C – clear separation between public and private services but both available; D – mostly private providers but state-subsidised). It is possible and helpful to think of the alternatives as positive, negative, as today or most likely, a surprise. Another helpful starting point is to see if there are obvious polarities or contradictions already developing in the Futures Wheel (positive and negative effects). This may indicate critical issues: how the same event can lead to different reactions, decisions and end results.

When the table is complete the students should draw connections between those cells that most logically match with each other (see Table 1). (For example, is it likely that an extensive public health care system would exist in a society with extreme individualistic values?) These four visions can then be given a name (metaphors make colourful, expressive names) and the vision results presented in a plenary session.

	A	B	C	D
theme one	idea one A	idea one B	idea one C	idea one D
theme two	etc			
theme three				
theme four				
theme five				



"vision one" "vision two" "vision three" "vision four"

Table 1: Futures Table. Making logical visions out of various elements/characteristics according to relevant themes.

It is recommended leaving sufficient time for the plenary session for presenting results and discussing the process. During the same workshop or for future project work, the table and wheel can further be used for eco-innovation brainstorming. Here, the students can give deeper consideration to the following points: the 'surprise' element (if one of the table's visions is "business as usual", what would be a surprising yet positive antithesis to this?); the events considered to be opportunities or threats in the wheel (what is the business opportunity here?); how one would avoid the 'negative' scenario elements; and how designers could work to reach the positive, preferable one.

Practical considerations. Allowing the students to decide on their own topic is considered problematic and takes significant time away from the actual wheel-building activity. It is recommended that the facilitator provide the topic or a choice of two or three topics only. The issue should be considered wide enough to generate challenging dialogue and allow the inclusion of sectors perhaps previously unconsidered by design students (such as the political impacts of a certain trend, or geographically distant impacts). It should also be narrow enough to work with manageably. There should obviously be an element that touches the heart of design activity and design-for-sustainability and, if applicable, the particular sector or topic the lecturer wishes to address. If the next project to come is Eco-Tourism Service Design, for instance, the Futures

Wheel workshop could lead into the project with the topic Ever-Increasing Global Tourism or similar.

The author has had success with the following topics:

What happens if the price of oil reaches $160 a barrel? (For example see Fig. 3.)

What happens if people start doing more for themselves? i.e. Wikinomics, open source lifestyles, expert users, prosumers, ProAm…

What will result if more and more of our tools and products become electronic?

It can be considered positive if what turns out to be design relevant or influencing design is surprising, in view of learning something from impact assessment. If this is the case, or if a design connection is not so apparent, this could also contribute to any eco-innovation discussion as mentioned previously.

Obviously it is up to the students to decide how to fill in the Wheel: the discussion on some impacts will naturally (even excitedly) lead from primary to secondary to tertiary, from inner to outer circles. Some groups will be naturally more systematic and fill in each circle as completely as possible before moving to the next outer circle. If the discussion seems to stall, the facilitator can point to gaps in the wheel or suggest other relevant areas.

Finally, the facilitator may also suggest using labels for the connecting arrows to inspire new ideas. This is at any rate necessary if one uses mind-mapping software such as Cmap Tools to create the wheel; as each arrow must be labelled, creativity can be used beyond simply “leads to”. Relationships may be indicated by the positive, negative, or neutral mentioned above, or qualifications such as “supports”, “helps in”, “very likely”, “not so likely”, “opportunity”, and “threat”.

3. Causal Layered Analysis

CLA is used here as a second futures method for adaptation because a Design CLA directly addresses the myths, assumptions and social discourses that surround design, technology advancement, and sustainable development. This can allow for deeper scenario work subsequently, as well as a deeper discussion on transition management, path dependence, and barriers and leverage points: in other words, how change can actually be effected. The latter capacity and the participative element make CLA comparable to for example Jungk’s Future Workshops (see Bell 1997, 300-5).

CLA was developed by Sohail Inayatullah in the early 1990s in order to focus on the vertical layers of discourse that may not be revealed by the more horizontal spatiality of foresight methods such as backcasting. These layers include myths and metaphors (the often emotive, archetypical, or unconscious dimensions of the problem or issue) and the “litany” (the surface, ‘knee-jerk’ reactions to an issue that may render a person helpless or fearful) (see Inayatullah 2003). This activity serves to expose how issues and problems are framed in society and how this framing limits true understanding (see Scenarios for Sustainability).

A Design CLA can follow a Design Futures Wheel in order to intensify the discussion or may be conducted separately. As with the Futures Wheel, the facilitator of a Design CLA uses a set of design-oriented questions in a discussion-based, environmental-scanning exercise to explore Inayatullah’s four levels: litany, social causes, discourse/worldview, and myth and metaphor. The goal is to deepen design students’ understanding of their work, their role in society (both perceived and desired), and, again, the impacts of their activities. Also like the Futures Wheel, a Design CLA encourages discussion on values and visions in the quest to define preferable future(s).

In the example by the author, the issue of the Baltic Sea is at focus, as it has many political, social, transnational, ecological, cultural and emotional perspectives that deeply affect many in northern Europe. (The previously mentioned topic of ever-increasing electronics could be

considered to be more design-relevant. With the Baltic Sea discussion however, as with any environmental or sustainable development issue, the role of design and designers can be raised in the latter part of the discussion.)

The facilitator may begin by eliciting general ideas on the topic. In the case of the Baltic Sea, comments are often quite predictable and tend towards finger-pointing, blaming other nations for the pollution. This is typical and leads easily to explaining the first levels of CLA. In other words, comments from the brief introduction discussion, no matter the topic, will almost certainly belong to the first two levels of litany and social causes, and the facilitator can then make this evident.

1. Introduce the layers. The LITANY (level one) is the most superficial layer of analysis. It can be considered the official public discourse on the topic, which is usually presented in newspapers as (often exaggerated) problems, quantitative trends, events and issues that do not appear continuous or connected. The result from the student's or participant's point of view is a feeling of helplessness or apathy (see Inayatullah 2003, 7). "It's St Petersburg that dumps all its sewage in the Sea." "It's the cruise ships who illegally empty their wastewater in the Sea to avoid harbour charges." "The government should do something." The facilitator should ask what students have read about the issue in the newspapers, to collect all topics and opinions, and can even bring in articles as evidence.

The SOCIAL CAUSES layer (level two) delves deeper into the topic in a more systemic way. Here information is more likely to be found in the editorial section of the newspaper as well as policy institutes and academic journals, in the form of quantitative data and interpretation, technical explanations and academic analysis, and even analysis of the precipitating action (Inayatullah 2003, 8). The students should here give deeper consideration to their former 'litany' statements and discuss where they would find richer, 'truer' (or at least semi-scientific), information on the topic. A STEEP or PESTEC framework is also recommended; students should talk about the economic, cultural, political, and historical factors involved. The facilitator and/or the students could also find examples of studies and reports that would help separate the fact from the fiction. In the Baltic Sea case, the author was rather surprised to learn the immensity of the impact Finnish agricultural practices have on the 'health' of the Baltic. (As this information came courtesy an enviro-biologist researcher currently studying the Sea, it could be worth considering inviting experts to the discussion if feasible.)

The WORLDVIEW layer (level three) goes deeper still. The facilitator should stimulate discussion on the various stakeholders, discourses and worldviews involved. What are the deeper social, cultural, linguistic, economic, and religious structures underlying the topic – or, in truth, constructing it (see Inayatullah 2003, 8)? Who are the various players, and how do they view the issue? Why? The workshop leader should be wary of stereotypes and overgeneralisations here, and together the group should try to paint an accurate picture of who is included, what forms the essence of their discourse, and why, if that question is answerable. In the Baltic Sea case participants were discussing if certain nationalities (or sub-cultures) have a different worldview because their philosophical or ontological relationship to 'nature' and the environment differs: a resource to be exploited like a road or a mine; a pristine thing to be kept isolated from human activity; something that brings back memories of childhood; or a source of spiritual energy and enjoyment. Finns like to claim the last of these.

This begins to lead to the fourth level, the MYTHS AND METAPHOR layer, which contains the deep stories, collective archetypes, the unconscious and often emotive dimensions of the problem or paradox. It includes folk sayings, fairy tales, ancient stories, and even marketing slogans (see Inayatullah 2003, 8, 10). Can the students uncover the myths behind the discourses mentioned earlier? What are the metaphors in play: is the Baltic Sea a road, a toilet, a sailboat's playground? How do artists and philosophers view the topic?

2. Causes and alternatives. In the next step the students should discuss the topic at each level with more of a problem-solving approach, in both identifying causality and then, most importantly, considering alternatives. A CLA table may be used as a tool (the tables in this example have been adapted from Inayatullah 2003, 32). As becomes evident, this analysis goes

through a step-by-step process similar to the Futures Wheel, but while the Futures Wheel extends the topic outwards in time and cause-effect, CLA extends down into the depth of the issue.

At the litany level, the facilitator may ask the following (see Table 2):

What would a current, overdramatised newspaper headline about this topic look like? (See Scenarios for Sustainability.) Who is responsible for the solution? What are the most appropriate short-term solutions?

Level	Problem	Solution	Who can solve it?	Source - information
Litany Official public discourse	Problem seems difficult to solve or easy to solve as depth is not seen	Short term approaches	Government	Television Newspapers
The Baltic Sea litany	What are the problems? Causes? Most visible characteristics?	What can be done? What are the 'instrumental' scenarios?	Who can and should solve these problems?	

Table 2: Causal Layered Analysis Table, Litany layer

At the social causes level, the facilitator may ask the following (see Table 3):

How and why did the issue arise? Who is involved? What is the source of the litany? Why was it presented? Who is being quoted? What are the underlying causes? (Scenarios for Sustainability) What role do designers or the design industry play now, if any? What partnerships could designers form to help solve the problem? What specific part of the problem can designers address? How does design research and theory inform the issue?

Level	Problem	Solution	Who can solve it?	Source - information
Social causes Systemic social science analysis	Problem because of short-term historical factors	Integrated approaches – systemic solutions	Partnerships between different sectors of society	Policy journals, editorials
The Baltic Sea system	PESTEC analysis	What is being done, by whom? What are the 'policy-oriented' scenarios?	Who can solve these problems? What partnerships can be formed?	

Table 3: Causal Layered Analysis Table, Social causes layer

Facilitator questions for the third, Worldview, layer may proceed as follows (see Table 4):

How has this type of issue arisen over time? Who are the stakeholders? What are their values? Who usually talks and lobbies about this issue? What do they stand to lose or gain? Who has the most control over the issue, and what are these dominant values? How are other, more marginal viewpoints controlled or contained? What is being written in fringe/periphery journals about this issue? What would happen if these other views became dominant? (Scenarios for Sustainability; Inayatullah 2003) Where does mainstream design fit in? Does it support the dominant worldview and hold the same values? Is design discourse related to this topic "part of the problem" or "part of the solution"? How? How could designers support the work of the 'preferable paradigm' stakeholders?

Level	Problem	Solution	Who can solve it?	Source - information
Worldview Discourse, paradigm	Constituted by frame of analysis – deep structure	Transform consciousness, change worldview, rethink self and others	Writers, philosophers, those outside the dominant discourse	Peripheral journals, ideological journals, philosophy courses
The Baltic Sea discourses	How is the problem seen in the Big Picture? What is the dominant worldview?	How else can we frame the issue? What are the 'worldview' scenarios?	What are the problematic worldviews, and how can they be adjusted?	

Table 4: Causal Layered Analysis Table, Worldview layer

At the final and most challenging layer, that of Myth and Metaphor, the facilitator may lead the discussion thus:

What is an image or phrase that encapsulates what has been uncovered so far? What work of fiction, movie, poetry, art, etc. evokes an image of the issue being discussed? Are there any myths that may constrain thinking or acting in relation to this issue? (Scenarios for Sustainability) Has design as an artistic and cultural form played a role in constructing and continuing the myth? What myth? How can designers as cultural leaders "change the story"? Alternatively, how can they 'promote' a myth considered socially and environmentally sustainable?

Level	Problem	Solution	Who can solve it?	Source - information
Myth and metaphor	Constituted by core myth, derived from an often traumatic or transcendent event	Uncover myth and metaphors and create processes to imagine alternative stories of what it means to be. Cannot be rationally designed.	Collective unconscious often guided by visionary, mystic leader	Works of artists, visionaries, mystics, and certain movies

		Emergence is necessary.		
The Baltic Sea deep stories	What is the underlying story, the underlying assumptions? The root metaphor?	What are the alternative metaphors? Preferred visions?	Who can create these new stories and images? How can they be legitimised?	

Table 5: Causal Layered Analysis Table, Myth and Metaphor layer

3. Changing the story. The actionable steps at this myth layer and the discourse layer are obviously much more difficult and long-term in scope (Inayatullah 2003, 11). However, in Inayatullah's own words, "[d]econstructing conventional metaphors and then articulating alternative metaphors becomes a powerful way to critique the present and create the possibility of alternative futures" (Inayatullah 2003, 9). Given free rein to unleash their imaginations, it is likely the students can create a new insightful, metaphorical, imagery-based vision, or amplify an existing one. This could even be done through illustration, poetry or drama if time allows.

The facilitator could now guide the students back up through the levels (or have teams tackle layer one, two and three individually), based on the ideal, preferable metaphor. (3) Worldview: how can designers, as professionals or citizens, help effect a shifted worldview, to move the framing of the issue to match the ideal vision? How can design work match this preferable worldview? (2) Social causes: what are the longer-term and shorter-term policies that should be effected, and by which groups of people? (Be specific.) (1) Litany: what are the official policies that should be enacted, and how should they be represented, for example, in the media? What are the regulatory priorities in the short term?

In the Baltic Sea example, a visionary metaphor may call to mind a sailing paradise; a smooth, blue, pristine surface with a delicate understructure that cannot tolerate foreign elements; an enclosed 'swimming pool' of sorts, where inputs have no safe escape route; and so on. The challenge in the workshop is to discuss how to rethink relationships and structures, and how to lead alternative groups (farmers, cruise ship and transport ship operators, coastal land owners, politicians, the list goes on) to a shared worldview where public and individual policy protects the integrity of the Baltic environment.

Practical considerations. The author admits that this workshop is rather difficult to conduct and even more difficult to gain a sense of achievement or progress, being still on the learning curve. It may be helpful to do preparatory research on stakeholder groups and state-of-the-art research findings to help the students move forward. It is important not to remain at or return to the litany level, such that after an afternoon of discussing, the students still feel that "somebody should do something". At the same time, brainstorming practical, shorter-term measures brings the issue to a clearer reality that is truly actionable: the students will have less a tendency to remain too idealist and 'hippy-dippy'. Ultimately the ability to reframe issues and rethink relationships will prove to be a valuable skill in future when one thinks of the challenges in promoting sustainable consumption, developing eco-innovative products and services, and defining one's career and life path.

In conclusion, the ultimate aim of workshops such as these is to sensitise design students to foresight activity and foster foresight ability: "The purpose of foresight is to look for what other people do not perceive; to cultivate that ability requires practice" (Loveridge 1999, 1). Foresight entails a combination of structured and tested information with subjective opinion and pattern recognition; it concerns *analysis* less than *synthesis* and *synthesisers* (Loveridge 1999, 14). The

author suggests that designers and design students are proficient at synthesising the rational and the intuitive; promoting futures thinking is therefore not a difficult step but is a crucial one in these times of uncertainty and constant change.

DESIGN VISIONS PROPOSALS AND TOOLS

The Reconstitution of the Domains of Everyday Life

A tool for assessing the health of existing conditions and a framework for designing sustainable solutions based on principles from the natural world

Gideon Kossoff[1]

Abstract

The interconnected issues facing humankind at a global scale must be addressed holistically at the level of the everyday if we are to transition to a sustainable society. This paper proposes a holistic framework within which an ecological critique of everyday life can be made and from which alternatives can be developed. The framework brings together 4 strands of thought that include: 1) Everyday life as the context for social and environmental issues 2) holistic principles from the natural world 3) a theory of needs and their satisfaction 4) nested, networked, self-organizing and emergent social forms. This methodology is used to disclose underlying principles of 'wholeness' found in pre-industrial societies in order to understand the shortcomings of modern society.

[1] Centre for the Study of Natural Design, University of Dundee (SCOTLAND). PhD researcher, gskossoff@dundee.ac.uk

1. Introduction

Social, cultural and ecological systems worldwide (life support systems) are in decline. The air we breathe, the food we eat and the water we drink as well as the buildings and streets, cities and countryside which we inhabit, are all part of an immensely complex web of life whose ecological, social, economic and cultural problems cannot be disentangled from one another nor addressed in isolation. Transitioning to a sustainable society requires methods for addressing these issues in an integrated and holistic way. In this paper I propose the application of holistic principles to everyday life which has the potential to bring about a reconstitution of the essential forms within which everyday life occurs; our households, neighbourhoods, villages, towns, cities and regions, and, ultimately, the planet itself. Such a rebirth of these archetypal social and cultural forms is necessary if we are to achieve what Manzini and Jegou refer to as the 'sustainable everyday' (Manzini and Jegou 2003) .

2. Everyday Life as the starting point

"It is the everyday that receives our 'daily inattention'" — George Bataille (Highmore 2002, 21)

Although it is the most fundamental level of existence, there has been relatively little systematic thought devoted to everyday life. Social critics such as Henri Lefebvre (1901-1991), Guy Debord (1931-1934) and Agnes Heller (1929-) have argued that everyday life, especially since the Enlightenment, has been trivialized, denigrated or simply ignored by mainstream Western thought. Sociologist Michael Gardiner argues *"With the transition to modernity, and the fracturing of the social world into a multiplicity of specialized practices, everyday life emerges as something that is 'left over', and hence of little consequence in relation to such 'superior' pursuits as politics, the arts, or science"* (Gardiner 2000,11). The lowly status of everyday life has legitimized the dissociation of specialized disciplines from it (economic, political, technological, healthcare, the arts, design, education, architecture among others), and they are now presided over by experts. These specialisms and the fragmented and increasingly abstracted knowledge they generate relate at best, to *aspects* of everyday life, but bear little correspondence to life *as we live it*. Guy Debord spoke of the *"evident will to hide behind a development of thought based on the separation of artificial, fragmentary domains so as to reject the useless, vulgar and disturbing concept of 'everyday life'.... Modern society is viewed through specialized fragments that are virtually incommunicable; and so everyday life, where all questions are liable to be posed in a unitary manner, is naturally the domain of ignorance."* (Debord 1961,239-240) The irony is that everyday life is reduced to *"a domain of ignorance"* yet much of it is designed and organized according to the dictates of an "expertocracy" (Andre Gorz cited in Gardiner 2000, 5) The result is the fragmented physical reality of our daily experience.

In order to transition to a sustainable society, we must apply holistic thinking *directly* to everyday life. A framework is needed which integrates all of its aspects without mediation from specialized disciplines or fields of expertise. This is not to say that specialisms should be eliminated, but rather they should operate within the context of a holistic framework which is *prior* to specialization.

3. Holism and human affairs

Holistic principles

The basic premise of my argument is that the same principles are present in healthy living systems (e.g. organisms, ecosystems, and the planet itself[2]) as in robust, sustainable societies. In recent decades there has been renewed interest in holism from science, popular culture and alternative healing disciplines, however it remains marginal in the contemporary social, political, economic and cultural discourses. In this paper I argue that there is a rich social 'organicist' or 'holistic' tradition that is of great relevance to sustainability practitioners and activists. In order to become a useful method for critique and design, the holistic tradition must transcend its past shortcomings and embrace contemporary concerns and new insights into the interdependent and networked structure of natural systems.

Since the Ancient Greeks using the metaphor of a living organism to understand and help order society has been a recurring theme in Western thought. Referred to in this paper synonymously as *Holism* and *Organicism*, this concept has been found either implicitly or explicitly within many political, social and economic philosophies and has been remarkably consistent it its application of holistic principles to society, but not necessarily in its conclusions (Phillips 1976).

The key principles adopted by social holists[3] are 1) 'emergence'; the concept that the whole is different and greater than the sum of the parts, 2) 'interdependence'; the idea that everything within a whole affects everything else, and 3) 'self-organization'; the structure and behaviour of a whole arises from within and is independent of external forces[4].

A 4th holistic principle that has yet to find its way into mainstream social theory is that of 'holarchy' and is perhaps the single most important idea with respect to the design of a sustainable society. This idea emerged out of twentieth century systems theory and posits that wholes in the natural world exist within extensive nested and networked structures. Systems at the micro-level are numerous and relatively simple (atoms, molecules, single cell organisms etc) and systems at the macro level are fewer but more complex (ecosystems, biomes, galaxies etc). The scientist and philosopher Arthur Koestler (1905-1983) coined the term 'holon' to describe each individual system. Holons are at once *wholes* in their own right but also *parts* of larger wholes or systems. Koestler coined the term 'holarchy' to describe nested structures of holons in the natural world (Koestler,1978, 23-56, 289-311). Biologist Joseph Needham (1900-1995) declared that *"The hierarchy of relations, from the molecular structure of carbon compounds to the equilibrium of species and ecological wholes, will perhaps be the leading idea of the future."* (Koestler,1978, 31) We argue that it should become one of the leading ideas of sustainability theorists and activists.

The Holistic Tradition

Historically, holistic principles have been employed at both ends of the ideological spectrum: conservative, when it is used to justify and maintain the status quo; and radical when it is used to critique and change the status quo[5]. *Conservative holism* sees society itself as an organism and bases its arguments upon a presumed, intrinsic social unity; any single change will affect everything else. Moreover, if society is already a 'unity', there is *no need* for change. For instance, sociologist Talcot Parsons (1912-1979) took as his departure point a supposed social unity or wholeness and argued that the function of society's interdependent parts (the family and the economic, religious, political and educational systems) was to preserve this unit. *Radical holism* argues that our society has become fragmented and uses the metaphor of the unity of the organic to generate norms to which it should aspire. In this case holism is used as a tool for

[2] Gaia theory, developed by scientist James Lovelock proposes that the entire planet is a web of symbiotic/systemic relationships that self-regulate to preserve the conditions conducive to life. See Lovelock, 1991. See Capra, 1996 for more on principles of living systems.

[3] The term social holism describes any social, political or economic philosophy which implicitly or explicitly employs the metaphor of the organism. It has usually been associated with various kinds of collectivism.

[4] A further important principle is that of 'growth and development' but this is beyond the scope of this paper to discuss

[5] This distinction between conservative and radical organicism/holism is based Werner Stark's distinction between positive and normative organicism. He argues that the former seeks to preserve the status quo whilst the latter seeks to change it by deriving norms, or values, from 'the organic'. It should be noted, however, that normative holism is not necessarily progressive or radical. The Nazis, for example, used holism as part of its ideological justification for totalitarianism. See Stark 1962, and Harrington 1996.

critique to establish a contrast between what society *is* and what it *could become*.

Radical holism developed as an anti-authoritarian tradition in the latter half of the nineteenth and the twentieth century whose representatives described themselves as anarchists, libertarians, communalists, socialists and social ecologists[6]. These include scientist/philosopher Peter Kropotkin (1842-1921), biologist/planner Patrick Geddes (1854-1932), philosophers Gustav Landauer (1870-1919), Martin Buber (1878-1965) and Murray Bookchin (1926-2006), historian/regionalist Lewis Mumford (1895-1990) and economist Jane Jacobs (1916-2006). The radical holists argued that society's organic social forms have been *"hollowed out"* (Buber, 1958, 11) which severely compromised the ability of communities to be self-managing and autonomous and they contended new organic social forms were needed to adequately address modernity's many crises.

Social theorist Gustav Landauer defended the organic cohesion of traditional society and argued that coercion in modern society could only be overcome through the reinvention of an organic community that arises out of the multiplicity of small interrelations of daily life. Religious philosopher Martin Buber (1878-1965) contended that industrial capitalism eats away at society's *"cellular tissue"* (Buber, 1958,14), undermining organic communal structures and leaving a vacuum filled by the nation state, which assumed responsibility of community based institutions. Buber proposed the repair of the cellular tissue of society through the creation of an *"organic commonwealth*"(Buber, 1958,136) a confederation of small, autonomous communities.

The historian/regionalist Lewis Mumford (1895-1990) was more explicit in his use of the term 'organic' in the social realm, and used words such as 'associative', 'mutualistic', 'integrated', and 'interdependent' to describe an organic society. Much of his work explored how, in modern times, diverse organic social forms were displaced by a single, centralising and mechanistic entity. He dubbed this entity the megamachine; a form of social organisation in which the processes of daily life had become automated, standardized, and quantified. The parts of the megamachine included the factory (devoted to standardized mass production), the standing army (the first instrument of mass, standardized consumption), and bureaucracies (in which human beings became interchangeable functionaries). Within this model, all society's life support systems; monetary, healthcare, education, and agriculture took on the same mechanistic characteristics (Mumford, Lewis, 1970).

Social ecologist Murray Bookchin (1921-2006) argued that the principle of 'unity in diversity', (as exemplified by natural ecosystems) has radical political and social implications: *"Natural diversity is to be cultivated not only because the more diversified the components that make up an ecosystem, the more stable the ecosystem, but diversity is desirable for its own sake, a value to be cherished as part of a spiritized notion of the living universe"*

He maintained that relationships within ecosystems are complementary rather than hierarchical: *"Virtually all that lives as part of the floral and faunal variety of an ecosystem plays its coequal role in maintaining the balance and integrity of the whole".* Bookchin argued that the ecosystem is so complex it cannot be managed, controlled or reduced to simple *"physico-mechanical properties"* (Bookchin 1980, 59)— its spontaneity must be respected. Using ecological principles as the foundation of his social critique he argued that hierarchy and domination are at the root of our modern crises. He argued that modernity's quest to dominate nature grew out of hierarchical forms of social organization.

The corollary of this critique of hierarchical/inorganic society is that an organic society would be characterised by social spontaneity and an absence of hierarchy. Bookchin cites anthropologists such as Paul Radin (1883-1959) who demonstrated that the latter were characteristics of many pre-literate, tribal societies and referred to them as 'organic'. He declared:

"We are travelling the full circle of history. We are taking up again the problems of a new organic society on a new level of historical and technological development — an organic society

[6] I use the term 'radical holism' to distinguish between those anti-authoritarians who refer to nature to justify their social norms, and those who do not.

in which the splits within society, between society and nature, and within the human psyche that were created by thousands of years of hierarchical development can be healed and transcended" (Bookchin 1980, 252)

Holistic principles and traditional societies

Social holism has been criticized for both its conservative tendencies and inability to adequately define a 'social whole'. Sociologist Scott Gordon complains that social holists have *"an almost limitless array of social entities to choose from"* (Gordon 1991, 657) and they do not account for why the particular social entity or collective they have identified is any more whole than the putative wholes identified by other social holists. Moreover, the wholes identified tended to be abstractions that bear only a tenuous relationship to everyday experience. An illustration of this inability to adequately identify authentic organic social wholes is the idea of the 'nation state' which Scott Gordon referred to as *"the most favoured collective entity"* (Gordon 1991, 658) and yet which embodies none of the holistic principles of self-organization, emergence, holarchic structure and interrelationships; indeed the concept is the opposite in its hierarchical, centralized structure. Sociological literature is replete with references to various types of abstract 'wholes' such as 'the general will of the people' (philosopher Jean-Jaques Rousseau, 1712-1778). This is not to say that such abstractions do not correspond in any way to human experience, but rather that they live as abstract theoretical 'fragments' that are dissociated from it.

A more tangible manifestation of the metaphor of organic 'wholeness' can be found in many sustainable, pre-industrial cultures in which holistic principles found in natural systems underpin everyday life. Emergence, self-organization, interdependence and holarchic structure were characteristics of societies as diverse as the early 20th century Ladakhi in India, the 16th century Hopi of North America and the Renaissance Sienese. It is not our intention to idealize these societies nor discount their shortcomings, rather our investigation attempts to understand what it was about everyday life in these societies that made them sustainable (i.e. they were able to flourish over generations in place and in relative resonance with natural systems).

Some sociologists have argued that such cultures were more organic (whole) than industrial and modern society and make a positive correlation between a society's degree of organic structure and the robustness of its social forms. The sociologist Ferdinand Tonnies (1855-1936) distinguished between pre-industrial societies characterised by 'Gemeinschaft' (tightly integrated, *'organic'*, social groupings based on kinship and face-to-face relationships in small scale communities) and industrial, modern (especially urban) cultures characterised by 'Gessellschaft' (loosely knit social groupings based upon contractual relationships) (Tonnies, 2001)

Sociologist Gerard Delanty notes the preoccupation of *"modern thought from the Enlightenment onwards ... with a sense of the passing of an allegedly organic world*" (Delanty 2003,15*)*, and describes this preoccupation as *"a discourse of loss*" (Delanty 2003, 11*).* For the radical holists this *'discourse of loss'* runs alongside what might be called a *'*discourse of hope*'* in which organic social forms that were lost can and must be recovered incorporating the technological and social advances of the last two hundred years. The problem lies in the failure to progress the organic metaphor in a meaningful way and elucidate what it was that made some pre-industrial cultures more sustainable and whole than our own. My argument is that a closer diagnostic look reveals the way in which holistic principles were embodied in their everyday lives, which in turn can provide us with guidelines for recovering organic structure in our own society.

4. The Satisfaction of Needs in Everyday Life

One of the most striking differences between traditional communities and the modern equaivalent is the fact that the former were relatively autonomous in their ability to satisfy both subsistence and non-material needs within their own boundaries. Development economist

Manfred-Max Neef (1932-) identifies ten needs that human beings have in common, but that are satisfied in ways that are unique to place, culture and era. The viability of a community depends upon how and if these needs are satisfied. These universal needs, according to Max-Neef are: 'subsistence', 'protection', 'participation', 'creativity', 'freedom', 'understanding', 'idleness', 'affection', 'transcendence', 'security' (Max-Neef, 1991, 13-54).

There is room for debate about whether or not Max-Neef has identified the 'right' set of needs and in its full application his method tends toward the formulaic[7]. What is relevant, is that within the traditional cultures discussed, social forms were emergent and arose out of the process of communities satisfying universal needs in place/culture specific ways and that their control over the satisfaction of these needs was directly related to the 'wholeness' or organic structure of their society.

In such communities, most needs—material and otherwise—were satisfied with relatively little recourse to the outside world. Food was locally grown, shelter and other artefacts were usually created from local materials, and energy was derived from available biomass, water or wind. Non-subsistence needs were also satisfied from within the community. For example, a common feature of traditional communities were councils which oversaw the affairs of the village, resolved disputes, coordinated harvests and satisfied the needs for 'freedom' and perhaps 'participation'.

5. Self-Organizing Social Forms

We can now combine the four strands of everyday life, holistic principles, theory of needs and nested networked social form to understand the dynamics of wholeness with respect to social form:

1) Self-Organization: a community is more likely to be self-organizing if it does not depend on external intervention or management for the satisfaction of its needs. Pre-industrial communities were not necessarily perfect self-organizing systems; there have been many social, cultural and economic practices within such communities that meant that some individuals were able to coerce or control others, and in as much as they were internally coercive, pre-industrial communities were imperfectly self-organizing. In *The Ecology of Freedom* (1982), Murray Bookchin argues that it was ultimately the coercive hierarchies that arose *within* organic communities that led to their downfall. Nevertheless, such pre-industrial communities could be said to be self-organizing *in relation to their external environment*.

2. Emergence: in as far as communities were self-organizing, they could be said to be emergent. No external dictates, design, blueprint or management brought them into being, rather, they emerged out of the ongoing process of striving to satisfying their needs.

3. Wholeness: traditional communities could be said to be more 'whole' than their modern counterparts because the relationships of which they were comprised were tight and mutually influencing and grew out of the mutual satisfaction of needs. These relationships did not exist solely between people (which is the focus for most social holists), but extended to include the natural world, the artifacts and structures they created *and* the relationship between the 'built' and natural worlds. Only through acknowledging and understanding the nature of this tight and semi-autonomous web of relationships can we begin to assess and reconstitute wholeness within social form.

4. Holarchic structure: one of the key characteristics of pre-industrial society was their ability to satisfy their needs *at different levels of scale* of everyday life which gave rise to distinct and clearly defined social forms. I have coined the term *Domains of Everyday Life* (Kossoff, 2007) to describe the nested (holarchic), emergent and relatively self-organized webs of relationship

[7] There is a body of work pertaining to human needs, (Illich 1978, Leiss 1978 and Maslow 1999), however only Maslow offers an alternative systematized theory. This is an area that the author would like to see explored by sustainability theorists and activists in order to develop a more flexible and practical system.

between people, their artifacts and nature which came into being as communities strove to satisfy their needs in place-specific ways at different levels of scale. These Domains of Everyday Life have repeatedly arisen throughout history are: the household, the village or neighbourhood, the city (or town) and the region. They provided the context within which everyday life was lived and resemble natural ecosystems in their structure.

Within the Domains of Everyday Life, many needs could be simultaneously satisfied. Max-Neef refers to this as the *integrated* satisfaction of needs which we argue is an important component of social wholeness. For example, a wide range of activities often took place within the domain of the traditional household. Not only did it provide shelter for the family, but was a place where the family's livelihood was generated without dependence upon an external market. Economist Scott Burns notes, that *"A colonial family of 1770, in a settled area such as Connecticut, made its own shelter, provided its own fuel and light, raised its own food, and slaughtered its own animals. It also made most of its own fabric and clothing. Money was scarce because there was little need of it.....such a family produced about 75% of its own* [subsistence] *needs within the household."* (Burns 1975, 73) A further example of the integration of needs might include the repair of the roof of a house as a village event, in which a community's need for shelter, security, affection, participation and creativity would all have been simultaneously satisfied.

At the level of the village, historian Norman Wymer (1911-1982) observed that: *"Every* [English] *village boasted its full complement of blacksmiths, saddlers, thatchers, builders, plumbers, carpenters, joiners, woodmen, wheelwrights, rake-makers, coopers, and tanners. In the cottages, too, the women would be busy spinning and weaving the wool from the sheeps backs, making linen out of flax, or quilting, while their menfolk toiled in the fields or village workshops".*(Wymer 1951, 37)

And historian Ferdinand Braudel writes that before the industrial era:

"90% to 95% of the towns known in the West had fewer than 2,000 inhabitants [ie what we would now be consided a modest sized neighbourhood] *yet normally enjoyed a full range of craftsmen and artisans and merchants and farmers... a typical English town of several thousand as late as 1880 or 1900 would have blacksmiths and shoemakers, plumbers and carpenters, bakers and butchers, brewers and millers, saddlemakers and harnessmakers, tailors and seamstresses, dentists and midwives, a pub and a church and a reading room, an inn and a market and a row of shops"* (Braudel 1973)

However, the Domains of Everyday Life were not given equal emphasis in all pre-industrial cultures. For many cultures certain domains were emphasized over others, and in some cases were completely absent. The homesteading culture, cited previously emphasized the domain of the household, but a hunter-gatherer culture would have emphasized the domain of the region within which they moved and to which they were very highly attuned; the domain of the city would have been non-existent. For the Ancient Greeks, the city ('polis') was the level of everyday life ascribed the highest status, and the role of the household was seen as a place for slaves and women. In the cities of medieval Europe, the household, the neighbourhood and the city were often highly developed social forms in their own right.

Each of the Domains of Everyday Life had its own particular role in the life of the community, and often the same needs were satisfied in different ways at each of these levels of scale. For example, at the level of the household, the need for 'affection' would be satisfied by long term, often biologically based, multigenerational relationships, whilst at the level of the neighbourhood, the same need would be satisfied by more freely chosen friendships. Needs might also be satisfied in different ways in domains at the same level of scale. For example, in a single region one village might satisfy its need for food by a diet based on arable crops, whilst another might satisfy this same need through fishing and small scale horticulture. Although the Domains of Everyday Life could be described as universal/archetypal forms that were common worldwide, throughout history, these archetypes were diversely expressed as an emergent property of people satisfying their needs in ways appropriate to their time, culture and place.

Whilst each domain was semi-autonomous, they were also mutually interdependent; with domains at the same level of scale and also between levels. At the same level of scale, households had relationships with other households, neighbourhoods with neighbourhoods etc. At different levels of scale, households had relationships with the neighbourhood within which they were nested, neighbourhoods with cities, and so on. The Domains of Everyday Life were not only self-organising and emergent wholes, but what Koestler called holons, or whole/parts (Koestler 1978, 27).

Each domain represented a different level of community, and each level of community had its own qualities and possibilities. Moving from inner domains to outer domains, from the household through to the region, relationships between people, their artefacts and nature become progressively less intimate and more transient, but more multiple and diverse. The pre-industrial domain of the household could be seen as a small, tightly bound 'community' based on relatively few, long-term relationships; the domain of the neighbourhood was a larger, less tightly bound community, but had more variegated relationships, and so on, moving out through the domains. It is this shift from 'thick' to 'thin' and *few to many* relationships that gave the domains their respective roles in the overall organisation of pre-industrial communities. For example, the domains of the household, neighbourhood and village were levels of everyday life better suited to the creation of livelihoods than the domain of the city, which provided a market that enabled neighbourhoods, villages and households to trade. The domain of the city or region was more likely to support universities, hospitals and other cultural institutions than the inner domains.

My argument is that the degree of sustainability realized by these types of pre-industrial communities was directly related to the robustness (wholeness) of the domains of everyday life which can be seen as the skeletal structure of society. One can also speculate that the ability of such communities to endure over long periods of time was due to their ability to retain control over the satisfaction of their needs.

6. The Fall and Rise of The Domains of Everyday Life

Even a cursory analysis of modern society reveals that it is not organized according to the previously discussed holistic principles. The Domains of Everyday Life are still present — we still have 'households', 'villages, 'neighbourhoods', 'cities' and 'regions'— but, to use Buber's phrase, they have become 'hollowed out'. Instead of functioning as semi-autonomous and robust wholes that integrate the satisfaction of needs in everyday life, today the domains are little more than fragments within externally controlled, unsustainable globalized systems. The inhabitants have little control over these globalized systems, yet are completely dependent upon them and have therefore lost control over the satisfaction of their needs. Max-Neef argues that control of the satisfaction of human needs by dominant minorities has been one of the hallmarks of civilization that has undermined communities, resulting in Buber's 'hollowing out' or loss of organic structure. In modern society this control has become extreme.

Satisfaction of needs has been almost entirely appropriated in modern society by centralized entities such as the nation-state and market economy. Radical holists and others have argued that this process of dismantling self-organizing, emergent communities has been an aggressive policy pursued by nation states. In his book *Mutual Aid* (1902), Kropotkin laments that in Europe nation-states

"weeded out...folkmotes...courts and independent administration....lands were confiscated...guilds spoliated of their possessions....cities divested of their sovereignty...the elected justices and administration, the sovereign parish and parish guilds...were annihilated: the state's functionary of every link of what formerly was an organic whole [absorbing] *all it social functions...*[it saw] *in the communal lands a means for gratifying its supporters..they* [the nation-states] *have broken all bonds between men."*(Kropotkin 1987, 182-199)

Lewis Mumford argued that the ‘Megamachine’, described above, was designed to establish *“predictable behaviour and remote control from the centre* [by transferring] *autonomy from each individual member and group in the community to the organized whole in which they would function only as obedient machine-like parts*.” (Mumford 1970,100) Local and community based social forms (including what I have referred to the Domains of Everyday Life) were replaced with centrally conceived, managed and directed institutions such as factories, the military, police, judiciary, joint-stock companies, schools, and hospitals.

The result of this centuries-long process many needs can now only be inadequately satisfied by recourse to distant and often unaccountable institutions. The result is that for most people on the planet, subsistence needs can now only be met by engaging in the globalized market, which is centrally controlled by a handful of corporations. Non-material needs such as ‘understanding’, ‘participation’,‘freedom’ and ‘security’ have suffered a similar fate as the political process, education, leisure, healthcare and so on have been appropriated by both the market and the nation-state.

As the process of satisfying needs is ceded from the Domains of Everyday Life to institutions external to them, the domains are transformed into fragments of these large, centrally controlled systems, and so lose their vitality and go into decline. The consequences are varied and global in scope and include, the impoverishment of domestic life, the decline of villages, the disappearance of distinctive neighbourhoods within cities, formless and ecologically damaging urban sprawl which eats into the surrounding countryside, the loss of regional culture and identity, and the ruination of landscapes. In other words, as the Domains of Everyday Life go into decline, so society becomes ecologically, socially and culturally unsustainable.

An important step in the transition to a sustainable society will be the reconstitution of the Domains of Everyday Life which will require their inhabitants to regain control over the satisfaction of needs. Such a revival of organic form would see households, villages, neighbourhoods, cities and regions reconstituted as sustainable, semi-autonomous but interdependent social forms that can become the context for healing what Murray Bookchin called *“the splits within society, between society and nature, and within the human psyche*”. (Bookchin 1980, 252)

Because different communities satisfy their needs in different ways that are specific to culture and place, the reclaimed domains would be diverse and varied in their expression. This decentralising process would eventually lead to the demise of institutions that currently preside over communities, and upon which communities are dependent. To the list of traditional domains that must be reclaimed we can now add ‘The Planet’ as a domain within which our everyday lives are lived and within many needs can be satisfied. Living sustainably in the domain of the planet will endow everyday life in a holistic society with a diversity and cosmopolitanism that traditional societies lacked.

6. The Reconstitution of The Domains of Everyday Life

In the sense that this approach creates a tension between what ‘is’ and what ‘ought to be’, it is utopian, however a more accurate description might be ‘ecotopian’, due to its advocacy of a society based upon ecological or holistic principles. A visualization or future-casting process is needed to generate clarity about what in contemporary society needs to be changed, and provide a guidelines for change. My intention is to provide a methodology to enable practitioners and activists to more appropriately critique and assess existing conditions, and to conceive and design solutions to bring coherence to the multitude of sustainability initiatives being conceived in a more or less piecemeal fashion worldwide. It is conceived as a way of creating a symbiotic relationship between theory and practice, and transforming everyday life from what Guy Debord called *“a domain of igorance”* into a domain of knowledge and grassroots activism.

Through the lens of this framework one can examine a particular domain and analyze how the needs that arise within it are being satisfied (or not) and design ways in which they could be satisfied more appropriately/sustainably. One can ask how the broken strands of interelationship between people, their artefacts and nature can be rewoven.

One of the most significant barriers to the reconstitution of the Domains Everyday Life is the fact that the issues pertaining to it do not correspond to either the academic disciplines nor professional areas of specialty. The problems of everyday life are, what Horst Rittel referred to as 'wicked problems' (Buchanan 1995, 12-18) and are characterized by incomplete, contradictory and changing requirements whose solutions are difficult to either recognize or achieve because of their complex interdependencies. The solution to one aspect of a wicked problem often reveals or creates others. Such problems cannot be neatly parceled up and handed over to sociologists, ecologists, economists, geographers, architects, engineers, psychologists, or even designers and will call for a reconsideration of both educational systems and the ways in which professional specialties are applied. Reconstituting the Domains of Everyday Life requires transdisciplinary collaboration between educators and practitioners in all disciplines. Since each domain is the creation of a community of people *living in place*, specialists must work as facilitators of a community-led process to recover control of the satisfaction of needs. Design, as the realm within which many disciplines converge and are applied is uniquely positioned to lead this ongoing process of the reconstitution of the Domains of Everyday Life. This would constitute a new kind of planning in which communities are redesigned from within.

The cultural theorist Mikhael Bakhtin (1895-1975) (Gardiner 2000, 20) argued that we need to seek out *"the shoots and buds of potentiality "* in everyday life. The framework proposed in this paper can help us identify and nurture these shoots and buds; myriad sustainability initiatives which are currently underway or as yet are only ideas. When enough of these are networked together at different levels of scale, they will form complex 'ecosystems of potentiality' in everyday life. If this potential is realized, the Domains of Everyday Life will begin to flourish and we will witness the rebirth of households, neighbourhoods, villages, cities, regions and the planet itself as self-organizing, emergent, and networked wholes. This rebirth is an essential part of the transition to a sustainable society.

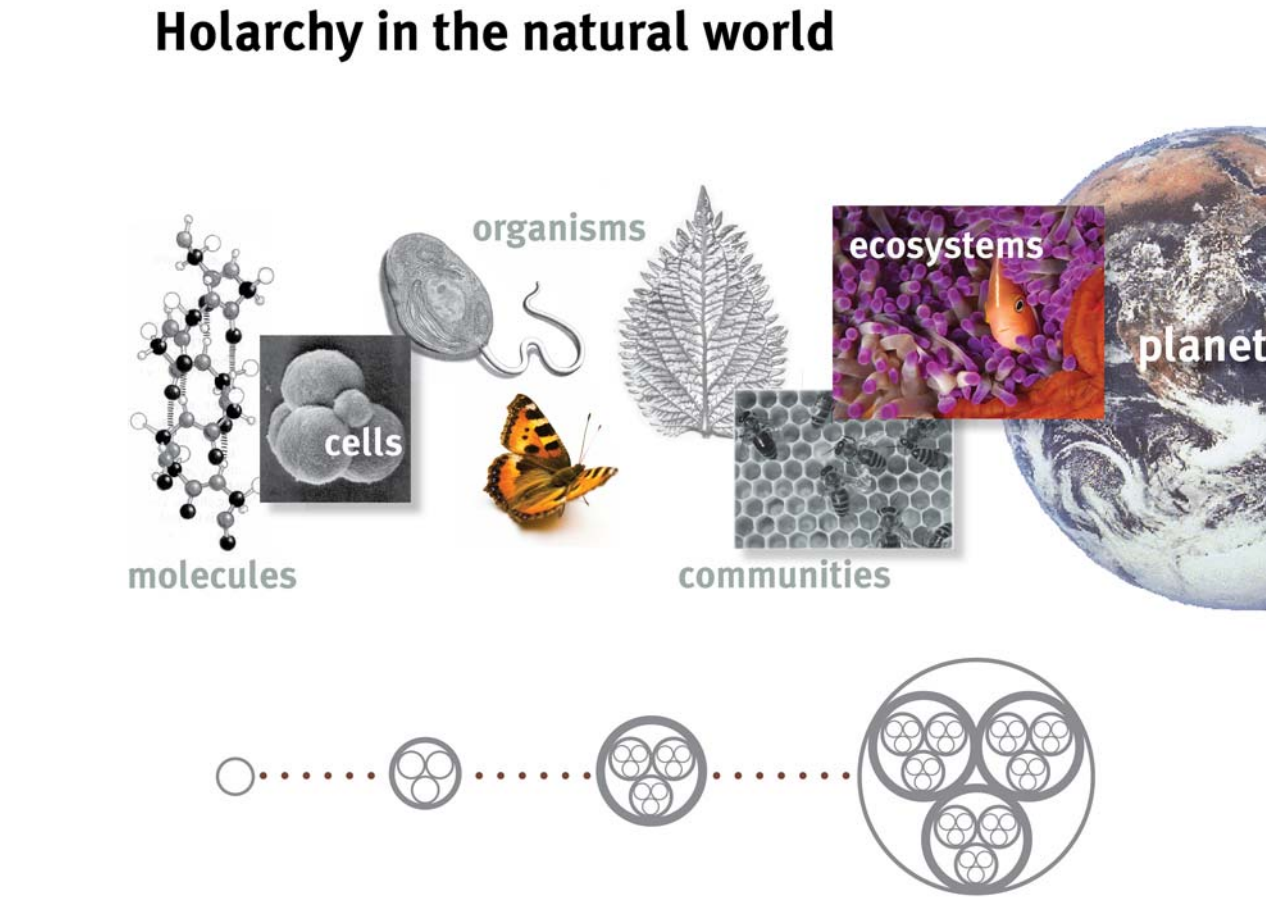

Fig. 1: structure in nature is comprised of 'holons', parts that are both semi-autonomous wholes, but also parts of larger wholes or systems. This organic structure is nested, networked and interdependent and is a characteristic of pre-industrial sustainable communities.

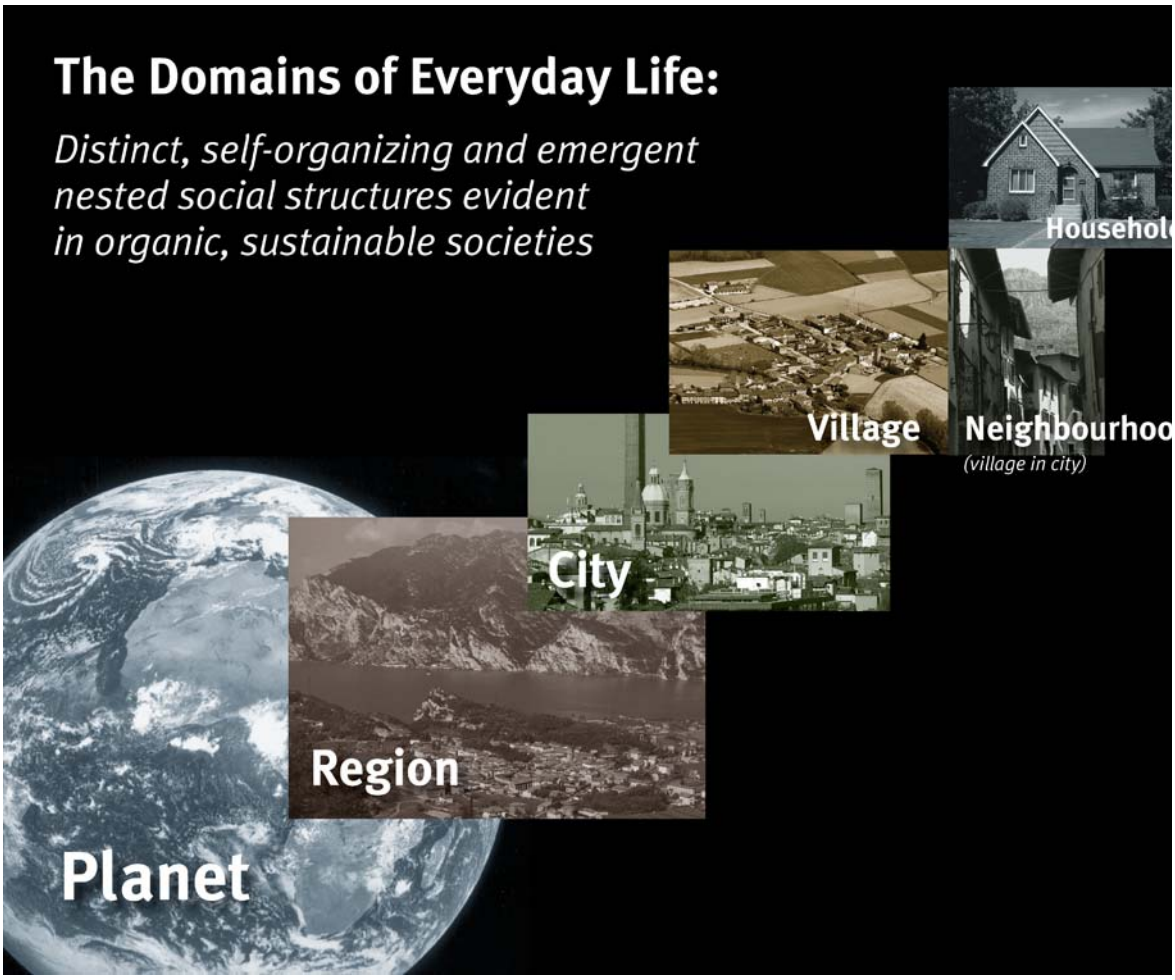

Fig. 1: within traditional, sustainable societies, similar archetypal, distinct nested social forms have emerged throughout history, across a wide variety of cultures. These 'Domains of Everyday Life' are: the household, the village/neighbourhood, the city, the region, and—in the modern era—the planet.

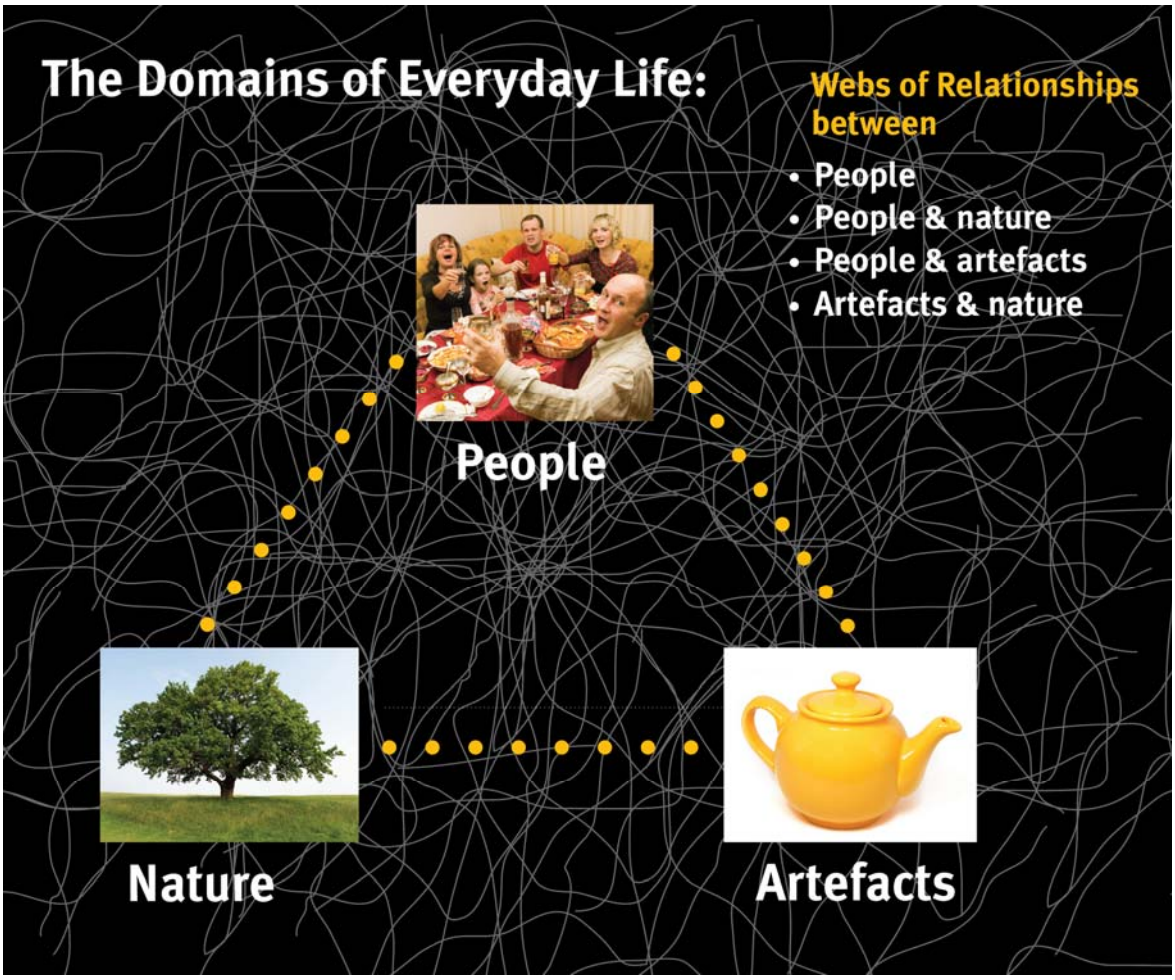

Fig. 1: the Domains of Everyday Life can be seen as nested ‘webs of relationship’ that exist between people, the artifacts they create and the natural world.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Designing innovative forms of intermediation and communication

Towards sustainable production and consumption systems

Lia Krucken[1]

Abstract

The aim of this paper is to bring to light novel forms of intermediation and communication between producers, consumers and organizations that support sustainable solutions for production and consumption. In order to illustrate how producers and consumers combine to meet the challenge of developing sustainable solutions for intermediation and communication, some examples from Brazil and Italy are presented, with a particular focus on biodiversity products.

[1] University of The State of Minas Gerais, Design School, lia.krucken@gmail.com

1. Introduction

The aim of this paper is to bring to light novel forms of intermediation and communication between producers, consumers and organizations that support sustainable solutions for production and consumption. In order to illustrate how producers and consumers combine to meet the challenge of developing sustainable solutions for intermediation and communication, some examples from Brazil and Italy are presented, with a special focus on biodiversity products.

2. Design in contemporary contexts

The designer takes on the clear role of facilitator of collective innovations and systemic solutions. The main design support actions identified can be grouped as follows:

- **Promoting vision and systemic innovation**: visualization of "the production and consumption system"; enabling innovative forms of intermediation and interaction among players; conception of scenarios and solutions for the future; development of transversal relations between people, organizations and values;
- **Supporting value creation for local qualities and resources**: recognition and communication of local identifying features and qualities; design of products and services strongly linked to the territory of origin; value creation and protection of "territory + community + resources" complex;
- **Fostering sustainable ways of production and consumption:** promotion of producer and consumer awareness about environmental, cultural, economic and social values embedded in products and services; promotion of new aesthetical values and ways of product quality perception; supporting the inclusion of the consumer invalue creation, as part of the solution, together with producers and stakeholders.

It is to be noted that the scope of design is being progressively enlarged and oriented towards a systemic perspective, which includes the projection and the planning of sustainable products and services systems. Hence, innovative tools and guidelines to support the design action are needed. Important advances in these means have been highlighted in the last decade (Manzini, 2006; Thackara, 2005; Manzini, Jegou and Meroni, 2004; Margolin, 2000; Castells, 1999), and will be examined in this paper.

Indeed, designers face a complex set of tasks, as outlined by the International Council of Societies of Industrial Design (ICSID, 2005): "*Design seeks to discover and assess structural, organizational, functional, expressive and economic relationships, with the task of: Enhancing global sustainability and environmental protection (global ethics); Giving benefits and freedom to the entire human community, individual and collective Final users, producers and market protagonists (social ethics); Supporting cultural diversity despite the globalisation of the world (cultural ethics); Giving products, services and systems, those forms that are expressive of (semiology) and coherent with (aesthetics) their proper complexity.".*

3. Creating value for products and territories

The relationship between local resources and productive communities has been explored by the LEADER European Observatory for Rural Development. It introduced the concept of "territorial capital" as "elements set available in the material and immaterial level which can

constitute, in some aspects, advantages and in others, disadvantages" (LEADER, 1999, p.19). It is important to consider the dynamic character of territorial capital: it can only be evaluated according to the history (its past) and recognition of past elements, and its specificities can support the construction of a strategy (future), in other words, "the territory project". Moreover, there are relations that are global (external networks, exchange with markets and institutions) and those that are local (local networks, interaction between actors and institutions from the territory) which are involved with the territory and are fundamental in the "territorial capital" analysis.

In this sense, territorial capital leads to what is considered as local wealth (activities, landscape, patrimony, traditional knowledge, etc), aimed at promoting territorial competitiveness.

The notion of territorial competitiveness is corroborated by Cristallo (2003), who introduces the idea of the "environment-company" or a decentralized company, i.e., the territory is seen as a "productive habitat". The term "productive habitat" refers to an articulated and complex system of productive activities located in a certain territory, within an environment in which all that is produced is narrowly linked to the binomial context-identity. In many cases the local company is determined by an informal economy that promotes the establishment and equilibrium of relations between territorial, human, physical, economic and intangible resources.

The hypothesis sustained in this work is that the design perspective can contribute to making society aware of the origin, history and values embedded in products. Design can help to establish the world and strategic vision of user-oriented offers, making more explicit the myriad of parameters to be considered in planning value systems. Besides, design can get closer to both sides of the production cycle through oriented communication: the raw material producers and the final consumer. Designers play a clear role as opinion leaders and can provide direction for developing more sustainable values.

4. Critical questions faced by designers

In conventional value chains we can observe several levels of activities that arise from the distance between the producers and consumers (Fig. 1). In this simplified scheme we can identify raw material producers, transformers, distributors and final users. In complex chains, involving a great number of actors, consumers are not always are able to identify the producers of raw materials. That is to say, proximity and traceability may be lost.

This framework can be useful in order to identify at which points design interventions occur (or could occur) and how value (of products and services) is created or enhanced to develop new forms of intermediation and communication. Therefore, designers face various questions, which will be discussed in this paper.

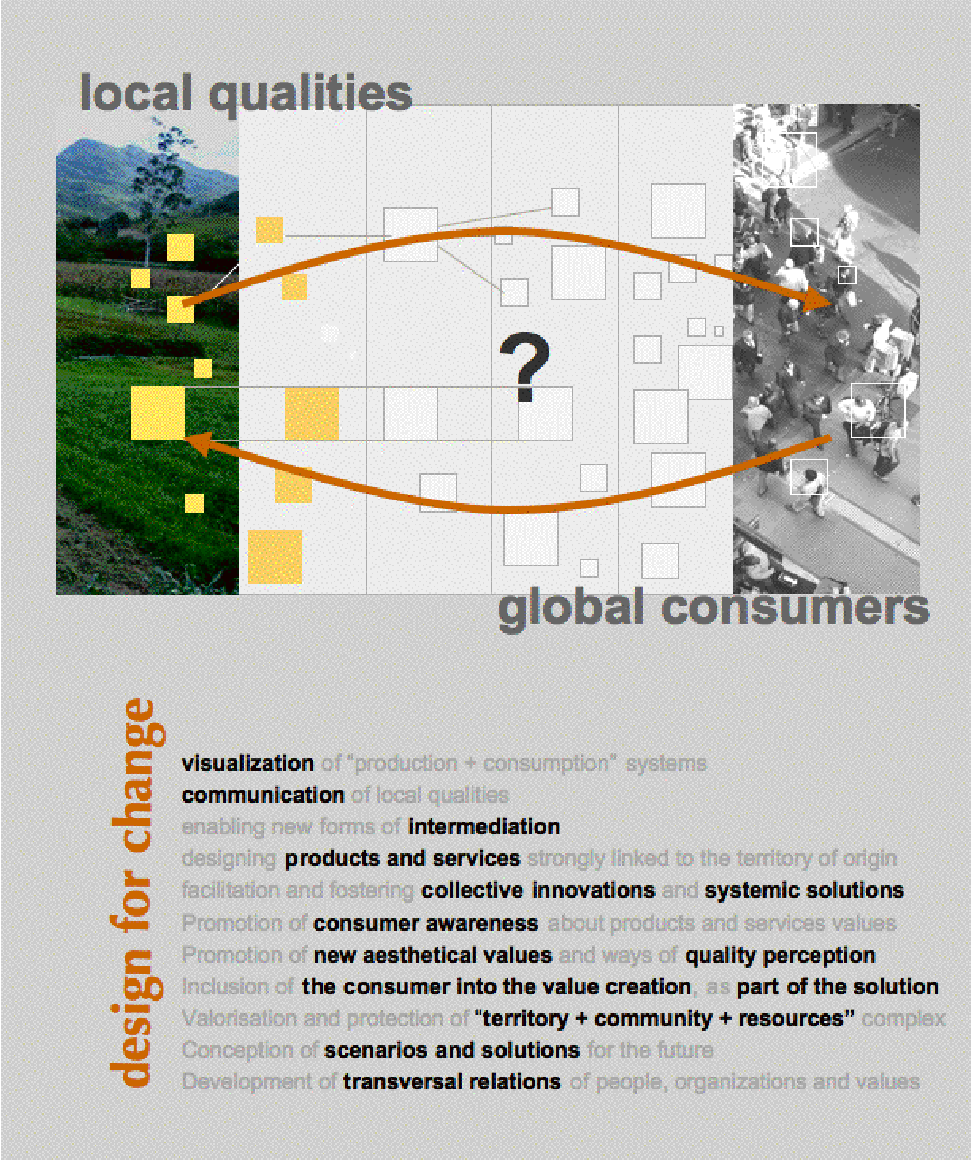

Fig. 1. Design contributions in the producer and consumer system.

Question 1 - How can product values and local qualities be communicated to global consumers?

There are two important pieces of evidence used by the consumer to infer product quality (*i.e.* perceived quality): traceability and authenticity. Both are becoming more important due to the proliferation of numerous, indistinguishable products on the market.

In general terms, traceability[2,3] is related to the technical quality of the product. However, overall quality encompasses cultural and social aspects that are much more difficult to trace in a global market. Therefore, it is important to consider a wide view of traceability, in which ethical and moral values of producing, distributing and consuming food products are taken into account.

[2] Traceability is defined as the "ability to trace the history, application, or location of that which is under consideration", according to the International Organization for Standardization (ISO 9001:2000).

[3] Food traceability means "the ability to trace and follow a food, feed, food-producing animal or substance intended to be, or expected to be incorporated into food or feed, through all stages of production, processing and distribution", according to Council Regulation (EC) No 178/2002.

Strategies to foster transparent and truthful relationships between producer and consumer include: a) green certification - such as biological agriculture (BIO), ecological and organic products; b) product origin and quality identification - as D.O.C. and Label Rouge; c) fair trade certification and “transparent price” charts – that can be seen in Illustration 1 and Figures 2 and 3 – and other informative labels.

These “indicators” can provide some information about production processes and their social and environmental sustainability, product quality and origin, the cultural and historic elements embedded in the products and their production processes. If communicated in an effective and actual way, this visibility improves the awareness that each product is a project, resulting from a relationship between people who produce and consume

Illustration 1 – Transparent price label: an Italian initiative

The ‘transparent price’ can be understood as a tool to allow the consumer to know exactly that part of the final price related to producers, distributors, commercial organizations, etc. It is composed of: a) value paid to raw-material producers; b) transportation related costs; c) commercial fees and taxes, import and export duties; d) transformation related costs; e) distribution related costs; f) products certification (such as biological products); g) market launch related costs.

A transparent price can encourage companies to build long-term relationships with a valued client base. This strategy is used by Ctm Altromercato, Italy’s largest alternative trading organization. Originally founded in 1988 in Bolzano (Italy), the organization became a consortium of world shops called Ctm Altromercato in 1998. It now includes more than 118 organizations (associations and cooperatives) that are responsible for the management of 230 world shops throughout Italy.

Illustration 2 – Environmental table: a Brazilian initiative of the Natura cosmetics company

The environmental table is similar to the nutritional facts on food packages (Fig.4). Its goal is to provide information on the origin and impact of the ingredients used in products and packaging. The information ranges from raw materials to the disposal of packaging in the environment.

The goal of the environmental table is to stimulate consumers' awareness in relation to the impact of their choices on the environment, society and themselves.

explaining the environmental table	
product

To promote "visibility" of products and services, it is important to understand the way in which the consumer perceives the product quality. The assessment of the product or service quality is conditioned by several aspects, which are represented in the "value star" (Fig. 5).

- **functional or utilitarian value** is measured by objective attributes related to the product´s intrinsic qualities. It involves the product´s compliance with technical or commercial hygienic regulations (related to the raw-materials used in product formulation, production processes, additional ingredients and safety of packaging), its ergonomics, performance and ease of use
- **emotional value** refers to affective motivations related to sensorial experiences when using a product (the senses of sight, smell, taste, touch and hearing) and the pleasure sensations of buying and consuming specific products. It includes a memory dimension (remembering past positive or negative experiences).

- **aesthetic value** is deeply influenced by the social cultural context (and thus related to place and period) and contemporary phenomena that establish the conditions of interpretation and valuation of a product. It is related to “the spirit of the time”[4].
- **ethical value** is related to social, environmental and economic sustainability of the product production, commercialization and consumption processes. To make the consumer aware of sustainable practices adopted in a product fabrication is also crucial.
- **cultural and symbolical value** is linked to product importance in production and consumption contexts, to the traditions, rituals, myths and spiritual meanings concerning certain products, to its historic and cultural roots and to the sense of belonging that the product evokes.
- **economic value** is assessed by the cost / benefit relationship.

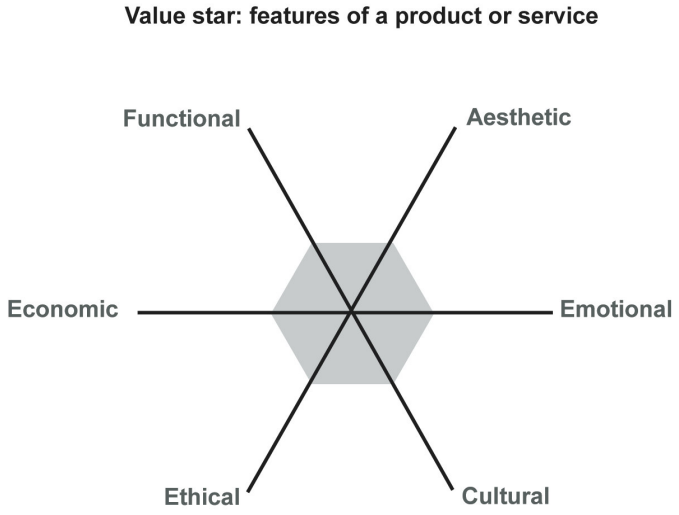

Fig. 5. The value star: features of a product or service.

The overall quality and value assessment of a product will result from the combination of all these six interrelated dimensions of value.

[4] Zeitgeist is originally a German expression that means "the spirit (Geist) of the time (Zeit)". It denotes the intellectual and cultural climate of an era. Zeitgeist. (2006, December 2). In Wikipedia, The Free Encyclopedia. Retrieved 16:53, December 15, 2006, from http://en.wikipedia.org/w/index.php?title=Zeitgeist&oldid=91562645

Question 2 - What kind of relations and solutions can be created to bring producers and consumers closer?

It is not enough to have quality products, nor is it enough to simply identify the market for these products. It is necessary to invest in the development of an integrated vision, articulating all the links that constitute the networks from producers to consumers and that exist between the two, be these nets formed by similarity (cooperation among participants that develop the same activity or possess the same profile, e.g. group of producers of the same product) or by complementarity (cooperation among participants that are complementary, e.g. group composed of consumers and producers).

Some successful experiences based on regional products are related to the support and promotion of:

- integration of small producers, in order to develop agrotourism related services and to organize campaigns for the promoting the value of local heritage and sights;
- organization of supply and purchase groups;
- agreements between producers and government for the supply of organic products for school meals, as it occurs in the "Projeto Sabor Saber" ("Flavour and Knowledge Project" – described in Illustration 3) in Brazil.

These initiatives widely demonstrate that the search for integrated solutions and networks' planning is crucial in promoting the value of local products and socio-environmentally responsible relationships.

Ilustration 3 - Flavor and Knowledge Project - Organic lunches in Brazilian schools

The "Flavor and Knowledge Project", part of the Brazilian Government's Student Food Program, involves schools and small producers, supported by governmental and non-governmental organizations in Santa Catarina State, Brazil. This project seeks to promote the introduction of organic food and knowledge acquisition by the student community of healthy consumption, fostering good eating habits and making them aware of the necessity of environmental preservation and the value of traditional production practices. (Source: Instituto de Planejamento e Economia Agrícola de Santa Catarina (2004), Santa Catarina State Government (2006)).

Contact between producers and consumers is fundamental for the exchange of information on habits and local cultures, stimulating conscientious and sustainable consumption. It is necessary to educate the consumer to recognize and value the diversity of local flavors, promoting the consumption of products adapted to local biomes and to the seasons of the year. In this light, the development of interfaces able to bridge the gap between producers and consumers is crucial.

The Slow Food Foundation for Biodiversity[5] initiative illustrates ways to organize and fund projects that protect our world's heritage of agricultural biodiversity and gastronomic traditions. Other initiatives, related to the development of horizontalities based on small local productions, are mentioned by Manzini (2005), Manzini, Meroni and Krucken (2006), Manzini and Meroni (2006), Krucken (2005).

[5] It was created by the Slow Food movement in partnership with the Region of Tuscany, recognizing that the appreciation of gastronomy must include the additional step of safeguarding our gastronomic resources. While the Slow Food Foundation for Biodiversity promotes projects around the world, its direct financial contributions are especially dedicated to the world's less developed countries, where conserving biodiversity means not only improving quality of life, but actually saving lives, communities and cultures. Source: Slow Food Foundation for Biodiversity (2004)

Question 3 - How to promote sustainable production and consumption systems?

The development of networks based on local resources is a complex activity. It is crucial to develop infrastructures and to plan for long term actions, which will direct the participants who compose the network.

On the basis of an analysis of some experiences, we can highlight some essential elements for the development of networks based on biodiversity resources:

- the quality and authenticity of the local produce, resulting from the sustainable use of resources, the culture and production processes ;
- the intention to commercialize the products is shared by the local community;
- management competences and propensity to collaboration and creation of networks (organized groups of producers, organized groups of consumers);
- competencies for the design and development of integrated platforms that bring together producers and consumers (strategic design of services);
- competencies to sustain the efficient communication of developed products and services, so that the consumer becomes aware of its environmental, social and cultural qualities;
- potential interest or acceptance of the products by consumers;
- technical, environmental and economic feasibility of the proposed solutions in the short, medium and long term;
- infrastructure for the distribution and commercialisation of the products and also for the interaction and coordination between the network's participants (access to information and communications technology , development of a user -friendly interface for communication, etc);
- support structures to further the development of relationships between producers and consumers (trade shows, events, etc).

These elements are dependant on several action levels, starting with individuals (producers, consumers), going through associative organizations, to government and trade organizations (that can contribute to the development of the physical infrastructure for the distribution of products (the logistics) and to the sponsorship of promotional events, amongst other actions).

Another fundamental aspect to be considered is related to the possible impact of the community's economic dynamization and of the new relationships that will be established. A plan for the commercialization of local resources should be based on clear objectives and strategies and shared by the community it affects.

It is especially in the planning and development of this network of participants and of quality relationships that Design can contribute.

5. Final considerations

An increasing awareness of territory and knowledge values that are embedded in products is to be noted. In this sense, properly oriented communication strategies are crucial in stimulating and maintaining an intense information flow between producers and consumers.

Planning and promoting communication are some of the more evident roles played by a designer aiming to promote local development. The key aspects to be considered in the

promotion of local produce are: transparency and traceability, history and meaning (reason for the product, consumption situation and context).

Thus, design actions are connected to the recognition and expression of identifying features and the promotion of a united culture to protect local resources as part of territorial identity. Design can be considered as a means of expressing local values and, in this way, can contribute to the promotion of value and conservation of biodiversity resources. It can also plan the development of innovative products and services related to the original resource, considering a systemic view of the region of origin (as emphasized in the notions of "territorial capital"). In consequence, it can contribute to the economic and social wealth of local communities, integrating many sectors, such as tourism, hotels and catering.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Notes on ecodesign, body and the post-human thought

Francesca La Rocca[1]

Abstract

The paper identifies some features of post-human thought based on recent contributions and connects them – firstly – to design perspectives that are able to affect the relations between objects, the body and the environment, and consequently to possible directions for research into eco-sustainable design.

Through a confrontation with post-human notion of the body, design can conjure up new mixtures and integrations of functions, new connections between body and technology, proposing renewed aesthetic conceptions, opening the door to the imagination of *new models of existence*.

Old ergonomic mechanics is accordingly laid to rest, replaced by a minute observation, free from preconceptions, of diverse and potential inter-reactions between man and objects.

[1] Seconda Università degli Studi di Napoli (ITALY) - IDeAS department. Professor, contact f.larocca@mclink.it

1. Foreword

The vast debate on the relationship between products and environment is currently developing in various directions: far-reaching theoretical and sociological reflections; analysis of design and technology in relation to life cycle issues; and in-depth research on the possibilities of eco-design.

But what broad prospects for change may arise through the discipline of design? If we are going to usher in a more advanced phase for the disciplines of design, we need to discard the idea of eco-design as merely a “first-aid kit” at the sick bed of production.

In place of this approach, the paper proposes the establishment of eco-design as a key discipline in the pursuit of new viewpoints and substantially different scenarios for the world of objects. *Great design energy, based on solid scientific assumptions but at the same time visionary in outlook* – this is the role that design can play in a more mature phase of ecological culture; it is only via this approach that design can mark a significant turning point in the methods of production of objects.

Why design should be in a position to *change the change* is fundamental the capability of design to *define its own disciplinary field*, starting from the role which is has historically had in the area of Modern Movement; the capability to renew itself and *continually rewrite itself* in order to decisively propose *its own point of view.*.

2. Eco-design, objects and the body

In the complex reflection on the outlook for the world of objects, which the culture of design is specifically required to carry out – entailing the contribution and combination of many disciplines – we can identify one element which is notable by its absence: *the body*. The acknowledgement of eco-design, as a way of more generally rethinking the world of objects vis-a-vis the environment, also interferes with broad sociological considerations; but in this context what is lacking is reflection on the body starting, for example, from the theoretical input of “post-human” thought.

And yet the theories of the post-human certainly impact on *new models of existence* -as suggested by the subtitle of the recent essay by Roberto Marchesini - which influence the culture of design (Marchesini 2002).

The “system of the objects” has changed today in relation to the prospects for modern design, and very radically compared to Jean Baudrillard’s sociological analysis of the 1968s; the relationship between people and objects has been transformed by technological evolution, by a changed conception of the body, and by the *imaginary* linked to the body.

We can identify three transformations that are crucial for the definition of the passage from modern design to post-modern design and which impact in particular on eco-design issues:

1) mechanical technology	electronic technology
2) unit of design: the product	unit of design: the product-in-its-environment
3) society based on objects	dematerialisation and miniaturization

But what terms should we use to define the transition from modernity to the post-modernity of the relationship between the body and the design project? At an initial approximation we can note two aspects: the only way that the body is considered within architectural functionalism in is in terms of an organic, rational machine, starting from the logical equation that nature is completely rational.; the only way that the body is considered within sustainable design is in terms of health,

starting from the logical equation that a healthy environment also means a healthy body. Both these conceptions, apparently distant one from the other, see the body as a pure entity, pure functionality/pure nature.

Post-humanism does not consider technology as something foreign to man and it rejects the customary dichotomous models upon which traditional western philosophy is founded: nature/culture, mind/body, material/immaterial. The post-human concept denies the autarchic nature of the human and anthropocentrism culture: no culture may be considered pure, neither in comparison to other cultures nor in comparisons with “others”- be it in the machine or animal world- in its own self same definition. (Pireddu 2006, 25)

In the 90’s the post-human movement declared the hybrid character in the subject-technology relationship and brought to light an aesthetics of the body invaded by technology. In this way the myth of *an original biological purity of man* fell once and for all, a myth which had been at the base of the beliefs of many modern-day ecologists until quite recently. (Marchesini 2002, 263-4)

In this sense, environmentalism is at the centre of post-human thought, but it must clearly acknowledge cultural processes as “hybridative” events between man, technology and nature.

The body is not a natural fact, a fixed and foundational base idea of old ergonomics, but rather something that has to be *continually invented*, as Michel Serres observes below:

"La bête a un corps réel. Nous avons un corps potentiel, virtuel, capable de toutes les métamorphoses. Une vache n'a jamais fait autre chose que brouter et ruminer. L'homme, lui, réalise toujours des prouesses nouvelles... Son corps varie à l'infini. En cela aussi, il prime sur l'esprit. Le corps invente, la tête aime à répéter. On mécanise bien l'esprit (l'informatique calcule, mémorise, décide même à notre place), mais pas le corps : la robotique ne sait toujours pas remplacer l'homme dans ses gestes quotidiens" (Serres 2000).

The fact that the body is currently removed from the reflection on design is confirmed by the fundamental *impasse* of a specific historical design discipline, namely ergonomics: if ergonomics has become bogged down with the concept of an *abstract and rigid* individual, eco-design now possesses the means to build immediately and plainly a new concrete brand of ergonomics based around a *flexible and hybrid* individual whose existence is implied just as forcefully in nature as it is in technology.

3. From traditional to new ergonomics

As Alessandro Mendini wrote, if I sit on the ground I am a chair, if I sing I am a musical instrument, if I walk I am a means of transport. The body is therefore a primary collection of objects available to man. Primates and Nomads condense down into themselves their own instruments which coincide with their own abodes. Starting from this complete identification, adjusting the relationship between the body and objects has been historically one of the duties of design.

Design is tied into other ergonomic disciplines whose outer limits have been studied by functionalism in a systematic manner. By means of a scientific approach which allows the efficiency of the body in space and in relationship to other objects to be calculated, modern ergonomics has claimed to fix objective rules, rules which are definitive for all times and places. It has also optimized several relationships between man and the objects that he uses. Minimum-existence has even stripped down the ergonomics of space and has postulated the bases for those lines of design which have created a principal foundation and aesthetics out of essentialism and reduction. Alexander Klein’s research into the *cell* in the 20’s were emblematic, which systemized living according to essential categories along with studies into minimum spaces and his working logics. The case of the so-called “Frankfurt Kitchen” is also significant, planned in 1926 on the basis of the theory of standardization of Frederick, an American. In the conception of

Le Corbusier, the idea of furniture and utensils as artificial limbs even led to the consideration of industrial objects as a type of “orthopedics”.

Insomuch as a “machine for living”, generally speaking the house sees man who lives inside it positioned as if he were at the wheel of an automobile , in a factory using a piece of machinery or in an office sitting properly at a desk. In these abstractions and idealizations of the relationship between body and object within which modern man lives, in both working and private dimensions, he carries out sequential functions which are without ambiguity.

From this a rigid concept of the body is derived, reduced to an organism-machine regulated by physical-chemical processes. In this fashion our body is no longer *our point of view upon the world*, but rather *an object of this world*. Its senses are not its opening onto the world, its possibility to live within it, but are scientifically “organs” and “functions”. The body’s here and now is not its anchor point in time but rather a moment in time among all times. Let us abandon our *experience* in order to adopt the *idea*, which claims to be valid for everyone, in all times and places. (Galimberti 2002, 79)

In the 60’s and 70’s the body’s codified postures were shaken up by design: the plan experimented with new positions, materials, social inter-relations bound to furnishings without rules, to transformable spaces and objects. The planning scene moved from the 60’s to the 70’s and took into consideration the idea of a compact space, disarticulated and multipurpose. Flexibility, discontinuity, ambiguity were the key words which dictated shapes for living far away from the mechanical concept of the grill, repetition, of the functional unambiguousness of spaces and objects.

Already in the 70’s, Joe Colombo also revealed the possibilities tied in with the extraordinary development of audio-visual and communication processes , the consequent progressive loss of the importance of physical distances and the chance therefore to carry out plans for a ubiquitous and flexible way of living.

With the advent of the electronic era, design progressively turned towards other ideas which were light, disembodied, integrated into communication equipment. On the inside of this process a series of details adapted to the life of the post-modern man were expressed; the willingness to go along with a more fluid lifestyle, experimenting new forms of living. The *design of interfaces*, - analyzed by Giovanni Anceschi in his homonymous book, becomes the focus of the project in this new scenario.

Under the pressure of technological changes and new studies of commodities in the 80’s, functionalism as a methodology, which began as a general picture dipping down directly to define instruments and ergonomics, appeared as a paradigm of time-limited feasibility. Also the traditional distinctions between the various steps of the project - urban, architecture and design - progressively lost significance. The *function,* with the passage from a modern to post-modernist project, took on a *nebulous, opaque* connotation.

A *widespread design* which was no longer identifiable with a clearly definable planning step, a *swarm of projects* as Branzi wrote, is at the base of the proliferation of the system of objects in the post-industrial phase.

The traditional ergonomic vision bound to the modern project fell into a reality in which on one hand the true adaption of man to his own environment relies upon a macroscopic physical step (the crisis of the ecosystem and the quest for eco-compatible forms), and then on the other hand the most important inter-relation is situated in a dimension of pervasive miniaturization and communication development.

Info-objects start to invade the very bodies of man. In a fashion which is progressively insistent starting from the 70’s, technology started to develop around the body clinging to its very skin, responding to a touch of the finger on a computer keyboard, a mobile telephone.

Up to around about 1950 technology came to be understood as something external, an instrument which could be laid aside without being “contaminated”. Starting from the 70’s it took

on a pervasive dimension; it came to be viewed as a reality in which the subject was completely immersed.

Info-objects resoundingly modified the way in which the instrument was perceived –it was no longer inert and idiotic but educated and interrelated to functions (Marchesini 2002, 263). Info-objects are unusual because they tend to mix themselves up and emanate their nature into all of the pre-existing objects. They also tend to meld one object into another in much the same way as an *adhesive of the family of objects* in their amalgamation (Righetto 2000, 98).

The modern object is one used and occupied by the body, but which is put away after it has been used. Recently dematerialization and miniaturization instead make it possible that the body be incorporated by the project in a totally different fashion.

The post-human movement of the 90's brought into the foreground the hybrid character of the relationship between body and technology.

4. Object and body: a new centrality

In creating a world of objects man has gradually lost his functions, turning them over to the outside, objectifying functions and relationships well beyond themselves. In such a way man has created a unity with his own body with these things, of utensils and a wide range of products. The abilities of our own minds flowed initially in writing and today this occurs in electronic memories. With info-objects which invade the body, in some way an inverse process is starting up-this process is however in its initial stages.

That which is however happening on a wider scale today is that continually greater attention is being directed towards the technologies of conscience and virtual interrelations. It is also being aimed at the idea of a type of progressive atrophying of the body with respect to the infinite possibilities of expansion offered to the mind.

On the one hand the *body*, on the other *things* as concrete material objects would appear to have lost their centrality on the post-industrial technological stage which is based upon miniaturization and the virtual. In the myths of "immaterial" and "performative", with the whole stress upon the "connection", *the object and the body both become debased.*

So on the one hand we have a huge expansion of the possibilities of the mind and a striking *extension of consciousness*; on the other, vis-a-vis the *infinitely performative* world of the virtual, the body is essentially debased. However, at the same time and to a greater extent insofar as it is actually inorganic, the world of objects is also debased.

The body, freed once more and even more so by the new technologies of communication, is actually in a "condition of inferiority" in respect of the mind, since the latter is offered the tools of ICT and virtual reality so that mental faculties are expanded exponentially.

In its turn, the object, a simple material product or an interactive complex system whichever it might be, risks to be seen as a predictable outcome of a planning process whose attention is centered upon the *foreshadowing of the relations.*

The object risks to "lose itself", swallowed up in cross-fire of connections, in the processes and time which give a structure to the course. This loss is healthy in that it offers the chance to rebuild the sense of the object within a complex scenario and a system of values; but, as Virno observes, the exasperated stress placed upon the idea of "connection" rather than a thing in itself which leads to the celebration of a performative virtual world has negative implications. One tends to debase material objects, subjecting them to a view that devalues the "thing-value", the status of the thing.

The most diverse schools of thought have railed against the reification with a disparaging fury, seeing it as a passage from the interior to exterior, from the unreachable in manifestation and observation. This is a fury widely unjustified on a theoretical level, based upon a superstition

according to which that which counts in the experience of the human-animal is invisible and intangible (Virno 2003). This is an abstract conscience which would have superiority in the rationalistic culture over the so-called “material” culture.

Today scientists such as Varela warn us that in the field of cognitive sciences a change of definitions is slowly taking place. At the heart of this change there is the conviction that the essence of conscience is in the first place *concrete*, incarnate, incorporated, experienced. This concrete consciousness and its historical nature, its context is not “noise” which prevent a general model from being compressed into its true substance: it is rather the way we operate and the place in which we are (Varela 1994, 143-4).

New discoveries in neuroscience offer further ideas for a replenishment of several notions concerning connections between man, the body and objects. In fact researchers have singled out neurons (known as *mirror neurons*) equipped with a surprising property: they activate themselves both when we carry out an action and when we see others doing the same. Mirror neurons allow our brain to connect observed movements to our own ones, and to therefore recognise the significance of these movements. These discoveries in neurophysiology demonstrate that space is not represented *per se* in a certain area of the cerebral cortex, but its make-up would depend upon neural circuit activity whose primary function is to organise that collection of movements, which permit one to react within the surrounding environment, localizing possible menaces or opportunities. Therefore space would be the primary constituent in terms of *potential motor actions* (Rizzolati and Sinigaglia 2006, 69).

Serres makes an observation on this point:

“Mieux encore, ce mimétisme jaillit du corps, du système nerveux comprenant *ces neurones miroirs,* découverts récemment par des cognitivistes italiens et dont nous savons aujourd’hui qu’ils s’excitent aussi bien lorsque nous faisons un geste qu’au moment où nous voyons un autre le faire, comme si la représentation équivalait à l’acte. Ainsi le mime devient-il l’un des formats universels de nos conduites. Nous imitons, nous reproduisons, nous répétons. La replication propage et diffuse le désir individuel et les cultures collectives comme les gènes de l’ADN reproduisent et disséminent la vie : étrange dynamisme de l’identique dont l’automatisme redondant, repliqué indéfiniment, va se répétant.” (Serres 2005)

In a way similar to non-human primates, we are not limited to just moving our arms, hands and mouths, but we reach something, grab hold of it and bite it. It is in these acts, in that an act is not a mere movement, that our experience of the surrounding environment takes on a form and that things assume an immediate significance for us.

The essay on the gift of Marcel Mauss brings to light an important point: giving is grasping and immediately afterwards giving up that which is grasped, proposing to another the same gesture to be grasped (Mauss 1963). The connections between giving, receiving and exchanging provide the basis for a “total social fact” and they make the gesture of grasping of the person who concretizes the mechanism of mirror neurons symmetrical.

The same *rigid boundary between perceptive, cognitive and motor processes* ends up revealing itself largely factitious; not only does perception appear immersed in the dynamics of the action which turns out being more pronounced and composite than was thought in the past, but also the *brain which acts* is also and above all *a brain which understands* (Rizzolati and Sinigaglia 2006, 3).

These new concepts invalidate any idea of “inferiority” of the body with respect to the mind, and they clear the field from an exitless dualism for design. The opposition between the old ergonomics (overshadowed as it is based upon a mechanical body) and new theories of interaction with the object would see a complete prevalence of the mind and the virtual insomuch as it is “abstract” (with all the attendant dangers connected to this).

We can therefore come to two initial conclusions: things- by which we mean concrete objects-carry great importance in that they are *the way for embodying relationships between men*. They are not the “translation” of abstract factors that would play in fields held to be of

greater importance in singling out economic and social dynamics. The body is not the wrapping paper of “higher” brain functions but is in itself the foundation of the conscience, as new discoveries in cognitive science have pointed out. Both the things that the body draws on from that *concrete dimension of the conscience* that is peculiar to design, and whose centrality within the discipline of design, must be confirmed strongly.

The centrality of the body in the post-human vision does not implicate a rebuttal of the virtual unless where it that means *a retraction of the imagination in a world already totally re-elaborated by man,* eluding the comparison with nature as another with whom to compare oneself.

However, the constant comparison with nature as “another”, the comparison with technology as “another”, through research into increasingly newer and newer forms of hybridation,” instead opens up new evolutionary directions also for eco-design.

The withdrawal into a world that is increasingly re-elaborated by the individual, as is the case with the virtual world and the ICT dimension, leads to the cancellation of the *hetero-reference* offered by nature and *vital to the development of the imaginary dimension of humanity* – and therefore also vital in order to rekindle that *great visionary design energy* which is the missing enzyme for radical change.

The machine is located in a grey area amongst plain things and the person, for its ancient reference to the organic and animal world; both machines and animals in fact have always established *the dignity of comparison, the dark mirror* with which to compare oneself in order to build one’s own identity .

Following Serres, man has the faculty to transfer his bodily functions in objects; and to take advantage of this freedom in order to go further." Quand les scientifiques n'ont plus eu à consacrer l'essentiel de leur temps à mémoriser le savoir des anciens pour le transmettre, ils l'ont mis à l'épreuve des faits, donnant naissance aux sciences expérimentales. Demain, le corps libéré par les nouvelles technologies inventera autre chose (Serres 2000) ".

Design may propose itself as an interpreter of the body’s new possibilities in the post-human era; propose new functions for contemporary body, liberated by new technologies, but still unable to express this liberty.

5. Gathering together the things of daily life

Historically ordained in the observation of things on a small scale, design has always concretely contributed and constructed the space of the connections between people, the space of the “between”, through objects. In this significant sense it loses the power to define if such objects have the status of real or virtual things; nor is there a need to change the level of analysis, if only in the orientation of effort and energy used.

Speaking of his own work, Sigmund Freud wrote “My only single intention is to gather together things of day to day life and to use them scientifically.”

This seemingly modest statement may apply as an analogy to that apparently modest role of design, which has always been seen as inferior with respect to architecture. Without too much effort we may transfer this statement from psychoanalysis to design. In effect, design is the discipline which in the 20th century has studied in a scientific manner the minute objects of everyday life, magnifying them and revealing in them aspects which were hidden and particular, and often before unobserved. Through the use of this “magnifying glass” design has been able to give expression to emotions and desires - also unconscious - in a technically impeccable form, which is that of industry, going far beyond strictly functional requirements.

In the contemporary cultural panorama eco-design is the chosen discipline to observe and plan on the level of daily micro-technology and micro-interactions between man and the environment.

Based on all these premises, we can propose two directions for design research associated with hypotheses for future activity:

1) work for a *post-ergonomics*, for new ideas of the role of the body, not linked to an abstract neo-purity as a corollary of environmentalism, or in opposition to the virtual world.

2) starting from a *microsociology of daily objects,* working for the construction of an eco-system of effectively *light* objects.

The dematerialisation is a key element, while at the same time designing a system of objects actually able to free us from the burden and the exponential torrent of things.

We can highlight an extremely critical point: the so-called "death of things" is not contradicted today – but rather confirmed – by the remarkable multiplication of objects, produced at an astonishing rate and destined to have extremely short, and often useless, lives (Flusser 2003).

The wall of products, the repetitive barrage of merchandise - more or less arranged in an orderly fashion - constitutes the true building blocks of modern-day space. These colossal systems of products, repeatable to the Nth power, are menacing as they are the harbingers of an infinite amount of refuse.

In a post-human prospective, eco-design may distance itself more and more from the idea of an original purity and inviolability of nature.

Once these prejudices have vanished, eco-design can instead dedicate its own energy to disproving with resolve the ill-omened effects which come out of the useless multitude of cheap quality goods, and above all to the inescapability of this process. These effects bound into the invasion of merchandise are at the same time *microscopic* and *macroscopic*. They tie themselves to a variety of processes which operate on different levels, from packaging to the development of distributive models such as hyper-markets and their illusions of *disproportionate possibilities*.

These illusions in the acquisition of goods end up diverting attention from the same sense of living. An uncontrollable growth model has in fact the *implicit abandonment* of a highly important series of goods as a consequence. These are goods which, in an effectively eco-sustainable society, should be *widely accessible and ubiquitous, above all free, not substituted by marketable goods and services.* (we can detect them for example, in green areas, unpolluted air, accessible and safe urban centres, clean sea and accessible beaches)

But what directions should the culture of eco-design be moving in if it intends to influence this sort of change? Certainly that which it is already wholeheartedly doing: planning eco-efficient objects and systems in which life cycles might be studied in a scientific manner. However, in a manner which contains a proposal of comparing itself with a *microsociology of ethical mediation of daily techniques* (Pacciolla 2006).

The excessive attention given by philosophical and sociological analysis to sociologically evident aspects – such as assembly lines, nuclear explosions or ICT – commits the additional error of cancelling the immense network of object-subject micro-relations that constitute our daily world, ending up by simply creating a gap, a no-man's land that is the terrain for all sorts of prejudices and fanaticism (Pacciolla 2006).

The idea of filling this silent space can be accredited to authors such as Michel Serres and Bruno Latour, giving a voice to objects of technology which infest the chasm of the western social conscience (Serres 2002). Getting over the merely instrumental vision of the technical object in that it is simply an *intermediary* in the action of the subject, Latour has tried to relocate our attention upon the operation of "translation" and "substitution" used by those *mediators* which we could define as *daily micro-technologies* (Latour 2002). The mediation of a thing marks structurally, our living.(Tursi 2006, 117) Objects do something, they are not simply the screens or back-projectors of our social life, they instead carry out an important role in the creation of social fibre. In other words it might be said that we have been overcome by that which we manufacture.

However, this does not concern an apologia of the social micro scale. Latour warns us that

the social world remains *flat*, without even the slightest of waves which might allow a passage from the micro to the macro.

Here the potential key-role of eco-design: always considering “the object in its environment” as a minimum unit - without expecting to embrace omni-comprehensive dimensions belonging to others disciplines– design can react in a decisive manner upon change. It is important to remember design often involves minute elements, but ones which are potentially relative to a great number of players.

The exponential diluvium of things - *completely differently ruled and directed* - may therefore turn out to be a decisive fact for change.

DESIGN VISIONS PROPOSALS AND TOOLS

“Parasitic” Design Strategies for Environmental and Social Sustainability

Vision of a Diffuse Universe of Parasitic Products and Services

Carla Langella[1], Francesco Dell’Aglio [2], Sarah Adinolfi[3]

Abstract

This paper proposes the vision of a novel scenario in the field of sustainable design founded on products and services which are defined "parasitic" because able to nourish themselves by draining energetic and material resources from surplus, wastes or from the "operation" of other systems.

The parasitic scenario can be imagined like a diffused “nebula” of smart and strongly communicating products that populate daily life, in domestic or public spaces, and are able to be visible by a great number and variety of people.

The paper will illustrate a design experimentation, verified in particular in the Campania region territory, where the decrease of consumption and dispersion of material and energetic resources is more than ever an urgent need.

[3] Seconda Università degli Studi di Napoli (ITALY), DISPAMA, department, PHD, sarahadi@libero.it; S. A. mainly contributed to the editing of paragraph 5.

Key words: bio-mimetic design, parasitic, ethical consciousness, surplus reuse, resource consumption reduction.

1. Introduction

The design discipline has extended its action range in the field of sustainability in the last decades. Starting from the definition of material qualities of products, contemporary designers have extended their intervention also to the construction of new conceptual and behavioural scenarios capable of conditioning people (Manzini and Vezzoli 2007, 242-252).

In this new dimension the communication of ethical principles, like the attention to sustainablility themes, represents an important responsibility for designers.

This paper suggests a new approach to design for sustainability called “parasitic design”, to create products and systems that “exist” since they “feed” themselves on material and energetic resources, which arise from the wastes and surpluses of other systems. These systems are often symbiotically integrated with highly dissipative systems, like malls or big industrial and office buildings to recoup their heat losses, water drainages or material wastes. Beside their functional efficiency, parasitic systems have a very important conceptual value.

The approach is set to take parasitism as an ethical message, which awakes people about subjects such as the scarcity of resources and the need to spare the not renewable ones. The contribution that this approach wants to offer to sustainability is to create sustainable products and systems, which convey sustainable messages. Products and systems are orientated to communicate with the greatest number of users in order to affect on models of consumption and on the community’s way of life in the deepest and widespread way. The research has sought to investigate on the idea of “the aesthetic of sustainability” in terms of communicative and ethical meanings.

The design for sustainability has provided precious methodologies and instruments in the last decades. These models, at present well consolidated, need to be applied and verified on a larger population, by extending an involvement process which, in the past, was limited to a very narrow and specialized target. It will be possible to translate principles and politics into concrete and radical changes only through great numbers.

The design of parasitic products and systems can take advantage from using a bio-mimetic approach inspired to processes and logical regulating parasitic living systems in nature. The vision shows a bio-hybrid universe of counterfeit similar to transportable, light, mutable organisms which are even capable of transforming and self-adapting themselves in function of the varying of contexts and conditions. A reappraisal of existing products in a “parasitic” way is able to solve local and specific problems taking advantage from locally available conditions.

2. Parasitic Approach. Biological References.

Parasitism is such a widespread phenomenal in nature, in organisms that live drawing nourishment from other systems. The word parasite comes from Greek παρασσυτισμός, which is a person who eats at someone else's table. In Biology “parasite is an organism that grows, feeds, and is sheltered on or in a different organism while contributing with nothing to the survival of its host”4.

Properties which generally identify a relationship of parasitism are:

[4] http://www.thefreedictionary.com/parassite.

- The parasite is devoid of self-life and it depends on the host to which it is more or less closely bound by an anatomical and physiological relation;
- The parasite has a simplified anatomical and morphological structure compared to the host's one;
- The parasite's life cycle is shorter than the host's one, and it ends up before the host's death.

In our methodological and project experimentation the aim is to sustain this idea not in the common negative meaning of someone who lives at the expense of someone else, but in a positive way of someone able to feed of the other's surplus. In this perspective the parasite becomes the "positive actor" that reuses the precious resources wasted by the system. So the meanings of positive and negative are switched.

On April 2007 at the NABA (New Academy of Arts), in Milan, a Workshop named "Parasite Design" was developed on the subject of the parasitism applied to design. The workshop was based on Marco Penati's idea, in which parasitism has been seen mostly in energetic and mimetic terms. The workshop carried out the design of some objects that change and modify their function by attaching to other ones. Without the "carrying objects" the parasite ones would not have any sense or life.

From our point of view, closely connected with environmental and social sustainability, it is not necessary that the parasite changes his host's functions. Its primary aim is to employ its waste. Furthermore, we aim to create systems that will parasite energy but even material surplus like water.

3. The Educational Aim. Strategic Approaches to Spread into a Social Community.

The approach that characterizes the "parasitic design" has a value that goes beyond the limited saving of resources achieved with the single product or application.

The value of these products is, in effect, of an educational kind, set to sensitize the greatest number of people about the irrationality of certain wastes, which characterize the way of life and contemporary uses. Their aim is to underline imbalances and inequality that everybody see but that almost nobody, for habit or laziness, detect in a critical and constructive way.

All parasite products and systems use a communicative approach oriented to induce behaviour models of consumption that are environmentally compatible and conscious. The scenario of parasitic products is arranged on two possible dimensions (strategic approaches) devoted to rouse a deep and widespread awareness:

- A household dimension in which parasite system takes part in the daily life of the living beings of the house, reminding them the preciousness of the resources used in their everyday activities. Systems that intersect little gestures and daily activities suggesting the reuse of resources usually not considered as such, as for example water that flows from an umbrella or from rinsed crockery, or steam from simmering of foods.

  Objects that awake the attention from automatic gestures and instil the doubt, the possibility to change, taking care not simply of that specific part of water, light, food or warmth used but of all the actions concerning with the resources. They can even report the presence of invisible streams that are potentially harmful for the health of people such as: electromagnetic fields created by household devices, wireless systems and mobile phones or toxic emissions.

  Parasitic systems bring forward settled ways of material and energy uses. The parasitism, in this meaning, gets a communicative and educational value, which

recalls people consciousness about the importance of measuring out precious resources and paying attention to the waste in the house daily life.

The research has tried to set itself towards products characterized by a symbolical value, which verges to poetic, and whose utility is more communicative and evocative than functional.

— An urban dimension to the urban design scale that fills with systems similar to offsprings, cocoons, flux prints, shells, that “clinging” to more material and energy dispersive manufactures or absorbing harmful streams (as smog and noise pollution) report their presence broadening the visibility of wastes and their consequences through their aspect. In this case products and parasite solutions are characterized by a strong communicative content and an highly, and sometimes abounding visibility that consents to the community to become curious and to interrogate about these “aliens” and their nature of “waste-catcher”, in a few words about the gravity of the wastes and the need to retrench, in a sustainable view, the activities in which they are associated.

Moreover, their existence and their message unveil even the gravity of some imbalances or paradox such as: the warm air that pour out from the air-conditioned buildings; the discrepancy existing among places too or in vain lightened and places dangerously too dark; the quantity of drinkable water used to wash objects. The urban scale of this dimension permits, particularly if the “parasite” is put in a very busy and crowded place, to give a communicative signal that will be received by a great number of people and that, according with our line of research aims, will affect in a widespread way on the rehash of behaviour models. These objects point out the irrationality of these wastes in an urban dimension that would appear as advanced and efficiently reorganized.

Both dimensions are characterized by a potentiality of daily impact in order to obtain a concrete leverage, and, as a consequence, a radical change, deep and widespread. Today it is necessary the shift from the deep awareness of few people interested to the problematic of the sustainability, to the awareness of many, to allow new styles of life able to make changes both locally and globally. Design has the role to make people absorb these ideas and to give the behaviours guidelines.

4. Parasitic Design View: Shifts between Literary Utopias and Technological Ratiocinations

The Parasitic Design is based on languages and images that come from several fields more or less adjacent to the design one. A multi-subject approach is than necessary in the construction of this scenario. Literature, cinema and contemporary art have an important inspiring role. But also the input of subjects such as electrical engineering, hydraulic and materials research are necessary to guarantee the practicability of the project experimentations.

The technological ratiocination has been unveiled of his structural unperfectiveness, especially to read the socio-cultural phenomenon of the modernity. Consequently we are able to feature the reality with a new approach and apply it in the construction of a changing universe of object, innovative in their generating principles of this parasitic design scenario.

The representations of the literature and of the cinema are often mutually mingled with the futuristic realities of the design. There are several examples in literature and in cinema that have often mingled themselves with the most different outcomes. We cannot think but to Jules Verne who was able to anticipate discovers that in his books seemed of simple fantasy but that later, would be actually realized in a serious and scientifically tested manner.

It would be enough just to quote the futuristic views of *Fahrenheit 451* by Ray Bradbury that in the cinema version by François Truffaut it becomes a future world animated by present objects. The design becomes representative of the metaphor of the future, that doesn't correspond to itself anymore but to an iconic idea of a foreshadowed world (Brunetta 2000, 646).

Also in *2001: A Space Odyssey* by Stanley Kubrick, inspired by the short story *The Sentinel* by Arthur C. Clarke, is realized a co-participation of several communicative medias, exclusive and original for the period. These aims can be found in the same Kubrick's words, when he says "everybody can inquire about the philosophical meaning of the movie as he likes, I tried to represent a visual experience, which goes round the comprehension to go deep in the unconscious with his emotional contents". Once more the present objects are representing a hypothetical future (Brunetta 2000, 829-830).

The relationship it is not always univocal; often science takes cognitive and testing paths starting from the literary scenarios.

Perhaps the inspiration of the late technological applications is the work by Frank Patrick Herbert who, with the series of *Dune*, faces difficult themes such as the human survival, the evolution, the ecology in the mix among religion, politics and power.

Symbolically programmatic is a quote by Frank Herbert who says: "Something cannot emerge from nothing" and he goes on: "The beginning of knowledge is the discovery of something we do not understand".

Apart from the literary and cinema success (David Lynch in 1984 took from the work by Herbert the homonymous movie, *Dune*) (Brunetta 2000, 257) it is sure the influence of the patterns by Herbert in all the latest technological experimentations on products and technologies called "parasitic" in our meaning, above all about the rehears and the supplying of alternative energetic resources.

The desert landscapes of the Arrakis planet, with their difficult ecology without every possible source of human nourishment, obligate the characters of the novel to sci-fi survival devices as expedient to save every single drop of water and to manage daily the life in a strongly adverse habitat.

The modern technology and experimentation have taken entirely from these hypothetical expedients to hypothesize extreme and odd applications. The fields of application are, at the start, just the one of military field, in which the expenses of the testing are more acceptable.

From *Dune* we could extrapolate some meaningful description that have inspired several research groups in the definition of converging hypothesis into projects.

Clothes, which take energy from the movement of who wears them: "*Paul sat on the edge of his bed and began stripping off his desert boots. They smelled rancid from the lubricant which eased the action of the heel-powered pumps that drove his still suit*" (Herbert 1965, 307).

The research in the filed of the electrical energy is inquiring about the quantity of energy that is possible to parasite exploiting the energy produced during the walking by trying to apply parasitic-power harvesting system inside the shoes. An example are *The Dada Sprees Supreme* atheletic shoes that have the characteristic of a "spinnah" built into the outer surface of the shoe, positioned on top of the ankle. While walking you put weight on the heel of the shoe and so the spinner moves. In this way the shoe harnesses the usual power of walking.

Systems that, thanks to the use of innovative materials, gather the atmospherically moist to feed plants: "*Each bush, each weed you see out there in the erg," she said, "how do you suppose it lives when we leave it? Each is planted most tenderly in its own little pit. The pits are filled with smooth ovals of chromoplastic. Light turns them white. You can see them glistening in the dawn if you look down from a high place. White reflects. But when Old Father Sun departs, the chromoplastic reverts to transparency in the dark. It cools with extreme rapidity. The surface condenses moisture out of the air. That moisture trickles down to keep our plants alive*" (Herbert 1965, 271).

Likewise the MIT researchers Robert Cohen and Michael Rubner were inspired by the behaviour of the Namib desert beetle, that is able to use the moisture captured with the special surface of his back, to develop a material that can capture and manage small amounts of water. As in the novel, in order to plant vegetation, special materials are used to create collectors, to get together even the tiniest quantity of the moisture of Arrakis planet.

Systems that takes drinkable water picking the condensation accumulate on rocks: "*Stilgar stopped at a yellow rock wall. He pressed an outcropping and the wall swung silently away from him, opening along an irregular crack. He led the way through past a dark honey-comb lattice that directed a cool wash of air across Paul when he passed it. "That air felt damp." A man behind them said "Plenty of air in the trap tonight*" (Herbert 1965, 315).

Using these easy strategy, the Arrakis citizens of the novel were able to drag water from the planet's atmosphere. Following the same aim Aqua Sciencs has developed a itinerant system that can generate fresh water by using the atmospheric moisture. The project is developed from DARPA society beneath a agreement with the US government to supply fresh water to US troops in Iraq.

Systems founded on smart textiles that take energy from the transpiration of the body of the inhabitants and from their breathing: "*The skin-contact layer is porous. Perspiration passes through it, having cooled the body. Motions of the body, especially breathing, and some osmotic action provide the pumping force. With a Fremen suit in good working order, you won't lose more than a thimbleful of moisture a day*" (Herbert 1965, 307).

The company CSIRO has created a wearable recharger system for Australian military called FIED (Flexible Integrated Energy Device). This tool is made of three components: advanced and conductive fabrics for the battery, a vibration power harvesting mechanism and a rectifier/power management system. The tool is used to power the electronic equipment of the soldiers.

The Instructables website thalks about the possiblity to build up a mechanism that scavenges power directly from the human breathing and lets carry on the energy as electricity for USB devices. The project is called Breath-Powered USB Charger.

In the aesthetical-communicative definition of the parasitic scenario we also take the hint from the contemporary art field, mainly from the analysis of the aims and the intentions of the programmatic and kinetic art.

The expressive needs of the programmed art were set in a new art and artist role in relationship with science and technology and of new methodological approaches. This happened in a period in which the thought about the society and the cultural changes were really intense (Dorfles 1999, 78). This kind of approaches, according to us, is what mostly ranged up with the aims that we wish to delineate when we talk about the theoric approach of the parasitic design.

The poetic of the kinetic and programmed art is about works in which the communicative effects take place from the psychological involvement with the audience. The possibility to interact is previewed and studied to stake all, statistics as well as random and probable factors. The aesthetical results are equivalent to the technological advances. The experimenting component is essential as the test of the models (Dorfles 1999, 79-80).

The communicative aims are undeniably fundamental; the geometrical principles are the rules for the representation. The work has the aim to support actively the comprehension and the knowledge. The artist change his "look", he works in a team with the technician and the scientist, he start to mingle art and society (Dorfles 1999, 79-80). In the same way the parasitic design approach has not to be only functional but above all communicative and dialectical with the user. According to us this is the path in which design has to approach to the project. A path not only functionalist and aesthetical in the strictly meaning but a path in which technic, function, aims, aesthetic and communication are integrated in the project, giving back an object semantically functionalistic.

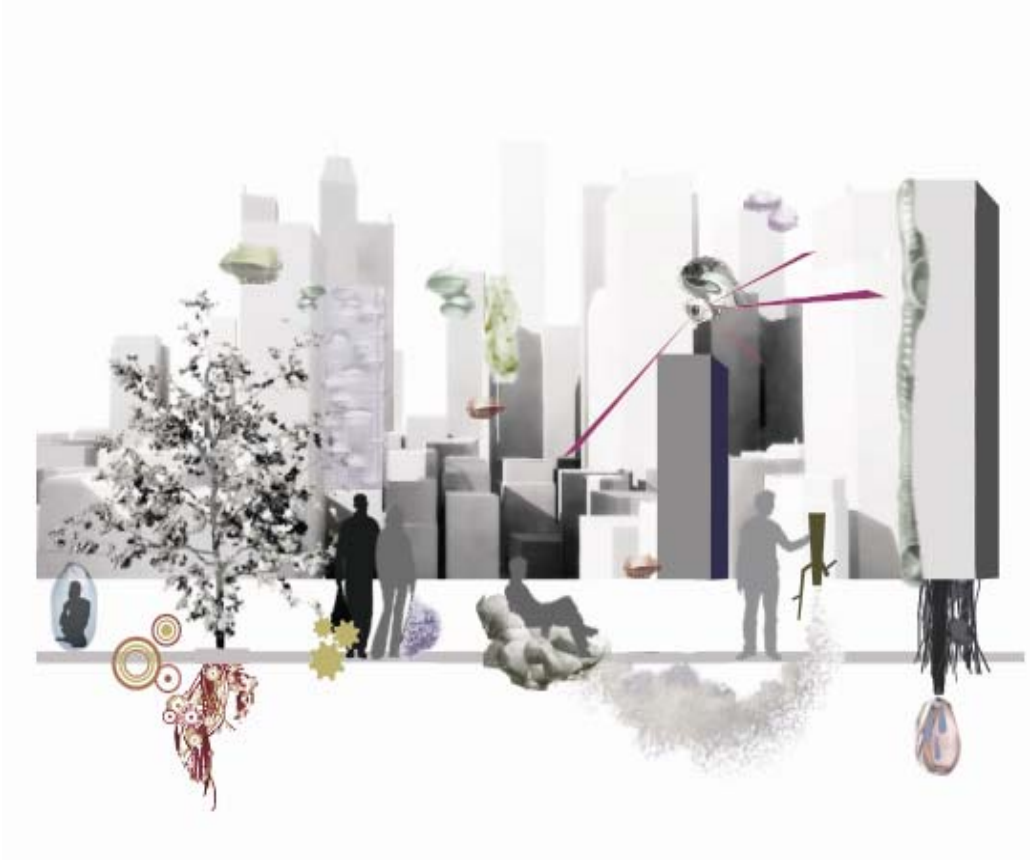

Fig. 1: Visualization of *Parasitic Scenario*

5. To Parasite resources. Strategic actions

The household scenario is made by a great number of objects with which the user relates daily. The relationship between the inhabitant of the house and his habitat is made, hence, of daily gestures, well-settled in the time, which decide the establishing of really strong relations among user and object or household devices. In the living dimension, the need to satisfy a demand face itself with a series of gestures, often ordinary and automatic, that tale the interaction with the objects which populate the household landscape. Every product, after having been taken as a “brand-new”, goes quickly in the common universe of accomplished wishes. Probably as we have a frequent and easy access to all modern conveniences we don’t reflect about the environmental effects, and in particular about the consumptions linked to the ritual gestures we repeat in the daily life. We don’t ask about what the lightening of a bulb or the opening of a faucet implies, there is just the need to enlighten or to wash, but not the consciousness of the consumption of electricity or water. The same unawareness comes out using some domestic devices that, besides using resources, produce emissions sometimes harmful for health.

Every action with an aim needs the use of resources to reach it. When action is too automatic there is the risk not to pay enough attention to the consumption. So asking about our

daily gestures means to give the right value to actions with an environmental impact and to the risk of a not proper use of the resource we dispose of.

To develop and nourish an awareness about the scarcity of the resources, several products monitor their energy use with electronic devices, which report with visual signs, lights or auditory messages of alarm an excessive use (Backlund et al. 2006, 6-7).

The parasitic strategy in the house dimension derives, hence, from the direct observation of the daily gestures and objects, and it proposes to intervene in their functionality or even better in the user behaviour automatism.

The household parasitic objects are born from the user observation in order to find out potential resource wastes, not to be released in the environment. Such an approach aims to rehash and optimize the use of resources, and at the same time, using the relationship of correlation between the parasite and the parasite object, unveils the dissipative nature.

The parasitic design approach proposes to involve people exploiting the strong relationship of cohabitation they set with the house devices, and to transmit an ethical message oriented to stimulate a deeper awareness. An awareness that is “turned on” when the continuous relations between the inhabitants and objects of the house is interrupted by the intermediation of parasites. This break leads the user to observe with different eyes his actions and to examine again the relationship between needs and resources wasted during their fulfilment.

It is not really important, in this view, that each of this little “domestic parasite” can save a little quantity of resources through the rehash. What makes effective this approach is, instead, the presence of these systems, in the greater number as possible, in everyday actions, which becomes a sort of educational path that takes place between the house walls.

The educational aim of the parasitic strategy is, therefore, to avoid that a series of wastes, hidden in the private scene, can have consequences on large scale when multiplied for the collectivity. At the same way more aware individuals are able to avoid minimal quantities of wastes that, in relation with the persons that daily do the same actions, become remarkable.

The design experimentation we are carrying out wants to define new products that come out of the analysis of the house scene and are sort of “offsprings” that use the environmental surplus of the house changing it in a life source for themselves.

Systems and products that answer to the innovative requirements and, above all, generate a discontinuity breaking the common stream of action, transmit the educational aim of the parasitic design producing important thoughts in the user.

The design experimentation addresses sometimes innovative technologies that can be able to support the conversion of the emissions in resources.

The view of the parasitic design spreads creativity borders to the field of the design for the sustainability. The creativity becomes essential to have a new approach with the consolidated domestic scene helping to wreck down the dominant idea that feeds the “vertical thinking” of the logical method. On the contrary the “lateral thinking” that uses the logic, instead of being driven from it, is able to help the human mind that excels in the elaboration work, to overcome the scarce attitude to have new ideas (De Bono 1967, p.17-23).

The design experimentation can be illustrated according to the kind of resource they refer, that is from the water to warmth, from the harmful emission to noise, from vibration to light.

- Making use of the technology licensed by the American company *Eneco,* that has created a device named "Thermal Chip", able to turn the warmth into electricity, the concept of the product line *No-ou* wants to report the abuse of some technological devices that dissipate thermal energy. An example is a “laptop stand” that turns the warmth left from the cooling rotor in a little quantity of energy to rehash for function linked with the computer use. The reuse of the thermal energy is characterized by a strong visibility and by an intense communicative content. In these systems the

parasite and the host are linked by a physical element in which takes place an unidirectional stream, where the functioning of one is completely subject to the excessive use of the other one.

- The increase of the electromagnetic waves, that are the cause of the so called electromagnetic pollution, deriving from the emissions of the growing number of telecommunications systems and of electrical devices, is an invisible risk for health. The product line *HERTZanHERTZ* is born with the idea to make perceivable the otherwise invisible electromagnetical fields just to sensitive the users towards the unrestrained use of some devices that can be dangerous for the health. Besides this, using the potential of the *Meg* free energy project, motionless electromagnetic generator, able to catch the electromagnetic waves turning them in to electrical energy, is possible to reuse a little quantity of the emitted energy.
- To face the thermal and water waste a product line, named Do't, has been created. It aims to report directly the wastes or simply to optimize the use of the same resources. They stop the fluxes before their dissipation becomes irreversible and turn them in reusable resources. The objects have simple forms and expressive functionality, to amplify their educational value suitable for every age and education level.

In the scenario that characterizes the urban dimension, people streams, information and energy mingle together. From these streams come out emissions of every kind: emissions of cars, crowd noise, strong vibrations caused from transportation means, air conditioning machinery warm air streams, lightening streams often outrageous and un-useful in the commercial or accommodation activities. These emissions can't be attribute to a particular being but are the result of a collective consumption of remarkable proportion. For these reasons in this context the user loses the direct and consequential relation established in the household dimension and the possibility to control the dispersion of resources.

The pollution and resource waste problems is particularly urgent in Campania region, where there is a high density of population with a scarce attention to environment and public places. To the urban scale the individual hides behind the multitude but, while his carelessness and unconsciousness can produce serious damages, his awareness can produce positive effect enlarged by the collectively.

We have imagined the landscape of parasitic products in the urban dimension as a skyline of strongly effective systems, not really mimetic, whose figurativeness is the support for a continuous and wide diffusion of the ethical message linked to the parasitism.

The communicative aspect of the parasitic objects in the urban dimension becomes an essential requirement, his understanding has to be immediate and easy, to catch the attention of those inattentive and frenetic citizens, who go blind through places. A products family that crowd the city as off-springs, cocoons, tentacles, which necessarily induce the mass to wonder about their presence. The same mass that question about the reason of a concentration of this sort of organic shapes in places particularly dense of humans, linking the subordination between the anthropic activities and the wastes. In the domestic dimension the visible energy stream between parasite and host objects activated by the user through the daily gestures, in the domestic dimension is substituted by the visibility of the urban parasitic organism that, with its invasiveness, report the relationship with the public dimension. The single user through the acquisition of a more aware use of the resources, makes a transposition of this teaching in his domestic universe to join his single efforts to the community ones (Silverstone and Hirsch 2003, 3).

In our design experimentation we often have conveyed technological support from other sectors. These experimentations have been taken from the field of the nanotechnologies resulting from the medical and military research. These are in effect the two fields in which the technological research gives advanced solutions. In particular in the medical field one of the necessities is to make autonomous, as part of the organism, all those artificial elements that the medical technology has settled-up in the surgical field (mitre valve, pacemakers, etc.). The basic

idea is to use the emission and the energies of the body itself for the autonomous functioning of the little prosthetic systems.

- *i-Acto* project has the aim to turn the energy made from the urban noise and vibration coming from the traffic through technologies experimented during the VIBES project (Vibration Energy Scavenging) that introduced a micro-device called *Mk2* able to generate electrical energy turning it from the environment vibrations. The skill of the device experimented is of 46 microwatts against the 52 hertz of the vibrations, typical values of the vibration in the industrial field. The energy afterwards is given to the citizen as free through columns that permit to transfer it in the telephone apparatus or to i-Pod devices in temporary energy mode. The energetic “download” emplacements can be put to re-functioning point of urban stop as the public transportations ones, giving to the user the possibility to use his own devices.
- The project called *Most-Moist*, is instead orientated to reappraise the different and several water urban emissions, from the ones produced by the air-conditioned machineries, as condensation, and the ones that is possible to rehash as the moist in big public spaces. The project uses the transfer of the innovative system *Aqua Sciences*, experimented by the *Darpa* society, as well as the US Government for its own troops in Iraq, for the production of drinkable water (the system is able to produce over 5 litre of drinkable water turning it from the atmosphere moist at a really reduced expense of just some cent to the litre). So the water rehashed is usable to feed complex and communicative systems of furniture or urban shielding, able to support also vegetal installations in different functional configurations.
- A design experimentation oriented instead to the rehash of the light of the night resources is the *Ligh10* project. The observation of the human environment above the design concept permitted to underline that a noticeable quantity of light is used in the night hours, without an exact functional need. In particularly the shops in the big expositive places like the malls, lightened even in the closure hours. The project, using the technology of the optical fibres, transferring the light to a far distance without dispersion, wants to focus the light urban sources towards street unlighted, making road signals in optical fibre that permits a better use and eventually a requalification of those urban areas scarcely lightened. The light signals are, besides this, projected following the orientation of the design and of the graphical communication to denote the intervention in a project that would be completely design oriented, as much in his functional aspects that in the communicative ones.
- The whole of the experimentation named *Humangy* is oriented to parasite the motor energy of individuals, and it is the only case where the used energy is not wasted, since it comes from a physiological process. This energy unveils itself useful since it is not usually rehashed, in particular the one where are turned the mechanical spurs linked to the crossing off a lot of people in places very crowded and the one linked to the movement of the youth in discos or in gyms.
- The product line named *Baby Power* is dedicated in particular to the children’s games where the parasitivism of the energy is particularly effective for the future generation, and that will face the resource border in a more dramatic way in comparison with today, to guarantee the planet survival.

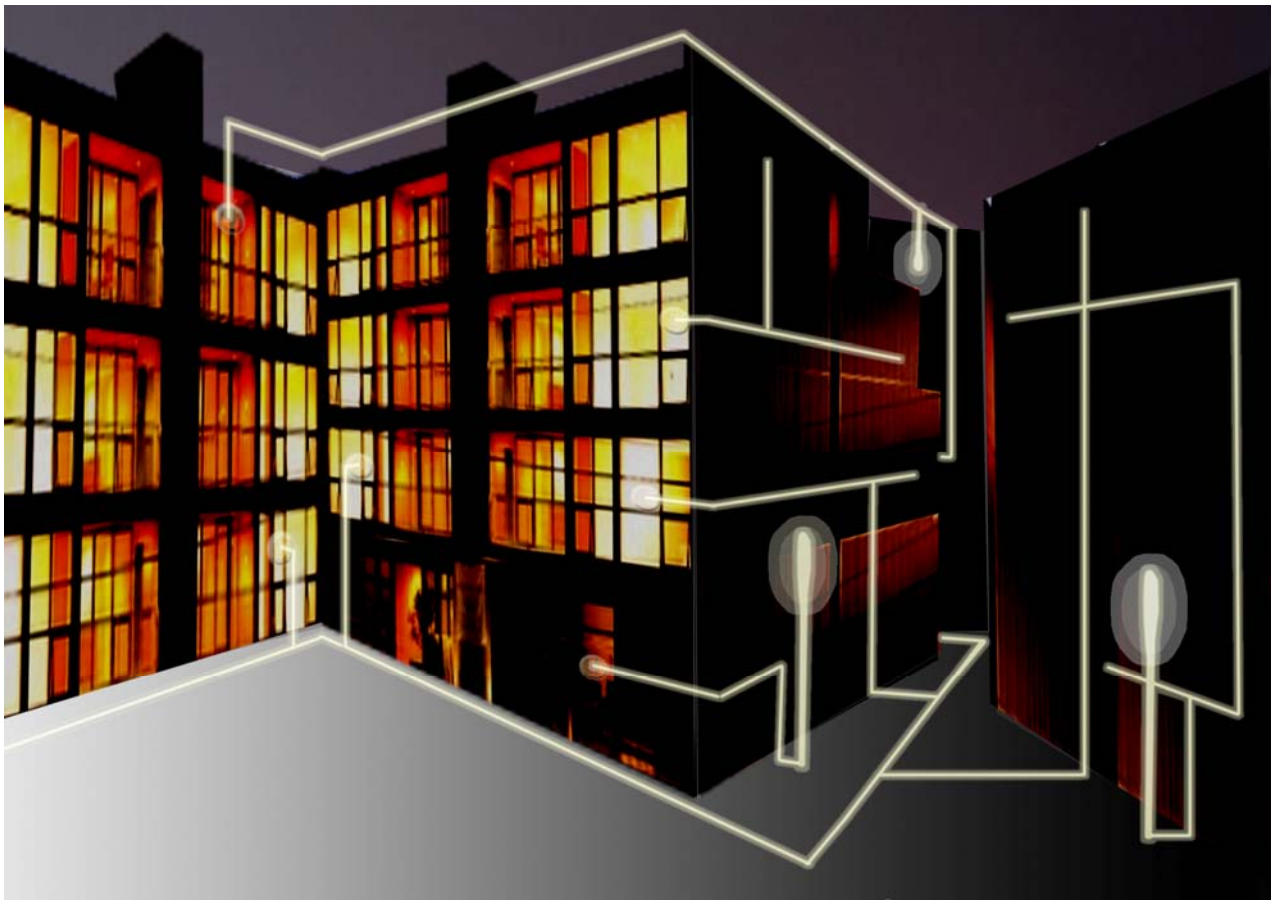

Fig. 2: *Ligh10* visualization

6. Conclusions

The parasitivism is not to be comprehended only as a material product but also as theoric and systemic. Parasitic is also every action giving even a low level of opposition to the environment, opposition, which above all results in a series of functional accommodations that we can define anonymous.

The mere presence of parasitic “actions” is itself a catalyst of attention compared with the physical-theoric precincts, where the common streams of social communication are cut off, acting as friction and exception points. Then such a parasitivism and its interpretation could represent the heuristics vector in the time of globalization.

One could even think that a parasitic orientation could figure the “fate” of every future object and action, as adaptive strategy of life, ideal in an environmental condition now-a-days chronically deprived of rules and of temporal meaning. This is typical of a hyper-complex society, which offers limited points of grip in short pauses, are these both theoric and material.

These are the spaces of the physical and theoric compensation resulting from that adaptive factor that is the success of the man-hood in the environment. In the design practice, concretized in design project, such as the aesthetical values and the relationship between shape and function, has to be necessarily reshaped in the perspective of a new technological vanguard. New “objectualities” are therefore defined as the iconic representation of new functionalities. The

future, already present, of the alternative energies, widely proved and applied in architecture, following the theoric field of the environmental sustainability, is the rearguard of a new period, the one of the self-produced energy. Here we define the theory of a future environmental approach, where the premises of a new method to this phenomenon represent new life surfaces, thanks also to the experimentation in technologies. Then we draw the new borders of the design creativity in the vanguard time that will be represented, necessarily, with a series of design “opportunities” punctual and performing .The basic points are represented by interstices and knots, as a result of the noticeable and critical points of a life chart more and more homogenous and linear.

Projects have been put inside a map to describe graphically the parasitic design scenario. They are inserted respecting the different impact strategies. In the map the projects have, therefore, a different design scale, that goes from the urban one to the residential one, with different communicative and technology complexity values. The projects are besides divided following the parasitic discipline fields, above all using as the discriminating feature the kind of resource to which they refer. So we have urban and private scales projects, which apply different technologies and aims to “parasite” sources and energetic emissions that go from the light to water and heat, from harmful emissions to vibrations. The purposes of designs at urban scale are the ones firstly comprehended in a subject about the social and educational aims of the parasite design. The concept of the scale project has in effect intrinsic aims such as the communicative wilfulness that we believe to be the path towards which all the contemporary design must and can essentially strive.

DESIGN VISIONS PROPOSALS AND TOOLS

Social Innovation and Service Design of community-based tourism

The case of Prainha do Canto Verde, in the State of Ceará (Brazil)

Marcos Langenbach[1], Elisa Spampinato[2]

Abstract

This work considers to critically debate the concept of social innovation in the scope of service of an emblematic case of Brazilian community based tourism.

On the basis of a theoretical debate of concepts, we will present the case of Prainha do Canto Verde, model of a socially responsible tourism, developed by the proper community valuing cultural, ambient, economical and social dimensions.

This experience constitutes in a new relational standard, that propitiates a more personal, direct and dialogical relation between the tourists and the hosts. The lecture of this new paradigm allows them to point to some important issues with respect to service design and on the proper role of the designer, as co-design and the multi-disciplinary projective.

1. Introduction

The objective of this work is to critically take into account the concept of social innovation and the interconnections with service design, having as reference an emblematic and successful case of community-based tourism. Prainha do Canto Verde is a small fishing community located on the east coast of the state of Ceará, in Brazil the promotional of a project of innovative and creative tourism, but over all a dialogical and participative base communitarian project.

The choice of Prainha do Canto Verde is a concrete reference in the debate of service design and social innovation, the fact that this initiative presents a different model for the development of the tourist sector. This new model, represents a new paradigm, which directly involves the residents to the revenues and the profits coming from the tourism activities. Based on a process of participative planning, a singular experience was developed that involves a series of services that respect the environment, local cultural value and at the same time promotes the dialogue between residents and tourist.

The initiative began with the intense mobilization of the community against the actions of real estate speculation developed by the tourisms great industry. This auto-organization stimulated by a threatened identity of survival, constituted the base to promote a type of alternative to industrial tourism, focused on the autochthones demands. The process that led to the model today consecrated of community-based tourism passed by various phases of construction and evaluation, between which was the analysis of the impact of tourism in neighboring beaches and the construction of future scenarios. The whole process was characterized by democratic and critical debate that, not only interested the community but also other represented actors, and other participants, between which NGO's, offices of government and other public and private institutions.

The delayed process of debate about tourism took to the setting some lines of direction in tourism activity to be developed in Prainha. It was decided, for example, that this activity would complement the main economic activity of the community, namely fishing, it would be managed by the members of the community and it would not change the local lifestyle. The result was a tourism model that allows tourists to have a different relation with the supplier of the service, a relation characterized by proximity, intercultural dialogue, and at last, a more spontaneous and real relation.

This type of relation that happens in the community-based tourism experience of Prainha de Canto Verde establishes a new relational standard, and represents, in our vision, a social innovation. The way that the community drew this series of tourist services was of participative form, empowering the local quality of life and valuing the proper cultural identity. Many of the instruments used by designers, such as the similar analysis, the development of briefing, the construction of future scenarios and the establishments of direction lines, among others, have been incorporated intuitively in the debate.

These elements will allowed to start a fertile reflection on the role of the designer in the participative process of creation and planning of services, and his possible contribution in creative action. At the same time, this leads us to possible interconnections and formats of contributions between professional design and "tacit", design between professionals of the area and the parts directly interested in the process. We will argue about these ideas and their "co-design" possibilities in the perspective of social innovation, thinking about projects focused on maintenance and stimulation of well-being of the local inhabitants in more real and genuine relations and the promotion of the social and eco-ambient support.

The text presents, first, the concepts of Social Innovation and Service Design, and secondly shows the case of Prainha do Canto Verde, in the light of theoretical reflections, to start a critical analysis.

2. Social Innovation

The concept of “innovation” has been around for sufficient time to be a central subject in the contemporary debates and over all in the developing countries it covers an excellent weight, therefore it brings the hope of change and inversion and/or overcoming of these situations and mechanisms of poverty and social exclusion which mark and define these realities. What interests us, however, is social innovation, or be it an innovation that is directly involved with the humans in the society.

Traditionally it is easy to observe the existence of one strong concept identification of innovation within the economical and technological areas, and when talking about social innovation the reference seems to be the only one possible and imaginable. Thus the experiences of detached and awarded social innovation, internationally and in Brazil, in reality have to deal essentially with technologies applied for social innovation, restricted in the economic field.

In this vision, therefore, the human as a social being appears as an object or receiver of “innovation”.

Contrary to this position, we believe that the basic condition to speak about social innovation is an active condition of the man as a social being, that means a being in a society and therefore the way of the man to be in society is fundamentally a relational way, we can extend our definition by affirming that the social innovation in our vision is dealing with types of relations, in particular, with the “creation” / experimentation of new relational standards, not forgetting that relations are an active condition.

To speak about social innovation according this perspective, in the scope of tourism, means to focus at two aspects, or better, two types of relations. On one hand, the relations between inhabitants where social innovation would have to deal with an inversion of roles in the local community of the proper destination. A situation in which the “silent native” (Krippendorf 1989) starts to speak and is assumed as a basic agent in his proper development. This has to happen, mainly with the participation of the community in some phases of the creation process, implementation and management of the tourist project. At the same time what is of basic importance is not to forget that for the creation proper instruments are necessary. These instruments of participation, in reality, would function as catalysts of new relational standards therefore, in fact, represent new rules of conviviality.

There can be created, thus, a public space for the meeting of inhabitants, in order to associate, and also for representatives of other institutions and other involved actors. This “new” public space could increase the possibility of the relation between the people and the conviviality between them, being a space of community meetings, in the words of Illich (1976), a space of conviviality. It is in this space that they will debate the future of the community, therefore planning a space of design, where is argued in participation the directions of the community.

To speak of social innovation in the scope of the tourism means also, to focus another type of relations beyond the one between inhabitants in the scope of management and planning, namely, those between tourists and autochthones. Generally this type of relation is characterized by distance and at times, contraposition, when not the separation of two worlds. To think about social innovation in this specific relational scope, therefore, would mean to imagine other formats of contact and interaction between these actors where the dialogue between otherness is allowed. Over all in the case of tourism in a communitarian base, where these kind of meetings happen more easily, therefore this is a kind of tourism that approaches the people more than conventional tourism, where the same sight of the local inhabitant is “not an enclosed experience” in the package offered to the tourist .

3. Service design

As Langenbach explains (2008) “design of services appears for the necessity to bring a more humane vision to the services, wherein new technologies are used by the society, toward an improvement in the quality of life, being, in a way to project and organize a form to stimulate and improve social relations” (p.32).

We want to think of service design as a knowledge about a vision that joins the aesthetic and the symbolic aspect to the one of functionality. The change of perspective is involved in a new use of t technologies that would really pass to be used by the society and toward an improvement in the quality of life, being projected and organized in a way that it is able to propitiate the form and to improve social relations. In this new perspective, design of services would be, therefore, the attempt to rethink the social relations; this vision would gain force by the necessity to bring a more humane look to services, since the form where the great majority of the services is planned and organized has generated great consuming of social fabric, destruction, poverty and misery beyond having contributed with an increase of scarcity of environmental resources.

The study of service systems, through a boarding of design, it would be a form of projecting more humane services. An important step in the boarding of service design is therefore, the same concept of “service” used by designers in the hour to project. The first question in the concept of services is to rethink the proper service. Manzini (2007) places the question as a change that has to do with our point of view, using each time the objects for the services, seeking the essence of the service. Goldstein et al. (2002) approaches this perspective, thinking about the deconstruction of the service through questions how it functions and what is it made of, and the integration of these two factors, or trough components making it possible to identify some elements of the concept of service, checking the relation to the necessities of the customers and redesigning these elements, understanding the idea of service as an experience. Another characteristic would have to deal with the fact that the nature of the service must be clear and to be shared by all the involved people in the service.

Understanding the redesign and the conception of the service by service designer is obtained to better understand the performance of designer and the proper concept of the service design. For Pine and Gilmore (1998) service design would be design of the experiences of the consumer. Candi (2007) speaks about the multidimensional vision of design, and strengthens its role as a distinguishing element, as well in the services as in the products, and places its success on the differentiation and the innovation. She remembers us that design has to think and to project the services on three dimensional bases: visceral, functional and experiential, with special attention to social relations between users and supply service providers. Transforming the look on the activity of the service into a relation where people of two types are involved (the user and the supplier), opening the possibility of an activity based on dialogue.

The man and his social relation, therefore, start to be the specific focus of service design. “The idea of service design means to me to seek improvement of services and to mainly study the interactions between the involved actors, with intention to make possible a more sensible agreement of work and life, opening space for the more creative, spontaneous and playful characteristics and relating these characteristics to the construction of true dialogues” (Langenbach 2008).

It seems, natural that this relatively new field of knowledge, study and somewhat relative application emphasizes experiences, but a type of experiences that involve people, or so to say, interpersonal relations. Design of service, therefore, seems to suggest the most proper space to rethink the forms and the formats of the relations, namely, the services.

So that social innovation deals with experimentation of new relational standards, and that service design has as focus the human and his experiences in social relations. We will try to bring these reflections in the field of tourism, a scope of activities characterized by reserved centrality on services.

We believe that it is interesting to bring this reflection to think about a possibility of more humane service terms and dialogue, in a relation to the question of the community participation so that the question of visiting tourists has to do with democracy and the social inclusion, beyond that the question of quality of life and ecological conscience. An already emblematic case and classic reference in community-based tourism is the case of Prainha do Canto Verde. The experience of this case that will be shown in the following segment.

4. History

Prainha do Canto Verde is a small fishing community situated in north-eastern Brazil, in the municipy of Beberibe, on the east coast of the state of Ceará, 120 km to the south of the Fortaleza, the capital. The community always lived of fishing and its culture is dependent on this activity. In the end of the 70's, however, the real estate speculation advanced on a great part of the east coast of Ceará and arrived in this community in 1979, with purpose to regularize an area of 2 km to the beach and measuring 750 ha (inclusive the sand bench), for one of the main squatters of the region, with a favorable decision of the judiciary of the region. This area was sold to the real estate (partner of the squatter) and from this situation the real estate dispute between inhabitants for the ownership of the land (rights of use) was started. This dispute extended for more than one decade and provoked diverse conflicts between the inhabitants of Prainha do Canto Verde and the real estate and its "body guards". To defend to the actions of the real estate, the community of Prainha do Canto Verde had the support of the Center of Defense and Promotion of Human Rights (CDPDH) and in 1989 the Association of Inhabitants of Prainha do Canto Verde was created. The fight for the land extends until today, however it is restricted the judicial sphere. The question of the land represented the common cause that took the community, under threat to proper survival, if auto-organize this movement of union contributed by identity reinforcement which is a basic in the creation of the new model of tourism of what they had become promoters for. We can observe, with Bauman (2005), he was there at the moment at which the Prainha felt the proper survival threatened, which reinforced the identity question. In this context of "reaffirmed identity", in a unfavorable economic conjuncture (a decline of lobster fishing and the utilization of fishing with engine and compressor – which is an illegal but widespread practice) the necessity appeared to debate about alternative economic resources for the community, between which the tourism was presented as one of the most interesting options, which favors also a strong investment of the state and federal governments in tourist programs. Thus the discussion about tourism in Prainha do Canto Verde started in 1994. It is important to point out that, the rising of "communitarian eco-tourism supported but still incipient organizational capacity of the inhabitants mobilized by the ownership of land" (Bursztyn et al. 2003).

5. What type of Tourism is this?

With the concern of negative impacts of tourism, registered in the experiences of neighboring tourists beaches, during four years there was developed a process of matureness through debates lead by the association of inhabitants, that culminated in the realization of the "First Seminary of Communitarian Eco-Tourism" in 1998 during which the inhabitants, together with other supportive institutions[3] had elaborated strategies for the development of tourism in this place. It was from these debates that the type of tourism that they wanted for Prainha were defined and also parameters and conditions were defined too.

[3] Between these institutes are Instituto Terramar, Conselho Pastoral dos Pescadores, secretary of environment (SEMACE), tourism (SETUR) and social action of Ceará State; *Bom Jesus dos Navegantes* school and the Mayor of Beberibe.

It was established that the type of developing tourism would have to be socially responsible, respecting the environment and valuing the local culture. It was also determined that tourism would have to be a complementary activity to fishing, which remains the main economic activity of the community. The intention was to preserve the proper way of "traditional" lifestyle and it was recognized that fishing had a basic foundation, therefore it was recognized that to value its proper culture it meant affirming the fishing culture. It was also defined that the tourist activities would be exerted by the proper inhabitants.

"The tourism that we want" became the motto of this new type of tourism and it bases on the desires and the necessities of the local community, and its capacity, in turn, the paradigmatic question of a new type of community-based tourism (TBC)[4], was developed from principles, estimatives and different values.

The mobilization politics in defense of rights to land was, therefore, the necessary condition, through its action of reinforcement of the identity, that allowed, the sprouting of this new type of paradigm. It is one strong identity, in fact, that bases the questions on the "tourism that we want?" reflects "who we are".

6. Let's see how it was developed

One of the first activities was to know the tourism experiences of the neighbouring beaches. They used three experiences of tourism of three situated beaches on the east coast of Ceará: Canoa Quebrada, Parajuru e Praia das Fontes, the reality neighbouring them; they had established some criteria, as the level of income, the chances of occupation and employment, the degree of social inclusion and the level of crime and use of drugs.

This exercise of comparison that uses some recognized parameters as extraction of positive and negative points, is part of the methodology used by designers for developing a project. In the *similar analysis*, they made comparison between products, services or initiatives, and they look at and analyze specific aspects, for succesfully project a new "product" and take in account the results of this comparison.

The inhabitants of Prainha do Canto Verde had projected a proper design of tourist services, and had decided that the tourism found in these next cases was not the tourism model that they wanted to adopt and had opted, thus, for new a proposal of tourism who were decided from a briefing, to be able to develop the project "the tourism that we want". The instrument of the briefing, another tool used for designers helped, them to define the lines of direction of the desired tourism, in a process of *construction of future scenarios.*

7. What steps and actions

The creation of a cooperative of tourism and handicraft (COOPECANTUR) was an important step in the organization of a community-based tourism. Who works in tourism must agree to be registered in a cadastre as rendering services in the paid cooperative with an annual tax depending on type of service. The services can be collectively or individually explored. The cooperates and the members of the council participate in diverse courses of qualification and seminaries, this has as consequence conviviality. A part of the resources of the cooperative is destined to social and educational causes, so that the resources managed with tourism will not only improve the ones that explore this activity but the whole community.

[4] "Communitarian tourism, or of communitarian base can be defined as one where the local societies possess effective control on its development and management by means of the participative involvement since the beginning, tourism projects must provide most of its benefits for the local communities" (WWF-Brasil 2001, 2).

The similar experiences of tourism in the region had signaled for the importance of the qualification and the education of the community of Prainha do Canto Verde. Diverse actions have been made in this direction, with the support of the Foundation Friends of the Prainha do Canto Verde and the Abrinq Foundation. It deserves a special prominence that a special auxiliary bourse-aid was offered for 15 children so that they could complete the studies in the capital Fortaleza; and the project “Child Constructing” aims to improve the education from the active participation of professors, parents and students.

In the seminary of communitarian eco-tourism, in 1998, it was also decided to invest in tourism of events and courses, constructing and using to advantage spaces and enabling people in realization activities and support of events, including equipment. Today it is an infrastructure that allows to concur a viable and attractive option in this type of tourism.

To extend the lodging capacity and to finance small projects a rotating fund for small loans was constituted, that is managed by the cooperative of tourism and handicrafts. The project wich search to amplify resources is analyzed by the direction of the Coopecantur, and the selected entrepreneurs receive qualification and accompaniment. Some examples of projects with granted loans are: freezer, ice-lolly plant, repairing Tour-Jeep, repair and construction of inns, domiciliary lodging etc. The money returned for the fund goes for new loans and it does not have insolvency cases.

The association of inhabitants possess a small inn that is in charge of the cooperative that paid it a concession, as well as the rent of a store of handicrafts and the communitarian center. The *Bom Jesus dos navegantes* school also receives rent for the use of the conference rooms, refectory, equipment in events, seminaries or courses. With the management centered in the cooperative, with a database on tourism in the community, and with the dissemination activities and contacts made by them, the planning capacity was facilitated and obtains better control to evaluate the impact of the tourism in the community.

The community-based tourism in the Prainha do Canto Verde brought with it a reflection on the importance of the cultural valuation in the community, there had been developed some actions in this direction, such as the book “Our history” for the literacy classrooms and the first series, with the objective to develop a pedagogical material, for the local reality and the local ways of life; the *Povos do Mar* school aims at professional valuation; a choral of children, who present in the festivities and in other localities; the proper sold products in the handicrafts store, where part of the income goes for the library and to pay the judiciary process and the mobilizations. All these projects insert the history, the culture and much more current subjects that need special attention, as the ecological and social questions. These projects and others count on diverse supports, such as the Terramar institute, the nucleus of ambient studies of IBAMA, among others institutions. The proper flow of tourist helps and motivates the cultural valuation, the conscience and auto-self-esteem of the community, with the tourists wanting to know the way of life and its history, its fight and its project.

The ambiental question in Prainha do Canto Verde was given a priority role. The first point to be argued was the pressure on the environment, in the case of population growth. With a young population with an increasing income was the increment of the tourism, the trend was to have, in few years, an explosion in the vegetative growth. With conscience of this fact, an action of family planning was developed interlacing sexuality. Moreover, Prainha did not have basic sanitation and had a gutter less than three meters of the surface. For these problems two projects had been elaborated, SODIS (Solar Water Desinfection) and the use of sanitary vases of compost. It was learned in the communitarian gardening school, to transform organic garbage into natural seasoning, and the communitarian transport (a Toyota of the association of inhabitants) assists in the garbage collection of the city hall. The ambiental question also became present in pedagogical materials and conscientive activities, as the ecological races that occur annually and mention the preservation of the coastal environment.

The small scale tourism organized by the proper community favored this series of actions, that woke the interest, not only of institutions and researchers, but also, of other communities

interested in seeing in close a communitarian based eco-tourism experience. The experience of the Prainha do Canto Verde resulted in recognizing social tourism (among others prize TO DO![5] ,prize "prêmio Criança 1997"[6]).

The fight of the land still continues, but the community already uses some norms for the use and the "sales" (right of ownership) of the land. This story shows some characteristics to us that has functioned as a guide for the process. The main reasons why this project of tourism was constructed are obvious. We are speaking of the participation, the valuation of the context and the local culture, the exchange of experiences, and also, dialogue with other contexts and other actors.

8. What was the result? A new paradigm in construction

> *"In short, the communitarian eco-tourism of Prainha do Canto Verde is inserted in a proposal of integrated and sustainable development, enclosing the diverse dimensions of the communitarian life and of the organization of fishing activities, education, health, environment, and the agrarian question. The tourist activity has subsidiary and complementary function in the economy of the community. It has important role in the conservation of its cultural and natural environment. Fishing and the land `are the identification elements' of the community base. The tourism promoted here is characterized for being developed by the community, organized, managed and operated in cooperative base by the proper inhabitants, and has as distinguishing attribute the declared intention of being today (and remaining in the future) of small scale. Its management is based on the principles of the communitarian auto-regulation"*
>
> (Rocha 2003, 122)

This union and mobilization, the call of external actors and the configuration of a debate and conviviality space has been the bases to create an environmental union internally and of a differentiated relation in respect to the actors involved in the process. The purpose was to develop a proposal from "down to up", the concern was about the well-being of the community and the balance of the ecological way of which it is part. This model represents a new paradigm in tourism and believes that the main innovation inhabits essentially in the type of relations that is possible to live. New standards of relation have been established, they defy the existing standard in the majority of the scopes of society, also in the area of tourism. In first place, it is about new relations between the inhabitants based on contribution, solidarity and in lending aids, for the creation of space of an open and democratic conviviality. This picture definitively opposes the one of individualism and competition that predominates in the majority of tourism experiences. In fact, when the members of the same receiving community are not totally excluded from tourist circuit, they are generally in competition aiming to get more individual profits with the tourism activities. But these new established standards are presented as more "innovative" in relation to the tourists. It's interesting to observe that the tourist in Prainha do Canto Verde is not anymore "the king" who can do what he wants, but opposed to it, has to obey rules, preexistent to his arrival that have been established by the receiving community. These rules represent limits (of use, load, etc.). The tourists, in fact, can live profoundly the day-by-day reality of the community appreciating it approximate to the inhabitants. A relation is made between the members of the community (hosts) and the tourists, which is dialogical in nature, the two find a relation of proximity of a total different type to conventional tourist services, a relation characterized for the

[5] Given by the German NGO of tourism and development studies (www.studienkreis.org).

[6] Abrinq Foundation.

unpredictability and proper singularity of each meeting. This new type of relation established with the tourist is based on an ethical relation between pairs, relations who are based on the respect of the other and therefore, foresees limits and rules, but at the same time leaves space for the meeting and dialogue in it. The majority of the times it becomes a form of cultural exchange, therefore frequently the tourist and the host belong to two different cultures. This type of relation favors and stimulates the interchange of forms of thinking and viewing the world, but also of sensibility and knowledge. This strengthens the value of each culture and increases auto-esteem of the involved actors. It transforms tourism, by means of services, into a meeting place and dialogue between cultures.

9. The design in all of this

Viewing the reflections of the experience of Prainha and the experience of social innovation that it represents, it is interesting to locate service design and to reflect on the possibilities of its role.

It seems that a services designer needs a specific focus on humans and their relations who are constructed by their own means, who have a role of great importance in new estimated developmental bases.

It is important to reflect on the fact that the experience of Prainha is the result of a determined historical context and circumstances, who are cultural and social specified, between a foreseen fight for survival, that mobilized the entire community under the threat of being destructed; the possibility of comparison with neighbouring experiences and at the same time refusals, that made possible a critical reflection on some options of tourism models; the presence of some external, national and international actors that on a side, meant the possibility to have a bigger resonance, and on another side, had the effect to instill more the identity and self-esteem of the community.

All these factors contributed to the case of Prainha, so that it continues being, a national and international reference for community-based tourism.

So it is necessary that service designer works from inside valuing the “experience lived” in each service and stimulating the personal relations of some systems, and stimulating the creativity and the personal interaction, but at the same time it is necessary that it looks inside each service for specific context, fitting it in its culture, looking to perceive and to understand symbolical aspect. This serves to value the differences and to provide a ampler experience, including the stimulation in personal relation, the lived experience and the pertaining dialogical relations in this experience.

Today the services are only utilitarian. The workers of these services are stimulated to fulfill specific, mechanically a script to transforms them into a part of a gear. The worker loses autonomy and is restricted time to use his creativity (Camus 1997). The user loses the wealth of the context in which he lives, seeing only the instrumental and functional aspect, losing to experience deeply that moment (Candi 2007) and that place. Parallel design, if restricted only to the scope of the projectation of objects and to visual communication, can run the risk to lose the vision of all, being worried only about the small “details” and, still more dangerous, finishing in reproducing the logic of the society. In another perspective, service design could be seen, for its sensitivity in relation to humans and his relations while experiencing, the possibility to not only bring for design a ampler vision, but exactly to load a definitive strategic function, namely, one of reinforcement of one determined “symbolic site” (Zaoual, 2006), stimulating the interpersonal relation, breaking the homogenizing cultural structure and extending the plural and multi-cultural character of our daily one.

In the words of Manzini (2007), a designer it could act as “facilitator” of this process:

> *He becomes a process facilitator who acts with design tools to generate ideas on possible solutions, then visualizing them, arguing through them, and placing them in wide, multi-faceted scenarios, which are presented in concise, visual and potentially forms.* (Manzini 2007, 8)

So that it comes to happen that a designer must know to assume a ampler vision, also of contributions in other multidisciplinar areas. The valuation of others, however, needs also to happen in relation to the world of the "silent native", so to speak dialogues in other areas of discipline must be included, so that the dialogue with other actors, carriers , and unspecialized persons, but who will be directly involved in the service. These unspecialized persons, in the case of Prainha had developed a tacit form of "design", showing that the act to project is intrinsic to the human being, independent of its culture and its specific knowledge. It is in this perspective that it makes viable the possibility to co-design, where a designer with his vision and tools can collaborate with the users futures, which are cultural beings with an active role in the society. In the development model where we are living, other visions beyond the one that worries exclusively about the functionality and/or the profit making essentials so that we can change the direction of the way that we are following, knowing that the route that we are taking has generated each time a worsening in the condition of life, of all levels and all classes. A change that helps the society in obtaining an ampler vision, based on dimensions that bring a more humane side. Designer has to assume its part in this challenge, creating solutions, pointing ways, and participating to this collective conscience actively, but knowing that it is only an actor in this process of change. Remembering as soon as the visions and the knowledge of design of services must exceed the limit of exclusiveness of the professional of design, being a base of proficiencies so that, other professionals in other areas of knowledge, and other users, can contribute in the development of more humane and convivial services.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Projecting new forms of neighbourhoods.

The creation of a link between the inhabitants as an answer to changes in society.

Francesca Lanz[1].

Abstract

In the last fifty years in Europe we could observe the end of traditional welfare, the fragmentation of housing's supply and demand, the beginning of a differentiated request that reflects a social situation no longer understandable by traditional criteria. Traditional homogeneity of social classes no longer exist, replaced by melted and coloured social groups. The mixture of cultures, the extension of active life, other complex social and economical factors, deeply will modify the project and the construction of future houses.

Anyway everywhere changes in the family's structure as well as in the ethnic and social composition of the cities demand a change in dwelling spaces.

Interior design is a privileged approach: from interior quality begins the quality of the whole contemporary metropolitan living and the sharing of areas and particularly of services could be a possible answer to the new needs in terms of habitation.

[1] Politecnico di Milano (ITALY) - INDACO department. Ph.D student, francesca.lanz@polimi.it

1. Introduction

«These inhabitants have their culture […] and for inexplicable reasons they are given exactly the opposite of what their "social being " demands in order to survive in harsh and merciless societies» (Kroll 1999, 39)

Even though agreeing on the impossibility of formulating univocal models or identifying ideal dwellings that can satisfy all the contemporary needs of habitation, we can show that on a European level, some general trends can be identified. These trends derive from some common demands formulated within different social groups and cultural areas. The ensuing spatial consequences are heterogeneous and diversified, depending on the geographical environment and the design tradition in which they are formulated and experimented.

The uncertainty concerning the idea of the habitat, as well as of the ways of living in it, remains. In a certain sense, the amount of time that people spend in their houses is increasingly limited, and «the contemporary dwelling- as affirmed by Luisa Bonesio – is a space that ever more precariously disguises its predominant function of hosting, for a few hours, people that spend most of their time plunged in spaces and rhythms of the planetary "Mega-machine", whose law is that of total external appearance» (Bonesio and Micotti 2003, 113). On the other hand, there are still many activities that families carry out inside their dwellings: in the kitchen, meals are prepared, people eat, children do their homework, the family gathers to chat; in the bedroom, people sleep, watch television, read, play, study…

The general demand, for one reason or another, is to have more space, both in terms of more effectively available surfaces, as well as of the number of rooms and functions contained in the house. This demand is common in the middle-high social classes as well as at the level of low cost working-class dwellings. The fact is, in any case, that these activities, which we could define *vital*, remain at the centre of domestic life and are therefore the sources of the demand for space on behalf of the inhabitants. In this way, the *inhabitants,* - those who carry out the etymologically indicated activity of *taking possession of spaces*, making them their own Inhabitant, from the Latin verb *habitare*, frequentative of the verb *habere*: to have, to possess-, are again at the centre of the design reflections in some current experiences of research and experimenting, on a European level.[2]

Those projectual trends, even in the variety and complexity of possible answers, have in common the attempt to answer these emerging needs, placing the human being as an inhabitant at the centre of the action. Here emerges a scenario involving the different (inseparable) levels of the fundamental relationship between man and his environment: from the relational dynamics with space to those with the other inhabitants, up to a direct involvement in the construction of this habitat.

Recalling again the words of Lucien Kroll: «No more shapes, objects, solutions, but urban actions, attitudes of the inhabitants and users, processes, experiences [...] We believe that, in a deliberately complex design, the live complexity could take roots more easily than in objects that anxiously deny its existence» (Kroll 2001, 37).

[2] The contemporary European living scenarios were analysed by the student of Ph.D. in Interior Design of the Politecnico di Milano during a research in 2006. The results of these survey are published in the book by Bosoni, Giampiero and Piardi, Silvia and Manfredini, Manfredo. 2006. Advanced Living Scenarios. Contemporary trends in European housing, Milano: Virus. A widen version of it will be published in 2008 in double languages, English and Chinese.

2. The creation of a network as an answer to changes in cosiety and habitat.

The demand of the inhabitants for more space, consequent to the new and different ways of using spaces, as well as the urge to bring the person back to the centre of the designing process, involves, on one hand, research from the technological and constructional points of view. On the other hand, it involves a re-thinking of the domestic design also from a programmatic point of view.

If the time spent by each inhabitant within the domestic walls diminishes progressively as the complexity of life increases, it is nevertheless true that the activities taking place inside the house are many, and increasingly varied. The recent experiments in the field of integration of working spaces within the residences are the first proof of these changes in the habitat (Farè and Pirdi 2003). On the other hand, changes in the family structure as well as in the ethnic and social composition of the cities, also demand a change in dwelling spaces. This change is however late in taking place and in having effective repercussions in the design process.

The role and meaning of the family in our society have changed during the last decades, correlated to variations in cultural, economical and demographic concauses and elements. Consequently, both the theoretical investigations and the operational interventions are deeply changing. The object/subject "family" is nowadays complex to interpret and difficult to define conceptually, due also to the passage from a plurinuclear and extended dimension to a mono nuclear and restricted dimension of the family itself. From the dimensional point of view, that is the number of components, families composed of one or two persons are on the increase, representing about 60% of all families. For example in Italy the number of family components is progressively diminishing: since 1971, the percentage of one-person families has doubled and nowadays only 57,49% of couples have children[3]; danish families are instead composed on the average of 2.19 people, while 36% of proprietary houses are occupied by a single person, 53% being women[4]; in France, 33% of the population lives alone and 24% are single persons aged more than 50 and 32% are families composed of two people: the average components in a French family are 2.3 persons[5].

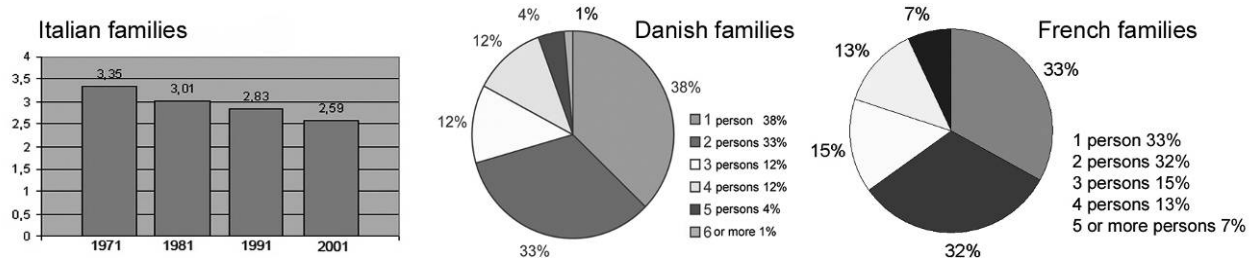

Fig.1: The changing in the family's structure. Components in European family units: Italy, Denmark and France.

As far as composition goes, we can say that the classical "modal" family, that is composed of parents and children, is diminishing, whilst families composed of childless couples and single parent families are on the increase. The presence of a single parent is no longer due only to

3 Italy: data taken from the 2001 census and re-elaboration by Istat

4 Denmark: data taken from *Population and elections, statistical YearBook* document and re-elaboration of the 2002 census by the Danish Government.

5 France : data taken from INSEE *Institut National de la Statistique et des Études Économiques* 2004 concerning the composition of family units.

widowhood, but, increasingly often, to separation of the couple, considering also the marked increase of separations and divorces.

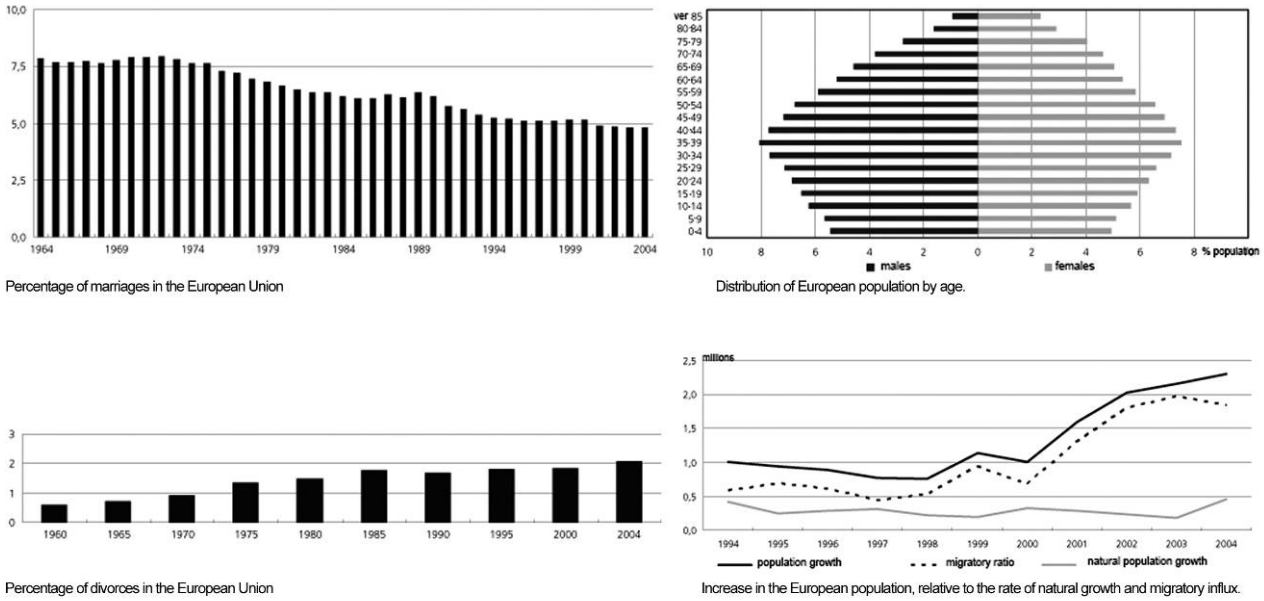

Fig.1: The changing in the european society. The graphs rapresent some of the several demographic and social changes in the making in Europe. Data taken from “L’Europa in cifre” Annual report by EUROSTAT 2006 – 2007.

We must then consider the “other types of family” meaning the abundant variety of family compositions, such as, for instance the “reconstructed families”, the enlarged families, with the presence of elderly people, or the families of persons who are not completely self-sufficient, aided by relatives or assistants.

On a European level it is still difficult to find the variety represented in demographic research, but at a national level, in the most recent census, an image of this situation begins to emerge [6]. If, on the other hand, we search for traces of these changes within architectural design, particularly in interior domestic design, we can today identify the first signs of innovation at a planning level, although, as we will see further on, not yet really formalised from the typological point of view.

The sharing of areas and particularly of services is nowadays one of the main proposals in many European countries, including recently Italy, who see in this a possible answer to the new needs in terms of habitation. Such a proposal allows in fact to increase the space available for the inhabitants, virtually extending the surface of their own house by including the common areas, saving money as well, by decreasing administrative expenses, shared amongst the various owners. At the same time, it can help the appropriation of spaces, and, above all, the creation of links between the various users (Hertzberger 1998) trying to create and stimulate, through interior design, relations and links between the various users of a space or a building. The project thus carries an increased social responsibility, playing a fundamental role in the creation of a *network* of the different actors, indispensable today to face the rapid urban, demographic and social changes in the making.

6 In the recent ISTAT research "Indagine conoscitiva sulle condizioni sociali delle famiglie in Italia”(Cognitive research on the social condition of families in Italy), presented in Rome on the September 20th 2006, for example, it has been necessary to redefine the family, choosing to consider both the officially registered and the “de facto” ones, adopting the criteria of “habitual co-habitation” and the concept of “nucleus” in order to identify, within the family, the subjects linked as couples or by parenthood, because within a family there may be one or more nuclei or none at all. The concept of the “family as an institution” is weakening in favour of the family as a “whole”. The variety of family relations, according to the criteria used for the Census, is divided into “marriage, kinship, affinity, wardship or bonds of affection”. A glossary had to be prepared in order to try and systematise and render comprehensible the new categories introduced.

The cities are constantly growing and their population becomes increasingly heterogeneous; the changes in the family structure mentioned earlier are accompanied by a gradual increase of immigration and by a progressive ageing of the population. At the European level, in about 30 years time, the population aged over 60, considering also the progressive increase in average life expectancy, will definitely be larger than it is at present, particularly if compared to the younger population. This will result in a revisal of the welfare models in the various countries.

What emerges is that the individual is increasingly alone and feels insecure even within the domestic walls [7]. Creating links between people is also one of the possible strategies to prevent social troubles, the development of fractures and the phenomena of social, ethnical or generational ghettoization [8].

Can design contribute to the future of cities? How shall we manage the social, cultural and urban transformations that are taking place, so that they can constitute a veritable resource for the cities and, above all, for their inhabitants?

These questions and considerations, surely of a very general and maybe utopian character, form the bases for some experimentation in the field of interior design focusing on the creation of links between people.

2. The sharing of spaces and services: the Danish tradition and research.

Looking at the European scenario, trends of active research in this field of investigation have been found in the Danish context, which has produced theoretical and experimental results of interest. The research and some projectual experiments are looking for a way to reinstate the social role of the house, going back to some fundamental and traditional themes of Danish residential culture. These themes include the attention for the context and the environment, the relationship between the residential initiatives, the institutions and the local communities, project sustainability and, above all, the concept and practice of sharing spaces and of life in common.

The experimentation concentrates on the attempt to design spaces enhancing social behaviours such as mutual assistance, which foster the beginning of a closer relationship between the users, thus contributing to the creation of a neighbourhood community. These aims are based on the idea that these types of links and dynamics, in addition to improving the quality of life of the inhabitants, have a positive influence from the social and economical point of view. First of all, as we have said, they promote integration, thus preventing and limiting the phenomenon of isolation; moreover, mutual assistance, sharing of goods, services and spaces, brings to a general decrease of wastes and can lower the cost related to the supply of a series of charitable services included in the Danish welfare model (for example, home medical care, elderly assistance, help in domestic chores….). In the specific case of elderly people, this model allows them also to continue to feel a part of the social context. The function of these spaces is then to foster the creation of links between people, and in order to achieve this, the strategies and suggestions are mainly found referring to tradition. In fact, analysing the typical Danish residential models, we find different typologies of dwelling that provide for the sharing of spaces or activities, such as *co-housing*, that was born in Denmark in the middle of last century.

Co-housing was born in Denmark in the ’60s from the ideas of the architect Jan Gumand–Hoyer (Durret and McCamant 1988) and has today spread particularly in the Scandinavian countries, in Japan, Australia, USA and Canada. In Denmark, it is a consolidated dwelling

7 See *Rapporto sulla Sicurezza Nazionale*, Quirinale, 20 june 2007, Roma, Italy.

8 We can unfortunately find many warning sign of this situation: the riots in Paris, the disorders in the Chinese quarter in via Paolo Sarpi in Milan, the current debate in Italy about security, the xenophobic event in South Africa, are just some examples and we cannot refrain from thinking of the recent and rather frequent news reports about elderly people “forgotten” on trains or in apartments in the outskirts of our cities, fights between neighbours that end in tragedy, or of undisturbed armed robberies in the apartments.

typology to the point that it is included in the master plan for large development schemes. In the last few years, the first communities of co-housing are beginning to develop also in Italy. At the basis of a co-housing project there are some common expectations and desires of the future inhabitants, such as the quest for a dimension of sociality nowadays lost in the big cities, the will to rediscover a sense of neighbourhood, a feeling of safety and belonging, and an effort to reduce the complexity of life, the management costs of everyday activities, and the daily stress. The groups of residents are generally intergenerational communities with the presence of singles, families with or without children, and elderly people, linked not by ideology or ways of thinking but by the common choice of living as a community, driven by the desire for a socially richer life. The residents are an active part of co-housing, co-operating in the design of the complex, as well as in its operativeness. They take care of everything together, starting from the choice of the services to be shared, up to the management of the structure and its rules.

Recently, particularly in Denmark and in the USA, senior co-housing (Durret 205) is spreading: structures of co-housing dedicated exclusively to people from 55 years up, who are given the possibility to live in a community with neighbours with whom they can share interests and also structures and social services. The apartments are totally accessible and the common areas are designed so as to offer spaces for leisure and community life, independently of the physical or mental ability of the single residents.

An example is the Mariendaldsvej senior cohousing in Fredriksberg (Copenhagen) by the Box25 architects. It was built in 1993 and the construction was financed by the Pension Fund with some government aid whit the collaborations of an academic team and the professor P. D. Mortensen. Construction costs were $3,200,000 and the rent cost is in the average for new-build flats in Copenhagen; care for the elderly persons is provided by the normal network of nurses and community helpers. The architects paid a lot of attentions to the ecological aspect of the project and they tried to create suitable, safe a pleasant environment for elderly people. Sustainable living features include heat exchangers, solar collectors, passive solar systems and the use of rainwater for toilets and laundry. The buildings are made by red bricks, whit an architectural language that try to keep a relationship whit the surroundings buildings; instead the horizontal and vertical connections have a completely different stile and they are made by steel and glass. It provides 22 individual apartments and several common living areas. Each apartments is fully accessible for users with wheelchair and it’s completely independent; the dwellings have got an high quality finishing, a kitchen, a toilet and, at least, one balcony to provide to every one privacy and quite. The apartments communicate whit the common areas, so it’s easy to pass from a private space to a common one. The common areas are used for several purpose for instance living and eating together, gardening, swimming pool, library and two guest rooms. This spaces have double high, floor to ceiling windows and mobile walls that make the ambient comfortable and flexible. The interior design encourages both social contact and individual space.

The possibility that senior co-housing community could be, under many points of view, a sustainable solution to the problem of the entertainment and assistance to elderly people began to be discussed in Denmark in 1987, after the progressive closure of clinics and old age homes which started in 1985, preferring a system of domiciliary care, surely more accurate and of better quality, though undoubtedly more costly from the public expenditure point of view. Today in Denmark, many communities of senior co-housing are operational and, also in Sweden and in the USA, the number is continuously increasing, with positive results both for the authorities and for the residents, who are generally satisfied by this arrangement (Paulusson 2004).

Anyway co-housing communities are not the only possibility and the attempt to create new forms of neighbourhoods, not just for elderly persons, it’s very strong in Denmark: five years ago Architects 3xNielsen won a closed competition for new buildings on the west end of the porcelain factory grounds in an old industrial area of Valby (Copenhagen). The competition programme called for proposals that would find place for three substantially different functions: a daily-care centre, a senior care centre whit senior care residences and family dwellings. “A city for all ages”, the 3XN’s proposal, was the only project that integrates the different functions in order to make different ages meet: the 3XN architects grabbed the opportunity to integrate the three generations

whit a proposal that would rethink generation blending in the city. One of the discussed issues in Denmark is how the elderly, no longer involved in the working life, still may be a contributing part of society in stead of being hidden away in some care centre, and in Copenhagen, as in many other European cities, a big challenges lies in the conversion of the old industry areas. The different functions were combined in to a single building that reinterprets the classical city block: the complex can be read as two buildings lying on top of each other. Each one is designed for its specific functions and for its special user's group. The two lowest floors have a clover-shaped plan whit efficient walking flows and calm areas without through-traffic: here we can find day care institutions, the kindergarten, senior care residences, senior training facilities, a centre for the elderly and a common house. These spaces are equipped whit several furnished common areas: it constitutes a secure a safe environment for the elderly that try to encourage meetings between the different generations. Then they become a working environment as well, with the need for efficient walking flows as calm areas without through-traffic. The senior residences are fully accessible also for the users whit wheelchair and they have to be independent and they are furnished whit a kitchen and a toilet. The views and the walking flows are project to provide a contact whit the other building's users. The two upper have a block shaped plan, partially column-borne: they lay different kind of family dwellings among which some 2-story apartments. Here is provided more privacy and individuality along with a best views of the city and the units have roof gardens on top of the lowest floors providing the quality that one expects from an urban dwelling. The project won the MIPIM AR Future Award in the 2005.

These examples show us a way for a new possible way of housign.

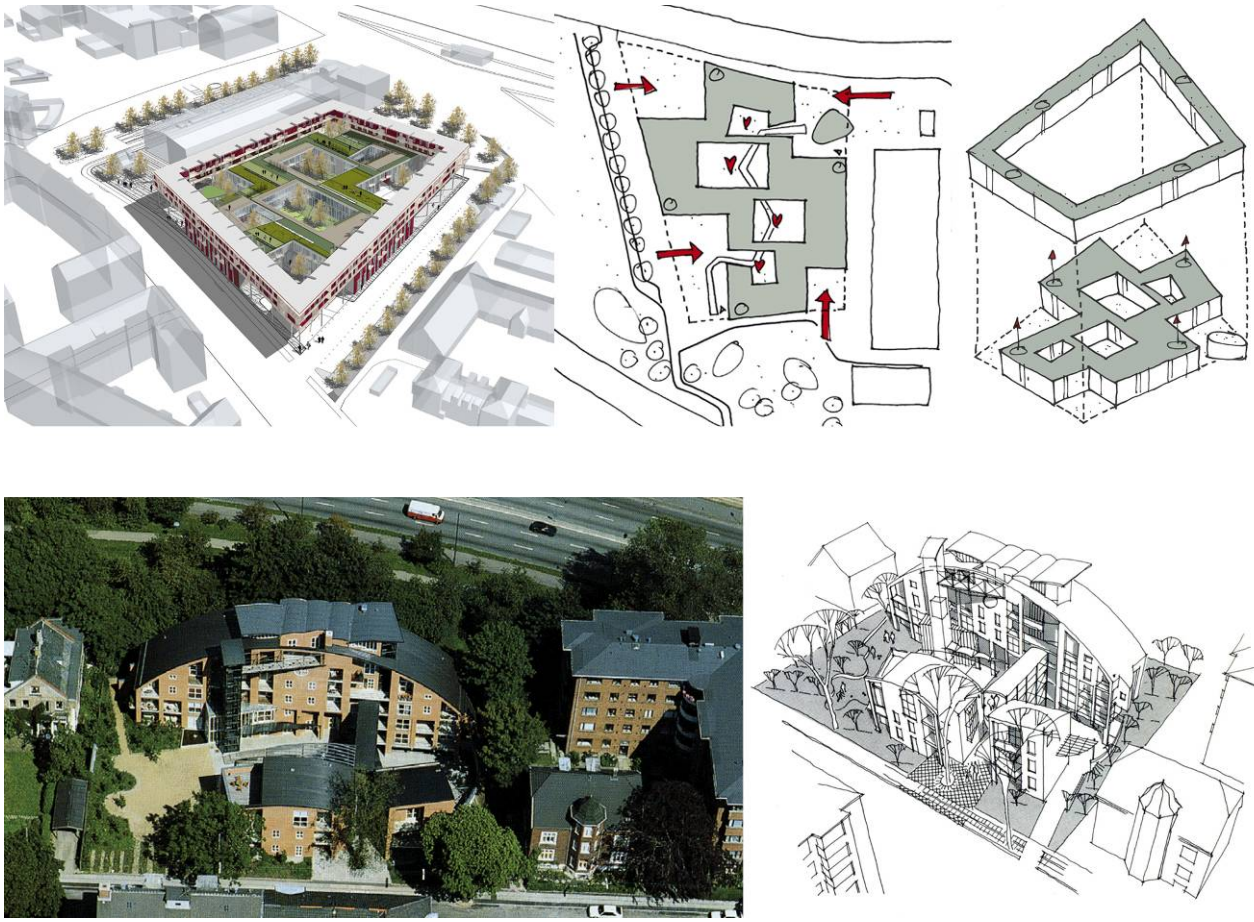

Fig. 3: New forms of neighourhood in Copenhagen. The project "A city for all ages" by 3XNielsen architects and the Mariendaldsvej senior cohousing by Box25 architects.

3. New forms of neighourhood in Beijing: an international workshop.

An international workshop at the Tsinghua University of Beijing in December 2006 provided the opportunity to check the capabilities of these planning approach also in a not European context.

In the last 30 years China, after the important changes in its foreign political behaviour, has become a gigantic mixture of cultures, ideologies and different classes, leading to a very confused situation in which the Chinese are trying to find a right direction for the future. Beijing has been at the center of great social and cultural events. The city was founded about four thousand years ago and, until a few decades ago, has remained virtually unchanged: his life was based on a efficient feudal system and a strong traditional culture. In 1949 the population in Beijing was around 4.2 million, in 2004 it was around 15 million: Beijing has become about 4 times bigger than fifty years ago.

At the rapid economic and demographic development, it is not followed, however, an adequate social development and today Chinese have to face several problems that pain their cities peer to those found in Europe: overcrowding, lack of social integration, need of conservation and requalification of the historical building of the city, demand for greater space and quality services and the will to conserve and recover the traditional values and ways to inhabit and living.

Today, the survival of the traditional houses is threatened from the fast development of the city: houses are demolished or recovered to tourist scopes like museums, restaurants, lodges and, sometimes, luxury houses for rich tourists, loosing their original function and becoming empty symbols of the past.

The Chinese society and the family structure is deeply changing and the traditional houses made by *hutong* (alley) and *siheyuan* (traditional court-yard house for one family) are anachronistic in relation to contemporary needs. On the other hand, high density solutions are too far from the tradition and the sensibility of the Chinese people.

So that during the workshop were asked to the student, Italian and Chinese working together, to develop a proposal to conserve and reuse some traditional houses placed in the historical part of Beijing, making them proper to host 3 o 4 families.

The traditional Chinese family is strictly related whit the traditional house (Gazzola 1999). The hierarchical structure of the traditional family finds immediate correspondence in the organization of the siheyuan where all the spaces are structured in order to accommodate the different members of the family. The inhabitants of the house were linked together by family connections and the perimeter of the house constituted fencing and a protection for the privacy of the inhabitants.

The proposal was the creation of a community of cohousing that involves not only one single siheyuan, but a wider portion of the neighbourhood encompassing the other courtyard houses and alleys, with the intent to create a network that can be expanded, revitalizing this part of the historical city and guaranteeing its conservation. In every house there were small apartments for four different families and several common spaces (guest room, laundry, studios…). The students decided to conserve the structure and the original system of the siheyuan and its main element (the central courtyard, the disposition of the different buildings around it, the surrounding wall and main income…).

While in the past the cohabitation of various persons and different families, in a single siyehuan was guaranteed from the blood link that band together the various inhabitants, today it's necessary, in order to make this cohabitation still possible, that there are new ties between the families of the siheyuan. The idea has been that this link could come from the aware choose to share some spaces and services.

The definition and the analysis of the common spaces and services was a fundamental part of the project. Today in China the distrust towards any kind of sharing is very strong: this is a reaction against the abolition of the private property during the years of the Cultural Revolution. Privacy and intimacy have always been two typical characteristics of the Chinese houses and they are today, above all, requirements priorities for the pekineses families. That's why the definition of the common services and the common spaces to share was not simple and in this phase of project process the different cultural formation of the students has been mainly felt. The result has been a compromise, for which, for example, every apartment has go a small space for the washing machine, while there is a common spaces to dry the wet clothes. The planning of the common areas has had like main objective to provide a better housing standard and quality services for the syheuan inhabitant and for all the neighbourhood.

The thougness has been largely rewarded by the remarkable work of exchanging ideas and comparison of points of view between Chinese and Italian students trying to create a common background and overcome the differences and habits, sometimes stereotyped, particularly rooted in the different cultures of living. It was possible and the result was very interesting.

4. Conclusions.

As we have seen, the European urban scenario is changing, but these changes are not only of a demographic or social kind. In the last fifty years in Europe we could observe the end of traditional welfare, the fragmentation of housing's supply and demand, the beginning of a differentiated request that reflects a social situation no longer understandable by traditional criteria. However very little attention has been paid on that, but nowadays the need of low cost and high quality residences is becoming more and more pressing.

The scenario, particularly focused on metropolitan European areas with high living tensions, confirmed the feeling of a fragmentation that concerns, first of all, people involved in the programmatic actions. Traditional homogeneity of social classes no longer exist, replaced by melted and coloured social groups defined by different parameters that, as some authors claim, can be based on behaviours and constitute contemporary tribes. The mixture of cultures, the extension of active life, other complex social and economical factors, deeply will modify the project and the construction of future houses.

Throughout Europe, with the progressive closing of industries, which started in the '80s and the unavoidable ageing of some areas of the cities, the need to intervene became increasingly urgent, in order to create new trends in the urban texture. This is an important opportunity to re-think many strategies and to develop alternative theories. The quest for a social quality and responsibility of the project is concerned, as well as the attention to the essential aspects of interior design, such as functionality, flexibility, the possibility of rationally furnishing the areas, keeping in mind that the house is a place of personal and social relationship for those who are living in it. It must thus reflect the way of living and daily habits, allowing and encouraging a progressive appropriation of both the internal and external spaces by the user (Farè 1992, 91-111) considering also other aspects of basic importance, such as the social dimension of the habitat, the attention to the context and to the ideals of the community (Keiding 2004, 571; Mortensen 2004, 572-579).

Residential typologies such as co-housing are rapidly spreading in all the European countries, and recently also in Italy. Here, in the last few years, the first experiments are taking shape and the debate about housing is becoming of current interest. Today it is difficult to judge whether this is only an "urban fashion" or whether these models really have a future. Undoubtedly there are many obstacles to be overcome, such as those of the economical type: the cost of these houses is still rather high. There are problems of practical management: the re-selling of the co-housing unit could, within a few generations, forfeit the principle of elective neighbourhood upon which these projects are based. There are also cultural problems: in Italy we do not have a housing tradition linked to sharing, and there still remain very many strong, hardly changeable stereotypes

about the house. Nevertheless, today the response seems to be positive, whilst the spatial effects of these new dwelling types still needs to be analysed. Interior design has the task of creating not only places in which to reside but places in which to live, where it is possible to find a dimension of essential sociality, in order to maintain, also at a larger scale, a more human, liveable and manageable dimension for the cities. The quality of a building is not only a fact of aesthetics, fashion or style, but it is an overall of complex elements, half-way between interior and exterior, private and public, working and domestic… As Hertzberger writes «The central question is the interaction between the form and the users, what they do reciprocally and the way they take possession of one other» (Hertzberger 1998, 115). The quality of life, supported by the interaction of man with the space in which he is living, becomes a fundamental pre-requisite for good living. This concept recalls the definition by Carlo De Carli of "primary space" or «relational space […] a space capable of receiving the body and gestures of man and of corresponding to his material needs» (Ottolini 1996, 87). The interiors are first of all destined to be lived in, used, filled by actions and gestures where the quality, nature and frequentation define theirs being and theirs characteristics. Interior design is considered as a privileged approach: from interior quality begins the quality of the whole contemporary metropolitan living.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The Sustainable Development of Traditional Urban Spaces in Wuxi, China

The changing of the road of Zhong Shan (2002-2007)

Jun li[1]

Abstract

Wuxi, as the representative of traditional Jiangnan water town, bears a great deal of ancient vernacular space forms. With the continuous development of urbanization, many new architectural forms also emerge, which are creations of public space in modern Wuxi.

Zhongshan Road lies in the central part of the city. It is nearly 2.14 kilometers long. It virtually inherits many elements from Wuxi's past. Now it is busting with the development of business, tourism and transportation. Inevitably ancient buildings gradually disappear. However, they are still important elements defining the city image.

Constructed space has gained multiple features and will be enriched by human activities, such as traditional customs, events and festivals, which create all the material, ecological, psychological and spiritual health for the space.

[1] Lijun(CHINA)-the Jingnan university ,the school of design. Environment art department, lecturer, lijun1221@yahoo.com.cn

1. General introduction about the Zhongshan Road

Wuxi ,with another name Liangxi and often called Xi for short , is a city in Jiangsu province , Located in 31º07¹of north latitude; Till 32º00¹; ,East longitude 119º31¹; Till 120º36¹, it is in the ,Yangtze River delta hinderland , and the southeast of Jiangsu province. It is to the East of Suzhou, the south of Taihu Lake, the west of Changzhou City, and the north of Jiangyin. With the Shanghai-Nanjing Railway, the Shanghai-Nanjing express highway, and the Beijing-Hangzhou Grand Canal cross downtown area, it enjoys convenient and fast waterway traffic. (lijun 2008.108)

Wuxi once was a famous rice distributing centre and since late 1800s, it has been one of birthplaces of our country nation industry and commerce,. Since 1930s, large number of famous national capital Corp. rise consecutively , such as Mrs. yang , Mrs. Xue , Mrs. rong , Mrs. Tang and so on , and modern times 'nation industry and commerce system has gradually formed, it has become one of the economic centre of southern Jiangsu area.

Wuxi is well known for that her elegant landscape and various humanity landscape, so it is praised as " a pearl of Taihu Lake ".

Wuxi city townsite has not changed all the time during the past 2200, and the city name is also unchanged The old city flat surface pattern appears for "curvature of the spinal column shape " and "one bends nine arrows " patterns. Centre city inner's modern times buildings, the garden villa, the tradition people habitants , historical buildings , and ancient workshop alley has strong history culture atmosphere.

This "one" bow point to the Zhongshan Road which cross the city straightly from south to north.

In the 28th year of Republic of China, the northern part of Zhongshan Road is expanded from the original 3-3.5 meters to 8-10 meters; from Shenglimen to Fengguangqiao the southern part of Fengguangqiao to Nanmen was not expanded. The government permitted broadening south part in 1954. In the august of the same year, all houses along a 1100 road to nanmen were pulled down. In Autumn of 1955 , project completed. The street had been broadened from 3-3.5 meters to 16 meters.

Fill the straight river inside town in 1958 , become No. 2 Zhong Shan Road swith the stone road surface,

Dismantle 208 family commerce houses in 1959, combine No. 2 Zhong Shan Road of 40 meters wide,

1979-1984 , dismantle private houses , broaden the road till 40-45 meters , and formed three pieces plants pattern , 10 meters of fast traffic lane , 5 meters of slow-traffic lane, two 2.5 meters of width green belts , 4.5 meters of width sidewalks.

So far, the entire zhongshan road becomes a 40-meters-wide block... (Fig. 1)

2. The main reconstruction project of the zhongshan road (2002-2005)

Except for relatively rich climatic and biologic resources, Wuxi is scarce of land, water and mineral resources. Besides, it totally depends on the input of other regions for energetic resources.For a long time, due to the heavy defect in this traditional economics and values which boasts that environment resource is valueless. Resources are greatly wasted and environment suffered great damage.

Recognizing the fast deterioration of global environment, and unprecedented urbanization processes in countries like china, it is necessary to incorporate global ecological view into local measures like china and it is necessary to incorporate global ecological view into local measures for improvement of human living conditions. Human settlements must be managed to be health not only for local inhabitants, but for the natural environment and the whole world's ecology, too. This view might be characterized as " both-eye-eco-view".

Change the traditional development pattern totally , renew tradition pattern of consumption , ascertain that science develops idea， construct resource saving type society. (Editor in chief Liren Wang, Wuxi Economic and Social Report in 2006, page 244) The realization of sustainable development depends on the lasting use of resources and the good environment.

Wuxi's development has experienced the process of modern and deep revolution. It needs high quality and high-level development, involving development transition of different levels and different forms.

After stepping into industrial society, science, technology, culture and other soft elements and soft industries take the leading position and determine the development and taste of the city and become the "Cultural City". The upgrade from "City Culture" to "Cultural City" is an inevitable qualitative leap in the evolving process of city culture.

Commercial Street of Zhongshan Road connects south and north of the city, which business, tourism and traffic are very prosperous. It is the aorta of business of Wuxi. It is the commercial street which ranks the seventh in total selling amount of the whole country.

- Historical changes of Zhongshan Road from 2002 to 2007 indicates that Wuxi is gradually stepping into the era of shaping cultural industry and experiencial economy with special cultural connotation and artistic connotation. New cultural industry of Wuxi has made great achievements. However, it is still in preliminary development stage compared with other cities. It is desiderated for preempting the high point in the competition of culture, science and technology, promoting the supgrade of cultural industry, and transfer abundatnt cultural resources advantage of Wuxi into cultural industry advantage.

- to outline the state-of-the-art of contributions that design research is today able to bring to social conversation about the future. The conference seeks to bring visibility to significant results. It will also enable us to make of the conference and its published output a tool able to demonstrate what design research can offer today to help re-orientate the transformation underway.

Significant changes of important areas of Zhongshan Road from 2002 to 2007 are reviewed in the following part, and the real motive for its changing is analyzed.

2.1. Renovation of Gonghuayuan

Ancient buildings on Zhongshan Road are gradually and inevitably disappearing in the recent hundred years. Due to its historical value, ancient buildings are still one of the important elements in determining the image of Zhongshan Road. With the construction of new urban space in Wuxi, the international life style will be further established.

Chengzhong Park on Zhongshan Road was constructed in 1905 and has always enjoyed the good reputation of the "First Park of China". It occupies about 50mu of land, is the important activity place for citizen of Wuxi, and a cultural symobl of modern Wuxi industrial and commercial city. （Xinhua news）

In 2005, Chong-an District of Wuxi conducted "expansion, green increasing and permeation", repaired some acient buildings, rearranged Qiqin Plaza and constructed the East Gate and

garden within garden—“Ziyuan Garden”. Citizen of Wuxi possessed a more elegant and comfortable emerald in the city.

The interconnection and amalgamation of the renovated Gonghuayuan and Chong-an Temple pedestrian street increases the humidity and lowers the of the dust amount of the whole block. Most roofs of the block are constructed into hanging garden. In this way, you can feel the loneness of the park when you are in the block and you can see the prosperous of the block while in the park. Chong-an Temple and Gonghuayuan will be constructed into 4A level scenic region and will take in the most tourists in Wuxi.

- The design of public environment has the features of universality and originality. Each city has its special geological, environmental and cultural elements. Shalang-sakyox wrote in his “City Culture” that human living is not simply operating in and on the city, it also originates from the city and the complicated particularity of city life to a great extent.

2.2. Evaluative Pedestrian Street of Chong-an Temple of Wuxi

As the famous historical and cultural city of Jiangsu, during scientific protection, development and utilization of historical and cultural resources, Wuxi references successful experience and gives off new vitality with the opportunity of intense international communication and the integration of east and west in the 21 century.

The development and exhibition of “Wuxi Business Culture” with the representatives of Chong-an Temple and Nanchan Temple are the best starting point for the development and protection of Wuxi industrial and commercial cultures, and the important way for the protection and development of history and culture. (Editor in chief Liren Wang, Wuxi Economic and Social Report in 2006, page 311)

Chong-an Temple has more than 1600 years of history. It has always been political center, commerical and trading center and cultural center of Wuxi since ancient times. It was constructed in the second year of Xingning in Dongjin (364). During the years of Xian Feng and Tong Zhi in Qing Dynasty, two big fires burnt down most architecture and left a large area of clear space which gradually evolved into the center of folk variety show and local flavour snacks.

In 2005, the new Chong-an Temple pedestrian street was officailly opened. It can be divided into above ground part and underground part. The above ground part takes east-west arranged stores as the main part. With the reconstruction of Shanmen and Huangting and the construction of Chong-an Pavilion, Buddhism cultural axes was formed; the former residence of famous musician Yanjun Hua (Abing) is in this place, too. The 400 square meters sunken plaza is the center of the underground part.

The renovated Chong-an Temple connects the history and the future, integrates traditional culture and modern civilization. With pavilions, small bridges and flowing water, ancient trees and tower shadows, waterfalls and sculptures, world famous brands, traditional brands, local snacks, western-style restaurants, restaurants and pubs, gold and jewellery, ect., it is worthy of the name of “business center, cultural center and green center”. All tourists will come to this place if they come to Wuxi. It becomes one of the four characteristic blocks of Jiangnan which also inculdes Shanghai City Temple, Nanjing Confucius Temple and Suzhou Temple of Mystery.

2.3. Museum of Former Residence of Bangxian Qin

- The protection and development of history and culture, concentration of festival celebrations, conferences and exhibitions, and the mobilization of mass culture are important promoting strategies for the leaping development of cultural industry. The exhibition of cultural celebrities and famous articles bring attraction and

competitiveness for the tourism and performance market. Expansion of cultural facility functions can bring functions of cultural facilities into full play and is the best way for the utilization of these facilities.

The former residence of Bangxian Qin near the commercial center of Zhongshan Road was the residence of Qin's family, and Zhuoru Qin is one of the descendants. From 1916 to 1926, Bangxian Qin and his family lived in the fourth building. At July 1986, people's government of Wuxi announced it as city-level cultural relic protection unit. At October 2002, people's government of Jiangsu announced it as province-level cultural relic protection unit. In 2004, it was constructed into museum of former residence of Bangxian Qin with the requirement of urban development.

Precious cultural relic data displayed in the museum become the education place for celebrities and Wuxi history. Calligraphy and drawing exhibition, memorial activities of Qin's family at this place attract a large number of townspeople. These bring the functions of exhibition, education and propaganda of city culture of the museum into full play.

2.4. The Formation of Cultural Commercial Center of Nanchan Temple

Jiangnan area has business-adored culture and paid attention to culture. Its jungle economy has always been developed since ancient times.

Nanchan Temple is located at the corner of Nanmen Canal at the end of Zhongshan Road. This temple was constructed in Tai Qing Years of Liangwu Emperor of southern dynasty. It was called "Ten Liang Brook Temples, Shouhuishan and Cinanchan" at that time. Later only a Shanmen stone memorial archway with four stone columns was existed.

In 1995, Nanchan Temple was reconstructed surrounding Miaoguang Tower. There were stamps, coins, flowers and birds, and antiques markets in the surrounding buildings. Together with snack and tea houses, temple-style market was formed.

After 2003, relying on Nanchan Temple, Miaoguang Tower, ancient canal and cultural commercial center of Nanchan Temple, the city was developed with the emphases on various kinds of special markets and the development of touring resources of the ancient canal. Local flavor snacks market, stamps and coins market, flowers, birds, fishes and insects market, antique market, book and periodicals market, and craftworks market were established successively. Therefore, business, tourism, ancient temple, ancient tower and ancient canal are integrated and the market is prosperous and flourishes. There are 1000 fixed stalls, 200 temporary stalls in the market. More than 3000 kinds of commodities are traded in this market and the annual trading amount is as high as 100 million Yuan.

2.5. Renovation of Street Space

Creating garden city with healthy landscape ecology is the important embodiment of modern development strategy of Wuxi. As the commercial center of Wuxi, Zhongshan Road radiates central hub of the whole city. With countless tourist everyday, it has the ability to exhibit the image of this city. In cooperation with the strategy of culture-based city, "humanized packaging" was implemented to the entire street in 2007. The purposes are optimizing and upgrading its whole function and creating a city street space with pleasant environment, strong cultural atmosphere, prominent fashion development, and harmonious and unified functions.

Detailed measures are enlarging greening area and constructing a large piece of greenbelt in every 500m; increasing various kinds of greening articles; adding plant landscapes and enrich greening design at open spaces along the street; increasing vertical greening and roof greening

and suitably renovate roof gardens within the allowable load of roofs and external walls of buildings along the street.

Simplify and modify incomplete public facilities, make people appreciate the history and elegance of Zhongshan Road, and perceive the captivating cultural charm.

Classify and treat buildings along the street according to their specific conditions, and form harmonized and unified integral elevation effect through cleaning, maintenance, rendering and renovation;

Commercial Mansion, Hualian Hotel, Liangxi Restaurant, and other buildings with relatively new exterior and modern color should be maintained and cleaned. Jufeng Garden, Huayuan City, Mingzhu Plaza, Yinchun Mansion, New World General Merchandise, Hongyun Hotel, Hengtong Mansion, Shidai Mansion, Chaoyang Mansion, the Second People's Hospital, Babaiban, Huijin Plaza, Jinjiang Hotel, and other buildings which were constructed in recent years with cement coating as external elevation should be cleaned and rendered to give them a new appearance. The external elevation of Lingtong Mansion, Yinlou, Zhongfa Mansion, and other old buildings which were constructed long time ago with ceramic tile facing should be renovated and brushed with latex paint to give them a new appearance. Civil houses at the north of Xingsheng Lane and commercial and living buildings along Shuiqu Alley should be demolished and the plot should be auctioned. The newly construction building style should be in harmony with surrounding environment of Nanchan emple. (Sunansanshi , sunansanshi blog, comment posted February 28, 2007)

Outdoor advertisement and storefront signboard should not affect the integral scale, style and tone of buildings;

Improve lighting engineering of buildings, stores, greenbelts and top identifications of high-rise buildings to make them into a continuous night scenery street.

At least increase 5 green, environmental protection and movable toilets through marketing channel; Make the street environment with humanity and ecological trend。The 2145 meters long Zhongshan Road is the densest street of population flow in Wuxi.

Zebra crossing of footway is made into colored zebra crossing; important road sections and areas (such as bus driveway, etc.) are obviously distinguished with colored road surface.

Mobile vendor scattering points are established on some branches, and they will work from 6 o' clock to 22 and a half. Vehicle, identification, management, charging and service will be unified; Adopt one time warning and second time confiscation management measure for dealing in the street and setting stalls outside the store; Remove and renovate civil houses at the north of Xinsheng Lane, and construct parking lot after dismantling.

Pave colored road surface on bus platform waiting area, install chairs on the bus waiting platform, and realize unification and modernization of the integral effect. During the reconstruction of road surface, environmental protection facilities, guideboard, urban map, etc., supporting facilities of bus platform should be improved.

Increase jiffy stands, each group with the length of 6 meters, and equips narrow flower bed built by wood-like material at the outside.

It is impossible for an elegant urban environment to be without self-contained public information system. The city which is lack of public information system is unsound, which manifests in incomplete functions and weakening city image.

In this renovation, all kinds of indication boards will be uniformly planned and designed with Chinese, English, Korean and Japanese to fully reflect the open city and tourist city image of Wuxi. The style, material and tone of the boards should be suitable with surrounding humanistic environment and regional atmosphere. For example, indication boards at Shengli Gate, Church, and other plazas are adopting bright red color. (South Chinese Wuxi imperial sacrifices temple promotion version block)

Install urban map and electronic map which can be interacted simply with the user at dense population flow places and crossroads.

Increase stainless steel garbage can; Install one garbage can in every 30 meters at prosperous road sections and one garbage can in every 60 meters at not so prosperous road sections. Distinguish disposable waste, recoverable waste and poisonous and nocuous waste, and install spitting facilities with easy to clean material. (Fig. 2)

3. Conclusion

Through 5 years of renovation, scattered cultural relics along Zhongshan Road are connected and combined. Small, scattered and excessive humanistic scenic spots with single function are turned into comprehensive scenic spots. Due to the continuous development of public facilities, sustainable utilization of the ancient city public space is realized.

Many years of renovation of Zhongshan Road provides public space for art and public activities of public recreation. Human activities, such as traditional customs, events and festivals, create all substance, ecology, psychology and spiritual health features of the space.

It is the traditional activities with local features that maintain the special atmosphere and configuration of the street while the large extent redevelopment of Zhongshan Road. It is the process of creating the harmonic coexistence of architectures and streets including its material structures, environments, local traditions, heritages and functions.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Breeding cultures of exchange

Can we design our hardware like how we are designing our software?

Thomas Lommee [1]

Abstract

Within design we are shifting our attention from product to process.

We start to acknowledge that a product can only be truly successful if it's embedded within a larger cyclical production process.

We are shifting towards production frameworks, design guidelines that suggest the use of certain materials, assembly techniques and dimensions in order to allow the end product to plug into existing cyclical processes. The designer of the future will be expected to be fully aware of these overarching frameworks and to understand their principles in order to respond to them with grace.

This paper is devoted to these emerging frameworks. It outlines two proposals in which it envisions how these frameworks could manifest themselves and what kind of objects (OpenSource Structures), services (balanced logistics) or even economies (cultures of exchange) it might generate.

[1] [1]Independent designer， thomas@intrastructures.net

Introduction

The 20th century idea of a seemingly infinite pool of resources gave rise to linear production processes, supply oriented infrastructures and huge amounts of waste.
Today environmental wake-up calls are forcing us to gravitate towards closed product life cycles, infrastructures that balance supply and recollection, and the notion of waste as a resource rather than a nuisance.
These shifts in perception are stimulating us to rethink the way we produce and inspire us to shape our supporting digital, physical and logistical infrastructures accordingly.
Within design we are shifting our attention from product to process.
We start to acknowledge that a product can only be truly successful if it's embedded within a larger cyclical production process.
Within the creative process we are shifting towards production frameworks, design guidelines that suggest the use of certain materials, assembly techniques and dimensions in order to allow the end product to plug into existing cyclical processes. The designer of the future will be expected to be fully aware of these overarching frameworks and to understand their principles in order to respond to them with grace.

This paper is devoted to these emerging frameworks. It outlines two proposals in which it envisions how these frameworks could manifest themselves and what kind of objects, services or even economies it might generate.

A. Optimizing production:

A1.Emerging frameworks

Within our built environment we can clearly identify two sets of frameworks from which new design principles can be derived.
On the one hand we see the emergence of several physical frameworks that advise us on material use and assembly methods.
They suggest to use of only those natural or synthetic resources that can either be infinitely recycled or fully degraded while in the process nurturing, rather than damaging, their surroundings.
As for the assembling part we are advised to restrict ourselves to only those joints and construction techniques that envision deconstruction without damage or loss.

Next to these physical frameworks we can clearly identify several dimensional frameworks, guidelines that aim at unifying the size and measurements of certain objects in order to shape modular systems for the obvious reasons of scalability, flexibility and simplicity.

Overall, the current debate has been gravitating towards the first set of guidelines, towards refining the principles of material use and assembly in order to establish closed resource and component loops.
But what kind of objects or structures would emerge if we would syncronize and refine the existing dimensional guidelines?

A2.Open structures.
Can we co-create our built environment?

This proposal investigates the option of a shared dimensional framework between the most diverse objects in order to generate one common open modular system.

In the past architecture has cranked out countless proposals for modular structures in an attempt to streamline efficiency and enhance structural flexibility. Although these systems represent honorable steps towards a more intelligently built environment we find ourselves today with an abundance of incompatible modular systems that often generate impersonal, uniform structures and a stockpile of fairly useless modular pieces after deconstruction.
So, if we want to improve the concept of modularity in order to generate diversity and enhance flexibility, we need to open up and synchronize our standards. We need to define one universal standard that will allow the broadest range of people to interchange the broadest range of modular pieces and thus reproduce dynamic patchwork structures rather than rigid, monolith blocs.

Since the last ten years we can observe a shift towards shared open architectures within our digital creations. We witness the emergence of accessible and free codes that invite end-users to participate in the development of the source code through an open exchange of knowledge and experience.

But also within our built environment, we should further align assembly and size in order to establish one common modular bloc that will facilitate open exchange and universal compatibility.

We need to distill a kind of physical ‘html’, a three-dimensional open source code from our built environment that will enable us to build our hardware like how we are nowadays building our software.
These universal dimensional guidelines envision closed loop systems where old components feed into new frameworks thus creating an endless variety of open modular structures (from simple cabinets to multistory buildings).
New components will replace old ones whereas old ones can be sold and reused, (or deconstructed to then serve as resource materials for new components, since their measurements are conform the dimensional restrictions). Each structure will thus have the ability to evolve and conglomerate old, new, cheap, expensive, original, bootlegged, manufactured and crafted components over time.

An open modular system will invite everybody, from the most remote craftsman to the biggest company, to design components using their own specific skills, materials and construction techniques within the same dimensional restrictions.
Online component databases will facilitate their exchange since all component designs can be uploaded onto one common component database in order to be discussed, reviewed, certified and traded among their end-users. This vivid exchange of components will stimulate continuous upgrades and allow the parent structures to adapt, expand or shrink according to current needs.

In a local context, components will float in between neighbors, creating dynamic houses within organic 'open' neighborhoods. From a global perspective, one universal standard will facilitate closed component cycles and generate 'living' structures that will stimulate widespread participation through open exchange.

The idea of open modularity isn’t new, our market driven society has already generated several open modular systems whenever their efficiency was able to enhance profit (from stackable shipping containers to standardized kitchens), but if we dig deeper we even find that we, as human beings, with trillions of modules (cells) per person, are modular from head to toe and experiencing the benefits of open modularity every single day.

Modular cell structures enable us to scale and grow, simply by adding new modules - cells - that interact with existing ones using standard interfaces.

They simplify the process of duplication. Duplicating a number of smaller, less complicated cells is easier, faster, and more reliable than duplicating a single complicated one.
Modular cell structures have the ability to rapidly adapt to their environments. By adding, subtracting, or modifying cells, incremental design changes could be more quickly tried and either adopted or rejected.
They are able to specialize the function of the modules. This delegation and specialization of cell tasks provides the same effectiveness and efficiencies inherent in teamwork.
And finally, they enjoy the benefits of fault tolerance. With cell redundancy, individual cells can fail without degrading the system, other cells carry on while repairs are made.

So why not borrow from nature's blueprint and shape our built environment towards an organic, modular puzzle of objects that, from micro to macro, float within closed loops and infinite cycles.

B. Optimizing logistics:

B1. Can we balance distribution and recollection?

The second proposal wants to amplify the first one by connecting it to an alternative logistical model that can facilitate the exchange of open modular components.

Although our total current logistical infrastructure has mastered supply and manicured delivery, it has given very little thought to recollection.
In the best case we sort and stockpile used objects according to material, but the fact that these products weren't designed with deconstruction in mind makes their recycling processes rather inefficient and expensive.
On the other hand manufacturers are discouraged to recycle their stuff since there is no sophisticated recollection system in place and prefer to invest their money in production of new goods.

So if we want to move towards open systems of exchange, where producers are eager to recollect consumed goods and consumers are eager to trade products (or open modular components), we will need to develop a transportation model that can facilitate its logistics, we will need a kind of public service that will balance distribution and recollection in order to guarantee flow.

The following proposal wants to answer this question by outlining a logistical service that gives equal attention to distribution and recollection in order to close material loops and support infinite product life cycles. It wants to do this by crosspollinating the transportation of goods with the transportation of people.

It proposes a fleet of identical (electrical) shuttle busses that connect individual houses with central transfer hubs while picking up and delivering both goods and people.
Much like worker bees circling around a queen bee, these shuttles don't drive along fixed routes or according to fixed time schedules but operate within certain zones (from and to a central train-, streetcar- or underground station) while stopping on demand.

Identical shuttle busses will guarantee a steady delivery and recollection flow within a certain neighborhood.
Central nodes will facilitate their logistical services by expanding from pure transfer hubs towards logistical hubs and service centers.
Companies that can benefit from the logistical services offered by the shuttles (like food/post-order deliveries, recycle/refill centers, laundromats, rental stores etc.) will cluster around these

central stations while underground, streetcar or railway lines will expand their capacities towards the supply and evacuation of goods in order to nurture or flush these hubs.

The integration of pick-up and delivery of both goods and people as well as a constant service flow will offer several advantages for all parties involved.

1. Advantages for the citizen
Citizens can now perform several tasks in one go, catching a ride to a nearby station can now be combined with disposing used, empty or refillable products and packagings (saving them a ride to the closest recycle center).
This quicker connection to the station also enables them to become less dependent on private transportation means to get around.
And next to that, they can rely on the system when sending goods from or to their homes (for example when buying or selling online).

2. Advantages for the manufacturers
In a society where manufacturers will be held responsible for what they produce, this system will enable them to doorstep deliver new products while at the same time recollecting old ones in a fast and efficient fashion.
Providing a context for recollection will therefor stimulate manufacturers to recycle used components and materials in new production lines.

3. Advantages for the government
Government will save costs in both waste management and public transport while at the same time creating new job opportunities and a road occupation that is geared towards public services rather than private use.

4. Advantages for all
Since costs per ride are shared, logistical services will be cheaper for all.
Citizens will enjoy the service of a taxi at the price of a bus ticket (or even pay for a ride with the products they dispose) while both individuals as producers will enjoy a cheap and efficient way to distribute and recollect goods.

To conclude, this system envisions a mixture of public and private transport, of distribution and recollection services, all operating within one multitasking shuttle, a hybrid vehicle that will be monitored and guided by highly refined communication infrastructures while performing complex logistical tasks.

C. Conclusion

Even though both proposals look from a very different angle, one will reinforce the other when combined, because both plug into the same vision and move towards the same goal: a circular society, a society with no drainage but only supply, an open culture of exchange.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Beyond localism, looking for sustainability

Designing "typical knowledge" active-action

Eleonora Lupo[1]

Abstract

It's commonly agreed that every action that is "local" is considered a sustainable action: especially when the concept of local is referred to local resources, local people, local production, local processes and their exploitation.

However, even if with this approach towards local capabilities, behaviors, attitudes and abilities, the local dimension in not a sufficient condition in order to guarantee the sustainability of a design intervention.

This paper aims to discuss and prove which are the real conditions that make the design practices of activating local identities, especially if addressed at enhancing typical knowledge in emerging contexts, sustainable in an intrinsic way, because they take in account these three factors: *ownership*, *control* and *impact*.

[1] Politecnico di Milano (ITALY) - INDACO Department. Ph.D., temporary researcher, eleonora.lupo@polimi.it

1. About terminology: being local is a process

Being local for a design intervention is not depending by the geographic dimension of an area, but is an approach aiming at making visible and emerging the peculiar characteristics of a context or a place, its milieu and heritage, rooted in places and embedded in people. The local dimension is more a condition than a project scale or ambit, in which the context becomes a design *requisite*, a design *practice* and a design *goa*l.

Local as *design requisite* means to consider the context as a bond and consequently the identity of a place an opportunity of design, taking in account its physical and intangible resources, collective image and social instances: according to Dematteis (1995) “a place is the result of the localization of social facts, values, meanings and relations” and expresses "possibilities already inscribed in the existing things”.

Local as *design practice* means to act in a context and to use situated practices as design methods and tools: the *hodology* (J.B. Jackson, 1994), a word from the Greek one *hodos*, (road, journey), and the *topological psychology* (Lewin, 1936) are practices that define the space lived by humans through their movement within the environment, and make it different from the geometric rationally measurable one. Acting in this kind of “existing” deals with the design capability of exploring, interpreting and transforming a context (physical or social) to make possible to better inhabit and activate it.

Local as *design goals* means to design for a context and its community working on affiliation and relations: the participation of the local community, focusing on empowering its sense of belonging, becomes the aim and not only the modality of the design intervention.

So, being local for design is a *process* based on a replicable approach that will never lead to the same result: the repeatability is not in the forms, but in the rules and method adopted that coordinate and monitor results from time to time to time different, depending on the context, but inevitably bound together by the recognition of local design requisites, practices and goals.

2. Beyond the localisation: territorialisation and contextualisation for the *active-action* of typical knowledge

In this theoretical framework, the paper points the attention in making sustainable the design processes addressed to the exploitation of local cultural heritage. The definition of cultural heritage refers to a complex concept, including both such traditional ambits as architecture, cultural landscape, art & craft, and other often intangible aspects like rituals and social behaviors, values, oral expressions, which are not immediately perceived or recognized as conventional heritage but are fundamental in shaping the form of artifacts, products, structure of society and organization of work, and are in a word, “intangible heritage”[2]. Those kinds of distributed heritage is often not represented or manifested in distinctive or emerging spectacular forms but is a valuable expression of typical creativity embodied in people, rooted in activities and places and can be defined as “typical knowledge”[3].

The typical knowledge is a crucial factor for local cultural identity and a key issue for sustainable development. Intangible cultural heritage is considered “*an invaluable factor in*

[2] The Unesco "Convention for the safeguarding of Intangible Cultural Heritage" (2003) defines Intangible Cultural Heritage (ICH) "as practices, representations, expressions, knowledge, skills - as well as the instruments, objects, artifacts and cultural spaces associated therewith - that communities, groups and, in some cases, individuals recognize as part of their cultural heritage" (Article 2.1).

[3] From now the expression typical knowledge will be used with the meaning of “creativity embodied in people, activities and places”.

bringing human beings closer together and ensuring exchange and understanding among them" (UNESCO Convention, 2003) and can become a dimension for sustainable (social, cultural and economical) development in terms of services, cultural offer and enterprises, being more integrated in a cultural and productive systems connected with the territorial identity (Greffe, 2005).

In other words, a focus on intangible heritage is *context oriented*: the relation with a local context is, for the cultural heritage, a dimension of sense making and value generation. In the same way, the typical knowledge is always localized, which means it is the result of specific local conditions and its experience and use by people will always happen in a specific place and time.

Three are the *local* dimensions of the typical knowledge: *localisation*, *territorialisation* and *contextualization*. The *localization* corresponds to a physical dimension (a place), easily recognizable, where the knowledge has been generated from and which determines its opportunity of fruition and dissemination. However, the context is not considered only as a physical localization, but the natural, environmental, cultural and territorial conditions which determinate the form[4] of the heritage: the link with that context and with its characteristics is important especially in the process of understanding the origins and the nature of the knowledge and its further development.

The typical knowledge is traditional and living at the same time. It is constantly recreated and transmitted and these dynamics makes it evolving and transforming during the time. According to Kirshenblatt Gimblett (2004), the typical knowledge "*is not dividable from the person who owns it and is passed on through performance*" (Kirshenblatt Gimblett, 2004). Through these performances the mutual relation of the typical knowledge with its context evolves in a system of horizontal relations with other heritages and human activities, in a process called *territorialisation*. While the process of localization is somehow natural, the territorialisation is an act of organization aiming at connecting the typical knowledge together and therefore is subject to be designed.

And, in addition, a deep connection with the context is very often for this kind intangible cultural heritage one of the reasons preventing its disappearing. A typical knowledge, for its nature, in order to be preserved by extinction, needs to be continuously performed and socialized: as a performance, it could not avoid, or rather should take advantages from the interaction with the surrounding environment, its dynamics of exchange, production and fruition and should not be separate by them. A typical knowledge usually can survive until it is required by the context where it has originated from: if the context change, the knowledge is destined to became marginal or disappear or to adapt itself to the changed context trying to preserve its specificities. For instance, a typical craftsmanship knowledge survives as a job until it's needed by the market and a clear example is this: in the Nordic culture, the typical wood shipping craftsmanship underwent to a deep transformation when the Vikings finished their sea explorations and this ability needed to find a different application: it gradually turned and specified towards the skill of designing the typical Nordic *stavkirke*[5] in wood.

In the contemporary world, the existence of such typical knowledge and traditions, is not granted for always because the globalisation doesn't help for a proper process of the value legitimating: sometimes its existence leads to underestimate its value, or more often, the act of safeguarding becomes integralism and drives to a static and philological conservation.

Instead, in order to properly preserve a typical knowledge according to its process nature and to the deep and continuous changes of the contemporary world, is necessary to transform and adapt the knowledge, preserving its specificities but integrating it within the changed context or embedding it directly in a new context. The *contextualization* of a typical knowledge is that complex design process that resides mainly in a deliberate reconstruction (physical or symbolic) of a vertical relationship between the knowledge and a context: if is this relation that generates

[4] We refer in particular to the definition which Flusser makes about the concept of form and in-formation, such as generation of models or ideas (Flusser, 2003).
[5] Middle Age church entirely built in wood, typical of Norway.

sense and value, when this link loosens or breaks, the exploitation process tries to rebuilt it or to make it understandable for people, revealing the link with its original place or setting the knowledge in an comprehensible frame and in a proper context for who is experiencing it, linking traditional meanings with new interpretations in a new place of experience, fruition and application.

This is what we call *active-action* of a typical knowledge: it's a *negotiation process*, that considers the typical knowledge a *living entity* that can be *activated in continuity* with its traditional features and meaning, but enabling it to dialog with the contemporary context and innovative applications, finding a new balance between uniqueness and repeatability of its skills, practices and techniques, in forms and numbers of relations which the heritage can face, avoiding any compromising distortion of its nature and the loss of its inner and symbolic value.

3. Sustainable *active-action* factors

It's commonly agreed that every action that is "local" is considered a sustainable action: especially when the concept of local is referred to local resources, local people, local production, local processes and their exploitation. Tha activation of typical knowledge belongs to this logic.

However, even if with this approach towards *activation in continuity* of local capabilities, behaviors, attitudes and abilities, the local dimension in not a sufficient condition in order to guarantee the sustainability of a design intervention. Unfortunately in fact, ever more often, the exploitation of local and typical resources has become an alibi to pursue a pervading model of economic exploitation, moulding informal "economies" previous based on relations and proximity, in structured dynamics of business. If the European Commission (2007) states as necessary the contribute towards local public awareness-raising of the importance of and encourages the social and economic repercussions at regional and local levels, it is because we assist always with more frequency to the application of indiscriminate dynamics of local community spoliation, extraction and expropriation of their values and knowledge, disguising in mechanisms of sustenance or conservation within the global re-productive economic system, those processes of disqualification of their tangible and intangible resources, knowledge and practices[6].

This paper proposes some conditions that make the design practices of typical knowledge active-action (enhancement and valorization) "sustainable". The reflections are articulated around some case studies/projects developed, autonomously or in collaboration with other researcher, during a three years PhD research in design. The PhD in particular considered the ambit of local intangible heritage and typical knowledge and its sustainable exploitation as experimental research practice.

The process developed for the active-action of typical knowledge is defined as follows:

- identification/acquisition;
- conservation/protection;
- transmission/fruition;

The identification phase is fundamental to pursue the awareness of the importance of typical knowledge: to respond to this, we propose a classification of the diverse forms of typical knowledge. They are:

[6] The fashion system is full of examples of traditional production and craftsmanship extracted by its original local context and used at a different global level without any remaining relation with it except than the residual and artificial guaranty of quality coming from the concept of place as "brand". In opposition with this view, any process of extraction of value from a territory should not be separated from a necessary re-appropriation and distribution of that value within the same territory.

- productive knowledge (art and handcraft products, traditional recipes, gastronomic products);
- relational knowledge (celebrations, rites, customs, popular and religious feasts and manifestations);
- riproductive knowledge (art, music, theater expressions, languages);
- knowledge owners.

For the following phases, the approach of activation leads to individuate innovative strategies, techniques and technologies aiming simultaneously to the conservation/documentation and to the transmission/fruition of the typical knowledge, experimenting solutions to spread and to create a sort of distributed knowledge embodied in people and supported by participative and narrative modalities like apprenticeship and interactive technologies.

In this framework, the activation of the typical knowledge can be defined sustainable when takes in account these three "bonds": *ownership*, *control* and *impact*. These three factors are the parameters used to evaluate the sustainability and the quality of the following presented case studies of exploitation. The *ownership* factor defines how much the depositary of the knowledge undergoing the exploitation is involved in the process; the *control* factor estimates the capacity of the owner to manage and decide how and when to use its knowledge; the *impact* factor evaluates the amount of the benefits that the owner receive back (directly or indirectly) by the exploitation process[7]. The impact is not supposed to be measurable economically: it's possible to foster a development in terms of identity awareness strengthening, or knowledge upgrading and exploitation and these impacts are only indirectly connected to an economic development.

As well as these three factors, the activation can follow two different but synergic paths: by one hand there is the experience or fruition of the typical knowledge, which have the objective to make the knowledge accessible and understandable through direct/indirect experience and fruition to a meaningful amount of people aiming at raising its awareness among individuals and communities. A deep comprehension and interpretation of the knowledge should be pursued by activating people participation and collaboration by interactive modalities like story telling and apprenticeship to promote and guarantee the learning and transmission of this intangible heritage through a new human living repository: "*as repertoire is always embodied and is always manifested in performance, in action, in doing"* (Kirshenblatt Gimblett, 2004).

By the other hand the transmission of this typical knowledge can be achieved through the incorporation of such heritage characteristics in new design solutions that include products, services, strategies: this should be designed preserving the knowledge specificities but putting it in a new context of use or application taking in account the continuity with its "tradition".

4. "In search of marginalized wisdom: Sham Shui Po craftspeople"

This research project has been develop in Hong Kong by the *Community Museum project*[8], a cross disciplinary group of researcher (composed by cultural programmers, cultural researchers and design educators) founded in 2002, aiming to explore, through the collection and interpretation of artifacts and visual evidence, *indigenous creativity* and public culture. In their mission "*the word community has three connotations: subject matter, settings and creative public*

[7] The knowledge owner should be aware of the process and benefit from the development generated (Unesco, 2003, Convention for the safeguarding of Intangible Heritage, art.11)
[8] www.hkcmp.org

interface". According to this, the project tried to represent the everyday living and value of the district of Sham Shui Po in Hong Kong, to articulated personal experience and under-represented histories. Sham Shui Po is one of the old district in Hong Kong facing its re-development and it's characterized by numerous small producers, typical cluster of material wholesalers and an emerging design community. It has developed a cultural identity related to a local economy and embodied in local craftspeople, like rattan furniture production, wooden cart making and sewing work. Their craftsmanship, their skills, their operation, space usage and community network reveal an interesting intangible asset that needs to be both preserved and developed. The project aimed at discover and record the local knowledge, creativity and skill tradition of the district that are almost doomed to extinct.

The researcher adopted a situated ethnographic approach of observation focused on the production processes, survival strategies and community relations of eight units of traditional handicraft industries, to produce an exhibition of systematic documentation and explicit visualization of such knowledge: starting from material, resources, tools and procedures it was possible to reaffirm the valuable characteristics of their business operation and how they cope with the limited space and resources. During the research in fact came out that the craftsmanship processes had close relation with the neighbour space and the community: for instance, the mobile stall of Wan Hing Accessories who sells ornaments, beads and related tools and materials always hosts an open air class were the owner, Mrs Kei uses to teach to customers the beading handicraft, transforming her working places in a communal meeting places too.

But it became evident too that the craftsmanship artisan processes are not only a valuable form of heritage but contain important concepts of contemporary design that may become an inspiration for emerging designers and creative industries. So, beside to the collective memory goal, the project pursued the further development "people oriented" of such local knowledge. In April 2007 Community Museum Project started to engage young local designer and older craftspeople in a cross-disciplinary experimental collaboration, with an aim to support with modern design concept the traditional craftsmanship. The activity developed interesting design prototypes that were shown in July 2007.

Yau Kee, a wooden cart production run by Mr and Mrs Lee Dai-yau, developed in more that 50 years of experience an environmental friendly process to realize his carts used mainly by construction workers and cleaners of the surrounding area: Mr Lee Dai-yau uses to transform recycled materials and to collect them established a mutual network with neighbours providing them with a long-life after sale service of maintenance of the cart. The collaboration with the designer Brian Lee leaded to the realization of a transforming cart/table: with a minimal modification of the existing production process it has been possible to design products of wider usage.

Relatively to the sustainable factors, in this project all the collaborations among craftsmanship artisan and designer were based on the same principle: to involve directly the owners of the knowledge in the activation process (they are personally involved in the act of codifying for the designer understanding and collaboration their tacit knowledge and processes), and to positively impact on them (making themselves the beneficiary of a mutual training in which they pass through practices their knowledge and simultaneously learn how to improve it). Finally they maintain the control of their processes without spoiling their capabilities, on the contrary, upgrading their skills and abilities in managing their knowledge and adapting it to new applications and contexts of use.

The kind of typical knowledge undergoing the activation is clearly productive knowledge.

In relation to the activation modalities, this project well mixes and balances the transmission of knowledge achieving it both by enabling the direct fruition and experience (even if for a relatively small groups of young designer) and new applications and incorporation in innovative design solutions. So we can say that the typical knowledge has been territorialized by creating new relations and connections, and contextualized by developing new functions and meanings.

5. Medvoices. Memories of Alexandria, a cosmopolitan city

"Mediterranean voices: oral history and cultural practices in Mediterranean cities" is a project financed by the European Union within the program Euromed Heritage. Euromed Heritage is an international cooperation program whose aim is "*to strengthen and consolidate mutual understanding and dialogue between cultures by the promotion of Mediterranean cultural heritage and public awareness-raising*" (European Commission, 2007). For the European Commission "*the main objective of any program for the promotion of cultural heritage has to be centered on the appropriation of cultural heritage by people themselves and therefore on education and access to knowledge of cultural heritage*". Public awareness comes from processes of education and re-appropriation: "*this objective involves in particular a real meeting of the people concerned with their own successive memories: a true reconciliation, in certain cases, between tangible and non-tangible heritage*".

In this framework the project Medvoices has been addressed to an ethnographic investigation into the cosmopolitan oral and social histories of 13 historic cites across the Mediterranean region, and particular urban quarters within them, through documentation, photographs, literature and interviews that testify extracts of everyday life (rituals, games, celebrations, events) that otherwise would in time be lost. Those cities are Alexandria in Egypt, Ancona, Beirut, Bethlehem, Chania, Granada, Istanbul, Marseille, Ciutat di Mallorca, Nicosia, Las Palmas de Gran Canaria and Valletta and are coordinated by London Metropolitan University.

The project wanted to interrogate the basis of the Euro-Mediterranean's 'common heritage' from an ethnographic and oral history perspective in order to promote an awareness of cosmopolitan and multi-ethnic aspects of Mediterranean area and to encourage respect for pluralism, tolerance and peaceful co-existence. The project challenged the customary emphasis given to 'monumental' heritage to emphasize its relationship to intangible cultural heritage: so the central activity was the creation of a searchable on-line multi-media database of the oral history and cultural practice of the cities in the network[9]. The categories used to organize the resources are: person, living together, work, worship, objects, spaces, play[10].

In this process of documentation the local communities were always considered the owners and performers of the cultural practices and the ethnographic observation has been conducted in a participative and empowering way leading them to reflect upon their own culture and values, sometimes also provoking intense discussion and stimulating further interpretation and socialization of their under-represented practices. So the project increased their awareness and consequently opportunity to manage their knowledge.

The project had a big impact on disseminating and transmitting those collected cultural practices in a wider stage, bringing them to a new audience through seminars and exhibitions and using the website. Thanks to these tools the cultural practices have been preserved from disappearance without any compromising of their specificity because they are continuously re-producible in a technology mediate experience for different users without spoiling the owners.

Concerning the active-action process this project doesn't foresee any new contextualization or application of those cultural practices but will guarantee the learning and transmission of this intangible heritage through the future generation.

6. "ExTra! Exchange tradition"

[9] www.med-voices.org

[10] It is obviously possible to search in the database also by location, language and resources type (audio, video, image, textual document).

The project called Exchange Traditions is part of the European network LabforCulture[11], an autonomous project initiated and hosted by the European Cultural Foundation. The network serves more than 50 countries and its aim is "*to share culture across Europe*". LabforCulture provides a platform for cultural cooperation between Europe and the rest of the world, giving access to up-to-date information and encouraging the cultural sector to become more experimental with on line technologies.

Exchange Traditions promotes the understanding and dialogue between different musical traditions present in Europe by encouraging cooperation between traditions and representing various cultures and minorities. In many parts of Europe, traditional music belongs to the living culture of daily life: it is an important factor for the cultural identity of each individual citizen and represents a valuable form of typical reproductive knowledge. But can be also a "place" to meet different culture: for instance immigrants bring their own musical traditions to Europe; these should be identified, disseminated and protected in the same way as those autochthonous. In activating this typical knowledge the project gives special attention to "cross fertilisation" within different musical genres and on innovative compositions and unusual applications of old traditions, with a special focus on integrating the use of multimedia.

Artists working in the field of traditional music (coming from both a traditional European music and heritage, a non-European musical tradition and an immigrant or cultural minority background) are invited to perform at various places throughout Europe and to participate at collaborative and creative workshops addressed at creating collectively new musical languages.

Relatively to the sustainability factors the owners of the knowledge are enabled to make their musical knowledge interact in a more active context and to transmit it hybridising with new expressions and languages. The beneficial impact they take advantages from is in the opportunity to strengthen a sense of identity more inclusive and cross boundaries.

7. Conclusions

The exploitation process of local knowledge and resources should generate favorable conditions for the community to control, enhance and take advantages, of the heritage they own, avoiding their spoliation. Typical knowledge active-action should be designed considering the safeguarding activity as a complex and integrated process of documentation and fruition, whose result can be assimilated to repertoire of knowledge which takes in account its inclination to be a performance embodied in people. For this reason it should consist in a collaborative process of knowledge sharing between the owner, the designer and the future users, and this involvement is shaped by local culture, attitudes and behaviors. This means that, the exploitation of local resources should use also a context based approach: it is a participative process, rooted in places and embodied in people, which always has a negotiating and local dimension that cannot be easily replicated in another context without any adjustment.

This process of active-action of typical knowledge is not aiming at a passive conservation: in fact it implies the possibility for the local communities to activate "in continuity" their knowledge, but make it evolving, which means enabling the local knowledge to dialog and interact with its contemporary contexts creating new relations and connecting its local specificity with a more global understanding which emphasize its nature and its value and permit its transmission without ambiguous distortions and not proper uses. Vehicles for transmission can be indifferently the design of modalities of experience, fruition and use of the typical knowledge or its incorporation in new solutions (products, services, systems). They both mean the design of an enabling platform, structuring flexible and adaptable (concerning the specificity of different heritages) but repeatable actions (according to the industrial nature of design) aimed at the active-action of the typical knowledge by their owners.

[11] www.labforculture.org

This transition, promoted by the typical local knowledge exploitation, from being aware of their own heritage to its appropriation, develops the capacity of the local communities in implementing their organizational skills in activating a sustainable development leaded by heritage; thus becoming themselves able to deal with its concrete forthcoming integrate management and exploitation.

So, the three parameters of ownership, control and impact will became, together with a context based adaptive approach, the guidelines/reference to support the design of typical knowledge sustainable active-action and re-active-action.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Technoforest

Designing solutions to humanly regenerate ecologically disturbed areas.

Barbosa, João C. L. [1]

Abstract

This paper recollects the story of how a group of designers decided to engage in ecological transformation and to collaborate in the structuring process of societal master lines development. The Technoforest design team is multidisciplinary and includes architects, product designers, illustrators, teachers, biologists, engineers. Due to the subject complexity and the diversity of people involved, Participatory Action Design Research was adopted as a method to develop actions aimed at designing a Technoforest. Geographically the Technoforest would reconnect two Brazilian National Parks creating an ecological corridor that links the coastal Serra do Mar with the higher Serra da Mantiqueira and the Brazilian western central plateau. Humans would dwell in the ecological corridor, participating in its construction, maintenance and development.

1. Introduction

The Paraiba River Valley is a basin at the southeast of Brazil, linking 3 industrialized Brazilians States: Rio de Janeiro, Minas Gerais and Sâo Paulo. The Paraiba River Basin comprises 55.500 square kilometers and brings water to 14.3 million people (8,7 million in Rio de Janeiro City) and also to industrial companies (steel, chemicals, nuclear) and agribusiness (sugarcane, fast growing tree plantations) located at the valley.

After the Paraibuna and Paraitinga rivers mingle to name it, the Paraiba River comes down from the Serra da Bocaina (a mountain range located at the north of Sâo Paulo that is part of the Serra do Mar). Initially it runs west but, due to a tectonic depression, it changes course towards northeast, forming a valley (50 km wide in average) between the Serra do Mar and Serra da Mantiqueira. After running for 1.120 kilometers, the Paraiba River meets the Atlantic Ocean at the north of Rio de Janeiro.

Originally, the Serra do Mar, the Paraiba River Valley and parts of Serra da Mantiqueira were covered with the luxuriant Atlantic Rain Forest. In and through the forest lived the "tamoyos" (original inhabitants). The forests were crisscrossed with trails designed and kept by the local nomadic population. These ancestral trails were found by the Portuguese and used as roads to link the sea with the central plateau beyond Serra da Mantiqueira (where gold and emeralds existed).

During the XIX century, after the gold mines were exhausted, a new era started at the Paraiba River Valley: coffee plantations. The forest was cleared and the Coffee Barons, using slave work, got rich with the green gold. The topsoil, now without tree coverage, quickly eroded. With the end of slavery (1888) and subsequent economic crisis the plantations disappeared giving way to new industries.

By then there were already railroads and a new road linking Rio to São Paulo. A good urban infrastructure, the wars in Europe and established markets also contributed to a new non homogeneous industrializing boom that led to the formation of the first Brazilian conurbation (between São Paulo and Rio).

Some remote valley areas near the Serra do Mar (and far from the road linking São Paulo to Rio de Janeiro) remained linked to the agricultural past and cities once prosperous became stagnant. These cities were nicknamed as "The Dead Cities", where nothing new seemed to happen. In these municipalities there are great areas covered only with grass for oxen. Being a non labor-intensive activity, cattle growing do not do much to increase job offers and communal development. Unemployment and related problems like drug abuse and violence are serious concerns. Nowadays it is urgent to recover and regenerate the living tissue of the Paraiba River Valley, not only because of the importance of its watershed to bring water to a huge population and to the valley industries but also because the population of the Paraiba River Valley itself is rapidly growing and demanding more of the existing ecological resources. Even the "Dead Cities" are coming out of slumber and growing in population.

As these "Dead Cities" lie at the border of protect areas (The Serra da Bocaina National Park and buffering zones) some of the most promising regional economic activities are related to tourism. Ecotourism, given the natural attractions of the neighboring National Park and historical tourism due to the existence of ancient colonial architecture of the coffee plantation era. In order to reinforce this economical trend the six "dead cities" municipalities organized and manage a joint venture called "The Historical Valley". This consortium develops a series of actions aimed at the improvement of regional tourism and local traditional handcrafts (traditional folk and religious events, local and regional cuisine festivals etc).

In this setting a group of designers decided to start working with Ecological Design and created in 2005 an organization dedicated to this task. What could be the collaboration of this organization to ecologically collaborate to the regional economic development and to the improvement of the local population life quality ?

2. The Green Rooms, ANPED and UniverCidade's Design Research Nucleus

The "Green Room Project" was designed by the Environmental Education Directory of the Brazilian Federal Ministry of the Natural Environment. Its basic aim is to make it possible to small organizations to engage in ecological practice with symbolic support of the Ministry, which provides each green room with a set of books and videotapes. There are already around 400 Green Rooms spread all over the country and they act as local organizations dedicated to the dissemination of socio environmental information.

Founded in 2002, ANPED (Association for the Development of Design Research) is a nonprofit organization dedicated to the development of design research and design education. Its main activities are related to the organization of Design Research Conferences. It has already organized three successful conferences on design research (2003, 2005 and 2007). During the year of 2005, due to the growth of the global Ecological Crisis and also due to specific contingencies like its members capabilities, organizational leadership and political connections, ANPED decided to undertake actions aimed at ecological problem solving. In this sense the organization presented to the Ministry of Natural Enviroment a proposal to create and run the Sertões da Bocaina Green Room (Bocaina's Backcountries Green Room) in the small city of Arapei, located in the poorest area of the Paraiba River Valley. ANPED's proposal included a partnership with UniverCidade's Design Research Nucleus.

UniverCidade is a private university located in Rio de Janeiro and its design course enrolls circa 1.000 students and 50 faculty. The Design Research Nucleus started to operate in 1997 and since then has been engaged in the development of Ecological Design practices. Some of its successful research projects were related to the development of eco friendly materials, the use of Amazon Forest materials as basis to product design, the stewardship and improvement of local natural reserves, the dissemination of eco information through the web and, as a permanent goal, the introduction of sustainability concepts and eco design methods in UniverCidade's design course curricula. The Design Research Nucleus staff is major contributor to the development of Sertões da Bocaina Green Room and has taken part in the design and outfitting of its premises (a multitask room with an area of a hundred square meters). From 2005 on the Sertões da Bocaina Green Room has been developing a series of activities like, short courses, workshops, lectures, business meetings, youth training (as environmental scouts) and the like.

Participatory Action Design Research

Communities of traditional backcountries are very suspicious of people and organizations that out of the blue appear with proposals to solve local problems. They have had enough from ideas not connected to their realities and, based on a history of failed projects, are naturally refractory to outsiders ideas.

In order to deal with this challenging situation ANPED adopted the use of Participatory Action Research (PAR), which proposes the engagement of teams formed by expert problem solvers and representatives of the local afflicted community. We introduced the word "Design" in the traditional PAR acronym in order to state clearly that ANPEDs goals are aimed at responding

to real problems through the design process of problem solving. We do intend not only to propose solutions but also to engage in their becoming a reality, a design product.

In this sense, all activities developed at the Sertões da Bocaina Green Room represent an end in themselves (education) but were also aimed at building a community of engaged partners and volunteers to discuss local problems and advance proposal for solutions. Nowadays, after three years of work, the Green Room team is connected with other people and organizations active in the Historical Valley. The staff of the Green Room also overcame prejudices and conquered the trust of key actors in the Historical Valley.

The Technoforest Project

Starting in 2007, ANPED created a multidisciplinary team composed of industrial, designers, architects, biologists, artists, sociologists and engineers which is presently designing a regenerating project know as “The TechnoForest”. Its purpose is to sow forests in the Paraiba River Valley and concomitantly design and construct villages that mingle and grow together with the forest.

If forests and forest products are valuable assets and if economic growth can lead to the betterment of human beings, why not settle the burgeoning population of the Paraiba River Valley in an economic activity, reforestation, which could on the long run provide sustainability ?

The Technoforest implementation would start between the cities of São Jose do Barreiro and Itatiaia, which are the closest cities (40 kilometers apart) located on opposite sides of the Paraiba River Valley. These two cities are respectively at the borders of the Parque Nacional da Serra da Bocaina and the Parque Nacional de Itatiaia. Also, located between these cities there is an artificial lake that carries water to the Funil Hydroelectric plant and, a major obstacle, the highway that links Rio de Janeiro to São Paulo.

The Sertões da Bocaina Green Room is located in Arapei, a city with 4.000 inhabitants located near São Jose do Barreiro and inside the area covered by the proposed Technoforest ecological corridor. Due to its strategic location, to its record of delivered services, to its connections with other research centers and to its political independency we intend to use the Green Room as the headquarters of the Technoforest project. As a general strategy we divided the project in the following phases:

01) Discussing the idea

02) Building visualizations

03) Committing partners

04) Developing detailed concepts

05) Building a prototype

06) Documenting processes and results

07) Enlarging the partners ring

Presently we are discussing the idea with an enlarged group of participants, refining and documenting the project and at the same time developing visualizations based on the available data (land ownership, topography, demography, rain regime, vegetation etc).

With the documented project and visualizations ready, we plan to find partners among the big regional industries, which ought to be interested in preserving and regenerating the socio ecological tissue in which their economic activities are embedded. A possible strong partners is for instance the CSN-National Steel Company which, if committed, could make available the steel parts necessary to build the basic structure to houses, schools, greenhouses, solar panels, sewage, rainwater collecting and transport systems. This kind of partnership would influence deeply the detailed design of the Technoforest components and the building of prototypes.

The drafts presented are a poetic interpretation of how could the TechnoForest be like. Its structural components includes water catchment, storage and sewage systems, photoelectric arrays, ground and elevated trails, civic centers, social service centers, workshops and lodging. Its main activities would be linked to the services needed to expand the area covered by forest and capitalize on the services thus provided: knowledge, water, fresh air, biodiversity, ecotourism, ecological education, eco design equipment and food producing.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design, Research, Italy.

Maps, visions and perspectives of academic design research in Italy.

Paola Bertola[1], Massimo Bianchini[2], Stefano Maffei[3], Beatrice Villari[4]

Abstract

This paper presents the final results of the DRM Research Project which had mapped all the design research activities realized in Italy (2003-2007) individuating actors, competences, themes, facts through a methodological approach based upon two different research streams:

- a first analytical stream based upon an analytical-quantitative approach in which the research mapped the explicit research activities using direct interviews and questionnaire-file;

- a second stream based upon a qualitative approach developed through a series of video-ethnographic interviews in which the research team build a sort of tacit reconstruction of whole research system.

The result is a report which contains a first vision of what is the nature of the Italian academic research activity nowadays.

1. Assumptions and objectives of the research

Where is our discipline headed? What does it concern? Which issues does it involve?

These are only a few of the many questions which often come up in conversation between people who are professionally involved in conducting research in design at the university level.

For this reason this research community[5] decided, at the National Convention of Doctorate holders in Design named *Design, Research, Perspectives* (Naples, July 2007), to promote a collective initiative[6] aimed at understanding the nature, size, quality and progress of research in design conducted in Italian universities.

The shared mission is that of constructing a series of *maps*, considering research as a *territory to explore*. From this concept arose the name of the research project: Design Research Maps, aimed at building an initial *geography* of national research and analysing its relationship to the field of education (the Ph.D in design).

The objectives of the research group are:

1 to explore the size, nature, thematic and disciplinary orientation of research experiences and research training (Ph.D.) undertaken by the Italian academic community from 2003-2007;

2 to construct an initial overall interpretation of data obtained from desk research and qualitative research and enrich it with a national and international comparison;

3 to produce an initial series of infographic interpretations, the *Maps*, which visually summarize the composition of the subjects, the characteristic and distinctive themes and relationships, the disciplinary approaches;

4 to work out a critical concept about the overall emerging situation and correlate it with processes of orientation, management and evaluation of the research training activity and the research activity itself.

The DRM research, starting from its initial assumptions, has tried to play a dual role: on one hand, that of an initiative capable of systematizing a variegated view of the research experience; on the other hand, that of a place which gives life and visibility to all those rich aspects and potentialities that the system expresses as a whole, developing methods of narration and language useful for presenting and conversing in different fields: political and institutional, economic and industrial, scientific and cultural.

---

[5] The promoters of DRM research project are:

- the *Coordinamento Nazionale dei Dottorati di Design*, which represents the schools of Ph.D. in design in Italy;
- the *Conferenza dei Presidi delle Facoltà di Design*, which includes the faculties and degree programs in design in Italy;
- the *Rete Nazionale di Ricerca SDI* | *Sistema Design Italia*, which is composed of 10 university agencies involved in research in design (www.sistemadesignitalia.it)

This paper is a result of a collective work process of discussion, analysis and elaboration, but the writing of the different parts of the text could be attributed to: Massimo Bianchini (paragraphs 1 and 2), Paola Bertola (paragraphs 3 and 4), Stefano Maffei (paragraphs 5 and 7) and Beatrice Villari (paragraph 6).

Attempts at conducting a systematic analysis of the nature of Italian design were experimented with through the SDI research project *"The role of industrial design in product innovation and the development of planning resources of the Italian system between local resources and global markets"*[7], a systemic research effort which involved 17 Italian universities. Its focus was the relationship between design resources and the national social, economic and productive system. The research built the first important general *fresco* upon the Italian Design System (Compasso d'Oro Prize for Design Research in 2001).

From the point of view of the international scene, the tests performed before starting the activity confirmed the lack of significant studies of the same nature and depth.

Notwithstanding some systematic efforts undertaken by big national institutions which are responsible for promoting this discipline, such as the annual report *Design in Britain* of the Design Council[8], there are no particular acknowledgements even in studies performed by other European and international institutions and centers of design (e.g. ICSID and BEDA).

For this reason it seems important to attempt to take a first look at the question of what constitutes *university research in design*: the goal is that of counteracting the one classic stereotype which says that university research is substantially *academic* research.

Or rather, *done by few, oriented to few* and producing results *that are often little usable* by other entities active in the design field, that is companies and public and private institutions.

Results instead seem to indicate exactly the opposite. University research *is not academic*.

It is multifaceted, articulated by discipline, ranging from macro to micro levels, result-oriented but also able to tackle the big questions posed by the state of our nation.

It is stratified, ranging from basic to applied research, where it is distinguished for its contribution to the development of a competitive strategy of the country, while at the same time paying attention to the trend towards the service sector which characterizes all the advanced capitalist countries.

It is still done by few, but appears to be growing strongly. It is enjoying a fairly healthy state but must be careful of the challenges of globalization.

It has an interesting potential for making contributions and has found its own identity, field and characteristics, in spite of being a recently constituted sector.

The DRM research project is thus more than a fresco, an initial imperfect sketch of what the system of resources and competencies of university research in the field of design is: and this appears to be an initial, important result which deserves to be communicated.

2. The structure of DRM research and the principal areas of investigation

What does working out a map of university research in design entail? How can the data be obtained? How can they be interpreted and represented?

These are some of the many questions which the DRM workgroup posed when starting the project.

---

[7] See Maffei and Simonelli, 2002; Bertola, Sangiorgi and Simonelli, 2002; Zurlo, Cagliano, Simonelli and Verganti, 2002

[8] The analysis of design R&D activities in the works of the British Design Council is focused onto professionals and companies. For further details see the Council website (www.designcouncil.org.uk), above all the section *Factfinder*. For the studies realized by other design centers see the ICSID website (www.icsid.org).

The matter of doing research on research in design resulted from the beginning in a fairly precise orientation in the initial phase of setting up the process, the methodology and the research activity.

To create the initial assumptions, DRM research was structured into different areas of investigation which allowed the workgroup to work simultaneously on different fronts, thus managing the complexity of the project; the next step taken started with the identification of the players and the research experience at Italian universities from 2003-2007.

These tasks demanded, as a result of their complexity, the tuning up of a set of operating instruments which allow remote operation and communication with the network of sensors positioned in the universities taken as samples and these are of two types:

1. a detection kit containing guidelines for classification and a data format (chart) to facilitate the collection of information homogeneously shared among the main offices of the relevant universities;

2. a kit for conducting video interviews[9] to be used in order to give a voice and a face to the protagonists of research.

Once the instruments were defined, the operational levels activated included:

1. a census of active entities in this field at the research level (faculty, degree programs, departments) with the relevant disciplinary Ph.D.;

2. a quantitative/qualitative desk analysis (mapping)[10] which identified the characteristics of the university research activity, the typology of the results, the materials produced and the subjects involved;

3. a qualitative analysis of research (interviews) and its mechanisms performed through the collection of internal perspectives of the community of researchers in order to understand the logic, the values, the practices.

These complementary activities, in which more than 80 people participated in different roles, including researchers, teachers, Ph.D. candidates, students and technical-administrative staff, synergistically competed to build an ultimate account which ranges from the description of the subjects to the identification of research experiences and finally to the interpretation and summary of what research in design has produced.

The research was then divided into two different macro areas, or rather, in the investigation of profiles and research activity conducted in faculties and departments and in the investigation of profiles and research activity developed in Ph.D. programs and degree programs and this effort was developed through the following phases (September-November 2007)

1. planning of research and production of instruments for the survey of data and for communication of research efforts (September - November 2007);

2. formal beginning of research activity through survey of data and performance of video interviews (December 2007 - March 2008);

3. validation and organization of data (March/April 2008);

4. reprocessing, interpretation and production of output for the communication of research results (April/July 2008).

[9] The project management for the videointerviews are by Beatrice Villari and Francesca Piredda (D.Com Research Unit _INDACO Dept._ scientific coordinator: Prof. Marisa Galbiati). The production managers for the direction and supervision of all interviews are Elisa Bertolotti, Walter Mattana and Francesca Piredda. Editing and post-production are by Mariana Ciancia, Michele Moscatelli and Simone Porro.

[10] The DRM map project is by Massimo Bianchini and D.Com - Research Unit (Dipartimento INDACO – scientific coordinator prof. Paolo Ciuccarelli). Art direction and infographic design are by Donato Ricci, Daniele Guido and Luca Masud.

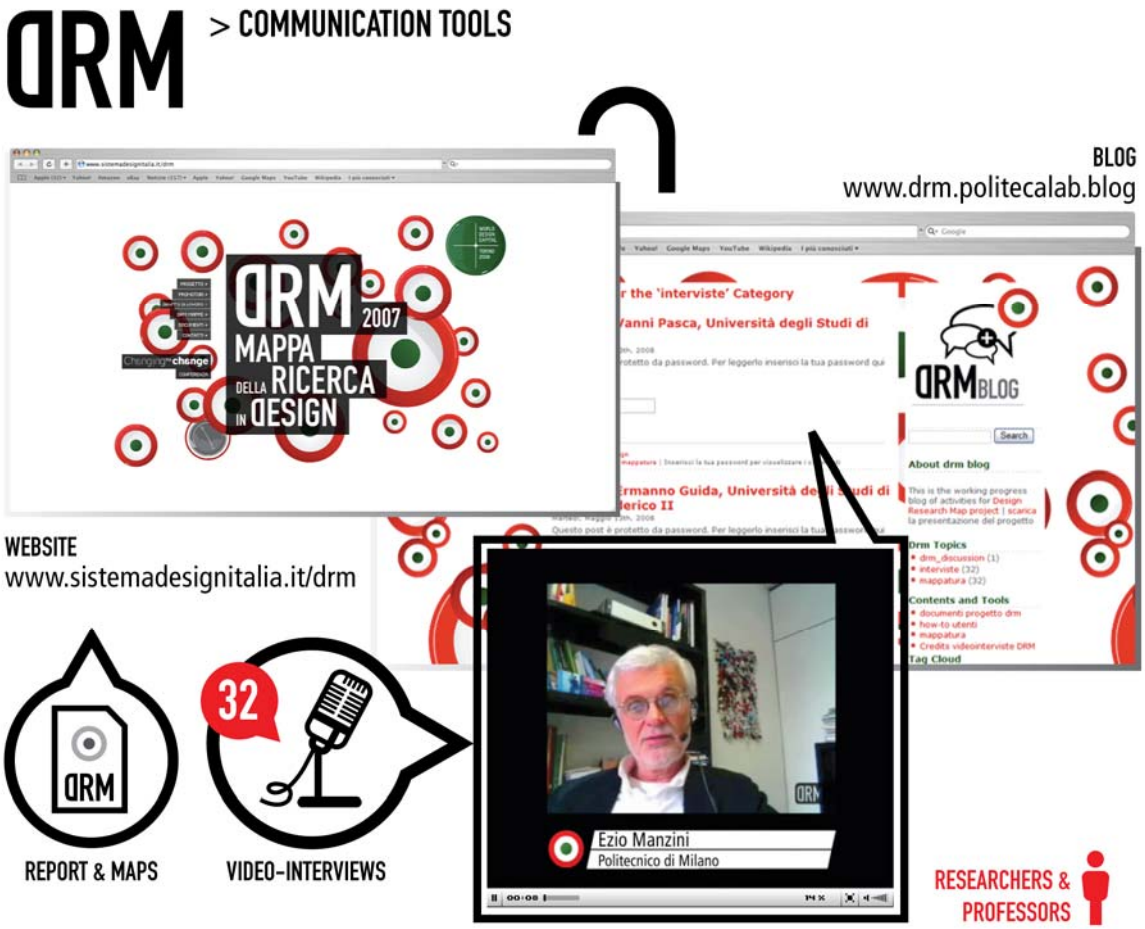

Fig. 1: DRM Communication tools

3. The methodology and the explanatory categories of research

DRM research has favored a methodology able to make explanatory elements emerge following the process of data collection. Efforts proceeded to the classification of players and research at the national level in order then to construct, based on the data collected, explanatory categories which are to highlight the emerging themes and the specificities of the national system.

The research activities taken as samples were thus subsequently interpreted using categories, at times typical of the disciplinary context of design, and at times emerging and transferred from other contexts.

The final result produced a mapping system of research which identified:

- the *nature*, or rather its *applied/planning* aspect, that is aimed at the acquisition of new knowledge of tools and the different fields involved in the activity of design; *instrumental*, that is aimed at the tuning up of methods and instruments useful for planning, or finally *basic/theoretical*, that is aimed at the acquisition of new knowledge of theories, methods and the disciplinary foundation of design;

- the *typology*, or rather the organizational methods of research which include the nature of public and/or private players involved and the relationships between them, their geographic incidence, the level of internationalization and the typology of the results produced;

- the focus, or rather it being centered on specific themes, from those of more common classification inside the academic disciplinary environment of design (Design of products, Design of interiors, Design of communication/interaction, Design of systems/services, Design of material), to categorization used in economic-productive classifications (code of ISTAT-ATECO[11] activity, economic studies related to the geography of the productive sector of *Made in Italy*).

4. DRM categories: a brief and cross-sectional reading

If the categories proposed above anyhow represent a rather traditional model of classification of research, a final level of interpretation is proposed which is created instead from the desire to return to the specificities of research in design in a new way. In the spirit of "Changing the Change" an effort was made to introduce a method of classification of research able to make the role of design explicit as a primary actor in the transformation processes necessary in the sustainable development of contemporary society. This type of categorization organizes research in cross-sectional thematic areas defined on the basis of reading of the summary of strategic objectives of research conducted by national and international institutions as a priority for the future of the human community[12].

The analysis of such different sources led to the proposal of eight thematic areas which represent a summary of the strategic priorities of research both at national and international levels and were used to map the research activities sampled. This method of representation can therefore represent a very effective method of communication, even with interlocutors outside of the specific disciplinary context of design, whose roles may be those of players and often promoters of processes of change and sustainable development. An effort was also made to unhinge the still common conception of design as related primarily to the aesthetic dimension of artifacts and to some specific sectors of application such as the sectors of furniture or textile and clothing in Italy.

The eight categories used are:

-1. New Made in Italy and the scenario of internationalization
-2. Identity, territory and local production
-3. Development of cultural and environmental assets
-4. Urban quality and security
-5. Social inclusion and health services and quality of life
-6. Innovation, industry and hi-tech development
-7. Energy, mobility and environment
-8. Education, training and scientific and technological research processes

[11] One of the classification methods which has been used for the DRM analysis is ISTAT ATECO 2007, in force since Jan. 2008. This classification is the national version of the European NACE rev.2, published in the Official Journal Dec. 20th 2006. For further information see the ISTAT website (www.istat.it). First of all the DRM staff individuated the ATECO codes to define the very nature of design research, applying them to the different research projects. Other codes have then been used to describe the different fields of research activities.

[12] Some of the sources which have been used are:

- the EU 7th FPQ 2007-2013: it defines the guidelines to develop European research activities, in which there are different research topics suitable for design research. The same topics are included into the “Quadro Strategico Nazionale” (national strategic research program) 2007-2013 promoted by the Italian Ministry for University and Research

This program individuates four main fields of activity and ten strategic priorities among which:

- Improve life quality, security and social cohesion;
- Energy and environment: sustainable and efficient use of environmental resources; - Development of integrated production chains and any related service systems;
- internationalization and modernization of Italian productive systems

The categories illustrated above were used to map all the activities of research in design sampled at the national level. This allowed for the elaboration of a new reading of such activities which shows the role that design plays in many strategic sectors of contemporary society, confirming its capacity of being able to promote processes of change even outside of those more traditional and consolidated sectors of application in this discipline.

Fig. 2: DRM Categories

5. The facts and figures of university research in design

The recent conclusion of the campaign of survey and aggregation of data produced a series of reprocessed and interpreted data which is shown below in an important initial summary[13].

The delimitation of the field: who does research in design in the public/private field

The research mapped institutional, public and private entities at the national level which are responsible for training and/or research in the field of design.

The first census was created (Design Directory - MilanoMadeinDesign[14]) which identified 139 subjects potentially active in two fields: University (16), Higher Institutes for Industry and Crafts (4), Academies of Fine Arts + Legally Recognized Academies of Fine Arts (44) and public/private Centers for research and training on design (75).

From this sample, attention was focused on subjects which operate in the university environment (16), isolating the active group (12 subjects[15]) in the field of research and in the field of training and research (14 Ph.D. programs in design active in 9 Italian universities).

In Italy, there is a total of 95 universities[16] in which a nucleus of research is active in the relevant disciplinary sector at each location. Therefore, the sample selected (12 out of 95) represents a significant nucleus. The main universities which conduct research in design is, in fact, 12.6% of the total number of universities which conduct research in Italy and this is a testimonial to the extremely active state of this disciplinary sector.

How many research projects were there in the 2003-2007 period?

Research in the field conducted through direct contact with subjects under examination, painted the first picture of research conducted in the 2003-2007 period, resulting in the mapping of 382 activities of research and 122 Ph.D. dissertations.

Where is research in design conducted? An unbalanced distribution

The first piece of data revealed is the distribution by performer of research activity at the geographic level : the current distribution shows a strong concentration in the north of the country.

76.5% of the research activity (292 out of 382) is performed at 5 athenaeums (Milan, Turin, Venice, Genova, Bolzano) in the north in contrast with 15% of activities undertaken at 4 universities in the Center (58 out of 382) and the remaining 8.5% at 3 universities in the South (29 out of 382).

The first point of comparison is the relationship between productivity in research and the number of teachers/researchers involved in the Scientific Disciplinary Sector of design[17]: only 127 people[18] who represent only 3.2% of the total scientific area of the planning, architecture and civil

[13] The data aggregations shown here are a first interpretation of the work done until now: any later refinement/validation could bring to non significant changes later on

[14] Please also see the on-line publication dedicated to the Lumbard Design Directory project (created by the INDACO Department, scientific coord. Prof. Giuliano Simonelli) within the MilanoMadeinDesign exhibition

[15] From this list of 16 universities the following ones have been excluded: Università degli Studi di Brescia, Politecnico di Bari and Università Telematica Internazionale as they have not provided any information. The Università di Sassari has instead partecipated to the DRM project, but having constituted a research unit only at the end of 2007, they have not developed any research

[18] Source: MIUR – Italian Ministry for the University and Research (see: www.miur.it)

engineering sectors[19] (127 out of 3,936 researchers) and 0.2% relative to the whole Italian scientific community (127 out of 62,625). The comparison of data between the number of research activities and the number of researchers shows a productivity comparable to research in all the locations, re-equilibrating the data for differences between geographical areas partly as a result of a dimensional lack of homogeneity. Therefore there is a positive index of an aptitude towards research which is common throughout the national territory.

A strong polarity emerges in Milan however, which also in the university field functions as an important hub of the Italian system demonstrating its propulsive capacity and its existence, in fact, as a *district of design*.

The possible explanations for this phenomenon are various: the presence in the north of entities which have a history, even if recent, are mostly consolidated and part of an economic, social and more vital and competitive cultural community. This is also proved by the strong growing connection that Milan and the other atheneaum of the north have with the local economic and productive fabric (pure applied research[20] represents 48.5%, with 184 research activities out of 382, of which 70% is concentrated in the North, 18% in the Center and the remaining 12% in the South).

Research in design: a growing phenomena

The success of research activity in the field of design is an evident fact, confirmed by the increase in growth in the number of research products.

The total growth curve which describes it shows a decisive increase in research activity by year which seems to have grown at a constant rate in 2006 and 2007, after which the growth seems to stop.

This fact can be partially attributed to the simplification of the survey of data (the 2007 data is partial because it does not consider multi-year research which will be concluded in future years) and also to an actual slowdown in research activity caused by the general situation of normative and organizational transition in Italian universities together with a slowdown in the economic cycle.

The data of the overall trend proves that a university system exists which in a short period was able to grow its capacity of *activating and producing research* for an express demand made both by public institutions and private companies. This includes an offer made by private players in the market documented by the already cited research project *Sistema Design Italia* on the system of Italian design, conducted in 2001 (Compasso d'Oro ADI in 2001).

The financing entities: design between public and private

In Italy, public and private interest in financing design in research is confirmed by the numbers: of the 382 subjects sampled, the total of public and private research activities with public participation (242 research activities out of 382) is equal to 63%, of which 70% is financed by local and national public players (179 research activities out of 242 financed by ministries and entities of research, regions, provinces, municipalities).

This testifies to the capacity of the university in encountering institutional entities: those private (businesses, consortiums, business and professional profit and non-profit associations) attest to about a discrete 45.5% (174 research activities out of 382). Finally, a by no means unimportant 22.5% of the research is financed by a joint effort between public and private entities.

[19] Area 09 Ingegneria Civile e Architettura (civil engineering and architecture) has been regulated by the Italian Ministry for University and Research (see: www.miur.it).

[20] During the analysis phase it has been defined as "pure applied research", without any possible further combination possibilities (that's to say applied + basic research or applied research + instrumental one). For a complete reading of the data see the table concerning the nature of design research.

Taking a look at the projects financed by international entities, a prime characteristic of the system emerges: the degree of internationalization of research in design is not high but almost reaches sufficiency relative to public entities (53 research activities out of 382) with a percentage of 14%. However the degree of internationalization is strongly inadequate in relation to private commissions which dips to a low percentage of 5% (20 research activities out of 382).

Even if it is true that university research in design is new and growing, this is not to be undervalued specially in a phase in which, at least in Italy, public and private investments in research are undergoing a slowdown in terms of resources and tools. If the system wants to be stronger and to grow, taking a look at Europe is definitely necessary.

The nature of research in design

From the primary work of classification of the nature of the research conducted, data emerges which describes how the system is mainly active in the field of applied research with a substantial presence in the area of basic and instrumental research.

More than 48.5% of the research (184 out of 382) is applied, while basic and instrumental research constitute lower percentages, 16% and 11% respectively.

This predominance of applied research shows a critical theme which necessitates greater in-depth examination: the data on applied research indicates on the one hand the capacity of the system to dialogue with private entities and, on the other hand, an increasing difficulty in this disciplinary sector to recognize itself within the normative framework of support of research (EU, national or regional) which is expressly connected to the profile of research offered by the discipline.

It is very interesting to note the data regarding research including multiple categories[21] which delimit an interesting area of demand for research from the point of view of competitive comparison with those entities in the planning sector (centers of public/private research and high level consulting-professional activities). In this case, the university shows an ability to offer competencies, tools and practices in all categories (which altogether constitute a considerable percentage of 52.9%): from *basic research* to that *instrumental*, including all the mixed categories (*basic/applied, basic/instrumental, instrumental/applied, basic/instrumental/applied*)

Even excluding the two pure categories, the percentage value, 25.3%, of the research group in the category of multiple samples, indicates to us a strength of university research in design or rather its ability to operate in different scales and levels of breadth and depth.

A further test performed involved the attribution of research activity using the general classification ISTAT[22] (activity code ATECO/NACE): this resulted in an interpretation of research activity in design from the *official point of view*: the results are the following:

[21] That's to say which includes multiple categories.

[22] The ISTAT ATECO Code (aligned with the European Code NACE) provides us with these categories through which design activities can be interpreted:

Code 70. Activity geared towards companies and management consulting (…) - consulting in marketing management; analysis and formulation of a marketing strategy, formulation of policies regarding customer service, price, advertising and distribution channels, design etc. (…)

Code 71.11 Activity in architecture studies

Consulting activity in the architectural field: planning of buildings and implementation of plans, urban planning and landscape architecture

Code 72. Scientific research and development. This includes three activities: 1) basic research: experimental or theoretical work carried out mainly for the acquisition of new knowledge on the foundation of phenomena and observed facts, not aimed at a specific application or use, 2) applied research: original work performed for the acquisition of new knowledge and aimed mainly at practice and specific application, 3) experimental development: systematic work, based on existing knowledge acquired through research and/or practical experience, conducted with the aim of producing and developing new materials, products and devices, installing new processes, systems and services and substantially improving those already produced or installed.

The research activity and experimental development, included in this area, are subdivided into two further categories: natural sciences and engineering; social sciences and humanities.

1. 62 research activities labelled only with the code 72. Scientific Research and Development and related to basic research;

2. 184 research activities labelled with a set of codes (58,59,62,70,71.11,72,74.10.1,74.10.2) which interpret the various typologies of applied research at the disciplinary level;

3. a hybrid area composed of 136 research activities which combine code 72 (+ one or more codes among 58,59,62,70,71,72,74.10.1,74.10.2) and correspond to the sum of instrumental research activities and those in which there are various combinations among the typologies.

The disciplinary areas of research in design

Traditionally it has been thought that design (and research in design) refers to and aims at stimulating innovation in processes of conception and production of industrial products. Definitely, this could still be considered to be at the heart of our discipline even if the data surveyed by research proves that the disciplinary perimeter is by now much more evolved and mixed. The data definitely show that the evolutionary path of articulation and specialization which the discipline has completed in the last fifteen years has brought to light a complex and advanced disciplinary geography.

Indeed, we can affirm that acknowledging that a strong concentration of interests lies in the field of *product design, fashion design, design of materials and components* (44%, 169 research activities out of 382), design has increasingly turned its attention towards new territories which range from the *design of environments* (13%, 48 research activities out of 382) to that of *design of communication and interaction* (19%, 74 research activities out of 382) and finally to the area of *strategic design* and *services design and design of complex systems* (23.5%, 90 research activities out of 382).

This presence of disciplinary diversity certainly represents a strength of the system which testifies to the capacity of university research in not passively overlapping research practices and professional projects which are still centered on typical Made in Italy sectors to a large extent.

The first interpretative categories

The DRM project was also an opportunity to perform the first test of the vision and direction of the design system (but perhaps also of the productive system with which it interacts), or rather of the capacity of research in design to predict new themes and new answers with regard to the major themes of contemporary living and the economic, social, cultural, environmental challenges

---

Code 74.10.1 Activity in fashion design and industrial design

- fashion design for textiles produced, articles of clothing, footwear, jewellery, furniture and other articles of decoration and fashion, as well as other articles for personal use or for the home
- industrial design includes all the activities aimed at the creation and development of plans and technical specifications in order to facilitate the use, increase the value, improve the aesthetic characteristics of products. Also included are the definition of materials, mechanisms of functionality and the choice of shapes, colors, external finishing of products. These activities may be performed taking into account aspects of human characteristics and needs, security, market interest and efficiency of production, distribution, use and maintenance.

Code 74.10.1. Activity of graphic designers

Graphics in advertising and websites, illustrators (given the relevance of present activity, this category is detailed in the activity of graphic designers of websites and in other activities of graphic designers).

Code 59. Activity in film production, video and television programs, musical recordings and audio

Production of film, video, television programs (television series, documentary etc.) or TV advertisements

Code 62. Production of software, information technology consulting and related activity

This area includes the following activities, aimed at supplying specific services in the information technology sector: writing, modifying, verifying software and assisting with software; planning and designing of information systems which integrate hardware, software and communication technologies; on-site management and use of information systems of clients and/or facilities for the development of data and finally other professional and technical activities related to the information technology sector.....

of our society. In order to perform this exercise of orientation and discovery, a classification of general thematic areas was used, those defined as DRM categories in the methodology constructed for this study.

The initial results find the university system mainly occupied with the sustaining processes of renewal of the national manufacturing system, today particularly at risk due to globalization, working on the development of the *new Made in Italy* and defining future *scenarios of internationalization* (36%, 137 research activities out of 382).

This data is particularly important if we analyse the close connection of this first area to research which is part of the category involving themes of *innovation, industry and hi-tech development* (about 10%, 37 research activities out of 382).

Almost half of the research activities sampled are part of this research area indicating, this time in a non-rhetorical way, the capacity of the university system to strongly contribute to issues involving the competitive productivity and economics of the country (the figures of applied research in the categories 1 and 6 surpass 60% with 110 research activities out of 174).

In these two areas, an array of research systems are present which include universities, institutions and companies, aimed at technology transfer, cross-fertilization among sectors, diffusion and exchange of best practices in order to stimulate innovation in and competitivity of companies, specially PMI, through the use of research in design.

The two macro themes in which research in Italian design is making a fundamental contribution in terms of exploratory research even at the international level, involve *territorial identity and local production* (7.6%, 29 research activities out of 382) and *development of cultural and environmental assets* (7.9%, 30 research activities out of 382). These themes, which open new disciplinary frontiers such as that of *design on territorial scale or for local development* and *design of cultural heritage and activities*, have seen this disciplinary research involved in experimenting with instruments, pilot programs and initiatives which favor alternative methods of development in slowly developing local areas and their resources (food farming industry, tourism and hospitality, neo-craftsmanship).

Connected to the two preceding ones to a large extent, there is the category of *Energy, mobility and the environment* (11.5%, 43 research activities out of 382) which sees the theme of design for sustainability involved in the redefinition of new models of consumption and creation of assets and services with low environmental impact and in identification of systems of sustainable products/services for the management of energy resources and of mobility trends of people and products.

The presence of DRM categories related to social *Inclusion and health services and quality of life* (4.5%, 17 research activities out of 382) and to *urban Quality and security* (3%, 11 research activities out of 382) is also important. Here, research in design is taking the first steps in finding innovative solutions to problems related to disability and to facilities and services for the treatment of people, but also to new issues related to security and quality of life, specially in metropolis and its work places.

Finally, there is the peculiar but important survey of the category *Education, training processes and scientific and technological research* in which the system offers an advanced thought process on methodological, instrumental, operational approaches applied to learning and research processes (12%, 47 research activities out of 382) .

Methods of disseminating results

A final related piece of data which better focuses on the difference between private research-consultancy and university research is that connected to scientific production which originates from research activity. The main data shows that the output of research in design can be divided in different categories and that 96% of the research mapped produced results in at least one of these categories.

In 55% of cases, the research activities sampled brought forward new concepts of assets or services for the development of the relevant project, in 39% of cases, they resulted in the concrete creation of new products, both as artifacts (or systems) which are material and/or non-material. Research in design conducted in Italian universities shows a certain aptitude for know how to do with a clear matrix and vocation for planning practices, both theoretical and applied, with a concrete capacity for translating ideas and activities to a tangible, marketable output.

Research in design is also characterized by its ability to know *how to think*. Almost half of the research conducted (189 out of 382) resulted in the development or refinement of a methodology, thus testifying to a capacity for codifying, modelling and reconfiguring the experiences had and the knowledge accumulated, thanks also to the variety of situations and entities with which relationships were entered into.

As far as the dissemination of the results, a peculiar characteristic of research in design emerges, that is communicating and spreading not only through traditional instruments such as publications and conventions (52% and 24%), but also through instruments such as seminars or production of info-communicative material (18% and 34%) which are perhaps less academic and more informal, but perhaps more in tune with the necessity for the communication of the results of research in design.

6. The facts and figures of the Ph.D. in design

Nature and structure of the Ph.D. program

Among the 16 universities sampled by the DRM project, 9 provide a Ph.D. program in Design making a total of 15 Ph.D. programs active in the national territory. Of these, the Politecnico di Milano offers 4 Ph.D. programs, the Politecnico di Torino offers 3 making a total of 15 Ph.D. programs active in the national territory, of which one is constituted in collaboration with Seconda Università degli Studi di Napoli and Università degli Studi di Firenze.

In the 2003-2007 period, among the universities considered, there were 8 Ph.D. programs already completed: of these, 5 are present in the north (62.5%), 1 in the center (12.5%), 2 in the South and in the Islands (25%). The Ph.D. programs considered actually have a recent history. Within the Italian panorama, the first Ph.D. program is that of POLIMI founded in 1990, followed by that at Università degli Studi di Palermo in 1991. Of the 15 active programs not yet concluded, there are those instituted by Università degli Studi di Genova, Università degli Studi di Firenze, Università degli Studi di Camerino and that initiated in collaboration with the sites in Florence and Naples.

In general, every Ph.D. program pertains to a Department of a different nature, in which the area of Design is integrated in some cases with those of Architecture, Technologies and Figurative Arts also because, historically, the activation of a Ph.D. program in Design was in Departments connected to the Faculty of Architecture.

This *productive* relationship between Design and other disciplines obviously has an influence on the thematic nature and orientation of Ph.D. programs put in place and affects their results. In this sense, the relationship with disciplines of Architecture is strong also for historical reasons and is the one more commonly found within Ph.D. programs in Design in Italy.

Didactic structure

The method of organization of internal didactics, for Ph.D. programs under consideration, may be subdivided into two big categories:

- *didactic organization with tutorship*, or rather a training model which predominantly provides a learning path based on the close relationship with reference Ph.D. candidates and teachers (Tutor), together with whom the Ph.D. candidate decides on the training course and research;

- *structured didactic organization (by coursework)*, or rather a model which provides a Doctorate program organized by specific Courses, which also have value in terms of earning credits.

The first model is followed by Università IUAV di Venezia, Università degli Studi di Firenze, Università degli Studi di Roma "La Sapienza". The *structure by tutorship* also characterizes the joint Program between Florence and Naples, while the other universities follow a didactic structure organized *by coursework*.

For the universities which adopt a *structured didactic* organization, diverse training offers have been identified subdivided on the basis of the nature of the program. It is seen that of the 8 universities considered, all offer *preparatory training*[23] and 6 have *basic training courses on research*[24] *and specialized training on research*[25]. Only 3 provide basic training courses on research.

The overall model which emerges is thus still dual: on one hand a training course which actively involves the Candidate within the academic structure with his/her participation in learning activities which are institutionalised and integrated in his/her own curriculum, and on the other hand, a training course in which the Ph.D. candidate predominantly learns thanks to the *maieutic* relationship and meetings with the reference Tutor and the scientific community. It should however be underlined that the clear predominance is of structured training in national Ph.D. programs organized within the Doctorate programs (11 out of 4). This means that for research activity, commitment and active participation at the site and in meetings with the scientific community is demanded from the Candidate.

The figures of the Ph.D. program

To understand the relationship between the number of Ph.D. programs in Industrial Design and national programs, data obtained from the site of MUR were compared to those obtained from mapping. The national sample for the 2003-2007 period shows 13,903[26] candidates in the total disciplinary area of research. Of these, the *average number of Doctorate candidates admitted each year* in the area of Design is a medium number of 66, of which about 7.6% is composed of foreigners[27].

Starting from the founding year of the first Ph.D. program in Industrial Design, the total number of candidates who enrolled was 220. Considering the 2003-2007 period, this sample is reduced to 116 candidates who were given the Ph.D. in Industrial Design.

According to geographic distribution, it is found that 70.7% of research takes place in the North, 6.9% in the Center, 22.4% in the South. The 116 dissertations considered are subdivided

[23] by *research introductory education* we mean those courses tipically linked to design disciplines

[24] by *research basic education* we mean those courses which aim to supply Phd students with the basic tools and knowledge

[25] by *research specialist education* we mean those courses which aim both practical research production and activities and research observation to

[26] Data integration 2003-2006 (source http://statistica.miur.it)

[27] Universities which declare that the participation to foreign Phds are Politecnico di Milano, Università degli Studi di Genova, Università degli Studi di Camerino. On these data we are not in possess of any pieces of information about the students' nationality. It would be interesting to understand if specific grants for foreign candidates are available, in order to clarify if the partecipation of foreign members is somehow directly encouraged.

as follows: 77/Politecnico di Milano, 18/Università degli Studi di Palermo, 8/Università degli Studi di Roma "La Sapienza", 8/Seconda Università degli Studi di Napoli, 4/Politecnico di Torino, 1/Università IUAV di Venezia. The number depends on the number of active Doctorate programs in each of the academic sites and on the related establishment. However, it is seen that Politecnico di Milano with 3 related programs sampled represents by itself 66.4% of the national Doctorate programs[28].

The disciplinary areas

The picture of national Ph.D. programs in Italy in the 2003-2007 period reflects a picture of divided disciplinary orientation: included are the most important disciplinary areas such as Product design (with a small quota for Design for fashion products), Design of internal and external environments, Design of materials and components, Design of complex systems/services/strategies, Design of communication/interaction.

To understand the nature of the themes encountered in Ph.D. programs, an analysis of the dissertation abstracts was performed which were then clustered with the same categories adopted in analysing university research in design.

The total of the research themes shows a predominance in the area of Product design (29.3%) and Design of internal and external environments (30.2%)[29], with a good percentage in the disciplinary areas of Design of communication and interaction (18.1%), and Design of systems, services and strategies (13.8%). This is followed by the recently constituted area of Design of materials and components (6.9%) and Design of fashion products (1.7%).

The nature of Doctorate programs

The 116 research activities sampled were then subdivided, using a criteria of multiple assignment, into the following categories: *theoretical research[30], project research[31], instrumental research[32].*

The predominance of instrumental research (59.5%) emerges immediately, which together with theoretical-instrumental research (23.3%), crushes project research and instrumental/project research respectively at 5.2% and 12.1%.

This data is important and testifies to the character of *research for research* on many Doctorate thesis in design, and, perhaps, underlines the disciplinary and operational self-referencing.

The Doctorate program, in effect, seems to be focused on the construction of conceptual, methodological and planning instruments which can support the different fields of the discipline, from training to the practice of research and planning.

This data is further reinforced by the final analysis of the orientation of categories of instrumental research (which has an overall value of 111 out of 116 research activities or 94.8%).

---

[28] The number depends on the Phd foundation year and also from the number of Phd course series in the analyzed period: 5 POLIMI - Disegno industriale e Comunicazione Multimediale INDACO; 2 POLIMI- Disegno e Metodi di Sviluppo Prodotto INDACO + DIP.MECCANICA; 6 POLIMI - Architettura di Interni e Allestimento INDACO + DIAP; 3 POLITO - Innovazione Tecnologica per l'architettura e il Disegno Industriale – DENER; 5 UNIPA - Dottorato in Disegno Industriale, arti figurative e applicate - DIPARTIMENTO DI DESIGN; 3 SUN - Design Industriale Ambientale e Urbano – DISPAMA; 6 UNIROMA1 - Disegno Industriale. Design, Arte e Nuove Tecnologie – ITACA; 1 IUAV - Scienze del Design – DADI

[29] The high concentration of researches relevant to Interior Design is due to the relationship between Design Phd and architecture Phd from which they originated.

[30] Mainly theoretical pamphlets imply the construction of new theoretical tools. Theoretical approaches have been considered as research tools.

[31] Dissertations in which the research resuts are mainly related to project/product/service/communication area.

[32] Dissertations which principally explore methods, approaches and tools related to design research. In particular the instrumental research is defined based upon three main categories: research tools, educational tools, project tools.

This further subdivision underlines this interpretation even more: a good 87.3% of instrumental research involves instruments for planning, with 9.1% involving predominantly theoretical aspects and 3.6% involving didactic instruments.

The relationship between themes of Doctorate programs and DRM categories

A reading of the areas of thematic orientation of Doctorate programs reflects an overall image which is *against the trend* with respect to the thematic orientation of university research in design.

The category of *Innovation, industry and hi-tech development* appear as the most relevant focus of researches (21,6%) followed by the area of *Development of cultural and environmental assets* (16,4%) while there is seen a significant and homogeneous distribution within the area of *New Made in Italy* (15,5%), *Social inclusion and health services and quality of life* (15,5%) followed by the area of *urban Quality and security* (13,8%).

This is followed by the areas of *Identity, territory and local production* with 16,4%, the themes of *Energy, mobility and environment* 6% and *Education*, training processes and scientific and technological research with 4,3%.

The results therefore describe Doctorate programs involved in defining explorations which are not, at least not immediately, marketable.

The stratification of the themes and the emerging of certain innovative, typically national themes such as *Development of cultural and environmental assets, Identity, territory and local production, urban Quality and security* indicate that perhaps, there is a *social or environmental aptitude*, mostly active, in Ph.D. programs.

The subject of investigation in Doctorate programs seems to be *reflexive: observing itself* in terms of research and training. The observations which are made in this field are actually aimed at structuring, amplifying, decoding the knowledge which characterizes this discipline in its applied and theoretical forms.

7. Final Considerations

Summarizing the final considerations of the research is a difficult task: this first census and attempt at interpreting university research and Ph.D. programs in design is set up as a first systematic initiative, but certainly does not exhaust and sufficiently detail many topics.

For this reason the first proofs gathered by the research may be used as an analytic instrument of orientation for two purposes: or rather to build ideas in order to orient training policies to research at the Ph.D. level or to reason and experiment with the theme of *research policies*.

The research allows us to make an effort to balance the didactic relationship among design/research training/research.

The public system of education in design has a history of 15 years only and has functioned in the long term even fewer years, but the overall results obtained are important:

- a public system of research effectively exists, a network of sites, competencies, entities which are developed by territorial distribution around an important polarity such as that in Milan; polycentrism and diffusion are two words which characterize university and Ph.D. research in design at this time;

- university research in design is not academic, it is distinguished by its ability to produce applied research and has found a positive relationship both with private and public demands, even though there is a criticality in its ability to attract research demands by international

private entities or be more competitive in the considerable foreign institutional front (specially EU);

- the growing trend of activity is *positive* and does not seem to reflect the current difficulties experienced at the university level, even if there are signs of recovery and problems experienced are perhaps related to the non-existent public or private support.

- the level of relationship with the world of applied research at a high knowledge level (very low number of existing patents) makes one think of an interdisciplinary relationship with better structured techno-scientific disciplines;

- the extensive disciplinary division testifies to the growth of a *complex* vision of design present in the system of research (but also in that of Doctorate training).

Particular attention is deserved by the comment on thematic division: if we hypothesize that we consider this research to be a *phenomenologic* exploration (Bertola P., Manzini E., 2004), then the considerations which may emerge represent a very powerful signal as to the characteristics which this research possesses.

We can definitely affirm that the system of university research in design and Ph.D. level research are effectively involved in processes of defence, growth and support of our economic, cultural and social system.

The themes connected to the innovation of product/process with respect to the productive industrial reality are strongly present and testify to a strongly-rooted relationship between *planning* and *doing*.

Besides this vision which confirms the historical path of evolution of Italian design there is another reality, which we perhaps do not expect, but which instead creates an interesting thematic opening for our discipline.

This research connotation can be summarized in a few key words:

1*. territory*, or rather the connection between quality and places to live and daily experience and the environment is intended as territory, social identity, resources and cultural assets and the collection of experiences and products/services which makes this sector usable

2. *sustainability*, or rather some great global questions (resources, transportation, energy....) as that of ecodesign and social innovation which produces products/services which create problems for the idea of a traditional lifestyle and consumption;

3. *socia*l, or rather interpretation always starting from fixed contexts related to the quality of personal life or collectively to the theme of relationships between people and places of daily experience, work, health;

4. *creation of knowledge*, or rather involvement in processes of reflection on models/methods/instruments of creation, use, fruition and management of knowledge.

There is thus space for original, rich, complex research which deserves to be studied and sustained and we believe that this work is the first step in getting to know and develop it.

DESIGN VISIONS PROPOSALS AND TOOLS

Changing the change conference
Design and values: materializing a new culture

Design vision

Cyntia Malaguti[1]

Abstract

The contemporary culture of the artificial environment production, based on unlimited nature exploitation and on intensive consumption, is incompatible with the major environmental issues. Starting from the analysis of the meaning of objects in the culturally built world, the article discusses how the objects participate in materializing and solidifying the principles and values that support the current development model. Finally, points out new kinds of associations that design can create and are essential to the building of a more environmentally friendly lifestyle.

The reflections presented here are exemplified by the author's research carried out through two different experiences: teaching sustainable design for design students and taking part - with an interdisciplinary team - in a monthly seminar called "Priceless Values".

1. Introduction: the relation design - environment

As it is common knowledge, the artificial environment in which we live in, is the outcome of a culture that determines a "way" of projecting, producing, distributing and consuming. The culture of creating such environment – performed by our contemporary society – got its foundations in the Industrial Revolution, but is inserted, mainly after the eighties of the 20th Century, in the context of what is called the post-modern society, characterized by the ephemeral, by the fragmented, by the discontinuance and by chaos (Harvey, 1989).

This culture led to innumerous environmental problems, posing the urgent need of rethinking the relation man-nature and find support on other basis. Firstly one points out to the critical need of introducing the notion of limits to the above mentioned practices. In a broader look, it is necessary to mainstream the concept of environmental responsibility in our relation with objects and the artificial environment as a whole, as it most often mediates our relationship with nature and with people as well.

Another important aspect to be understood is the systemic vision of the entire human activity. Such as the ecosystems, human activities are deeply interconnected and thus the consequences of a badly planned action are felt – in a higher or lower scale – way over the area where it took place. Inputs and energy used in one activity or process generate, in addition to the end product or service, different effluents and residues. From some sources came the inputs; some place will receive the effluents. In the ecosystems, outputs of a process are inputs for others, maintaining, in ideal conditions, a dynamic balance. Therefore, although the prevailing vision today is that any human activity causes impact on the environment, it is fundamental that one try to minimize these impacts, including, among others, a more thorough study about the existing connections between these activities. In addition to this study, a new model of human relation practices is being experienced, not without conflicts and learning: that of the search for complementariness, for segmentation; for agreements and partnerships, be it in the realm of the so called productive chains, or in land use or even in social relations.

The perception of the importance of the designer's participation in this necessary change process, introduced the concept of "ecodesign", currently integrated to the concept of design itself and understood as *"activity by which, connecting the technically possible with the ecologically necessary, brings about new proposals that are socially and culturally acceptable"* (Manzini, 2005, 20). And, he ranks such proposals in four levels of interference: environmental redesign of what exists; project for new products or services to replace current ones; project for new intrinsically sustainable products-services; proposition for new scenarios that meet the sustainable life style.

This article intends to look upon this last level, supporting itself, as a starting point, on the concept of sustainable design, proposed by Tony Fry (2003, 31).

"While embracing all that is ecodesign, sustainment design (the design of sustainments) serves a more fundamental function. Which is to contribute progressively to the ability to sustain…. it advances structural change towards an economy and culture with an ability to sustain"… "Sustainment design starts with the absolutely basic question of ' what is to be sustained and why'….This shift means a major engagement with lifestyle, workstyle, technology, culture and the relation between the form of an economy, the unsustainable and sustainability".

2. Design and its meanings in the society of consumption

To reflect on the role of objects in the sustainability of a certain lifestyle it is necessary to return to their dimensions or functions. According to Berndt Löbach (2001), products have three

main dimensions: the practical or functional, the aesthetics, and the symbolic. Each of these dimensions, but mainly the latter, is intimately related with the meaning of the objects.

Vasquez (1996) adds onto objects yet another dimension, as a result of the others: the economic, which turns the object into "currency", means of circulation or payment. To these object dimensions one assigns values, a term that comes from the Greek "*axiós*", which means that which makes sense, i.e., has a direction, what is significant and relevant. This means that in relation to them and to the dimensions mentioned, one makes judgments, appreciations that vary according to their usefulness, beauty, significance and relation established between them and other objects, within the system of objects associated to a certain culture.

The objects and their meanings thus contribute for the materialization of the culturally built world. They represent, synthesize and therefore support culture and all its related values and principles. As Bourdieu points out (2004, 10):

"Symbols are par excellence instruments of "social integration": being knowledge and communication instruments (cf. Durkhenian analysis of party) they make consensus possible around the sense or meaning of the social world which contributes fundamentally for the reproduction of the social order: 'logic' integration is the condition for 'moral' integration".

And how does the meaning of objects move from the culturally built world to individual consumers? Grant McCracken (1990) analyses this movement. First of all through the propaganda and the fashion system, consumption goods are associated to certain categories (such as social class, gender, age, occupation) and cultural principles (ideas or values according to which cultural phenomena are organized, assessed and construed), which compose the culturally built world. From the consumption goods these principles and categories are transferred to the end consumer.

This entire process is connected to the consumption mechanism as several authors have already spoken about. McCraken also brings up the concept of "displaced meaning" for the object. According to him, in the life of us all, there is a considerable distance between the real and the ideal world. We thus keep our dreams and desires, while always trying to shorten this distance. Objects, due to their capacity of materially representing this ideal world, function as its concrete and lasting signals. They are a part that symbolizes the whole and brings it close to us, soothing internal conflicts and frustrations. The economic value is associated to this symbolic value they hold, reinforcing the consistency of this symbolism. Finally, they are very diverse and encompassing and are able to respond to different tastes, styles, cultures and specific needs.

Slavoj Zizek (2005), Slovenian philosopher and psychoanalyst, complements this vision when he comments on what we know and what we do not know of the world. He reminds us that in the unknown world there are things that we know and are not familiar with, but there are also things that we do not even know we don't know or are not familiar with. On the other hand, in the known world there exist not only the things we know we know. There is yet a last critical relation: the known unknown, or the things we don't know we know. According to Zizek it is exactly with these known unknowns that design deals with. For this reason therefore, it is an ideological device as well.

Different human desires and needs are associated to values that sustain and stimulate the strengthening of the current lifestyle, materialized in objects such as: happiness, linked to the accumulation of goods and to wealth; eternal youth and the fear of death, associated to the compulsion for novelty and virginity, while constantly discarding and changing product; the appearance of wealth, associated to the excess and the stimulus to waste; the pursuit of identity in reaction to the massifying phenomenon associated to the adoption of successive trends; the freedom transmuted in right of choice among multiple consumption options. As Moles (1981) already underlined, the object turned in to a message outside itself and out of its materiality.

This has taken place to such extent that in our society human relations are often no longer person to person. They have become relations person-object, where the second looses its person dimension to start fitting into a merely utilitarian and service function, a function to meet a

need a desire or a determination of the first. Bauman (2004) highlights that the other human beings start to be judged according to these objects' standards, according to the volume of pleasure they provide and in terms of their "monetary value".

3. The materialization of new values and meanings

The construction of a path towards sustainability also touches upon the reflection about the role of design in this process of change. As a path towards a sustainable life, John Charles Arbucle (1994, 17-25) proposes what he calls "compassionate design" supported by three strategies connected to attitudes of participation and action: re-symbolize, regenerate and redesign. According to him *"the capacity to re-symbolize is to acknowledge that the fundamental change takes place at the level of the image".* Regeneration, however *"…is a conversion process. It is the capacity for deep changes that grows within us, when we begin to nurture new values, new ways of seeing things and of recovering the energies in our heart. It is where change starts."* Re-design corresponds to *"Our capacity to create ourselves and to build our world".*

What is it that could be re-symbolized, regenerated or re-projected, for the fostering of a sustainability oriented culture? One of the critical aspects in this process are the values and their different ways to materialize in shapes, colors, materials, sounds, textures and several other perceptive-sensorial features of objects and the systems they integrate. Even Santa Klaus has already been used in soft drinks promotional campaigns and the color of his outfit changed to red so as to create a subliminal association with the product's brand! And wasn't it the same red color, the most sacred to the Russian Orthodox Catholicism, the one adopted by the communist flag? On the other hand, more recently recycled paper was repositioned in the media, turning from a symbol of second category packaging into a sophistication indicator, in a communication effort to value more environmentally sound options.

So if we catch up on the questions posed: what values sustain the society of consumption? What objects convey such values? Would it be possible to re-symbolize, regenerate or re-design these objects, or even create new ones carrying other meanings? What values would be fundamental to help in the construction of a sustainable society? What would be the role of designers in these transformations?

No doubt the questions are broad and complex and we are not pretentious to the extent that we may think we will answer them fully in this article. However, one may risk a few answers, even if provisional. The following table tries to confront some of the principles associated to the consumption society, to "substitute" values, yet pointing at some activities that help strengthen the second. Somehow, in several of them, design already takes part by developing tools, equipment and support infrastructure.

Table 1: Values and promising practices: from consumption to sustainability

Values and consumption	Values and sustainability	Promising practices
consumption in the sense of destroying, devouring, consuming 'till total destruction	care, conservation, fruition;	- gardening, vertical orchards - outdoor sports such as sailing; climbing, trekking or rafting
Accumulation/Building up of collections and superficial experiences	broadening and deepening of each experience using human sensorial organs better identification of new uses	- recycling of objects and materials and exploring new properties such as the sound of objects for new musical instruments

Convenience associated to the “use and throw away”.	Other “conveniences” such as survival, maintenance, balance;	- all repairing and maintenance services - selective collection initiatives - rental of clothes and different types of objects
Virginity, novelty, eternal youth	Old age, history, memory, experience and brands accumulated in time, durability	- second hand commerce, customization of clothes - furniture recovered, painted or reused
Luxury as ostentation, appearance or exclusiveness, boldness or transgression for free	Luxury as a demonstration of attitude committed to a cause, courage for ruptures Luxury as quality of life	- efficient public services network, such as public transportation, education and health.
Creation of idols as referential of identity and beauty to be followed	Respecting and valuing diversity; Enhancement of the concept of beauty	- events and opportunities for exchange and sharing between cultures
Individual property and ownership	Valuing the common good, the collective, the communitarian.	- urban furniture/equipment - playgrounds - public transportation

Each one of the correlations shown in the above table could be object of study, identifying activities, participants and related objects, their characteristics and type of contribution towards sustainability; in addition, one might discuss the role of design vis-à-vis each one of them.

There is yet another fundamental question: who would the agents of this process be? Two contrasting dimensions are part of human nature: that of creature as a living being among many that inhabit planet Earth, and that of creator, as a being who, to live, interferes and transforms nature, creating an artificial world as a second nature. This second dimension, that of the creator, is deeply achieving for the human being, as various theoreticians on human needs and desires demonstrate. However, since the Industrial Revolution, society was divided in producers and consumers, with power associated to the first. The creation of artifacts was progressively linked to capital, concentrating in the hands of few and distancing people from their potential creator, devaluing artisan activities and splitting people into two groups: creators and consumers. Thus the concept of “compassionate design” – from a sustainability sand point – should contemplate / look to a creative process shared better among all its stakeholders. As Manzini says (2007, 15):

“…designers should accept the fact that they can no longer aspire to a monopoly on design, since we are living in an era in which everybody designs. They should accept that today design is not only executed in design studios, but everywhere.”

4. The sense of place, of the collective and of the community

We would like to spend some time, however, on the last line of the correlations between values, taking as baseline Augé’s (1994) and Bauman’s (2004) observations, respectively, about

the “non-places”, and about the sense of community. We live in an extremely individualistic society, where the “common good” is not felt as something belonging to all; more and more, public environments are experienced solely as transit areas, belonging to no one. Even though paying our taxes, we feel responsible only for the spaces, services and objects that we buy, that are our exclusive property.

As Marc Augé (1994) highlights, the urban man today inhabits a space he calls “non-place”. According to him, places, from the anthropologic perspective, hold three fundamental features. They are identitary, relational and historic.

Nevertheless, the places that design/compose our reality today carry very different characteristics…In the city we live in, people are generally born in a clinic and die in a hospital (when they get there in time). Points of traffic and places occupied temporarily, such as hotels and holiday camps are continuously multiplying. In this world what prevails is solitary individuality, the passage, the temporary and the ephemeral. This environment Augé calls the non-place; always responding to specific ends (creating a solitary tension and not welcoming entirely); the text always invades the space (“follow the right queue”, “smoking forbidden”, etc); there is no time for history for it is only traveled through; it creates its own system of identifying its visitors by controlling access.

Within this scenery we’ve lost the sense of belonging and the responsibility for the collective. Without the perception of the value of the “common good”, the sustainability speech is, for many, impoverished; it becomes very difficult to recover the systemic and relational vision of phenomena, mentioned in the beginning of the article. Can we strengthen the sense of collective by means of design?

Adding onto Augé’s vision, Bauman (2004, 96) also highlights that:

“The greatest and probably most fundamental success of the market’s attack has been, until now, the gradual but consistent (although in no way to be considered complete and irreparable) ruin of the skills of sociability”.

He however points out that there exists yet a *“gray zone”* in this offensive, represented by some communities, neighborhoods and circle of friends, where members may still consider themselves *“partners in life and for life”.* Environments where solidarity, compassion, sharing, aid and mutual empathy still exist.

5. Objects and community activities in practical cases

- experiences with design students

Analyzing some didactic exercises in the field of design, personally experienced, we identified two relevant cases for discussion.

The first one refers to the development of a set of packages for craftsmen in the region of the Ribeira River Valley (one of the State of São Paulo’s poorest areas, living mostly on banana plantations), after a competition for the undergraduate students of an industrial design college. The request was made by SEBRAE (Development Support Service for Micro and Small Enterprises), intermediating a group of women who worked in a cooperative system, developing a series of goods manufactured with banana-tree straw (baskets, hats, vases, rugs, etc).

The idea was to use as principal raw material the paper made from the banana-tree fibers which they had learned to produce with the scrap of material used in the handcrafted goods. The relationship between students and the community lasted for about one semester and about twenty sets of packages were created, three of which were awarded a prize and one was selected for implementation. This resulted from the evaluation made by a Committee with members of the community itself. Despite the existing interaction between students and

community during the competition phase and after that, during the training to produce the selected packaging, the system was not implemented.

One of the possible reasons for that could be that the process was not conducted in a "peer-to-peer" way: SEBRAE always intermediated all interactions. Another one could be the leaving of the group leader. Also, SEBRAE's request intended to service a much broader and heterogeneous group of craftsmen without a previously structured network. From that, we learned that professors conducting processes such as this should be in charge of a deeper reflection about the meaning of such experiences in the education of future designers, about the most suitable procedures as well as the duration and type of relationship to be established among all involved in the process.

The second didactic experience, was the follow-up of program conclusion projects for graphic design students in a college in São Paulo, who chose the "environment" as core theme for the year 2007. In this case, each student was free to choose both the type of project and the target public. Among the almost thirty projects made, there were many campaigns, publications and brands for products that addressed environmental issues. Within the focus of this article, however, what deserves to stand out is that many of the projects shifted from an educational or protective position towards fragile communities, to a "peer to peer" approach, be it in campaigns targeting the designers, in electronic games (stimulating a playful experience), or even in some campaigns and events.

An example of such an approach was the "see the city" project, which making a play-on-words with the word "veracity" (in the Portuguese language), placed images of São Paulo's degraded areas on the Internet. Within the proposal of "viral marketing", the website offered the internauts the possibility of making personal interferences in the images eventually posting them to exhibition and voting in a blog. In this case one may notice, not in much detail though, that the authors wanted to instigate the "look" of citizens towards details of the city, taking ownership of it as their "place of dwelling", and waking them up to an active attitude towards it to risk a "virtual reconstruction" of the landscape from an enhancement perspective.

In this second experience freedom and increased maturing of students allowed some reflections and more encompassing formulations about the role of design vis-à-vis the environment. Nevertheless, they better specific guidance to better fundament their works, both from the social and environmental issues' standpoint and for the designer's possibilities of action.

- observing collective practices and the use of objects

Other reflections connected to the role of objects in the strengthening of sustainability oriented values, and, especially, of the sense of community, were provided by the five year participation (2002-07), in a professors' interdisciplinary group, which conducted a monthly seminar called "Priceless Values". This seminar, sponsored by the Palas Atenas Association, was addressed to teachers of the public elementary schools of the municipality of São Paulo.

While addressing – in one of the seminar modules – the theme of human relations, the objects and the role of the latter in the materialization of values and principles, we faced some peculiar situations in the history and traditional practices of some groups of the Brazilian culture. In these, the object was the core of a collective activity where fundamental values – escaping the mercantilism logic of life proposed by the consumer society – were kept alive. What objects were these that played this critical role? Five of them caught our attention in particular; the little Indian bench, the *Cuia de Chimarrão* (mate pot), the *Berimbau*, the *Tucum* ring and the bicycle.

Benches manufactured by the indigenous people and used by different Indian tribes from North to South of the country before the discovery land mark in the year 1500 AC, carry to this day, a strong symbolic dimension in addition to its function of use which is that of sitting down on it. Although in the day-to-day little benches can be used indiscriminately by all individuals of a village during rituals, moments in which they experience their beliefs, they become attributes exclusive to certain individuals such as Chiefs and Shamans, representing a bridge between the material and the immaterial, the tangible and the intangible, the natural and the supernatural.

Their shapes, very rich and elaborated, distinguish themselves from tribe to tribe and user to user, reflecting their entire symbol related universe.

The *cuia de chimarrão* (mate pot), on its turn, is an artifact that together with the tripod to support it, the *"bomba"* to suck the mate plus the hot water kettle or thermos bottle is obligatory among the apparatus of an authentic *gaucho* (those born in the Southern state of Brazil). The *chimarrão* was originally a very hot tea drank by the Guarani Indians to which the Azores immigrants, the *Bandeirantes* (explorers), *Tropeiros* (on-horseback cattle guides) and many others got accustomed to, given their energetic properties; today the habit of taking *chimarrão* from the *cuia* is spread throughout many states of the South of Brazil. The manufacturing and use of *chimarrão* set follow rigid standards, which a good "*mateiro*" (lover of chimarrão), knows very well. An in-group practice among family and/or friends, a moment for relax, to chat time out, tell stories, drinking *chimarrão* according to the rules of the traditional ritual. The first mate (of worst taste) is the *cevador's* (the one who prepares it); after him the round will start by the eldest or someone one wishes to render homage to.

Similarly to what occurs with the peace pipe, the *cuia de chimarrão* passes from hand to hand, going round in circles, with all people putting their lips at their turn on the same *bomba*. Every one must drink all the content of each "mate" (full dose) until the *bomba* "snores", since finally air and not tea is being sucked.

Now the *Berimbau* is a musical instrument that originated in Africa and was brought to Brazil by the slaves. It is traditionally used to play the percussion and beat the rhythm of the *Capoeira* dance/fight rounds. Considered a symbol of the black culture resistance in Brazil, *Capoeira* is "experienced" as a game. A circle is formed where all sing and clap their hands at the rhythm of the *Berimbau* and in the center two players at a time perform a sequence of movements in a silent dialogue and tuned action and reaction, mimicking a wrestle. A player, however, doesn't touch on the other; each *blow* is only "marked' by the beat of the *Berimbau*, as if it were a dance where the most important is the synchrony between both, the evolution and the movement skills. The winner doesn't destroy his opponent but shows his superiority through the sequence of his blows and is acclaimed by the people in circle. A key element for C*apoeira*, the *Berimbau* – such as the *cuia de chimarrão* – is handcrafted following a series of strict criteria to guarantee its correct performance as a musical instrument.

The *Tucum* ring belongs to a completely different category of objects, connected to a different social group. Also manufactured manually from an Amazon palm tree's small, rigid and black seeds, it's used mainly by intellectuals who "embraced" the indigenous cause and the poorest. It symbolizes a peoples' alliance, as an individual and as a social being, to carry ahead the vindication of rights and these people's hope for a more human and fraternal world. According to some, the start of its spreading was in the seventies, especially after the CIMI (Missionary *Indigenistic* Council), hence its strong dissemination among some sectors of the Brazilian Catholic Church, engaged with these causes.

Finally the bicycle, which apparently has no relation with the previous objects, has more recently provided an interesting collective experience in the large urban centers: the night pedaling. This practice has greatly spread throughout Brazil after the nineties, through a radio show. Journalist Renata Falzoni rode her bike across the city of São Paulo in the rush hours, giving tips about alternatives pathways and points for a "happy-hour" stop, indicating a "distinct" place on the way, suggesting the listener to take a break and "escape" from the daily stress. The idea of exploring the heart of the city by pedaling, originated the so called "night bikers". Today they are organized in "clubs" or groups, which after 9pm usually, do the programmed Internet-informed tours. There are different paces and routes according to the profile of the group and the day of the week; a series of rules is part of the practice, as well as the use of some specific complementary objects such as ID T-shirts and helmets.

What do the exposed objects and their relative usage have in common? Although they here described briefly, one may realize that they do not fit into Baudrillard's (1973) and Moles'

(1981) classification system for objects and they fulfill very distinct functions such as a seat, a drink container, a musical instrument, a decoration and transport equipment.

6. Drafting an analysis

Some authors assisted in the study of these cases, mainly the second group, in the perspective of analyzing their contribution for the strengthening of a sustainable society. From the first to the second group of cases, the focus is shifted, from the point-of-view of the creation of the objects, to their use. It is not the attribution of value, but the value effectively attributed to the objects that are being considered. They are appropriated by their users, which have great intimacy with them, getting to know the most adequate ways of using them, their potential, their most relevant characteristics, and knowing how to carefully choose a "good" product for that practice.

Certeau (1994) and Canclini (2003) bring interesting approaches about the consumption process, which assist in the qualification of the cases presented. Certeau says the consumption can also be considered as an astute "production", disperse, silent and almost invisible, which is manifested in the ways of using products. But here, we cannot say that the products in question have been imposed by a dominant economic order.

He divides this "production" into two levels: the tactic and the strategic, the first being defined as *"...a calculation that cannot count on itself, nor, therefore, with a frontier that distinguishes the other with total visibility. The tactic only takes the place of the other. Then it insinuates, fragmentarily, without apprehending it entirely, without retaining it at a distance."* (Certeau, 1994, 100)

On the other hand, the strategic level is defined as *"...the calculation of the relationship of forces that make it possible from the moment in which what the person 'wants' and 'can have' is isolated from an 'environment'. This postulates a place capable of being circumscribed as itself and therefore capable of being the base for the management of their relationships with distinct exteriority."* (Certeau, 1994, 99)

According to this division, the products considered have allowed their users to have a position closer to the strategic, allowing a more aware behavior, as actors in a process. The practices to which they are associated would be important in strengthening this position.

Canclini (2003, 73) highlights the character of consumption as a practice associated with citizenship, which can be applied to the cases dealt with here, when he comments that:

"We can act as consumers placing ourselves in only one of the processes of interaction – which is regulated by the market – and we can also have as citizens a more comprehensive reflection and experimentation that takes into account the multiple potentiality of the objects, which makes use of their 'semi-optic virtuosism' in the varied contexts in which the things allow us to meet with people."

And when this occurs, in his opinion, the consumption can become a place of cognitive value, useful to think and act, in a significant and renewed way, in social life.

Another peculiar aspect to the cases mentioned is that none of the practices analyzed were to meet the objective needs of daily life, although the majority of them have practical functions. Bizzocchi (2003), based on the Hedonist doctrine, considers that the human practices are ruled by two basic principles: the search for pleasure and the escape from suffering. From there they support their modal structure on the "*want to do"* or on the "*should do"* – and eventually on both. He calls the first practice Hedonic and the second pragmatic, comprising those that give practical and effective resources for the resolution of the human problems. Evidently, both are important for our well being and, analyzing the various human practices, both principles occur on a greater or lower scale. However, on observing the examples presented here, we can say that

the Hedonic aspect is more relevant in all of them, i.e. the search for satisfaction, for pleasure, much more than the solution to a practical daily problem. And, also:

"If it is true that the ultimate end of human existence is to find pleasure, then the Hedonic activities are end-activities, because they lead straight to pleasure, to the extent that the pragmatic activities are means-activities, by which we accomplish the first stage in the search for pleasure: the elimination of the sources of dissatisfaction." (Bizzocchi, 2003, 40)

In his opinion, this motivation is constituted in the pith of the cultural practices. It is this that configures and solidifies traditions. Complementing this vision, Giddens (2003) highlights that although the traditions and customs have constituted the essence of life of most people during a major part of history, the current interest for them has decreased in detriment to the discussions about modernity, post-modernity and their meanings. In his opinion, the traditions were and are constantly invented, as well as altered or transformed, and we should try and understand why. He also observes that they are properties of groups, communities or collectivities, defining a kind of truth, offering a structure for the action, which can remain unquestioned. They are necessary and will always persist, because they give continuity and form to life, like rituals and ceremonies that are repeated time and time again. Although, on one side there is an association of them with conservatism, in our global society it has reemerged.

"As the influence of tradition and custom becomes thinner at global level, our own base of identity – our own sense of individuality – is changed. In more traditional situations, the sense of identity is sustained largely by the stability of social positions occupied by individuals in the community. There, where tradition declines and the choice of lifestyle prevails, individuality is not immune. The sense of identity has to be created and recreated so that it is more active than before." (Giddens, 2003, 57)

According to Giddens, it is in the midst of these traditions, even though they are not very old, but constituted recently, like the ride of "night bikers", where values and moral commitments are strengthened and raised above common everyday concerns; values that we want to defend, in case they are threatened; values by which it is worth living.

7. Final considerations

With the examples described we tried to demonstrate the relevance of more thorough studies on the practices considered as current or recreated traditions, where the ultimate end is not the resolution of everyday problems, but the practical performance in itself, through the satisfaction it gives, by valuing the sense of community that it brings about in a perspective of strengthening the transition towards a more sustainable society. In a certain way, requiring special attention, the objects that make such practices or attitudes feasible are almost like "fetishes", under various angles; their form, materiality, changes and players in the process of creation and appropriation. In all the cases, the participants of the practices acquire great intimacy with these objects, getting to know their characteristics, uses and cautions quite well, knowing how to enumerate the qualities of a "good product".

Retaking the initial proposition of the article, of reflecting on the meaning and values transmitted by the objects, as well as their importance in the process of change in question, the cases presented highlight the importance of being aware of which values need strengthening since, the objects used are mediations between people and not just mere objects; because they are not just objects, but also inter-subjective, not just problematic, but dialogic. (Flusser, 2007) And, in this process, we do not only need this awareness, because the processes of attribution and appropriation of value, performed respectively by the creator and by the user of the objects, are not necessarily coincident. *"No design can be 'perfect', and coincide completely with the theoretic model according to which it was created."* (Flusser, 2007, 208)

Based on this assumption, it is essential to change the idea of what it means to be a designer today, as highlighted by Manzini (2007) and previously mentioned in this article.

Thus, reconsidering Flusser, the challenge of the designer today is to emerge from himself and from the world around him a form that involves both of them, revealing the way in which people emerged from the world to experience it; not imposing an idea about something considered previously as amorphous. And, to work intentionally towards sustainability, maybe the concept of “maieutic product”, proposed by Morace (1990), could be reconsidered, defining that which is able to strengthen people wisdom in confronting their own existence, to generate a new quality of life, and to achieve perceptions and much deeper emotions.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Sustainable mobility design in contemporary towns

High social and technological innovation alternative mobility system

Antonio Marano[1], Giuseppe Di Bucchianico[2]

Abstract

One of the most important factors of the contemporary city environmental crises is the warped idea of the local transport. As a matter of fact they are based on the widespread of the “car monoculture”.

Within this problematic field, the present paper illustrates the design called *Friend Bus Service Solution.* It is based on the possibility to modify and regenerate local transport system, making them more flexible, more attractive, and nearer the users need. The study compares with the experience implemented in many parts of the world, and it develops according to the design methodological approach for sustainability.

The main results obtained concern the pre-figuration of probable scenarios of alternative mobility, the sight of twelve sustainable services for mobility, the concept design and the interior design of a modular vehicle for public transport.

1. Introduction

The fact that our cities are unbearable depends mostly on the use of private cars which are considered, too often, the unique means of transport by which it is possible to afford any different kind of mobility within the urban habitat.

In metropolitan daily routines, city connections within the urban mobility are narrower and narrower. The urban mobility is considered as a whole of people and things flows which supply the metabolism of a city, its environmental quality and its social defence. These kinds of relationships often cause discomfort and difficulties, high economic and energy giving costs caused by traffic congestion, high level of sound and weather pollution, risks of street accidents both for cyclists and pedestrians. As a matter of fact, they evaluated that, in Europe, traffic jam costs are equal to 0.5% of GDP (gross domestic product).

In modern society, therefore, they feel the need for a sustainable urban mobility that will be able not to weigh too much on the local social and economic system.

By promoting alternative forms of urban mobility, on the contrary, they may start virtuous process of reduction for urban chaos with the consequent increase of street security and reduction not only for street accident risks but also for the economic and social costs linked to them. Nowadays it is possible to afford and solve urban mobility problems through both the carrying out of local mobility system based on transforming course in pedestrian way and the assisted use of nimble means of transport linked effectively to fast public means of transport for long distances. As a matter of fact changes in the city way of living require a different organization of the urban mobility. All of that is possible through the regeneration of technological and social networks that permits to optimize flows, to coordinate exchanges among different means and facilitate the shared use of vehicles and equipping.

2. Aims of the research

In the problematic field of the urban mobility and in the view of sustainability, the present paper reports the results concerning a social and technological high innovation of an alternative mobility system.

The general aim of the current research consists of the re-launching of the multi-world mobility in order to improve the whole efficiency of the local transport system, the economical cost reduction for mobility, the regeneration of the metropolitan social contest, the improving of the environment quality for specific urban contests and the psychological and physical health of the users.

Nowadays, it is possible to favour the use of public means of transport thanks not only to the stimulus for present environmental influence but also to the possibilities offered by the new information technologies applied to the local transport system. According to this view of change, the specific aim of the paper consists of re-launching the alternative mobility through the proposal of a *Friend Bus service solution.*

The idea consists of supporting the use of public means of transport, and creating at, the same time, cultural as well as social and economic conditions in order to attract large sector of population through a wide and differentiated system of services aimed at improving the alternative mobility and the quality of the metropolitan life in general. They have been looking for a proposal that systematizes technical knowledge, sustainable services referred to new form of alternative mobility that is innovation in the eco-friendly field. Moreover the paper is also aimed in prefiguring probable city changing by the light of the information technology applied to local transport. According to this position they research, first of all, an inter-modal mobility system

capable of favouring socialization, exchanging experience and knowledge, taking active participation of all the users of the service; secondly they research how to satisfy the way to reach job, schools, entertainments and information point of locations by the community in accordance with men health and environmental quality of the urban contest.

3. The international movement for alternative mobility

In many cities they are developing and carrying out mobility systems characterized by a great variety of local transport alternatives such as fast flowing public transport, sharing taxis, car-sharing and car-pooling services, virtual mobile office, cycle-lane and the possibility of going on foot pleasantly.

All of that takes place in Groningen, The Netherlands, which, with its 60% of transport by bike, is considered the world capital of bicycles. But it is also common to Italy, exactly in Ferrara where 30% of mobility is done by bike along efficient and safety cycle-lanes. When you arrive at the city you will leave your car at the parking site and exchange it with a bike offered to the citizen's disposal by the town hall. They also take care to reduce the number of vans and lorries that every day reaches the city in order to supply any kind of goods. For the same reason, in the nearby suburbs, they prepare some platforms capable to intercede the whole commercial traffic by compacting goods and by stopping those vehicles that enter the city for few deliveries. Car-sharing is also expanding in many European regions. It consists of a car sharing system born in Switzerland and it is capable to eliminate the use of, at least, eight vehicles. A recent research has shown that those who belong to a group of car sharing use their cars less frequently and in a more intelligent way than those who has got one. Taxi-sharing services are spreading rapidity, even if they are integrated with other public transport modes. Moreover, many are the cases of inter-modes present nowadays in order to facilitate the exchange train-bike. Among the initiatives in favour of sustainable mobility, we can find also those designs that help families in routine duties, such as bringing kids to schools called *Walking Bus* in Great Britain and *Andare a Scuola a Piedi (Going to School on Foot)* in Italy. *Mobility Manager in outsourcing* services are increasing in number and they can represent an actual support to mobility within companies in a manner that is similar to the organization and running of a sustainable mobility for fairs, conventions and great events.

As regards proposals for public transports, recent innovations concern the optimization of the local transport network as well as the experimentation for authorized technological solutions. Among the former we can mention Lam, high mobility lines, in order to obtain frequency and higher speed than the normal lines through reserved tracks and with the help of preferential traffic-lights device. An alternative may be quality bus lines such as *QBCs Quality Bus Corridors* that characterize initiatives promoted by *Dublin transportation* (Dublin City Council) with the aim of incrementing the use of public means of transport, bicycles and to increment going on foot. Among the second we can find different technological systems such as *TVR, Transport sure Voie Reservee* (TVR-Bombardier), done at Rochefort, in Belgium, where, to drive the vehicle, only one rail is exploited and it is put just in the middle if the lane: the *Civis* (Comune San Lazzaro di Savena), with automatic driving manufactured with optical sensors capable to elicit the position of proper track painted in the middle of the lane; the *Stream* (Trasporto Pubblico Locale di Trieste), the evolution form of the trolleybus without any air contact; the *APM*, *Automated People Mover,* (International Airport Automated People Mover Association) electric automatic system without driver, the mobility of which occur with single or multi vehicles on rails or driveway; the *PRT, Personal Rapid Transit* (Personal Rapid Transit) that consists of only one nimble rail travelled by little cages (for not more than six people), their mobility is automatic without any operators; the *Sky Web Express* (SkyWeb Express), a system made up of three/four passengers vehicle that travels long only one network rails in elevation. Great scientific interest has risen in the past few years from the results reached by Mit in Boston through the *Smart Mobility System* design (The SENSEable City Laboratory). Those designs are based on the idea that the urban *wireless* network can modify local transport and render it more flexible and nearer to the users needs. In Bogotá they have recently adopted the

TransMilenio (TransMilenio). It is an innovative *Bus Rapid Transit* system (*BRT)* that uses fast flowing public means. The design works out as a light rail system. Transport lines are subdivided into local and express, the former travels within the neighbourhood, the latter covers long distances and have few stops. That design has already been exported to Chile. It will be exported soon to Columbia, Thailand and Nigeria, and it is an interactive one as its vehicles and stations are provide with a series of technological aids such as optical recognition smart cards and a monitor for real time information.

4. Design methodology

Research developed according to a methodology approach that changes sustainable products and services in a synergistic way. According to that they followed a methodological scheme subdivided into four stages, the development of which occurred from the service to the concept of a sustainable product (Marano 2007, 153):

1. *Preliminary stage of knowledge* of the physical, social and economic characteristics define quality and no sustainability of the environmental contest. In order to satisfy that it is necessary, on one hand, the sharpening of our ability to recognize both degenerative phenomenon of the physical and social quality of the metropolitan environment, and the local identities that render feasible a sustainable proposal of transformation. It is also necessary, on the other hand, to identify suitable instruments and methods to elicit all the complex relationships and the reciprocal influences among the different components proper of the scenery of reference. Furthermore it is also necessary a wider integration of the design within the other disciplines such as sociology, economics, planning and technology.

2. According to the above relevant knowledge (stage 1), promoted through the methods of the systemic thought, they go ahead with a *scenery stage* in order to research sustainable solutions (Manzini and Jégou 2003, 51), qualified by a coherent system of products and services characterized by a high regenerative capability with low environmental impact. That implies the sharpening of the conceptual and effective instruments both of the strategic design concerning address and trend, and of the service design concerning the formulation of the interaction between services and users.

3. Sustainable solutions (stage 2) define the design *brief* related to the key products of the proposed services. It is *one of the work programme stages* that fix the level of innovation of the product required by the sustainable solution. All of that presses for a checkout and for the use of adequate instruments of the design and of the evaluation of the ecological compatibility.

4. Finally the conditions required in the programme stage (stage 3) have the role of controlling the stage concerning the drawing up of *new concepts* for products essentially sustainable. That means a wider ecological awareness and the use of specific design guidelines oriented towards sustainability (Vezzoli 2007, 83-120), within the promising attempt of assigning a moral value to an industrial product.

5. The *Friend Bus service solution*

On the basis of these guidelines the theme of alternative mobility in contemporary towns has been afforded. The application field is related to the project called *Friend Bus Service Solution.* It is based on the idea that it is possible to change and regenerate public transport systems, making them more flexible, attractive and closer to users requirements.

Multi-modal mobility

The solution suggested aims to get large classes of users to re-approach public transport, by means of an integrated and diversified system referred to common services meant for the improvement of metropolitan life quality.

The proposal is made of a multi-modal system involving innovations both in technology, functional and social field in order to favor: socialization with exchange of knowledge and experiences, active participation of all service user; roads map, culture and daily life information supply. It takes advantage from the latest innovations referred to wireless networks and miniaturized transmitters to optimize flows in the urban network in order to organize exchanges among different means. Further, the use of information and communication technology allows to detect more easily the users requirements located in the urban network, re-shaping continuously the service offer. *The Friend Bus service solution* is based on the use of long urban buses trains, able to become more flexible either physically, or due to the service offered in order to get into the roads network more easily. It is connected to a wider multi-modal system favoring on one hand, mobility by walking and biking and, on the other hand, the train, which is one of the most effective types of fast and long distance transport. Further, the system is arranged by sharing the use of vehicles and equipments.

Alternative mobility service system

The Friend Bus service solution consists of twelve alternative mobility systems responding to the requirements of different and potential groups of users. The services intercept the largest range of actions, socially and economically more sensitive, connected to metropolitan daily routine. These services have been named according to the solution they offer. Some of them (seven) are referred to new forms of bus-use: *FRIENDbus* for socialization*; BOXmarket and TakeawayBUS* for shopping and refreshments; *RechargeBUS* to get economic benefits advantages; *BUSgallery*, *BUStheatre* and *BUSbar* for culture, information and entertainment. To these, other five services are to be added arranged according to a model perfectly fitting the previous ones. They are referred to mobility by bike, by train and by private means of common transport: *BIKEadvertisement* to obtain by biking economic benefits; *TeleBIKE, CoachBIKE* and *VIDEOoutliers* for mobility and information related to students and tourists, *InteractiveMAP* for sharing the use of private vehicles.

Each type of service suggests a solution proposal and has been represented through the narrative model based on strategic design communication tools (Meroni 2003, 235): title, demand and brief description to restrict the idea at the basis of the solution (title) in its essential and evocative lines; to point out the necessity dimension where the idea comes from (demand), to report the organization objective aspects and their functioning (description); storyboard to visualize by means of associated images linked to didactic texts the essential situations and the service benefits.

The *Friend-bus* primary services are:

- 1. *FRIENDbus: how to make new friends and arrange a weekend outside the city joining other people using public transport?* “FRIENDbus” is a service on–line available on public transport network enhancing socialization by allowing the users to make new friends by sharing their own interests and activities they carry out. By enrolling themselves in the system database, the service, connected to the Net used also on buses, gets in touch the people potentially interested to share activities and traveling experience in the outskirts of the metropolitan area.
- 2. *BOXmarket: how to arrange shopping without going to the supermarket by using the bus ?* “BOXmarket” is a service which, meant also for those people who don’t have much time at disposal, allows to buy on–line fresh products from home, from the office and even from public means of transport. The service uses the bus for transporting the shopping booked in advance which the user, by using a pre-registered personal pin-number will collect directly at home in “BOX-markets” located near the bus-stops or delivered at home by the service operators.
- 3. *TakeawayBUS: how to book and collect directly our own meals from the bus?* “TakeawayBUS” is a service which allows to collect the meal directly from the bus meant for those who have short time to spend on cooking and on a correct diet. Helped by a nutritionist, users can select and book on–line the most suitable meal

according to their own nutrition requirements. The bus is equipped to have the food collected and prepared in packaging easy to be carried which will be delivered back the following day getting on the bus again to go to work, for example.

- 4. *RechargeBUS : how to get around the city by using cleverly the mobile phone?* "RechargeBUS" is a service involving telephone companies, the urban transport management company and commercial activities meant for being promoted on buses. The user, by purchasing a telephone re-charging card is "identified" by the system each time that he/she uses means of transport. In this way he/she accumulates scores in proportion to the distance covered according to use frequency. In this way the user has the right to save some money on his/her transport-subscription card, or in alternative can get cheaper prices when purchasing items in the shops joined to the initiative.
- 5. *BUSgallery: how to get around in the city for "art immersion"?* "BUSgallery" is a service allowing young artists in town to get to be known and allowing travelers to approach contemporary art during their daily trips on the bus. Artists publish on the service website their works which can be observed and "voted" by travelers directly from terminal-displays placed at bus stops. The most "clicked" art–talents will be able to exhibit later their artworks directly on the Bus-gallery meeting and talking to the users who have voted for them. In the same exhibition area arranged on the BUSgallery, books and culture activities can be exchanged.
- 6. *BUStheatre: how to enhance and promote music and theatre entertainment traveling in the city by bus?* "BUStheatre" is a service allowing street performers and comedians to perform their shows freely on buses giving the user the possibility of spending pleasant entertaining moments during their daily route due to work or other reasons. The project includes also fast food service. Further, in motionless configuration of the bus-system and directly on board, users can watch shows organized and directed by little local theatre companies.
- 7. *BUSbar: how to reach safely entertainment night- clubs and pubs drinking some more cocktails?* "BUSbar" is an aperitif-cocktail and entertainment service directly arranged on local buses meant for the "people of the night" tours. The service promotes and enhances encounters among people and it has been thought to make the traveling of young people safer toward entertainment places promoting at the same time commercial activities arranged for night-fun. The user can book on-line a seat on the "BUSbar" enjoying the service on board which provides live-shows, aperitifs information and discounted entrance-pass for entertainment places.

Services to be added to *Friend-bus* are the following:

- 8. *BIKEadvertisement: how to travel fast in the city without polluting and obtaining at the same time an economic benefit?* "BIKEadvertisement" is an ecological transport service joined to bike mobility. Sponsors wishing to use the bike as a mean of advertisement, are enrolled at the service centre. The local user or the tourist can book the bike on the phone receiving also information on the itinerary maps and on fitness activity to be done on the bike in order to get a better body shape. Therefore, traveling by "sponsored" bike in town, and in proportion to the route covered, discounts and facilitations can be obtained contacting those companies joined to the sponsor-system.
- 9. *TeleBIKE: how to travel fast and get information in the city avoiding the car?* "TeleBIKE" is a service for local ecological transport linked to the use of bikes. The service involves telephone, public and private companies dealing with mobility and communication. By purchasing a telephone re-charging card, the user has the right to pick up a bike, in the local Bus-points arranged in town, equipped with navigator. By introducing the telephone card into the navigator, the user takes the bike and is always updated on the best itinerary, short and safe, to reach any point of the town.

Further, the user is enhanced to drive more kilometers by bike because in this way he/she can accumulate scores on prizes on his/her personal card.

- 10. *CoachBIKE: how to travel with our own bike?* "CoachBIKE" is an inter-modal transport service allowing anybody to travel easily by train with his/her own bike and then, if necessary, by bus too. This enhances to privilege the combined use of light and common means of transport. The multi-modal system is made by connecting the railway system with the public transport network and the city–biking lanes, which allows to tour in the cities without polluting them or provoking cars traffic-jam. The user can book on-line his/her seat and, if necessary, a bike on the train. The service organizes tours meant for tourists, even for groups of users interested in visiting the most beautiful places in town, thus enhancing new forms of socialization.
- 11. *VIDEOoutliers: what to do for not missing university-lessons when traveling*? "VIDEOoutliers" is a service which allows university students to follow lessons from the train in case of delay or on a trip back. The commuters get in contact with the service web site, available in agreement with University, to tell their requirements according to time–tables and courses attended. By booking the seat, each student can attend the class, or part of it, by video-conference downloading it, when necessary, also on his/her hard-disk.
- 12. *InteractiveMAP: how to improve the private car use in town?* "InteractivMAP" is a service allowing easy traveling in the city getting to know new people and sharing transport costs thus polluting less. This is possible thanks to an interactive map system located along the main road itineraries, near the *Bus-stop,* providing information both on public transport network and on the shared car mobility network. In this way, the user can get a further service plus the bus. He/she can share the use of private cars with other local people, when necessary, either for going outside the city or for particular transport situations.

The *Friend bus* system-product

The analysis of services organization and functioning characterizing the *Friend Bus service solution,* has allowed to identify its *key-product:* the "*Friend Bus* System". It is an easy and modular vehicle of public transport, made of specialized and interchangeable mobile units, comfortable and accurate in their inner space, flexible and adaptable to be re-shaped according to the needs and services offered to the users.

As starting point of the project development, the "*Friend Bus* System" brief has defined the specific and general targets of research, the users' needs, technology and functional requirements of the system. The *Friend Bus* System is meant for a larger target than that traditionally related to public transport (students, elderly people, immigrants and low-income people), since it is aimed to offer a wide range of services not only referred to transport but above all related to cultural and social activities. The product requirements are focused on technological and functional features of a public transport modular vehicle, made of interchangeable, flexible units, adaptable to be re-shaped. Information on the latest technology and computer science innovations in this field have been acquainted (miniaturized transmitters, wireless exc.). From the analysis of the present condition it is evident that the development regarding means of public transport is mainly referred to the improvement of mechanical, propulsive and functional efficacy. Generally, the new Buses are characterized by the re-design of their interiors and their bodyworks. Only in the latest years some studies on experimental level have faced the theme of urban mobility according to system terms, providing solutions mainly based on the best computer science technology innovations.

The concept "*Friend Bus* System" is made of a Motor and several Bus Units (BU). The Bus Units are made of mobile Connection Units (CU) and Specialized functional Units (SU). The mobile Connection and transport Units are the parts composing the jointed mechanical system. They contain the access module, useful to disabled people too, and the connection module between the two levels and the single SU. The functional Specialized Units, instead, are true and

real modules differently arranged and equipped in relation to the different services offered: on the first level there are no seats but only supports and equipments are placed in the centre; on the second level, space is made of a large access area and a gallery equipped with seats, terminals and different elements.

The "*Friend Bus* System", projected in this way, allows a great aggregation and functional flexibility. The study has specifically analyzed two possible standard configurations: in motion and motionless.

The system, when in motion, shows long jointed CU "trains" where different SU can be placed. The Specialized functional Units are placed time after time on the mobile Connection Units in consideration of the fitting required. For example, different combinations can be obtained according to specific use requirements by the users, or requirements linked to optimize the service or in occasion of local venues and exhibitions.

The system, when motionless, is transformed in a fitting strolling system, which can be placed in the squares or in the strategic points of the city. The Bus Units can be system-aggregated according to as many as required in relation to the venues organized or the service required. Therefore we obtain a jointed system adaptable to the features of outer spaces. Further, each Unit is connected to the other by means of extensible tunnels, assuring the continuity. In this configuration the Bus-Units offer differentiated use dynamics. The lateral walls of the first level can slide enlarging the inner space creating a series of crossing points; on the second level, the transparent covering can be opened shaping the gallery below like an open terrace. In its whole, the chain of Bus-Units obtained, is a continuous architectural and spatial system articulated on two floors.

The study, in the end, has been focused on the interior design of the different SU to define the fittings and the distributing solutions. The two levels of the Specialized functional Units are connected by inner stairs. They are differently equipped: touch screens assuring the service of the Net-surfing; book-shelves and exhibitors; bike-racks, seats and supports, containers and various distributors. The furnishing is light and characterized by soft shapes and new materials to assure comfort, durability, safety and distributing flexibility. The fitting elements of the interiors are well combined and continuously linked to the panel of the outer covering. An orientation of aesthetic research is obtained, developing the "*Friend Bus* System" language toward organic shapes of contemporary time.

6. Main Results

Friend Bus Service Solution system represents an alternative solution to the traditional urban mobility based mainly on the use of private car. The proposal satisfies the needs of developing a sustainable urban mobility, with multi-modal characteristics capable of reducing environmental and economic costs caused by traffic congestion and, at the same time, favour the regeneration of the social structure through an integrated and differentiated system of collective services.

According to this motivation, the obtained results concern mainly the building of possible scenery of alternative mobility in contemporary city through the description of a sight and some proposals. In particular:

- The pre-figuration of probable city changing, above all thanks to the data processing innovation applied to the problematic area of the urban mobility, that gives the possibility to optimize flows, coordinate exchanges among different means and to facilitate the sharing use of vehicles and equipping. Modified local transport system, according to the alternative mobility, offers new form of routine lifestyle feasible and sustainable;
- The visualization of twelve alternative mobility services. It is about solution proposals to the need of mobility, and to the need of social and economic regeneration for the

local population. Designed activity aimed to the description of management and financial aspects has consented to stress the advantages of the service: optimizing time run, mobility cost reduction, safety increasing, a wider range of socializing and inter-personal relationship developing possibility, rising of wealth and of the contest quality, promotion of personal ability, development and increasing of the economic and commercial activities;

- The concept design of one modular vehicle for local transport, called *Friend Bus Service Solution*, made up of specialized and interchangeable mobile units reassuming according to users needs and wants. The system allows a great aggregative and functional flexibility in order to give aggregative and functional flexibility and can give life to numerous structures, both in movement and in motionless;
- The interior design of the Specialized Functional Units, with particular care for the fitting out and of the not printed distributive in order to favour activities and usage modes linked to different services offered.

7. Involvements

The research has been developed according to a degree thesis in Industrial Design at the Faculty of Architectures in Pescara, G. d'Annunzio University, Chieti-Pescara. The headline of the thesis was: Alternative *Mobile System. Services, Products and Knowledge for the Urban Sustainability.* The lecturer was Professor Antonio Marano, the co-examiner was Professor Giuseppe Di Bucchianico, and the final year student was Alessandro Jovine. The present paper. that reports synthetically the main obtained results, was written by Antonio Marano (exactly paragraphs : 1, 2, 3, 4, 6) and by Giuseppe Di Bucchianico (paragraph 5)**.**

DESIGN VISIONS PROPOSALS AND TOOLS

The sector of household electrical appliances

An integrated system

Gian Paolo Marino[1]

Abstract

Defining future developments of the planning and production concepts, as well as the environmental outcomes of big household appliances (fridges, freezers, washing machines and dishwashers), entails the opportunity to briefly figure out what the evolution in the sector has been like, in the past ten years.

The lapse of time taken into consideration is the one that was marked by an increased need for talking about the issue of product ecocompatibility.

Today we dispose of a number of outcomes that form a very articulated patchwork that has, on the other hand, no “compactness”.

This results in the need for a clear uniform future vision able to lead us towards an operational strategy for tomorrow, in compliance with a shared methodology.

[1] Politecnico di Torino (ITALY) – 1 Facoltà di Architettura, DIPRADI department (Dipartimento di Progettazione Architettonica e Disegno Industriale), Lecturer and Fellowship Researcher, gianpaolo.marino@polito.it

1. The “out of the box” thinking

A great breakthrough has been made in the last six or seven years, regarding the household electrical appliances; but what now seems to be arguable – maybe in function of the strong competitive advance from the East – is that the scientific community and large size producers feel they need to move proactively towards the total innovation of the sector.

The great studies carried out to improve the overall performance level of large size household electrical appliances has reached a point where most of the optimizations demanded by the market and the Law in the past decade have been achieved.

Nowadays, the market has finer products able to customize washing, optimize energetic and water consumption, without decreasing the cleaning and cooling performance quality, **reduce the use of harmful or polluting materials and many others.** The evolutionary need of the sector has led both research and production towards exploring subjects which, until a few years ago, were looked at suspiciously, as if they conceived by visionary minds.

As opposed to the early trend to focus on the performance improvement of the single electrical appliance, nowadays we tend to evaluate the evolution opportunities of the sector, in relation with the social evolution and man’s wellbeing. That implies considering the user as a main actor playing a leading role within the complex production system. We are giving birth to the first experiments in a systemic, service and energetic reuse in cascade. In short, these embryos of ideas or even these first real innovative applications, are laying the foundation for the future development in the sector.

These productive strategies, however, even though they give concrete answers to different and urgent problems of technical and legislative nature, they propose solutions in a non homogeneous way, as if they were all “watertight” sector.

What is still missing today is precisely the perception that we all need to act following a new operational scheme, exempt from pre-constituted rigid rules, which is able to address the entire productive field towards the attainment of a common virtuous goal.

Researching, defining new concepts and applying them onto prototypes or real objects, is still carried out separately: we are watching the birth of new inquiry sectors, the partial solving of issues which have been, for years, stimulating designers, researchers and industrialists. All this is, however, performed in a single way.

What becomes necessary to do, then, **is to think in alternative ways, “out of the box”**. Until now, the industrial production has always been looked at design in compliance with a planning linear vision. But the world that lies around the realization of a product (whether it is an household electric appliance or any other object), is something that is really much more complex.

The current productive regulation of linear type needs to be rethought accordingly to the evolution of the environmental, use, productive, competition and global markets complexities.

This regulation has to be readdressed towards a systemic vision.

What we need today is a sort of strategy which will be smart enough to manage all these complexities, **because we all know that every serial product can actually be regarded as an interrelated and complex component system and that the final system-object is the addition of every constituent subsystems the system-object itself is made of.**

2. A vision by components

The matter of design by components is a current investigation field particularly appealing to the designers who are asked to take part in the planning of lifelong durable goods (e.g. fridges,

freezers, television sets, computers, etc.). Such an interest has been particularly vivid in Europe especially since the introduction of two recent directives, one limiting the use of certain environmentally dangerous substances inside the appliances, and the second one regulating waste disposal (namely the 2002/96/EC *WEEE-Waste Electrical and Electronic Equipment* directive and the 2002/95/EC *RoHS-Restriction of Hazardous Substances* directive).

But this kind of interest is not sufficient to explain the operative, design, industrial and managerial complexities involved by the realization and marketing of a product. **The final product** is something that goes beyond the mere material and technological concreteness: it **is a real product-system that involves more than one operative competences and that puts into action a series of links between the physical place of production and all the parallel systems that encircle it.**

It is therefore necessary to begin with an awareness and a second consideration of the whole system components if we aim at a better understanding and plan new global strategies.

As far as the industrial products are concerned, reconsidering a system implies the analysis of the possible planning, economic, productive and environmental advantages, as all these activities are strictly related one to each other.

Like when playing dominos, we need to trigger with decisiveness and awareness the fall of the first pawn, after having patiently and ingeniously arranged the total system generated by every make up of the initial planned scheme.

The abstraction proposed by a type of design made by components – at first of material and technological kind and then of managerial and environmental quality – **makes the whole problem easy to read and analyse** (within a logical inclusion of all cultural and scientific contributions), not only by the individual designer, but also by other experts who are called for to partner him: the emerging scenario shows the features of complexity, rather than a disciplinary closure.

The question now is the following: what do we mean with the term “Design by Components” with regards to industrial manufacture?

In brief, **Design by Components**[2] **is the planning of all those intrinsically interrelated elements (namely, components) making up the system-product.**

Each system-object is, in turn, considered to be an integral element (that is a component again) of a more complex system, which may involve non only the productive realities but also those ones related to the territory, the economy, the environment as well as the society.

The Design by Components is a strategy/methodology of design developed, since fifteen years now, inside the *Politecnico di Torino* through an intense research activity mainly focused on the sector of household electric appliances that has already lead to interesting result, as we will see. It is necessary to remember that such a strategy is moreover extensible to other product categories, by virtue of its own nature of adaptability, if every industrial product is considered as a system which is, in its turn, considerable as to be a part of a more complex system.

When we talk about Design by Components we do not only make reference to the planning of the parts (both external and internal) an industrial product is made up of, as we may perceive after a first superficial reading, but we also make reference to the underlying reasoning about the system that encloses the product of which it is part and parcel.

Design by Components is, to all intents and purposes, **the up and downstream conception/planning existing behind and throughout a more complex process** that looks at the finished product as the concrete exemplification of ideas, thoughts and the more diverse

[2] For more details about the “Design by Components” methodology, please see the following papers:
Virano, Andrea. *DESIGN BY COMPONENTS. An operative methodological tool for the ecocompatible industrial design.*
Cozzo, Brunella. *MACROCOMPONENTS. An alternative proposal for the production of home integrated systems.*

strategies, all entangled and interrelated one another, in strict connection with the life cycle of the designed item.

3. The system: a new kind of design approach

It is certain that defining future developments of the planning and production concepts, as well as the environmental outcomes of big household appliances (fridges, freezers, washing machines and dishwashers), entails the opportunity to briefly figure out what the evolution in the sector has been like, in the past ten years. The lapse of time taken into consideration is the one that was marked by an increased need for talking about the issue of product ecocompatibility.

Up to the present, the diverse and complex research has been mainly focused on sartorial studies such as energetic optimization, innovative materials and performance improvements.

Today we dispose of a number of outcomes that form a very articulated working platform that has, on the other hand, no “compactness”.

This results in the need for a clear uniform future vision able to lead us towards an operation strategy for tomorrow, in compliance with a shared methodology.

Such a strategic vision unavoidably requires a change of route and, at the same time, that **the realization of an open system cannot more prescind from the fact that every actor involved by the productive chain is tied**, more than ever, **to another and that everyone must act in synergy accordingly to the concept of shared responsibility.**

Acting in agreement to this principle of “duty sharing” is not only an idea in progress but a pre-emptory concept that is pushing forward. Until a few years ago most of the states belonging to the Northern side of the world (namely the “consumerist” ones) had huge difficulties relating to the environmental subject. Apart from Europe, today the United States also have finally had to confront and admit the seriousness of the consequences raised by the enormous waste of the planetary resources, and this has inevitably caused us to be proactive, without waiting for the others to make a first move.

Designers, manufacturers, legislators, economists and not least, the end users, are the actors starring in this articulated “role-playing game” where rules have not been clarified yet.

The lack of clarity is mainly due to the fact that each actor thinks and acts to his own advantage: designers prioritise shape and functional management, manufacturers focus on investments and profits, legislators are in charge of tackling contingent problems. Users, on the other hand, expect greater comfort and premium quality, as well as competitive prices, leaving the solution of problems in other hands.

We need to understand that all the entities involved, are not separate parts, but intrinsically related elements, which are part of a complex tangle of relationships. For such reasons, a holistic approach to these problems will explain how the accomplishment of any system (in this instance that being the one of the industrial object) is strictly related to the bond existing among the actors who operate on the same level, making a synergetic attempt to achieve the final success, either from a planning, industrial or economic point of view.

The winning product is the one prioritizing the ecosystem.

In this system designers are given a starring role. They are asked to design lifelong durable goods with a lower environmental impact, as well as unalterable performances, aiming to achieve a uniform obsolescence of all materials and components. An equally important role is awarded to producers, those in the industry and financially responsible for the waste disposal of electrical and electronic appliances during the whole cycle, up to the collection centres and the final processing.

Moreover, an equal prominent role is also given to all those characters who, in some way, are directly or indirectly responsible of the management of inputs and outputs of any product from the beginning to the end of its life-cycle, in relation to those parallel systems that "nourish" the product itself or that from this latter draw the proper "nourishment".

A similar kind of scenario requires all the actors involved to have open-minded technical, strategic and ethical skills and abilities, to be receptive towards new uses, tolerant and willing to transfer know-how from one sector to another, free from all sorts of preventions and provided with all-accomplished supplementary creativity.

The data gathered from the monitoring of the sectors of small and large size home appliances which has been carried out in the last fifteen years, clearly show the road to be travelled in the future. The real novelty in the evolution sector is the one offering new open systems (where system outputs become other system inputs), enabling the relationship between the production world, the territorial and social-economic contests, the final consumer and, consequently, with the environment.

Being able to move confidently within such a complex system and, consequently, submit a joint strategy action, entails clearing one's mind, refocusing on the objectives, paying attention to the salient points that have led the innovation process of the large size home appliances in the last period of time.

4. Future development of the sector

The possible future vision is, then, **the one suggesting looking at the whole home appliance sector (and also all the other industrial production fields), under an integrated system point of view**, providing for each product not to be analysed individually, but as part of a much more complex chain, aiming to make requirements concrete and to perform in compliance with a much wider scenario[3].

Here below you'll find a possible evolution key thematic map to be faced in the forthcoming future, about:

environment

- quick adaptation skills of manufacturers to the current and future environmental rules;
- development of the idea of total integration of large size home appliances with the house water and energy supply systems;
- evolution of the reuse principle in cascade of water and energy resources which would be, otherwise, dispersed in the environment.

technology and industrial production

- improvement of the relationships occurring within the manufacturer/consumer chain, by means of the very object;
- increased efficiency during the product assistance and maintenance phases;
- overall adjustment and improvement of production systems with regard to systemic complexities deriving from the extremely articulated contemporary and future society;

[3] For more details about the "Systemic Design" vision, please see the following paper: Bistagnino, Luigi. *SYSTEMS DESIGN APPROACH.*

- development and application of wireless technologies in the service of the “ubiquitous community”, used to perform distance check of appliances (applied domotics), carried out by manufacturers and customers;
- promotions of basic and applied research to define and solve current and future problems;
- further improvement and adaptation of the technological evolutions that have been achieved until now (energy saving, noise reduction, optimal choice of materials used in relation to life-cycles), to the new systemic production perspectives.

house and society

- encouragement of cleaning and food preserving systems and services, inside town apartment buildings;
- optimization of large size home appliances, in relation to the need of diversified house space;
- focus and adaptation of the sector to the social changes with reference to the urban, suburban and rural territory.

Thinking in terms of integrated systems is undoubtedly the strongest form of innovation, an innovation which will be able to lead to a radical change of products, as strongly opposed to the mere carving of individual parts.

If we wish to achieve such a goal, we will strongly need to think:

- **that every product component will play a leading role in the future systemic development;**
- **of integrated production systems, instead of individual product chains;**
- **that the whole sector will have to be geared at supplying services in compliance with the evolution of social, economic, territorial, environmental and housing backgrounds;**
- **that the whole product park will be run aiming for a higher maintenance quality level;**
- **the production process evolution will no longer focus on the end-user company but will involve the renewed role of component designers.**

In order to boost such a modification in the current product strategies, would be necessary to move the barycentre of productive/economic interests towards a progressive rebalancing of the collaboration policies between companies, also in the case they are competitors.

A similar groundbreaking vision of the industrial world, would surely lead to a revolution of the operating strategies and positive relapses and benefits in terms of environment, economy, production and design:

environment

- to grant any kind of allowances for the firms which:

        - adopt end-of-life strategies for its own products;
        - develop new antiwaste strategies (e.g. raw materials, energy, etc.);
        - respect and apply the ecodesing guidelines;
        - conceive new monitoring and controlled checking systems;
        - develop new planning teams which may suit the new environmental demands;
    - to create a context-free legislation regulating ecosustainable planning of the product, and not just to a part of it (as it usually happens with the energetic improvements made in household appliances, in the occurrence of a planning stagnancy of the whole product);
    - to sensitize the society towards new ethically correct production strategies and new product aesthetics;
    - to support small/medium size entrepreneurs when creating and consolidating alternative markets.

economy

- reinstating jobs that were lost, by boosting maintenance of the product park throughout the use phase and the strategic management of the end-of-life cycle of products;
- rebalancing markets (refocusing production on the end user and reconverting offshore production into a new end-user, being productively identical to the initial market or totally diversified, nevertheless in line with the local economy);
- planning or revaluating a product rental service;
- promoting or launching alternative markets (eg. Second Life Markets).

production

- differentiated serial production as a mark of distinction, personalization and an added competitive value;
- revising processing cycles (which are probably more complex than the current ones);
- planning new strategies for:
    - EcoFriendly production system management;
    - planned end-of-life cycle dismissal of the product;
    - controlled distance maintenance;
- constant confrontation with production realities operating on a competing level, being alike or totally unlike one from the other, in order to boost mutual improvement, not only to compete;
- sensitizing planning teams towards:
    - simplifying connections (e.g. standardized interfaces, uniformed checks and programmes);
    - rethinking about components;
- disassembling procedures (still to be invented, through the preparation of suitable information system devices or other tools);

- assembling procedures (easier than the current ones, if everything will be planned ad hoc).

design

- rethinking about a creative process free from mere functional and formal preconceptions;
- predicting the technological updating of the product;
- proposing a new aesthetics for component-based products;
- enhancing links between users, object and industry;
- configuring the overall scheme of the uniform obsolescence of all the components;
- acting in integrated systems and not in individual parts;
- introducing the operational functionalities of a product inside the system where they occur and relating them to it;
- considering generated outputs as inputs, so as to reuse them in the surrounding context.

5. Changing the rules: integrated systems design

In the light of these observations, we will be able henceforth to act with the awareness that **all household electrical appliances are part of an integrated system (with the territory, the society, the environment, the residential units, …)** and that **they are not the mere single pieces of each production chain**, so as to originate the new product design conception of tomorrow.

On the basis of the above mentioned principles of integrated systems design, it will be possible to imagine that:

- **the fridge will need to be placed within a "food nourishing and preserving system";**
- **the dishwasher will need to be integrated in the "food cooking and eating system;**
- **the washing machine will not only have to be conceived exclusively to wash clothes, but designed as part of the "washing system".**

All these systems, bounded one to the other with a double thread by the idea of daily life (buying-preserving-consuming food, dirtying dishware, tablecloths, clothes, etc.), are in turn likely to be integrated one within the other. If each appliance is reanalysed and reconceived as the ring of a chain, and not as a separate element, we will be able to reach the goal successfully, that being the updating and evolution of the sector altogether.

Innovative ideas such as these already have some proponents in the industrial sector. During the conference *"Cambiare le regole – il settore degli elettrodomestici: un sistema integrato"* (*"Changing the rules – the household electric appliances sector: an integrated system"*) which was held at *Politecnico di Torino* in collaboration with *CECED Italia*[4] in early May 2008,

[4] *CECED Italia*: association representing the household appliance industry in Italy. It is part of the European network *CECED* (Conseil Européen de la Construction d'appareils Domestiques, namely the European Committee of Domestic Equipment Manufacturers). *CECED Italia* supports the development of the sector by activating the more effective measures in order to strengthen the positioning

Italian household appliance and component manufacturers demonstrated a strong commitment to working together to tackle the evident stall in the economy which is affecting the whole sector.

Asia's growing presence in the global market, the environmental emergencies, the impoverishment of natural resources, the strict European legislation and the overall decreasing quality and safety levels of competing products are urging industrial figures such as *Electrolux*, *Whirlpool* and *Indesit* to modify their own manufacturing strategies.

During the conference it became clear that there is a strong motivation to restore the dignity of products which are "Made in Italy" by viewing household appliances in this new manner, as integrated systems.

Among the several suggestions proposed then, it is worthwhile citing that one about the possible future re-conversion of great disused productive spaces into new places where it will be conceivable to produce reduced/required numbers of products, instead of the current large quantities; on demand, customised products to be realized with mature components by specialised staff which will be able to give the projects, once again, that special "handmade touch" which is a distinguishing element of the Italian design tradition.

The idea is to develop manufacturing plants in which more than one concurrent companies will allowed to use the same components which will be directly produced on site or in nearly placed production plants.

A similarly innovative manufacturing strategy using "integrated systems clusters" would permit greater efficiency in the monitoring and handling of both up and downstream processes, thereby reducing wastage of raw materials and energy. This type of strategy also means that larger numbers of producers, component manufacturers, designers and technicians could work together in accordance with the above mentioned principles of shared responsibility, with the aim of combining the synergies of multiple industrial powers to improve overall quality through an increased focus on customer service and environmental awareness.

This sort of revolution of the industrial mentality will certainly be neither easy nor immediate. In the years to come, it will be necessary to predict and plan all the constituent parts of a product, their materials, duration, replacement and all there is to know about the life cycle of an object. Indications are still rather uncertain, technologies and materials keep on changing a lot faster and more deeply than social, cultural and production changes.

Facing the infinite opportunities offered by technological innovations, industrial culture and design will point out the need to assume our own responsibilities, as being able to choose forces us to plan at the same time all the variables that are part of production and dismissal of the objects on many levels.

In conclusion, it is mostly up to the large size industries to make the sharpest change and to drift away from the logics of goods designed for the end markets, by focusing on the technical and quality evolution of components and by changing the production rules in favour of systemic strategies deeply integrated with their own territorial, social and economical contexts.

of Italy – which is one of the world-wide leaders in this line of business – within the international market. The association actively promotes the dialogue among all the Italian interlocutors as well as, together with *CECED*, between these latter and the national manufacturers and the rest of the European/international Institutions.

DESIGN VISIONS PROPOSALS AND TOOLS

MetaCycling

Extending Products' Life Spans Using Virtual Communities and Rapid Prototyping

Philippe Lalande[1], Martin Racine[2]

Abstract

This research paper introduces the MetaCycle project, which aims to optimize the creative potential of designers by reuniting them within a virtual community serving the common objective of prolonging the life span of consumer products. The goal of this virtual community is to develop an interactive framework through which consumers can benefit from unique and innovative updates to products that are reaching the end of their useful life. Relying on the exploitation of Rapid Prototyping (RP) technologies, the pooling of a large number of creative minds also allows the generation of a new category of unique products. This paper covers the theoretical and practical aspects of establishing an appropriate web interface for the creation of a Metacycling community.

1. Introduction

For the last forty years, many critics have voiced concern over the damaging effects that the growth of consumerism was having on the world's ecosystems. A number of insightful designers were particularly present among these activists decrying the wasteful habits of industrialized countries and criticizing their underlying values. Representatives from the various design disciplines have been pointing out the fallacy of the idea of progress as being dependant on unending growth and in demonstrating that increased exploitation of the natural world without regard to impacts on the environment will inevitably lead to both depletion of non-renewable resources and poisoning of the planet through increased production of toxic pollution. Jane Jacobs argued that architects were destroying the ecology of the built environment through the promotion of urban sprawl (Jacobs 1961). Victor Pananek leveled his criticism directly at designers themselves (Papanek 1984). He accused the profession of being instrumental in the suicidal race towards ecological disaster by contributing to the relentless rise of consumerism. At an even earlier date, Buckminster Fuller, through his writings and his innovative projects, argued that engineers and architects should adopt building methods based on those of the aircraft industry (Fuller and Meller 1970). He proposed that these could economically and efficiently replace traditional building crafts in the creation of shelter for all.

Progress has been made since then, but not sufficiently to offset the increased demand of developing nations. In this new context, designers need to play an ever more important role in putting forward proposals for changes that will increase the efficiency of our means for production and reduce the negative effects of society's excessive consumption.

Today, several promising initiatives have been proposed to tackle the problems engendered by increased consumption of durable goods. The term durable, used to qualify products meant to outlast a single use, has in fact become inappropriate to describe the vast majority of industrially produced consumer goods. While these may be categorized separately from "throw-away" products, they are anything but durable and all too soon find their way to the trash bin. So far, most of the proposals meant to increase product longevity, revolve around the concept of re-use, which considers used products or parts of products as potential raw material for new products. Websites such as Reddish Studio (http://www.reddishstudio.com/furniture/ bathandbeyond01.htm) and Design WS (http://www.designws.com/pagina/1jorre08.htm) present the results of creative efforts aimed at finding a new use for old parts, while "Can You Recycle This" (http://www.recyclethis.co.uk/) not only solicits solutions, but also suggestion of products in need of being re-used. Re-use also has its niche markets; Ikea Hackers (http://ikeahacker. blogspot.com/) showcases new uses for used Ikea products. The principal advantage of re-using as opposed to recycling, where products are disassembled and channeled back into the stream of raw material production, resides in the retention of the material's physical and chemical properties as well as its geometry (McDonough and Braungart 2002). These dimensions can collectively be considered as embodying "design intention" and represent value, which is lost in the recycling process. Their conservation, however, imposes severe demands on the creativity needed to build these parts into a new product.

The originality of the Metacycle approach is in the application of digital technology, particularly that designated under the term "Rapid Prototyping", as a means of facilitating the re-affectation of old products to new uses. It is along this axis that our

research efforts have been directed, linking various digital technologies with modern social phenomena in an effort to prolong the life span of manufactured products and thus reduce the deleterious effects of over consumption.

Rapid Prototyping (RP) defines a number of different technologies that share the capacity of producing three-dimensional, geometrically complex physical shapes directly from a computer modeled 3D digital file (Burns 1993). Typically produced with 3D Modeling software, a file describing a part is sent to an RP machine which “prints” the object, layer by layer, without any human intervention. Developed over the last twenty years, a half dozen technologies have reached commercial maturity, each one operating according to different physical and chemical principles and each one producing parts in a different range of materials including various thermosetting and thermoplastic resins, metals, sand, wax and plaster. These RP technologies are principally employed for the production of models used in various phases of new product development. However, a small and growing area of application is in the production of parts for final use. This is the domain occupied by the Metacycle project, which proposes that parts produced by RP technologies could be used in conjunction with existing parts from used products in the design of new products.

The premise at the root of this research concerns the organic nature of manufactured objects; like living things, objects can change over time. Jonathan Chapman considers that a product’s life span is determined in large part by the attachment linking it to its user and that this could be enhanced by the product’s ability to evolve and change over time (Chapman 2005). While this ability is often seen in the area of software design (Winograd 1996) where updates, patches and versioning enable programs to evolve not only to correct errors but also to meet new needs, some researchers, such as Neil Gershenfeld (Gershenfeld 2000) and Donald Norman (Norman 2005) have made attempts at transferring this aptitude to physical objects.

This paper describes research aimed at establishing a network of designers applying their creativity to proposing how existing objects could be enhanced and modified in order to take on a second life. In previous work (see http://preco.ca), the researchers established the feasibility of using digital manufacturing technologies and in particular RP for repairing products. They took this to a second level in META[morphose] (Lalande and Racine, 2006) by experimenting the application of RP to the up and side grading of products, thus enabling them to evolve. Metacycle configures this technique into an operational framework by creating a virtual community of designers linked by their common interest in the creation of new products from old. This process of mass canvassing, dubbed “Crowdsourcing” by Jeff Howe, one of its earliest proponents (Howe 2006), challenges the authority traditionally accorded to individual experts and, in its place, sources a wide basin of unfiltered talent in the quest to solve difficult design challenges. Used extensively by commercial enterprises such as IBM and Dell (www.DellIdeaStorm.com), virtual communities are a growing phenomena that transcend strictly economic imperatives to include political, social and even ludic activism (www.thinkcycle.org, www.facebook.com, www.secondlife.com).

2. Methodology

The methodology used was a form of action research. It is through this design project that it is hoped to better understand the implications of attachment between users and objects. By asking people to participate actively in the design of second lives for their everyday possessions, information will be gathered pertaining to the benefits and the limits of a community approach to eco-design and the value of the internet for fostering user participation in the design process. The Metacycle website is intended as a research project on collective sustainable initiatives. Thus, it is proposed to make “Metacycling” a verb of action.

To create this creative community focused on giving a second life to everyday objects, the first task was to design the website in such a way that it could accept and manage the creative ideas of the public (Figure 1). For this, an area was developed called the Design Lab where users could actively participate in the design process. In order to get a quick overview of what this project implies, participants are first invited to the Explore Ideas section where they can browse concepts that have already been submitted (Figure 2).

At the same time, this section enables voting on a scale from 1 to 5. Not only is this the first possibility of active participation, it is also a means of better understanding what the crowd considers a strong Metacycle idea. Additional information can be obtained on each of the ideas presented in a full-page detailed description.

After satisfying their curiosity, users move on to the Solve Challenges section of the Design Lab which presents 10 objects that are Metacycling challenges. The Metacycle team carefully chose 10 difficult to recycle objects: toothbrushes, VHS cassettes, hockey sticks, computer mice, swimming goggles, markers, flashlights, Walkmans, cell phones and thermoses. After having chosen a challenge, additional information pertaining to the size, materials and other characteristics of the object is presented with a reminder of the Metacycle guidelines: “Revitalize Functionality, Maximize Reuse, and Reduce Waste and Energy”. After having accepted the Creative Commons terms for the non-commercial use of their ideas, users can submit their images, models and/or instruction manuals. This content is automatically uploaded into the Explore Ideas section for others to browse and vote upon. If ever an idea gathers a large amount of positive feedback, the Metacycle team will promote it into the third and final section of the Design Lab labelled Featured Solutions.

A MetaAward logo is apposed to the idea profile and depending on the design development required, a possible production is envisioned with Rapid Prototyping technology. In summary, the Design Lab helps participative users along the design process in going from inspiration by exploring ideas, to ideation in taking on a challenge, to production of a featured solution.

On another front, the Metacycle website documents the foundations of the research. This second part of the website presents the background information and the goals supporting the efforts invested in developing the Metacycle project. Not only is it oriented towards other researchers who wish to learn more about the Metacycle project, but more importantly, it is intended to inform the creative users who are attracted by the participatory nature of this project. In one section, information about the earlier research efforts in Préco and Metamorphose is provided as well as the background of the research team. Another section presents the lab facilities and the technologies that have been used throughout these research endeavours. The eco-design section showcases the evolution of the environmental practices. The past was characterized with the idea of the 4 R’s: Reduce, Reuse, Recuperate and Recycle. Present-day strategies emphasize sustainable product development like design for disassembly and life cycle analysis. In the future, not only will the tools of the present help create more sustainable products, but also, design research is seeking ways to increase the emotional relationship between products and their users. The research aspect of the Metacycle website ends with technical, ecological and licensing guidelines to help participants optimize their design efforts. Primarily, the research section aims to inform and encourage participants so they can engage themselves into the Metacycle initiative.

The launch strategy of the website contains three distinct stages: the pilot project, the soft-launch, and the official launch. As the pilot project, several groups of design students were asked to upload ideas and suggest interface improvements. This proved

to be a valuable source of feedback for the Metacycle team on two different levels. For one, the students were able to assess the clarity of the information presented and the usability of the website interface and secondly, the Metacycle team was able to evaluate the presentation and content of the uploaded solutions. This pilot project led to numerous interface improvements and provided the validation that on a small scale and with a controlled sample, the website was an effective tool to collect promising second life design ideas.

To launch the Metacycle project on a wider scale, the Metacycle team will hold a design competition entitled, *Ideas Wanted.* This competition will act as the soft-launch of the Metacycle website. The competition will be promoted internationally to most design and creative communities using the Internet as the principal pipeline. This will be the first time that the general creative public is asked to join the Metacycle community and participate in the project. The primary goal of the competition is to start nourishing the growth of the Metacycle community and to encourage participation in the Metacycle design lab. The secondary goal of the competition is to have a Metacycle success story - an idea that was initiated as a result of the Metacycle project and that shows promise to revalorize a large quantity of objects.

The competition asks users to choose one of ten selected objects and to transform it into a new, functional and eco-responsible product. The only imposed restrictions are that the concept must be original to the participant, it must be posted in the Metacycle design lab, and the presentation must contain at least one descriptive image. Otherwise, despite encouraging near-professional design caliber and graphically strong presentations, all ideas will be accepted regardless of level of development, clarity of presentation or form of communication (sketch, computer rendering, photograph or other). As soon as the idea is posted to the design lab, it will be visible in the explore ideas section where participants will have the opportunity to see all previously posted entries as they brainstorm and develop their own idea. Furthermore, the public can rate the uploaded ideas so participants will be able to see which concept is the current public favorite. This should bolster the participants' motivation to submit competitive concepts.

Once the competition is closed, however, the official winning idea will be chosen by a jury, independent of the public vote. The ideas will be judged on four main criteria: functionality, the new object must respond to a real need; ecology, the transformation leading to the new product must reuse a maximum of existing materials, produce a minimum of waste and require as little energy as possible; creativity, the proposed idea must be original and elegant; and feasibility, it must be possible to develop the proposal within the context of today's economics and technologies. As the grand prize, the winning idea will be developed by the professional designers of the Metacycle team and a physical model of the concept will be produced, a service valued at more than $15,000 CAD. Because all commercial rights will remain the property of the participant under the creative commons non-commercial license, the winner will then be free to exploit his or her professionally developed concept as they wish.

It is hoped the soft launch will generate a wealth of information for the Metacycle team. The ideas posted to the site will begin to reveal the nature of the content that can be expected from community design participation. The community will show whether they are more inclined to describe their ideas with a simple sketch, or display a 3D model of a component that would need to be rapid prototyped, or even post pictures of an idea they have already executed. Also, the success of the promotional strategy, competition format and incentives for participation will be evaluated. The results should offer valuable information for development of the official launch which will be a high profile competition slated for the fall of 2008. Lastly, the nature and quality of the submitted Metacycle ideas will be analyzed to evaluate the commercial potential that the

Metacycle community holds and to nourish a reflection on possible business models for the project. One of the goals of the Metacycle project is to create a long term, self-supporting initiative; one which is commercially, ecologically and socially viable.

3. Results

One of the principal qualities sought of the ideas submitted by the Metacycle community is design integrity. Particular attention was focussed on attaining this goal both in the design of the website interface and in the identification of the initial target audience. While the site does offer some guidance for participants in terms of RP technology and the satisfaction of user requirements, the level at which this information is provided is aimed at encouraging those with at least basic design abilities and aesthetic sensibilities. A second factor mediating in favour of design quality is found in the initial Metacycling examples posted on the website. The thirty-three proposals with which the site was seeded originated from design students and design professionals.

They were developed over a two year period as part of the research project prior to the launching of pilot version of the website. Betraying their origins, they all show an advanced degree of design definition which, it is hoped, will influence the quality of future content. The effectiveness of these levers in maintaining a satisfactory level of design integrity in the pilot project will be one of the factors which will be closely evaluated before opening the site to a general public. The researchers seek to attain a just equilibrium between an open access to large numbers of participants and a high degree of design integrity in the solutions proposed. A final controlling mechanism geared at promoting design quality is found in the third section of the Design Lab, labelled Featured Solutions. This area will showcase mediated solutions offering the most promising technical, aesthetic and ecological features. The Metacycle team will have full authority in the selection of solutions highlighted in this section in spite of the ratings compiled from public voting.

A second factor which will be attentively examined as a result of the pilot project is the size of the development gap to be filled in bringing the conceptual Metacycling proposals to eventual production as valid solutions. This gap is particularly important in view of the objective of assuring the Metacycle community with long term stability. It is recognized that this objective is strongly dependant on the implementation of an appropriate business model which will undoubtedly rest on the exploitation, in one form or another, of the proposals generated by the Metacycle community. Initial examination of the seed projects has led to variable results in this respect. The feasibility of some proposals would appear considerably uncertain while others would seem very easily put into production. The narrowness of the development gap will probably be a variable to be factored into the selection of proposals to be included in the “Featured Solutions” section.

Initially, all ideas submitted to the Metacycle website are subject to a Creative Commons intellectual property license that permits idea remixing and/or redistribution for non-commercial purposes only. The purpose of this license is to encourage the promotion and use of the open source design content available on the website while at the same time reserving commercial rights to the originator of the idea. The rights to any added value would, of course, be retained by the author. In other contexts there have been examples where well known brands have forbid the resale of their products if the original intended use has been altered. Despite presently not intending to sell Metacycled objects on the website, the Metacycle team will respond to such action, should it arise, on a case by case basis.

Any initial business model will be designed to evolve as the website and Metacycle initiative grow and develop. The principal goal of the Metacycle community is to provide an interactive framework in which designers can help each other and their fellow users to benefit from innovative, open source designs revitalizing their end-of-life

products. Originating as an online framework, it is envisioned that Metacycle participants eventually interact outside the alternate reality of the internet and come together at Metacycle design expositions or interactive design fairs. Certain ideas may be recognized as having enormous potential if properly executed on a larger scale, possibly Metacycling thousands of otherwise useless objects. In such situations, any potential commercial value and appropriate action will be evaluated accordingly. Business models based on crowdsourcing design content are currently being tested by such sites as http://ponoko.com. Aside from commercial exploitation, Metacycle could be supported by partnerships with companies who recognize the importance of extending the useful life of their products. Recently, Citroën sponsored a design competition that asked designers to transform 3D components from its cars into new designs of everyday objects (http://www.aedo-to.com/citroen/eng/index.htm). Such companies could use the Metacycle community as a tool for reducing the environmental impacts of consumption. The Metacycle emblem, a stylized butterfly, embossed on a product, might one day remind consumers that a second life for the product in their hands is but a few clicks away at Metacycle.ca

4. Conclusion

The objectives of the Metacycle project are to limit the extremely negative environmental impacts caused by prematurely discarded products. In a recent study by the Québec Provincial Government (see http://www.cyberpresse.ca/article/20080226/CPENVIRONNEMENT/802260835/6730/CPACTUALITES), it is noted that 59% of all electronic apparatus end up in landfills, 20 000 tons in 2004. This trend is accelerating every year as products are becoming ever cheaper and are offered in an ever wider range of styles and colours. At the same time, the lifespan of electronic devices is getting shorter as new features are being introduced on a monthly basis. Once in landfills, these products contaminate soil and water with toxic chemicals including lead, cadmium and mercury.

In an increasing number of countries, governments are introducing legislative measures to force manufacturers to take back and recycle their products after their useful lives. This is good news, but those measures will take time to implement and only target electronic devices. We need an alternative to the current "throw away" model applied to all the types of products we use in our daily activities. Metacycle is a search for such an alternative, encouraging designers to look at discarded products not as waste, but as a resource for developing new useful applications and thus extend their life-span.

Although the Metacycle initiative is based on positive ecological principles, it has its limits. Over-consumption and planned obsolescence are not directly diminished. Metacycle could be perceived as attempting to find solutions once the problems have occurred, instead of addressing the issue of creating sustainable products in the first place. This type of initiative should definitely not prevent designers and manufacturers from attempting to create products with less impacts on the environment, "from cradle to cradle" as McDonough and Braungart would suggest (McDonough and Braugart 2002). In spite of these limits, Metacycle sends an implicit message, which is to underline the irresponsibility of discarding products that still have the potential of being useful, playful and ingenious. It relies on creativity and social exchange to stimulate innovative practices and positive behaviours. It can be used as a tool enabling the general public to give a second life to products and encouraging sustainable consumption.

Moreover, giving the general public access to Rapid Prototyping technologies is one of the unique aspects of the Metacycle project and makes it clearly distinct compared to other initiatives, which generally favour the "Do it yourself-DIY" strategy in order to give second life to discarded products. Our previous research project (Meta-

morphose.ca) led us to evaluate positively the benefits of RP for generating 3D parts. For example, we have exploited the potential of RP to produce joints that adapt perfectly to the form of existing objects. Therefore, we can imagine creating RP parts that could connect a number of plastic pieces together in order to create new objects, such as lampshades or construction kits. Very often, we have noticed that the challenge behind the reconfiguration and reuse of existing products is to connect pieces that have different and complex geometries and that were not initially designed to be assembled to other parts or products. Thanks to their facilities, the Metacycle team can produce parts using their own Rapid Prototyping lab and send them by mail to the interested users who will place their orders on-line. Eventually, as the Rapid Prototyping services expand, people will have the option of downloading the 3D model directly from the site and have it produced at their local RP service bureau.

Undoubtedly, RP has immense potential and opens a whole new opportunity for the reuse of objects. The main challenge however, is to communicate to non-designers the principles of Rapid Prototyping and its different technologies (STL-stereolithography, FDM-Fused Deposition modelling, SLS-Selective Laser sintering, etc.). It is clear that such techniques are still quite uncommon for the general public, while a majority of people still ignore the sole existence of such technologies. This is why the team of professional designers behind Metacycle is key to support the site. The team's role is to seek the most interesting and creative concepts with the help of the public's vote, and to develop the potential of a posted idea. For the benefit of the Metacycle project, it seems important to focus on innovation and avoid having the technical aspects of RP impose a limit on the creativity of the virtual community. As the site evolves through time, it is hoped that a number of successful projects will be developed and then featured on the site. In the long term, those featured projects will help the public understand the potential of RP and educate the users with regard to this new technology for extending products' life spans.

Criticality Meets Sustainability

Constructing critical practices in design research for sustainability

Ramia Mazé[1]

Abstract

Sustainability requires a wider awareness of the changing conditions for design today – rather than focused solely on preserving nature or conserving energy, per se, this opens up for challenging assumptions about relations between design and society and for constructing new forms of critical practice. Tracing tendencies in conceptual and (post)critical design, this paper argues for further developing the critical discourse within design today and design research as an important arena for extending the ideological and artifactual production of such discourse to users and stakeholders. In relation to my own experiences within the Static! and Switch! design research programs, these perspective are anchored in conceptual, operational, and practical examples of critical practices applied in the area of energy awareness.

[1] Interactive Institute (SWEDEN) – Design Research Unit. PhD, Senior Researcher and Project Leader, ramia.maze@tii.se

1. Introduction

While often at the forefront of expanding material consumption, designers are now increasingly facing the issue of how to achieve the opposite. The disciplines of industrial and interaction design, for example, grew up around interest in increasing the profitability of the emerging electric and electronics sectors – but, today, the challenge is to change reverse behavioral patterns of energy (over)consumption. Particularly as other parts of the world are rapidly growing in design competence and consumer power, is time to rethink how the powerful and persuasive forms of design might be redirected to critical practices of design and research in the area of sustainability (Buchanan 1989 ; Redström 2006). Just as product and interaction design have helped introduce the design products that we depend upon today, researchers and practitioners in such disciplines must participate in a raising awareness about the consequences of design production and consumption.

Design has long been about the expansion of material welfare. On behalf of clients, design is bound into larger projects of continually increasing economic and symbolic capital. Design is no longer, if it has ever been, solely about satisfying basic human needs of an individual or society, but also about creating needs and even manufacturing desire. However, the reality of limits to the environment – limits to the availability and resiliency of physical resources – also suggests limits to an economy based on the exploitation of such resources (Manzini 1995). Sustainability, and related arguments for an ethical, humanitarian, and critical role for design in society, presents certain challenges to the idea of design only ever ‘in service’ to expanding production and consumption at the cost of the environment (Mazé 2007). Such challenges suggest the need for an increased intellectual and ideological reflexivity within design, as a basis for changing ways of thinking and acting within the discipline as well in relation to clients and consumers.

There are a range of existing and emerging responses to the challenges of sustainability in design. With respect to the problematics of material exploitation, for example, there are calls to shift design thinking away from the production of the ‘new’ towards the revaluation of existing material goods, for a closed and continuing loop of material production, recovery, and remanufacture, and for moving from a materials economy altogether. As some turn towards immaterial design, others return to materiality in terms of the longevity, durability, and sustainment of things through use, interaction, and engagement. Others argue that sustainability is not only a question of material resources but of psychological endurance and sociological durability, through which products are sustained within social practices of consumption. (Chapman 2005 ; McDonough 2002 ; Shove 2003 ; Verbeek and Kockelkoren 1998)

This expanding range of perspectives challenge established notions of what design should be about, and also imply increased interactions with other domains of knowledge and systems of production. In order to understand and craft things with increased and lasting meaning, it seems that designers might need to relate to ideas perhaps more proper to psychology, sociology, anthropology, and material culture. Since designers must not only take into consideration immediate design process and discrete design objects, but effects and consequences that might arise long after, they might engage more extensively ideas about ‘futurology’, ‘futures’, and ‘foresight’ more familiar in the domains of business, economics, and politics. Extending far beyond the established knowledge tradition within design, this requires that

design relate critically and productively to theories and practices in other disciplines without sacrificing disciplinary integrity.

Constructing critical practices in design research for sustainability

This paper traces one approach to design research for sustainability, drawing on a history of conceptual and critical tendencies in design that employ design materials and form for purposes of 'problem-finding' in disciplinary discourse and wider society. Arguing against design 'in service' to ideas imposed from outside and above, critical architecture and anti-design have been arguing since the 1970s for an ethics and ideology proper to design – "Otherwise we will end up by designing beautiful electric chairs or mountains of rubbish," as Superstudio proclaimed (Lang and Menking 2003, 120). Through such retrospection, we might draw out strategies for designing for 'poetic'- or 'critical distance' between design products and those who encounter or consume them, a distance that might enable reflection or debate on sustainable issues. Indeed, this has influenced how we have related to material expressions and interactions in a design research program that is described further in this paper.

Further, critical practices also expose certain possibilities and problematics for design research. Such critical practices have been reconfiguring the relation between theory and practice, both for purposes of building an intellectual and ideological foundation within and proper to design and also for relating to critical and social theory from other disciplines. Further, contemporary conceptual and (post-)critical practices argue not for criticism or evaluation of past or existing things but for the proactive production of new and alternative ideas, an ideological and artifactual production concerned with materializing a 'criticism from within' one's own discipline. Alongside theories that have become some of the critical terms within design discourse, the growing discourse around sustainability constitutes another and essential set of relations that we must find rigorous and generative ways to incorporate into our thinking and making. Given the problematics of (inter)disciplinarity, this requires new and means of constructing and conducting critical practices in design research.

In recent years, I have been part of a collaborative effort to develop design research programs related to sustainability at the Interactive Institute in Sweden (www.tii.se). Since 2004, we have grown a relationship with the Swedish Energy Agency (Energimyndigheten) to inquire into how design and technology might effect energy awareness and behaviors. This has been the focus of two research programs, Static! and Switch! that are presented in this paper. While discussions of Static! as a whole, and the individual prototypes created within, have been presented elsewhere (among others, Backlund et al 2006), this paper draws out some of our thinking behind the program in terms of 'critical practice' and discusses relations to paradigms of practice-based research in the applied arts (see also: Mazé 2007 ; Mazé and Redström 2007). Further, this paper draws out issues from Static! and its relation to critical practice and extends these to describe our approach to our current program called Switch!

2. Critical practices

Design is located in an ambivalent place, wavering between the concerns of culture and capital, which may be more decisively dealt with in other fields. In architecture, for example, criticality has a vivid tradition since a dramatic rethinking in the 1970s of criticism and critical theory within the discipline and within the profession. While contemporary architecture seeks to escape the rigorous and restrictive criticality of the past, product and interaction design are only beginning to feel out intellectual and ideological underpinnings. As John Thackara notes, “Because product design is thoroughly integrated in capitalist production, it is bereft of an independent critical tradition on which to base an alternative” (Thackara 1998, 20). This lack would seem to pose a challenge for designers looking for alternative tactics and values than those present in mainstream production and consumption – indeed, such alternatives might seem essential to sustainable design today.

(Post-)Critical architecture

In architecture, critical discourse has been an arena for developing relations to theory – or, more precisely, ‘Critical Theory’, posed by the Frankfurt School, and ‘critical theories’, as more generally refers to subsequent poststructural, feminist, and postcolonial theories. Based on structuralist thinking, the debate in the 70s ended an ‘era of manifestos’ (generally characterized by a few polemic positions and loose relations between theoretical rhetoric and practical reality). The debate was an attempt to separate ‘operative criticism’ or ‘instrumental theories’, located within inevitably biased positions within professional practice, from theories originating from and operating without, for example in historical or philosophical projects. An outcome of this debate was the emergence of what has been called ‘critical architecture’, concerned with excavating a ream of autonomous knowledge proper to the discipline of architecture. (For background to this discussion see: Allen 2000 ; Hays 1999 ; Hays 2002 ; Rendell, Hill and Fraser 2007)

Examples of critical architecture, such as deconstuctivist works, operate through strategies such as the systematic reversal or transgression of the visual and spatial expectations of form, experienced as an disorientation of cognitive and perceptual faculties. More recent approaches resist negating or inverting norms, constructing a more subtle interplay of historical, social and spatial factors to expose and alter the construction of different sites and situations in terms of power, gender, or class. Inherent in strategies associated both with the ‘critical’ and ‘post-critical’ is the use of built form to evoke a conceptual attitude or experience. Where deconstructivism tended to posit the building as a text, which might then be ‘read’ in terms of norms and their rupture, other strategies might be understood as a sort of ‘embodied conceptual art’, in which bodily performance takes precedence.

Theory has a role in establishing a ‘critical distance’, whether this is distance from mainstream practice or from other related practices, and defining an attitude or position in relation to the conditions within the discipline and those circumscribing it from without. In this sense, criticality, as deployed in architecture, has a purpose and a context, expressing a point of view as a response to existing conditions. Further, as Michael K. Hays articulates, “Critical theory… provides a chance to reflect upon what there is, but also to imagine something different – to question and transform rather than describe and affirm” (Hays 2002, 148) The term ‘critical’ can be posited as “the constant imagination, search for, and construction of alternatives” (Hays 2002, 326), the variety of (post-)critical practices within architecture open up a space for architectural

practice as an arena for conceptually and physically ‘constructing doubt’ within the observer or inhabitant as well as making ‘forceful propositions’ about alternative or future realities.

Conceptual and critical design

In other fields of design, such as the relatively new fields of industrial, product, and interaction design, the basis for criticality is less definitive. At the same time as post-critical architects are reengaging with the material, procedural, and political conditions that circumscribe the profession, product and interaction design are attempting to establish critical terms and construct theoretical bases. As market logics and popular culture have long determined almost all of what happens within product design, designers are seeking and creating alternatives. There are a range of perspectives in contemporary design – amended as ‘conceptual’ or ‘critical’ – that draw on a heritage in radical crafts, anti-design, and critical architecture to diversify or counter mainstream design. (For background to this discussion see: Blauvelt 2003 ; Dunne and Raby 2001 ; Kristoffersson 2003 ; Robach 2005)

Conceptual design draws on the strategies of conceptual art, shifting focus from the maker and the object to the concept behind. Aaron Betsky characterizes the task of conceptual designers such as Droog as "as gathering objects on the streets and reusing them, with the designer adding only something invisible: the concept" (Betsky 2001, 51). High and low materials, precious substances, readymades, technology and trash, may be combined to expose issues of ‘taste’ and ‘good’ design – even material scarcity may speak to ethics and (over-)consumption. Dunne & Raby posit the designer as a sort of ‘applied conceptual artist’, drawing on critical theory and modernist aesthetics to challenge assumptions of ‘utility’ and ‘usability’ in industrial and interaction design. While relating directly to everyday life and utility, conventional terms are revealed to be essentially contested, along with related traditions of judgment in art and design (history) discourse or of technical rationality and scientific positivism. Rather than ‘in service’ to culture or capital, design form and craft are viewed as vehicles for ‘problem-finding’ – rather than ‘problem-solving’ – within disciplinary and societal discourse.

Even as these tendencies engaged with social and political theory, the activity and materiality of designing are nonetheless seen as the basis for ‘active critical participation’ (to borrow a term from anti-design) in larger ideological systems. From modernist aesthetic theory, for example, strategies of decontextualisation, defamiliarization, and estrangement are applied to discourage unthinking assimilation and promote skepticism by increasing the poetic distance between people and products. Such techniques are not merely applied for purposes of analysis or commentary, but for crafting constructive counterproposals and projective critiques. Made concrete in experiential and material form, socio-aesthetic theories from (post-)modern discourse are embodied to interject a critical distance or resistance to easy assimilation between ideas and things. Design form opens up such critique for wider speculation and debate – beyond ‘problem-finding’, conceptual and critical design might be said to ask questions and open these up to designers, clients, critics, and users.

Research through (critical) practice

In the terms of research most established in relation to design, those of history and theory, developing an ‘intellectual stance’ within a discipline requires the development of a relation to critical and social theories on the terms of historiography and philosophy. These were certainly the terms that have preoccupied such a discussion within architecture. However, even within this

discussion, alternative conceptions were being proposed and acted upon. Proposing a notion of ‘criticism from within’, for example, Jorge Silvetti argued on behalf of establishing a relation to theory and ideology through the languages proper to architectural practice – that is, the activities, mechanisms, logics, and forms of making (Silvetti 1977). Rather than the study or criticism of architecture, this posits a notion of criticism as architectural practice and in the form of architecture.

Along the lines of Christopher Frayling’s distinction (based on Herbert Read) between research *into*, *through*, and *for* design, a possibility is opened for knowledge structures and production by means of design processes and products (Frayling 1993/4). Indeed, central to critical practice as discussed here is engagement with the conceptual realm of design. While design craft, techniques and form remain central, these are employed to direct attention to the ideas and ideologies behind and beyond the object in and of itself. In Dunne's case, “the electronic objects produced in the studio section of his doctorate are still 'design,' but in the sense of a 'material thesis' in which the object itself becomes a physical critique... research is interpreted as 'conceptual modeling' involving a critique of existing approaches to production/consumption communicated through highly considered artifacts” (Seago and Dunne, 1999, 16-17). Indeed, the artifact produced within critical architecture and design might be considered as a materialized form of discourse.

Explicitly dealing with the materialization of concepts, theory is engaged not only in external or retrospective descriptions, but as an integral part of the design objects as such. While criticism of design can only happen after and about an object that has already been designed and materialized, this opens up for another form of criticality. As Jane Rendell articulates, “Projects that put forward questions as the central tenent of the research, instead of, or as well as solving or resolving problems, tend to produce objects that critically rethink the parameters of the problem itself” (Rendell 2004, 146). Resulting objects may not solve or resolve problems that might the focus in professional practice, but operate to open up and expose problematics. While it may not be up to design to solve or resolve the complex problematics of the ‘prevailing order’ that circumscribes the discipline and the profession, design may expose and articulate these in ways that make them more accessible to understanding – and to change.

Constructing critical practice

Past conceptions of criticality (such as those debated in architecture in the 1970s) relied on distinctions between different disciplines and disciplinary concerns. For example, borders might be defended or challenged in terms of discrete ‘systems of production’ – that is to say, the concerns, techniques, and knowledge proper to one discipline that might distinguish it from others. Separations between history, theory, and practice were made in order to distinguish respective theoretical frameworks and knowledge interests proper to each. Further, each discipline could be seen as a system of production in and of itself, defined by a distinct and autonomous set of normative features, upon which a critical relation or knowledge exchange between disciplines might be based. Indeed, (de-)constructing such distinctions may be important to a disciplinary project – just as architecture is currently seeking to ease the borders separating theory from practice, newer fields are seeking to establish knowledge foundations and disciplinary boundaries.

However, the contemporary situation of design research and sustainable design are more aptly characterized in terms of multi-, inter-, and trans-disciplinarity. Further, in (post-)critical practice, the interpenetration of theory and practice in the processes and products of design renders such distinctions difficult and perhaps counterproductive. This implies a need for other

approaches to constructing critical practices of design and research. One such approach has been developed by Thomas Binder, Johan Redström, and colleagues (Binder and Redström 2006) that characterizes examples of design research that will be described in the next section.

– Research program. As an alternative to disciplinary distinctions, the research program acts to frame a 'provisional knowledge regime'. The program refers to a set of theoretical and experimental strategies and relations between, a set that is relative rather than absolute but that nonetheless functions to frame a common ground for constructive and collaborative work.

– Experimental design. Driving the program are a series of practical experiments that inquire into and exemplify various concepts and questions set out in a research program. The purpose of experimental design is not to operate as a proof or test of the program, but to learn about, reflect upon, and challenge certain conceptions. The relation between an experiment and the program, and between experiments within a program, provides significant basis for knowledge production on a (transdisciplinary) basis.

3. Criticality meets sustainability

On the surface, sustainable and critical design might seem to be at odds. Indeed, the concerns of 1960s ecological, organic, and pacifist movements were not necessarily congruent with those of contemporaneous radical and anti-design (Burkhardt 1988). Where green and sustainable design may earnestly try to solve pressing, large-scale problems, conceptual and critical design embrace irony, complexity, and ambiguity in order to ask and pose, rather than solve or resolve, questions. However, sustainable and critical design intersect in contesting – rather than affirming or acquiescing to – mainstream or traditional notions of production and consumption. Starting from this shared concern, the intersection of criticality and sustainability might contribute to the ideological foundations in design, as discussed in the previous section, and expand strategies from critical practice to design research for sustainability

Located at a critical distance from mainstream design, and from typical approaches to sustainability, a space is opened up in between, wherein a spectrum of new possibilities might be investigated. It is precisely these possibilities that we have been probing into at the Interactive Institute. For some time, we have been interested in conceptual and critical design strategies to materiality and aesthetics, as well as how the spatial and temporal aspects of designed and interactive forms relate to more existential issues, such as the emotional, ethical, and social values embedded in technical systems. Further, we are interested in how to relate to use as an ongoing achievement, a form of 'active critical participation' (to borrow a phrase from anti-design) involving agency in continually reinterpreting and reflecting on things. Thus we are interested in moving critical practice beyond 'problem-finding' for its own sake but in how questions might be opened up and passed along for reflection – as well as debate and choice – among users and stakeholders.

This means that design cannot only enquire into the conditions for design – those that circumscribe practice and comprise form – but must consider how critical practice and alternative aesthetics condition use. Further, design may materialize 'forceful propositions' about concerns located outside of design – such as sustainability. These are some of the starting points for Static!

Example: Static! design research program

Conducted between 2004-5, Static! was the first research initiative to develop out of a growing relationship between the Interactive Institute and the Swedish Energy Agency. The agency has many research programs directed toward systems, infrastructure, and industry but few focused on private consumers. Participants came from electrical and mechanical engineering, human-computer interaction and interaction design, product and textile design, philosophy and the social sciences, and the conceptual design group Front was a partner in the program. As a first engagement with the Energy Agency, we aimed to create some depth in our research program as well as a breadth of examples of what design research might be in this area. While this means that our prototypes and studies were, thus, correspondingly diverse, the focus here is on those developed in terms of conceptual and critical design.

Research program

The research program in Static! built upon a set of existing and ongoing theoretical concerns in our work at the Interactive Institute. For some years, we have been examining the presence of information and communications technology in everyday life, influenced by phenomenological and aesthetic theories, as well as participatory and critical design. Themes such as ‘slow technology’ (Hallnäs and Redström 2006), ‘technology as material’ (Redström 2005 ; Redström, Redström, and Mazé 2005), and ‘public play spaces’ (Mazé 2007) have countered presumptions of ubiquity and usability, seamlessness and efficiency, within mainstream design and Human-Computer Interaction. Developing alternative forms and interactions, our work has been concerned with putting designers, users and stakeholders in touch with the aesthetics and complexity of new technologies.

Within Static! these interests were further developed in terms of two main ideas: the idea that, as designers, we can work with energy not only from a technical but also from an aesthetic point of view, thereby integrating in a more powerful way the often separate areas of design and engineering; and the idea that product use need not only be about utility and ease-of-use, but also about critical reflection on energy through the objects at hand (Backlund et al. 2006). Countering the tendency in (especially modernist and formalist) design to conceal technical and service systems such as electricity, we shifted from thinking about energy merely as something to optimize or hide away, but as an expressive and valuable material within the spatial and temporal form of everyday design things and micropractices of use.

Experimental design

In the form of prototypes, we created a series of experimental designs to test and craft alternative approaches to our two main ideas. Drawn out of responses gathered from initial probes and interviews into local families and households, we took a starting point in a set of domestic products, such as curtains, radios, lamps, cables, and radiators. To expose the energy within and surrounding these in the home, the form and materials of these products were decomposed – literally and conceptually. For example, Front ‘de-engineered’ material surfaces, such that light or heat would interact chemically to alter decorative patterns (Figure 1a); the workings of an ordinary radio were hacked so that its sound would become overly-sensitive to electrical over-consumption within a local system (Figure 1b); daily interactions with a curtain woven with solar panels and fiberoptics turn it into a self-sustaining light source (Figure 1c).

These objects materialize the patterns and cycles of natural and electrical energy, as well as of habits in the short and long term.

Designing, or redesigning, familiar products to expose the (inter)dependency between energy and our products and actions, these are meant to redirect the focus of attention in mundane interactions. In relation to conceptual and critical design strategies, these examples experiment with the aesthetics of anti/utility or (un)ease-in-use. The disruption of form and/or function relates to theoretical conceptions such as how design might change the focus and availability of things to our actions and choices (Redström 2001 ; Verbeek 1998). In addition to immediate expectations, these examples also explore temporal strategies, such as transformability and open-endedness, repetition and decay (Bell 2003). Thus, we explore variations on how to design things that create a 'critical distance' or 'resistance to assimilation', to borrow phrases from critical practice, ranging from overt to subtle alterations of sensory perception and courses of action.

Further, we designed experiments in which prototypes were deployed into various situations in order to investigate the reception of such alternative 'aesthetics of energy'. Indeed, we took 'reflection in use' was taken literally – as reflection by users on and through their own consumption, interaction, and choices – as well as rhetorically – as the situation of ideas for 'consumption' within wider public, institutional, and cultural contexts. On one hand, the radio and curtain were deployed into long-term multi-household domestication studies, to inquire into immediate and longer term questions of change in relation to household dynamics over time. On the other hand, the wallpaper was created to decay over the course of an exhibition within a contemporary art and design exhibit, opening up for another sort of discussion about form and taste. These and other of the prototypes were also presented in conferences, publications, media, and exhibitions targeted towards the energy and technology sectors as well as the general public.

4. Discussion

To the extent that we have been interested in critical practice as a basis for 'problem-finding' within design discourse, we have also been interested in critical practice as 'design for debate'. Much of critical design, however, has been confined to galleries and books, rarely moving outside the ideological modes of production in art and the media. As George Baird notes, "the museum has continued to be a more receptive venue for critical work than the street" (Baird 2005, 5). Instead, we have turned back to everyday things and mundane interactions, considering the intervention of subtle changes in appearance or changes over time. Through materials and form, ideas and ideologies become available both for aesthetic reception and for everyday consumption.

For us, it was precisely utility – proximate interactions and everyday experience – that provided a site for enquiry where the conceptual and practical concerns of design practice and research might intersect. Alternative 'aesthetics of energy' have been about expanding the diversity and precision of techniques for inviting a poetic distance between 'critical objects' and equally 'critical subjects', such that energy issues might become more present in everyday life. Indeed, the tension between 'aesthetics' and 'reflection' exposes a range of overlapping concerns binding practices of production with those of consumption by means of the forms between. Intended tensions within the research program, such as those between notions of the 'reified object', typically in focus in art criticism and design history, and the 'deified subject', as might characterize some phenomenological and sociological perspectives on design, continue to raise theoretical questions.

In addition to our conceptual concerns with use, Static! moved beyond to observe the transformation of perception and behavior. Still considered as forms of 'ideological production', the prototypes were not intended as end products or final solutions, as typically treated within evaluation studies based on usability. Instead, the domestication study focused on the role of the prototypes in emergent social relations and value dispositions within the household context and family life. In addition to 'proper' use and a significant increase in people's awareness of their energy use, reactions to the curtain also included increased sensitivity to the dark Nordic winter, re-arrangement of artificial lighting in the home, and the use of extra lighting to power the curtain. In their own homemade experiments, some used the radio to make their own tests of electric waste in their homes and, in other families, the ownership of energy pedagogy was reversed as children appropriated the radio. (Figure 2) (Routarinne and Redström 2007)

Figure 2: Pictures from the 'domestication' studies of the Energy Curtain and Erratic Radio

Rather than resolving our theoretical speculations, experimental design in Static! exemplified certain ideas and extended them for consumption outside our own 'knowledge regime'. While we did find affirmations of our original intentions in the domestication study, we also discovered a range of further and unexpected interpretations and behaviors. Indeed, the household study even prompted studied experiments within the households themselves, raising new questions about the relations between 'critical objects' and 'critical subjects' and between research by design and/or by use. For us, it became clear that it was not the object in itself that conveys or portrays a message, which might be more typical in 'design for debate', but the interactions among and around objects within a context and over time that might convey a more local and ongoing form of reflection, even criticality, in use.

In examining the parameters of a particular set of theories, questions, and problematics, critical practice works by means of form and formation, thus inevitably interjecting new readings and interpretations. In Static!, we discovered a range of further critical potentials to emerge in and through the extended use of 'strangely familiar' objects. In this case, it was not a question of users correctly interpreting the message or intention of the object, but of discovering their own relations to energy, as well as to one another, by interacting with the objects. This illustrates that a critical practice may not operate only in retrospect – through intervention, we might also act in a projective and propositional way. This is precisely what differentiates critical practice – in its material and operational forms – from hermeneutic practices of interpretation and analysis (Allen 2005). Static! affirmed certain hypotheses, allowed us to sharpen certain ongoing questions, and – importantly – opened up a range of new avenues for research along with new issues. While we are only starting to investigate such issues, it is these issues frame our approach to a new program called Switch!

Example: Switch! design research program

One success of the Static! has been to sustain – and grow – commitment to design research within the Swedish Energy Agency. In addition to a nuanced and first-hand view of design research, the Energy Agency has also been encouraged by vivid discussions in the public, consumer, and commercial sectors. Adding to their core set of research programs, the agency has launched the area of 'Design, Energy and IT', which has funded further research projects at the Interactive Institute as well as stimulating interest in this area among other research institutes and universities. This has led to the successful applications to the agency for further research programs. The recently initiated Switch! program builds on what we learned from Static! by shifting focus beyond discrete people-product interactions. In Switch!, we take an architectural and urban scale to investigate the intersection of material, social, and technical systems that effect values around energy use within a locality over time. We have tried to capture this interplay of issues within the term 'energy ecologies', which relates to our investigation of 'social ecologies' in the domestication study of Static!

The term 'ecologies' relates not only to theories from sustainable design and environmental science, but we are also exploring relations of design to ecological thinking in relation to perception, psychology, ecosophy and sociology, thus regenerating our 'knowledge regime' based on our finding from Static! Switch! also makes an explicit intention to understand – and design – prototypes as arguments, triggers or teasers, prompting not only self-reflection within situations of use but also reflection on local value systems and wider social norms around energy and energy consumption. This research program started in April and will finish in 2009. Future work will involve the development of experimental design prototypes and designing experiments in which these prototypes are situated in analytic, debate, and idea-generation forums with local communities, designers, and public sector stakeholders.

Concluding remarks

This paper presents an approach to the challenges that sustainability poses to design practice and discourse. Within design history, there are aesthetic and formal strategies in and around questions of responsibility, accountability, and criticality. As discussed, conceptual and critical tendencies in architecture and design open up the possibility for operating at a 'critical distance' from conventional notions of design production and consumption. I might even argue, as Silvetti does, that such critical voices and dissenting examples are necessary for developing a disciplinary discourse. However, within a diverse and critical discourse, there is also a need for building common ground(s), even on a provisional and local basis, such that multiple disciplines and divergent perspectives can develop and exemplify ideas together. Through 'research programs' and 'experimental design', critical practice might move from debating critical terms and designing critical objects to learning from making and using of these within constructive and collaborative practices.

This paper traces a trajectory through a 'history of ideas' in art and design to the experimental design of forms that embody and exemplify different theories. Building such an account exposes that our work has some relation to research *into* design but, also, research *for* design. Furthermore, to the extent that our prototypes embodying various theories for design were not intended as final or closed products, but were further mobilized and staged in experiments in households, exhibitions, and other forums, it might be said that we have been conducting research *through* design, in which artifacts act as vehicles for further inquiry and further projects. This latter approach has been less present in Static!, since the domestication study happened quite late and with an expert in the social sciences engaged expressly for this purpose. As we frame Swich!, however, to further consider the social aspects, we are incorporating expertise from design ethnography and participatory design directly into the program, in which the development of experimental design prototypes and methods for designing experiments with stakeholders becomes integral to the process.

Attempting to describe our work through these prepositions is not to simplify, but to articulate the complexity, of doing design research. Design research is made up of multiple practices – the personal practices and associated communities of practice of social scientists, designers, engineers, philosophers, and so forth. The additional domains of knowledge and systems of production relevant to sustainability further complicate the picture. However, this expansion in the factors that must be considered within contemporary design serves to highlight the need for deepening the intellectual and ideological basis within the field. We need to further develop a basis for relating critically and rigorously to the knowledge and expertise external to but circumscribing design. From such a basis, it also becomes possible to act, react, and interact with a range of continually shifting players within the field. Within and across the foundations of different disciplines, design research might play an important role in constructing the conditions for critical practices that are also reflective and generative, agile and regenerative.

Acknowledgements

The work presented in this paper has been developed at the Interactive Institute. I would like to thank all of my colleagues in Static! and Switch! and the Swedish Energy Agency. Static! was led by Christina Öhman, with Johan Redström, Sara Ilstedt-Hjelm and myself as research directors. Switch! is led by myself with research direction from Johan Redström. The Disappearing-Pattern Wallpaper was developed by Front (Sofia Lagerkvist, Charlotte von der Lancken, Anna Lindgren, and Katja Sävström) with Spets. The Energy Curtain was developed by Anders Ernevi, Margot Jacobs, Ramia Mazé, Carolin Müller, Johan Redström, and Linda Worbin. The Erratic Radio was developed by Anders Ernevi, Samuel Palm, and Johan Redström. The study of the curtain and radio was carried out by Sara Routarinne from the University of Art and Design Helsinki.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

SUSTAINABLE PRODUCT DESIGN:
From delivering sustainable products to enabling sustainable lifestyles

Alison McKay[1], David Raffo[2], and Dan Trowsdale[3]

Abstract

The delivery of sustainable patterns of consumption and production demands dramatic changes in behaviours of individuals, organisations, communities and society at large. This paper focuses on the development of young designers. Results are presented from a five year research programme whose aim was to explore means by which sustainability might be embedded within design curricula. Understanding gained is informing the specification of future generations of design tools that will allow designers to experiment with alternative future scenarios and models of new products before they are introduced into markets. With respect to project goals, the process has enabled the embedding of sustainable development into the curriculum through the student research informing the whole student base with up to date contextual data.

1. Introduction

"*The major cause of the continued deterioration of the global environment is the unsustainable patterns of consumption and production, particularly in the industrialized countries. Developed countries must take the lead in achieving sustainable consumption.*" —United Nations, Agenda 21

The delivery of sustainable patterns of consumption and production demands dramatic changes in behaviours of individuals, organisations, communities and society at large: far more than merely the design and production of eco-friendly products. As consumers begin to recognise the impact of everyday products, consumer goods suppliers are beginning to respond. For example, the RITE Group (RITE, 2008) is aiming to support companies in delivering

[2] University of Leeds, david@davidraffo.com
[3] University of Leeds, d.b.trowsdale@leeds.ac.uk

sustainable and ethical textiles and clothing through their global supply networks. Initiatives like this create a demand for product designers who are able to take both a holistic view of the social systems within which the products they design will exist and a detailed view of both technical and human aspects that are key to delivering these products to market.

The focus of this paper lies in the development of young designers who are able to operate in contemporary contexts. Results are presented from a five year research programme whose aim is to explore means by which sustainability issues might be embedded within design curricula. The design researchers were students who participated in a sustainable design project. Since its inception in 2004, over 200 students have completed the project. A three phase process (McKay and Raffo, 2007) is used where student designers research a problem area, define a future vision and then design products that could be a part of this vision. The process is designed around Frayling's design for research methodology (Frayling, 1993). The starting point for each project is a social dimension, beyond concern for the environment, of something that needs to change to improve sustainability. On this basis students define a vision which sets the context for the development of designs that could be a part of their envisioned future. Students are exposed to a level of context that is, in the authors' experience, unusual in undergraduate design education, and the visual presentations of results are powerful, engaging and enable the sharing of messages with a wide audience. The projects themselves focus on the sustainable design of consumer products which, in the worst cases, have high environmental and social costs through their production, use and disposal.

Through the visualisations associated with this paper, we present results from projects completed between September 2006 and February 2008. Sustainability in five problem areas was researched: mobile communication, out of town shopping, energy in daily life, domestic waste and sustainable toys. The visualisations include results from the team research phase, future scenarios that the student in these teams envisioned and designs students created to be parts of these futures.

2. Structure of the paper

In Section 3 background literature on the incorporation of sustainability into business accounting systems, tools for the evaluation on sustainability and the incorporation of sustainability into university curricula are reviewed. A process that was developed to enable the incorporation of sustainability into project-based learning activities of second year Product Design students is presented in Section 4; examples of results from this process are shown in the visualisations associated with this paper. Finally, in Section 5, learning from using this process is used to propose requirements for emerging design tools.

3. Background

The delivery of sustainable lifestyles demands that the full sustainability impact of a product is recognised: full in terms of both the whole life of the product and the way in which it fits into the systems it will become a part of. The triple bottom line, which provided a means of considering economic, social and environmental factors when considering the costs of products and activities, is increasingly being adopted by businesses as a means by which the sustainability of manufacturing organisations can be quantified. For example, Gibson and O'Donovan (Gibson and O'Donovan, 2007) report an Australian study showing an increase in the amount of sustainability information, largely environmental but also addressing other aspects of the triple bottom line, since the early 1990s. This is done in the context of corporate governance and its linkage with corporate social responsibility. A problem with the use of the triple bottom line lies in the lack of a consistent means by which societal and environmental impact are measured. As a result, whilst it is useful for individual institutions in allowing them to quantify their sustainability, difficulties are typically experienced when it is used to evaluate the sustainability of products and

services that span organisational boundaries and, as a result, triple bottom line accounting systems that are incompatible with each other. Foran et al (Foran et al, 2005) propose a triple bottom line accounting system that addresses this issue and so allows the sustainability of products and services to be assessed across organisations in a supply network. Developments in these areas are enabling the sustainability of products and services up to the point of production and delivery to the customer to be measured.

Ness et al (Ness, 2003) provide a categorisation of sustainability assessment tools that includes tools used at different levels of detail, for example, policy versus product related tools. Lifecycle analysis is a widely promoted tool for evaluating the sustainability of products. An example application of lifecycle analysis is given by Banar and Cokaygil (Banar and Cokaygil:2008) who report a comparison of the environmental impact of life cycle analysis of two fruit juice drink packages: a carton and a glass bottle. Anecdotal evidence, however, indicates that the cost of applying lifecycle analysis is often prohibitive (it is applied to specific products on a case by case basis), some data needed is difficult to acquire and its focus on environmental issues means that it is not well suited to supporting decision making in context of the triple bottom line. Marchand and Walker (Marchand and Walker, 2008), in a discussion of sustainable consumption, discuss the need for product designers' foci to extend from improving the sustainable efficiency of products through finding more sustainable ways of delivering the same results to consumers through to reassessing the needs to which the product is responding. For the longer term, improving sustainability performance requires well founded theoretical frameworks that can be used to inform actions. Sustainability science has been put forward as a new discipline whose focus lies in understanding relationships between social and natural systems (Kates et al, 2001; Swart et al, 2001). Key challenges lie in enabling practitioners, such as policy makers or designers and manufacturers, to deal with complexities of both natural and social systems, and of the interactions between them.

Despite the fact that a theoretical foundation is still at a formative phase in its lifecycle, the need to incorporate sustainability into university curricula is widely recognized and many case studies are reported in the literature. In response to the demand for engineers to be able to deliver sustainable solutions, Jeffrey et al (Jeffrey et al, 2004) identify a need for engineering education to equip engineers with skills that will allow them to consider problems holistically and bring together relevant context specific skills in establishing solutions. They propose a model for engineering practice that includes both engineering and sustainability concerns and illustrate it through a water treatment case study that was used in a Masters level engineering programme. Rowden and Striebig (Rowden and Striebig, 2004) describe the use of a personal computer as a case study for the introduction of environmental and ethical issues into engineering curricula; with respect to the triple bottom line, the focus of this case study is on interplays between social and environmental sustainability. Boks and Diehl (Boks and Diehl, 2006) describe the integration of sustainability into an undergraduate industrial design progamme through a client driven team project and Fisk and Ahearne (Fisk and Ahearne, 2006) describe the use of concept maps as a tool for engineers in a postgraduate programme to address softer aspects of sustainability such as social and political issues. A common theme in all of these papers lies in establishing means by which students can learn to address the complexities of sustainability in their design activities and solutions. In this paper we describe a process that has been developed to allow student designers to address the complexities of sustainability and consider how they might respond through design solutions. The process allows student designers to explore and build well-founded design contexts, create visions of futures which are creative yet relevant and then propose concepts that have the potential to change how these futures are considered.

4. Process

The overall structure of the process aligns with the first three steps described by et al (Sanders et al, 2004) in the methodology part of the Design for Results^{TM} framework: Discovery ("Building shared context"), Diagnosis ("Formulating the situation") and Design ("Creating a

preferred future"). The three stage process was created with a view to allowing student designers to explore and build well-founded design contexts, create visions of futures which are creative yet relevant, and propose concepts that have the potential to change how these futures are considered. In this section each phase of the project is introduced with an emphasis on its aim, learning outcomes and criteria that are used to assess students' work.

4.1 Phase 1

This is the context setting part of the project where students research a real problem, considering it from environmental, economic and social viewpoints. At the beginning of the project students are asked to state a preference for a project area in which to carry out their sustainable design project. The project areas offered in 2007/08 (the most recent delivery of the project) were energy in daily life, mobile communication, sustainable toys, out of town shopping and domestic waste. Teams of approximately five students are created with a view to allowing each student to work in their preferred subject area.

The result of this phase is a team poster that is presented verbally to the whole student group by what ever means the team chooses to best present their findings. Through the poster students should have demonstrated an ability to

- analyse a real-world problem from environmental, economic and social viewpoints;
- carry out basic research to gain an appreciation of the scale of a given problem; and
- identify trends in a given problem area.

This phase of the project is worth 20% of the total project mark and is assessed against the following criteria: clarity of message, visual impact, appropriate balance of graphics and text, and demonstration of an understanding of the issues to be addressed in the problem area. The posters are presented to the whole student group so that each student has an opportunity to learn about the wide range of issues to be addressed. An example of the results of this phase, from the area of sustainable toys. is given in Figure 3.

4.2 Phase 2

During this phase of the project students identify intervention points in the situations they defined in Phase 1. They use the results of their research, and what they have learnt from seeing the presentations of other teams, to build up a clear view of the current situation in their chosen area and, from that, produce a vision of a better future and a brief for a product within that future situation. The result of this phase is a team vision for a future where a rule has been changed and individual design briefs. In the visualisation presented in Figure 5, the future vision was, "In 10 years time, very limited amount of transport will have access to out of town shopping centres. Regulations state that cars will have NO access to these facilities". Through their future vision and individual briefs students should have demonstrated an ability to:

- analyse research results and use the results of this analysis to inform the definition of a vision for an alternative future;
- define a future vision;
- identify design opportunities in a future vision; and
- create a design brief for a new product that could be a part of an envisioned future.

This phase of the project is worth 15% of the total project mark (5% for a team vision and 10% for an individual brief). In assessing the team vision we look at the extent to which the vision answers the following questions.

- Does it provide a picture of a possible and improved future by 'changing the rules'?
- Does it say what the rule change will be?
- Does it have economic/social/environmental breadth even if rule change is only in one area?

- Does it show a thoughtful response to the research?
- Does it create an opportunity to 'do things differently'?

In assessing the briefs we look for evidence of links between the brief, the vision and the research and an aspirational and futuristic technical specification that fits with the team's vision and includes clear goals where at least some of these goals should be quantifiable.

For the majority of students, the definition of the design brief is the most challenging aspect of the project and additional support has been put in place as the project has developed to ensure that all students have a brief that is tractable for them. In supporting the definition of the briefs we aim to ensure that all students have a clear goal and have identified a product they are going to design.

4.3 Phase 3

During this phase of the project students design solutions that respond to the briefs they defined in Phase 2 and integrate these designs with results from the previous two phases. The aim of this phase of the project is for students to design a product that satisfies the brief they created in Phase 2 and demonstrate how it fits with their team's envisioned future.

The result of this phase is two-fold: an individual design portfolio for each student which is presented to assessors in an interview and a poster presenting their team research team vision, individual brief and final design. In compiling this poster students are encouraged to update the results of the previous phases to reflect the formative feedback they have received through the project. Through their design portfolios and students should have demonstrated an ability to:

- generate a variety of design concepts that respond to the brief and address sustainable development issues identified in Phases 1 and 2;
- evaluate the design concepts with respect to a range of quantitative and qualitative criteria;
- select a design concept for further development;
- develop a concept design definition that responds to sustainable development issues;
- justify the final design definition, as a response to the brief and in the context of the envisioned future, and identify areas for further development;
- demonstrate design skills in the form of a presentation [visual and verbal] that presents a convincing story of the concept proposed; and
- integrate research and design concepts and communicate them as powerfully and as lucidly as possible to a less knowledgeable audience.

This phase of the project is worth 55% of the total project mark (20% for the portfolio and 35% for the poster) and students are assessed individually. In assessing the portfolios four broad aspects are assessed: the range and variety of design concepts generated, the quality of the final design definition, the extent to which the final design is demonstrated as responding to the brief and the extent to which the design process has applied learning from other parts of the programme of study. McKay and Raffo (McKay and Raffo, 2007) provide fuller details of the assessment scheme for this part of the project. The poster is assessed using the same criteria as those used for the team poster in Phase 1. Figure 5 shows a portfolio page that was a part of this phase of the project in 2006/07 and Figure 4 shows a poster from 2007/08.

5. Requirements for emerging design tools

The delivery of sustainable lifestyles demands that sustainability be assessed both up to the point of delivery to the consumer and after it has been acquired; the assessment needs multiple foci, including the sustainability of the product itself and the sustainability of the system that

includes other products the consumer uses and the social systems to which they belong. In addition, there may well be benefits from considering other kinds of collections of products, analogous to the benefits accrued by service delivers who, through offering product related services, are able to manage (and learn from) experiences gained in supporting individual products as parts of fleets. For example, companies managing fleets of aeroengines can use learning from the maintenance needs of individual engines to create patterns of performance that can, in turn, be used to inform maintenance strategies for the whole fleet. Similar benefits may be possible at other stages of the lifecycle, such as disposal.

As highlighted in Section 3, it is widely accepted that evaluating the sustainability of design options demands consideration of a wide range of factors including the societal, environmental and economic issues covered by the triple bottom line. Pope et al (Pope et al, 2004) review a range of approaches, including the triple bottom line, to sustainability assessment. With respect to design tools, Suh (Suh, 1990) proposed a design cycle including decision making, synthesis, analysis and the flow of information between the activities. This is illustrated in Figure 1.

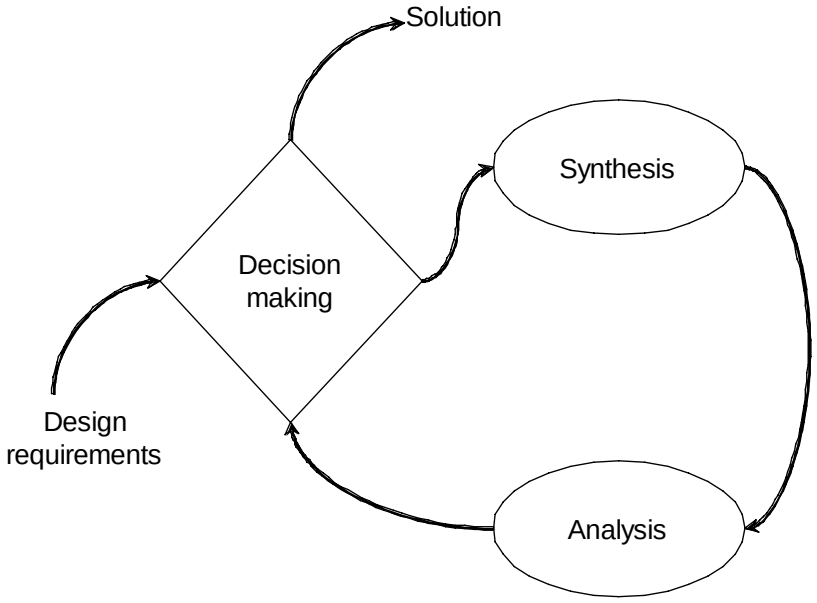

Figure 1: Activities in design cycles (adapted from (Suh, 1990))

Sustainability assessment typically supports design analysis and decision making. Since the systems within which products will live are socio-technical systems the design analyses need to include both hard and soft aspects of the systems and, importantly, interplays between the two. For this reason, appropriate analysis tools are more likely to be simulators rather than traditional engineering analysis systems that are founded on the laws of physics. These simulators might include both computational and human elements so that insights into how products might behave and be used can be gained. From the results of the students' research, a key area for the development lies in support for the information flows. For example, Phase 1 research results are used to envision an alternative future but there is a lack of systematic and feasible ways in which these futures can be articulated, rule changes expressed and then the implications of rule changes observed. This concerns how designers might be able to assess alternative rule changes and the products/product systems that might flow from these rule changes. In essence, design tools are needed that allow alternative scenarios to be modelled in ways that take account of both social and technical factors, and then what-if type questions posed and alternative system behaviours predicted: hence the need for simulation tools. Such tools are important because they will enable designers to identify key points that would be best addressed from the research – something like a sensitivity analysis on the scenarios so that the "right" futures and rule changes are identified before the design brief is formed. In considering future scenarios it is important that designers are not limited in the outlooks they might take and that means are provided where as many players in the future scenarios as possible can be represented (both model- and viewpoint-

wise) since alternative futures are likely to involve different ways of doing things and as such the nature of design solutions may change – not only may a new 'product' have radically different values but that product may be replaced with services or more likely new combinations of product/service – so it is not a better phone [in sustainability terms] but a better way of allowing/supporting communication.

Ness et al (Ness et al, 2007) provide a classification scheme for sustainability assessment tools that includes indicators such as the wellbeing of people in a region, product-related tools such as lifecycle analysis and what they refer to as "integrated assessment tools" which typically use scenarios to inform policy decisions. Ness et al's product-related tools would be well suited to the end of Phase 3 where the product designs are evaluated but there is also a need for analysis tools that will support the evaluation of the products as parts of the envisioned futures students identified at the end of Phase 2. Fisk and Ahearn (Fisk and Ahearn, 2006) describe the use of cognitive mapping with postgraduate engineering students as a means of supporting analyses of complex social and political situations.

In addition to considering people using products, there is also a need to consider the chains of people (in societal groups) and organisations (in markets) involved in a product's life (Foran et al, 2005) and the flows between them (Ness et al, 2007). The emerging discipline of Enterprise Engineering is intended to provide a theoretical basis for the design of enterprises, and so enterprise networks, that are fit for purpose. This demands understanding of interplays between products and the processes and enterprise networks that create and support products through their lives (Thomas et al, 2006). Enterprise Engineering provides a framework that builds upon the view that an enterprise, of which a supply network is just one kind, can be regarded as an organic entity with its own life-cycle. Building upon this premise, there exists an enterprise realization process with three key steps: Define, Develop and Deploy. Three aspects of an enterprise need to be realized during an enterprise realization process: Purpose, Agency and Products and Services. These can be brought together to form the framework presented in Figure 2 and populated with questions to be answered when the goal of the enterprise is to enable sustainable lifestyles. It can be seen that enterprise networks sit in the agency row. However it is developed to serve some purpose (in the Purpose row) and deliver products & services (in the products and processes row). An enterprise operating system is the means by which an enterprise mobilizes its capability to deliver value to stakeholders through solutions. The enterprise operating system is a socio-technical system and the means by which enterprises deliver solutions that meet their stakeholders' strategic intents. What constitutes fitness for purpose depends on the goals of the enterprise concerned. In the context of this paper, the goal of the enterprise is to enable sustainable lifestyles.

An enterprise operating system simulator could provide a way in which alternative product designs could be evaluated in the context of envisioned futures. Representations of designed things (products, services and enterprise networks) could be used to gain insights into how they might behave in parts of their lifecycle after design. The models could be used to provide insights into alternative futures and allow understanding of factors to be considered and trade-offs to be made in developing these futures: building models that will allow us to simulate alternative futures. The simulations are likely to be blends of computational models and human activities, for example, through role plays or improvised performances. From the perspective of how people live and consume, it might, for example, be more sustainable to buy one non-fairly traded non-organic cotton T-shirt and wear it 100 times rather than buy 10 fairly traded organic ones and wearing each one 10 times. It is widely accepted that actually delivering sustainability requires changes in how people behave. So modelling and simulation is likely to take us some way but for society to become more sustainable requires education of consumers. One educational opportunity could be for people to participate in simulations. Taking the simulations out of computers and using computers in different ways could be a means of delivering sustainability. For example, computer-based models could be used to build alternative future scenarios that we could then explore by populating them with real people doing real things. Alternatively, virtual people in virtual environments (such as avatars in second life (http://secondlife.com/whatis/) could be used in simulations.

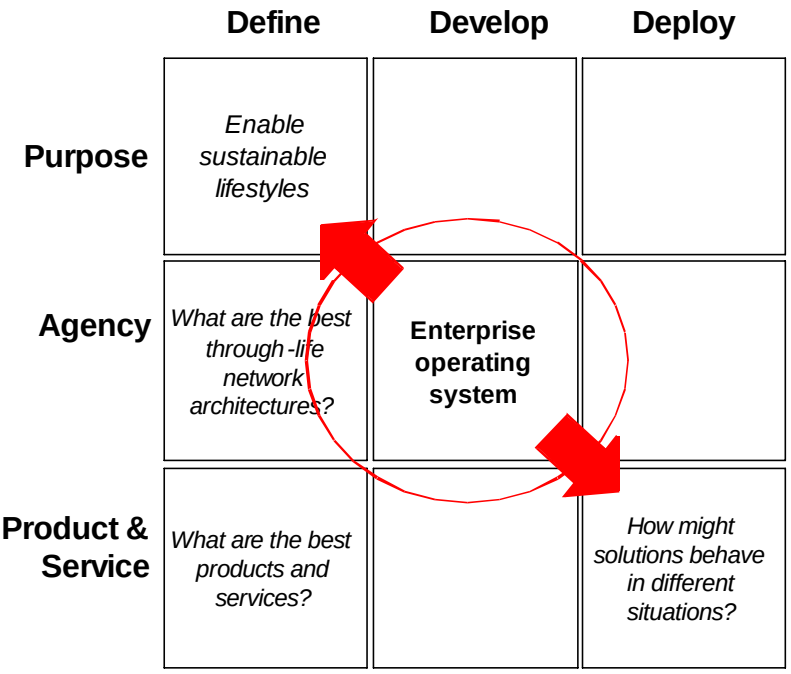

Figure 2: The Leeds enterprise engineering framework applied to sustainability

6. Concluding remarks

The transition from designing sustainable products to designing products that enable sustainable lifestyles requires designers to take both detailed views of the products they design and holistic views of the social systems within which these products will spend their lives. Through the work reported in this paper we have created a process that allows young designers to explore and build well-founded design contexts, create visions of futures which are creative yet relevant, and then propose concepts that have the potential to change how these futures are considered. In a recent publication (RAEng, 2007), the Royal Academy of Engineering identify the need for modelling and simulation as tools for creative design. Understanding developing through this project of how designers might operate at different levels of abstraction is informing the specification of future generations of design simulation tools that will allow designers to experiment with alternative future scenarios and models of new products before they are introduced into markets. We anticpate that these simulations, and the modelling that will underpin them, may form an important part of the future of how design works and in doing so add a new dimension to the design process with design tools supporting designers from the initial creative process through a method of assessing ideas against the research criteria and later, in the evaluation phase of the design process, adding new methods of simulation of different routes to an agreed goal.

Acknowledgements

The work described in this paper resulted from a visiting professors scheme in engineering design for sustainable development, run through the United Kingdom's Royal Academy of Engineering (RAEng). Thanks are due to the 2006/07 and 2007/08 Level 2 Product Design students who participated in the delivery of the project and whose work forms the visualisations.

DESIGN VISIONS PROPOSALS AND TOOLS

EXPLORING INDIGENOUS INNOVATIONS:
Ascertaining the Scope for Design Interventions for their Successful Commercialization

Shashank Mehta[1], Ravi Mokashi-Punekar[2]

Abstract

This is the era of innovation-driven economy. Today's fiercely competitive and increasingly saturated global markets, rapid technological breakthroughs, information technology (IT) integration, have all left the old weapons of achieving any differentiation / edge, inadequate. Innovation is today the key to any business success. Coupled with this, the increasing awareness of ecological and sustainability issues, scarcity of materials, stringent IPR norms, mass customization, they all have resulted in the demands for the solutions – innovations, that have emerged / evolved based on local needs and the ones that focus on the 'quality of life' of all of its stake holders. Tomorrow's business will compete on originality, and only the local user and the local context can provide these much needed edge, and thereby the unique strength. Indigenous innovations, it has now been recognized, is crucial for any developing nations to achieve cumulative growth of economic and social developments.

One would in India, come across amazing innovations – solutions that may have been developed / innovated to meet and solve the specific needs and requirements of the person or region. The very nature of the composition of Indian society – primarily an agrarian and service economy, large middle income and rural segment, crafts and SMEs as the main industry sectors, they all encourage development of indigenous and ingenious ways to earn their livings. By their very nature of development, these ideas / innovations will have inbuilt considerations of many of the ecological and sustainability aspects. There is, therefore, a great scope of developing these ideas and also the traditional knowledge into contemporary applications for local solutions. This would benefit the large numbers of people living in the region and would also generate

employment opportunities. These indigenous innovations / ideas / knowledge could thus form a significant resource that can be developed into marketable products and thereby help creating business successes, and in turn providing a vital direction for the country like India, to transit into an innovation-driven economy.

These solutions, as they will be mostly in the form of appropriate modifications/ refinements or improvements in the existing products, will fall under the category of incremental and ‘bottom-up’ type of innovations, and thus will require further, critical interventions and hand-holding efforts for their transition to markets. Design intervention will here help bring in the much needed empathetic understanding and holistic vision to connect and integrate all the various efforts towards a positive outcome. Designer would, while utilizing the unique strength of the innovation/idea, help connect these indigenous innovations to the users’ aspirations, and in the process help overcome those typical constraints of resources, skills etc. He/She would thus act here as a catalyst to bring in the much needed new changes and new vision.

Synopsis

It has now been recognized that indigenous innovations are crucial for any developing nation in order to achieve cumulative growth, both economically and socially. These innovations, as they will be mostly in the form of appropriate modifications in the existing products, will require further critical interventions and hand-holding efforts for their transition into markets. Design intervention can help bring in the much needed empathetic understanding and holistic vision to connect and integrate the various efforts towards a positive outcome.

One would come across amazing indigenous innovations in India that can be developed into marketable products and thereby help in creating business success. These could provide vital directions for a country like India, to transform into an innovation-driven economy.

Innovation – A Necessity

Tom Peters reminds us in "California Management Review": *'Get Innovative or Get Dead'*. Innovation, has long been recognized, as a major driving force in economic growth and social development. According to the Growth Theory, developed by the Nobel Prize-winning economist Robert Solow, technological progress and innovation is the greatest engine of economic growth. Studies have shown that industrial policies of the world's developed nations give importance to the strategic role of innovations in generating new business ideas which will translate into greater economic growth. For any country aspiring to become a developed nation, it is imperative therefore, to transit to the innovation-driven economy (Goh 2005).

Economic condition of business organizations and the society as a whole, today depends on their capability to produce products and services that are better, cheaper and faster than their competitors. Innovation helps bring in this much needed change and improvements at all levels of business and economy. This helps improve the economic position of all the stake holders involved. Innovation today, is essential for the long-term growth of organizations.

Innovation is also the key to success in all social developments. Creative ideas and innovations challenge existing norms and foster positive growth. They help improve the overall quality of life. Innovative ideas can cross over the hurdles of social apathy, conservative mind sets and orthodox attitudes to usher in positive changes in society. An innovation changes existing rules, norms, thinking and structures to create a novel transformation. Innovations thus, help achieve sustained change in a given environment. Innovation, has thus become the key to the sustainable development of the society.

Characteristics of Innovation

Though the importance of innovation has increased over the years, there exists a clear anxiety and major difficulty in its understanding, both in terms of its definition as well as its process. There is limited knowledge as to why, when and how innovation occurs.(Szmytkowski 2005).

According to the *Oxford Dictionary*, the word 'Innovation' first appeared around 1297. Joseph Schumpete, in his publication "The theory of Economic Development" (1911) had described the motor of the development as the innovation itself (Szmytkowski 2005). Gerard H. Gaynor, in his book *Innovation by Design*, based on the analysis of views and comments expressed by prominent researchers of innovation theories over the years, arrives at a simpler definition—

'Innovation = invention + implementation/commercialization'. While invention is described as the first occurrence of an idea for a new product or process, innovation is the first attempt to carry it out into practice. The emphasis here is on the 'newness' of the idea. Innovation creates new value rather than new knowledge. Innovation is not science or technology. It is about business. Innovations are, generally classified into three broad categories, ie.; incremental innovations, new-to-the-market/society innovations and breakthrough Innovations. Most innovations take place incrementally. Innovation can occur from the bottom-up or be sponsored from the top-down. Each approach will have its strengths and limitations (Gaynor 2000).

Innovation depends on four major elements: resources, infrastructure, culture and process. Innovation cannot take place if any of these four elements are missing. All four are equally important. Innovation encompasses three overlapping dimensions, which are –individual/ you, team/s (that also include you), and the organization/group. The individual/you will be the centre of the entire process of innovation, as only an individual will have new ideas. But taking ideas to market involves team work, for, one person cannot do it on his/her own. One needs to combine several different types of knowledge, capabilities, skills and resources to convert invention/idea into innovation. The leader of the team here, plays a key role to effectively coordinate this process to achieve the goal/tasks. The *personality* of the organization/group, known commonly as *culture*, plays a vital role in innovation. The innovation process generally falls under three major phases that are; *generating ideas, harvesting ideas* and *developing and implementing these ideas*. The common factor in these three phases is teamwork – synergy amongst the group. '*Innovation is about action, it isn't about perfection.'* believes IDEO (Gaynor 2000), (Kelley and Littman 2004), (Adair 2003).

Changing Market Trends

It is observed that, market trends are now shifting from *'globalized'* to *'regionalized'* and further to *'localized'*. The increasing cost of energy and transportation has forced the industries to shift their focus from mass production at one location to batch production at several locations, which solves the problems of logistic support and sale of the product at different places. Scarcity of materials and the ever increasing concern for environment has further pushed industries to localize and customize their products. The fierce market competitions have further forced the industries to localize and customize their products to penetrate each and every segment of the market including the rural segment. The companies are thus forced to shift their focus from mass production to mass customization of their products. *The future therefore belongs to the products that will satisfy the physical and mental needs of the consumer, incorporate the traditional, social, cultural and ecological aspects of the region. They should be produced locally, but in terms of appearance, efficiency and performance they should be world class* (Mehta 2003). The products/solutions therefore will need to be based in the local context so as to be culturally acceptable and economically feasible. This demands local participation and utilization of indigenous knowledge. Stringent IPR norms have further pushed

organizations and nations to emphasize on developing their own in-house / local solutions; namely — indigenous innovations.

Indigenous Innovations – A Way Ahead

Indigenous innovations can aid developing nations embark on a cumulative path of positive growth; thereby helping them join the ranks of the more advanced nations. Local challenges and opportunities that are as varied as the individual communities themselves, provide great opportunities to stimulate economic growth by capitalizing on the local knowledge and resources residing in the communities. '*One style of innovation that really works in a country as large and diverse as ours, is grassroots innovations: this includes inventions for a milieu that is quintessentially Indian. … they are critical to how Indian ingenuity can be directly used to transform our circumstances, in ways that elite corporate research laboratories never can'* wrote Arindam Banerji (Banerji 2004). The need to promote indigenous innovations as evolving alternatives to development has now been well recognized.

In China, the government introduced a fifteen years plan that primarily focuses on its urgent need for expanding its capacity to create "indigenous innovations". The plan, known as "National Medium and Long Term Program for Scientific and Technological Development" was introduced in the year 2006. It identifies innovation as a new national strategy for China to advance into the ranks of innovative countries by 2020. Although the industrial sector in China is burgeoning, much of this it is low value-added, labour intensive manufacturing. Majority of the industries are large multinationals owned by foreign companies, or the state-owned corporations. Realizing the urgent need to stimulate cutting-edge indigenous innovations, so as to reduce the dependence on foreign technology, the plan aims to foster smaller, entrepreneurial companies, because they are the drivers of innovation. The term 'Indigenous Innovations' is translated by them as "independent, self-reliant, and indigenous", one that combines three distinct elements: original, or genuinely new; integrated, or combining existing technologies in new ways; and assimilated, or making improvements to imported technologies (The AeA Competitiveness Series, 2007).

Significance of Indigenous Innovations

Approximately 80% of the world's population, relies on Indigenous Knowledge for either medicine or food (Nakata, 2002). The theme of utilizing indigenous knowledge to create appropriate solutions occurs repeatedly throughout developmental literature. The indigenous communities have always been innovative, but not mainly for commercial reasons (Puffer 1995). These innovations have been in the areas of farming, traditional healing, making of domestic equipments and so on, all of which were and are environmentally friendly (Sopazi and Andrew 2005). Farmers innovate due to necessity, changing conditions and curiosity, doing informal experiments on new ideas either from their own – and/or learned from other farmers, researchers, extensionists and/or other information sources like the mass media (Reij and Water-Bayer 2005). For the last 10,000 years farmers have exchanged ideas, technologies, seeds, and innovations among themselves (Rai and Shrestha 2006).

Indigenous innovations can help find the best solutions for local problems. By utilizing the indigenous knowledge and existing resources available, and in turn also generating new employment opportunities, indigenous innovations help foster self-

confidence and self-respect amongst the community. This eventually leads to economic growth and social change in the community. Indigenous innovations encourage local self-reliance, decentralization of decision-making and fair access to natural resources. As these solutions emerge from the local context, they will be more likely to be accepted by the community. Fostering *'innovation attitude'* amongst the community through appropriate hand holding, encouragements and promotion of indigenous innovations will create positive a attitude towards life and its challenges. This will help safeguard the community morale. This will also capacitate the innovators and the community against external threats that may be in the form of changing socio economic environment, introduction of new products and technologies, or even natural disasters (Puffer 1995), (Rai and Shrestha 2006).

Need for a Global – Local Approach

Combining indigenous knowledge with scientific knowledge can help create solutions that are culturally acceptable, economically feasible and environmentally sustainable for the society being aided (Puffer 1995). The old notion of research & development (R&D), as an isolated process carried out in a laboratory, concerned with generating new technologies and/or applications that are then transferred to the passive users, has now changed. Research and development is now widely seen as a learning process that follows inclusive, participatory, exploratory and experiential approach. Also termed as user-led approach, wherein the user becomes an integral constituent of the R&D team. It is therefore critical to create an enabling environment, for seamless fusion of indigenous and scientific knowledge by utilizing complimentary expertise and experience of people, and the one that is based on mutual respect. This will help stimulate and foster the culture of indigenous innovations in the country.

Indigenous Innovations - Meanings and Associations

It will be worthwhile at this stage to look at the terms “Indigenous”, “Indigenous Knowledge”, “Indigenous Innovation” and “Innovator” and their meanings and associations that are found in various literatures and research papers.

Indigenous

> *Originally, "indigenous" was equivalent to "local" or "folk" or, when applied to knowledge, "informal knowledge". In the 1960s to late 1970s, the word then took on a more overtly populist flavour of "grass-roots politics" and "folk culture" in the sense of "indigenous" as opposed to state or "high" culture. In view of the marginalization and destruction of the ecozones inhabited by ethnic groups, the meaning of the term "indigenous", at least as applied to knowledge, has today come to be used in a context in which "non-western" or "anti-western" knowledge, or the knowledge of minorities, as compared and contrasted with knowledge at the level of the nation state.* (Antweiler 1998).

Indigenous Knowledge

> *Indigenous knowledge is the knowledge that helps a society make decisions about activities, such as agriculture and education that are acceptable to their lifeways. All indigenous knowledge is by definition born out of and therefore primarily relevant to the respective locality. It is not always understood because it is an ingrained part of a culture's lifeways (*Puffer 1995), (Boven and Morohashi 2002).

Indigenous Innovations

*The term indigenous innovation has the same meaning as the following terms: traditional innovation, rural people's innovation, farmers' innovation, local innovation and community innovation, and indeed other related terms. Generally, the term innovation refers to an idea that is new or perceived to be new or altered. If this new idea or improvement of the resources is accomplished through traditional methods or knowledge systems, then it is called an indigenous innovation. It is often the case that, indigenous innovations are environmentally friendly and sustainable when compared with scientific innovations (*Sopazi and Andrew 2005).

*It has been viewed and understood that while local or indigenous technology or practice is recognized as a common practice already adapted and widely used, Innovation is considered more of something new that may have emerged from traditional practices but not necessarily the same(*Rai and Shrestha 2006).

Innovator *(…in the context of indigenous innovations)*

*Someone who develops or tries out new ideas without having been requested by outsiders to do so.' "New" is something that was started in the innovators' lifetime and not inherited from parents, like a farming techniques or a different way of organizing things (*Rai and Shrestha 2006), (Reij and Waters-Bayer 2005).

Characteristics of Indigenous Innovation

Based on the above views it is understood that the term 'indigenous' also has political connotations. Today it has come to be associated with the terms like 'rural', 'grassroots', 'anti-western' and the one based with minority. However, the dictionary meanings of the term are fairly broad based and include 'native', 'original' and 'home-grown' among others, and are lot more appropriate in the context of innovation and its implications on economic and social development.

Indigenous knowledge is ingrained into the culture and exists largely in tacit form. Unlike the western knowledge system (scientific knowledge system) that is easier to communicate and articulate through formal language including grammatical statements, mathematical expressions and specifications, indigenous knowledge is difficult to explain through formal language. Though it is probably the oldest system of knowledge and has evolved with the evolution of mankind, it is not properly documented. It has therefore generally remained constrained within the community/region. By the very nature of its evolution, indigenous knowledge will be different at different locations and with different people (Nakata, 2002).

Indigenous innovations are primarily based on their evolution as well as their applications – in the local context. These solutions/innovations are developed mostly through informal, unorganized and experimental basis, by individuals, group of interested/ affected people from the same community. As the solutions would evolve largely for necessity – to solve the problems at hand, and not for any business purpose, they will have inherent weaknesses, in terms of their replication, production and/or commercialization. They will also have limitations in terms of their migration from one culture or tradition to new environments. Within the specific context/boundary, these solutions will be most effective, both in terms of their suitability as well as sustainability.

For a diverse and densely populated country like India, that is also large in size, indigenous innovations, if encouraged and hand-held properly; offers tremendous business opportunities. For the contemporary Asian economies, the definition of indigenous innovations— “Independent, self-reliant and indigenous”; will be more inclusive and appropriate.

The innovator/s is generally part of the same community facing the problem/ necessity for new solutions. The solution/innovation will largely be the result of personal/interested group initiatives and commitments, in terms of time, resources including finance, and also the risks involved. The solutions will therefore be dependent on the experience, expertise, exposure and enthusiasm of the innovator/s. As both the innovations and the innovators are very much part of the normal life of the community, it becomes difficult to identify/segregate them for their documentation, analysis, planning for further action, or their promotion.

Interventions for Indigenous Innovations - Documentation

Identification, and detailed documentation of these indigenous innovations will be the starting point for any intervention, which may be required/planned. Identification of these innovations demands extensive field survey and investigation. Advertisements through local audio, video and/or newspaper channels, organizing specific competitions, seminars, fairs for local innovators and scouting trips/visits to local areas/villages are some of the methods used to locate these innovations and their innovators. Government and non-government extension/field workers, researchers, students, local functionaries, etc. need to be roped in to scout these ideas.

At the global level, there has been a growing interest in documenting and describing indigenous innovations/indigenous knowledge. According to documentations at the United Nations Development Programme indigenous knowledge fuels multi-billion dollar genetics supply industries (Nakata,2002). Efforts are directed to record and validate this knowledge for its inclusion into scientific knowledge which can then be tried and used for varied applications and contexts. However, safeguards against exploitation and/or extinction, politics between beneficiaries are some of the contentious issues that need to be addressed and resolved. Today, indigenous knowledge is being seen as a commodity, something of value that can be extracted and exchanged, refined, value-added and/or applied to new situations (Nakata, 2002).

Holistic understanding, sensitivity to environment and empathy to local community, while documenting indigenous innovations/knowledge will therefore help protect and augment community interests.

Many national and international organizations and resource centres, actively supported by various global agencies such as World Bank, UNIDO, UNESCO, USAID and many others are now working towards the collection, dissemination, development and extension of indigenous knowledge and innovations. These organizations and resource centres provide a platform for sharing and exchanging knowledge, information and idea/innovation, peer-to-peer learning, and for much needed collaborations and networking with various experts and supporters. They also help raise awareness amongst the community, the role of indigenous knowledge and innovations for the development and growth of local economy. These organizations, while promoting this knowledge about innovations at various levels, help safeguard the interests of the innovators and the community. Besides these, the organizations also provide the much

needed incubation and hand holding support to bring these innovations and knowledge into the mainstream.

The database of Indigenous Knowledge and Innovations is available on the World Bank website - www4.worldbank.org/afri./ikdb and a publication titled 'Best Practices using Indigenous Knowledge', jointly developed by Nuffic - the Netherlands based NGO, and UNESCO's Management of Social Transformations Programme (MOST) are some of the excellent examples of the efforts being currently made at the international level, for documentation and dissemination of Indigenous Knowledge and Indigenous Innovations information (Boven and Morohashi 2002). At the national level, the National Innovation Foundation (NIF), established by Government of India in the year 2000, has documented over 50,000 innovations and traditional knowledge practices from over 400 districts of the country (IEC: IUCN Commission on Education and Communication). This information is shared with the local communities and individuals through the 'Honey Bee Newsletter' that is published in eight different languages and distributed in over 75 countries. The knowledge and information thus transmitted in vernacular languages will help ensure people-to-people communication*. 'A honey bee does two things that we intellectuals often fail to do i) it collects pollen from the flowers, which do not complain, and ii) it connects flower to flower for pollination. In the Honey Bee network, it is a matter of principle that we always credit the knowledge we collect from people and we share any benefit arising from this knowledge with them fairly'* , explains Anil Gupta, executive vice-chairman NIF(Gupta 2000). The NIF also announces innovation awards and competitions at the national level to recognize and reward these innovators.

Interventions for Indigenous Innovations - Hand-holding

While the organizations mentioned above are focusing their efforts towards documentation, dissemination, promotion and protection of indigenous knowledge and indigenous innovations, various other organizations are working in the field to provide hand-holding and incubation support to convert these local innovations into commercially viable solutions/enterprises. One such international organization, PROLINNOVA (Promoting Local Innovation), set up by ETC – Eco-culture, a Netherlands based NGO, is today actively involved in various African, Latin American and Asian countries. Through their unique Participatory Innovation Development (PID) programmes, PROLINNOVA creates institutionalized partnerships of local innovators and scientists/researchers/academia to jointly experiment on innovations (Rai and Shrestha 2006). This helps to bring the local innovator at the centre stage as a leader/coordinator and equal partner of the entire development process. Similarly, the PFI (Promoting Farmer Innovation) project, the ISWC (Indigenous Soil and Water Conservation) project and many such projects implemented in Tanzania, Ethiopia and other African nations, arrange village workshops that facilitate farmer-innovators to organize themselves into cluster, to then carry out joint experiments/refinements/improvements on their innovations/ideas (Reij and Waters-Bayer 2005). This, while reducing isolation of these innovators, stimulate community-led social development processes. The village workshops, while together improving the identified indigenous innovations, will also discuss and identify problems/issues bothering the community that can then be solved jointly. Rural Innovation Network, RIN, Kerala; Rural Incubator, Hyderabad; Grassroots Innovation Augmentation Network, GIAN, Ahmedabad; etc., are few of the Indian organizations, today engaged in similar pursuits of development and hand-holding for indigenous innovations. These organizations help the innovator carry out market research, product refinements, sourcing of resources including capital, and its protection

through IPR applications etc. They provide a platform for collaborations, partnerships for further development, and also if required, the identification of a possible entrepreneur/company to finally pass on the innovation for a royalty.

Interventions for Indigenous Innovations – Case Studies

GIAN, Ahmedabad, successfully supported Amritbhai Agrawat, an artisan-innovator from a small village in Gujarat, to further develop his innovation of a four-wheeled bullock-cart integrated with tilting mechanism. This new innovative cart eliminates the drudgery for the farmers/labourers involved in manually carrying and spreading the farm manure in the field. The tilting cart can be used single-handedly by the farmer to distribute manure over the entire field. GIAN arranged the innovator to refine and improve this new innovation, get the necessary micro-finance etc. and also helped Amritbhai file patent for his innovation, which is now licensed to three entrepreneurs on district basis for its production (Gupta 2000, 20-21). Another success story is that of the 'rain gun', innovated by Anna Saheb, a local innovator in Kerala. Anna Saheb was successfully supported by Rural Innovation Network, RIN, which helped to understand its market potential, its further improvements and finally its technology transfer to another company. (Banerji 2004) Both these case studies are the examples of successful interventions for implementation/commercialization of indigenous innovations so as to benefit both, the innovator - in terms of satisfaction and financial gain - and also to their many users, for getting products/solutions suitable to their needs and contexts.

Criteria for Selection of Indigenous Innovations

Indigenous innovations, as they are not clearly defined, thereby make it difficult for the field/extension workers to differentiate them from the traditional practice or technological advances. These indigenous innovations/solutions could either be in the form of innovative modification/value-addition of the existing/traditional product/ process/ application or entirely new innovation that may have emerged locally or transferred from outside. PROLINNOVA's Nepal unit, based on their experience over the years, has developed criteria that could be used as guidelines for the field workers while selecting these innovations (Rai and Shrestha 2006). The important criteria for these guidelines include its technical feasibility, economic viability, environment friendliness and its social acceptability. The innovation should be locally evolved/developed using local knowledge and skills, by addressing the person's/community's immediate or long term needs. The solution should also be widely replicable while getting the innovator's consent and his/her level of interest are one of the important criteria of selection, suggested in the guidelines, its adaptability (how easily can it be used/ modified), use of easily available/accessible local resources, its affordability and cost effectiveness in terms of time and resources are few of the desirable criteria suggested in the guidelines. These criteria for selection of indigenous innovations help prioritize these innovations as per the context, understand the level of innovation and also the need and type of further interventions required.

Design – a Key Constituent of Interventions

The interventions/supports offered by these organizations would largely be in the domain of marketing – to carry out initial market research to understand market and business potential, and/or for marketing of the new products; planning and management of resources, finance; technology – product refinements, modifications, product testing

and production/replication; capacity building through training and exposure, etc. Besides these, the organizations also support the innovators for documentation and protection of innovations, promotion and dissemination of innovation and knowledge to larger audience, interface with government, academia, industry, etc., and the much needed co-ordination, networking and hand-holding. The hand-holding supports, including documentation, are generally carried out from anthropological perspectives. By the very nature of these interventions, they focus largely on market and business potentials, that is, commercialization of these innovations.

There are however little interventions visible in terms of idea/content refinements/ improvements. Design interventions, here can bring in the much needed user perspective, and help the solution sharply target its primary objective as indigenous innovation, to satisfy the need, the skills and resources available, and the local context. Product refinements, from its functional, production/fabrication, packaging and transportation, maintenance and service and also aesthetics aspects, will help convert these preliminary ideas into marketable and sustainable products. Designer's ability to view the problems from various different perspectives, empathetic understanding and unique focus on quality will help bring in holistic understanding of the problem at hand. Besides this, his/her ability to create and evaluate multiple alternatives, while helping to communicate with varied stake holders - each with different backgrounds and expertise - will help reduce numbers of iterations and thereby precious time and resources. The Grassroots Innovation Design Studio, GRIDS, set up at the National Institute of Design, NID, in collaboration with GIAN, Ahmedabad, helps provide this crucial design intervention support to the local innovators and organizations.

Characteristics of Successful Indigenous Innovations

Successful indigenous innovations, according to Paula Puffer, quickly become permanent local knowledge of the community (Puffer 1995). Paula Puffer, from her study of several such innovations, has derived some of the features that she found were common in these innovations. These features include its affordability, easy availability and reduced risks. According to her, a successful innovation generates income and at the same time saves labour. It should be easy to understand and should easily fit into current practices. These innovations produce readily visible results within a reasonable amount of time. They meet multiple needs of the user/community and are attested by evidence from several sources, including those most trusted in the community. These innovations take into consideration things such as taste preferences, nutritional beliefs, etc.. The innovators, designers and organizations therefore can try to incorporate as many of these features as possible, to improve/refine their indigenous innovations to increase the potential of their acceptability and thereby their success.

The best/successful solutions, according to the UNESCO/MOST publication titled 'Best Practices using Indigenous Knowledge', demonstrate positive and tangible impact on the living conditions, quality of life or environment of the individuals, groups or communities concerned. They are innovative, and offer creative solutions to common local problems. These solutions create sustainable effects, in terms of eradication of poverty, social exclusion, etc., and especially through participatory involvements. They also act as source of inspirations to others and also as a model for generating policy initiatives (Boven and Morohashi 2002).

Indigenous Innovations and India

India, with its rich tradition of over 5000 year old civilization, posseses infinite treasure of indigenous knowledge and practised wisdom that are being constantly used and practised in the daily life. *Creativity, in each of the culturally cohesive Indian societies, was recognized as a quality as essential and ordinary as the act of breathing...,* observed Dr. Kapila Vatsayan, a noted historian, during her convocation address at NID in 1989. Over seventy percent of India's population today, lives in more than 5, 50, 000 villages spread across thirty-five states of the country. Agriculture and crafts being their main sources of income, use of indigenous knowledge and indigenous innovations is here a necessity and therefore a common practice. As for Indian industries, majority of them comprise of Small and Medium scale Enterprises (SMEs). Fierce competition amongst these more than 3.57 million SMEs and auxiliary units drive constant innovations – indigenous innovations - for refinements and up-gradations of their products and processes. Also, a vast majority of the country's population comprises of people from rural and middle-income group segment. Indigenous innovations here are a necessity for them, in their struggle of daily life. *Indians by nature are highly enterprising and they find ingenious and amazing ways to make the most of whatever resources and skills at their disposal to earn their daily living. ....Design is the way of life in India* (Mehta 2003). There is therefore, a rich resource of indigenous innovations available in India that could be meaningfully exploited to stimulate social and economic developments at all levels of the Indian society.

Conclusions

This is the era of innovation-driven economy. Today's fiercely competitive and increasingly saturated global markets, rapid technological breakthroughs, Information Technology (IT) integration, have all left the old weapons of achieving any differentiation/edge, inadequate. Innovation is today the key to any business success. Coupled with this, the increasing awareness of ecological and sustainability issues, scarcity of materials, stringent IPR norms, mass customization, have all resulted in the demand for the solution – innovations, that have emerged/evolved based on local needs and the ones that focus on the '*quality of life',* of all of its stake holders. Tomorrow's business will compete on originality, and only the local user and the local context can provide this much needed edge, and thereby the unique strength. Indigenous innovations, it has now been recognized, is crucial for any developing nations to achieve cumulative growth of economic and social developments.

The very nature of the composition of Indian society – primarily an agrarian and service economy, large middle income and rural segment, crafts and SMEs as the main industry sectors, they all encourage development of indigenous and ingenious ways to earn their livings. Its rich resource of indigenous knowledge evolved over the years, is been constantly used and practised in the efforts of their survival, and also their progress. One would therefore, come across amazing innovations – solutions that may have been developed/innovated to meet and solve the specific needs and requirements of the person or region. By their very nature of development, these ideas/innovations will have inbuilt considerations of many of the ecological and sustainability aspects. There is, therefore, a great scope of developing these ideas and also the traditional knowledge into contemporary applications for local solutions. This would benefit the large number of people living in the region and would also generate employment opportunities. These indigenous innovations/ideas/knowledge could thus form a significant resource that can be developed into marketable products and thereby help creating business successes,

and in turn providing a vital direction for the country like India, to transit into an innovation-driven economy. *Indigenous design and development capabilities are the keys to gaining a competitive edge.…One of the very important ingredients for success of the vision of transforming India into a developed nation by 2020 is the evolution of creative leaders,* said His Excellency, the President of India, Dr. A. P. J. Abdul Kalam, during his 25th Convocation address at NID on 5th January 2005.

Indigenous innovation, by its very definition, is the one that is evolved locally, utilizing local knowledge and locally available materials, skills and resources, to solve typical local problem/s. It has to be culturally and economically acceptable to the community. Ideally, the indigenous innovation, if it is exported or transported out side its locality/region, should render itself ineffective, inappropriate or it may cease to exist completely. The boundary of the locality/ region will be flexible and may include region, states or countries, depending upon the type of solution/s and its applications. These solution/s could be in the form of non-conventional use of a given product, local improvisation/modification with scope of replication, new application of the product/materials, combination of traditional skills and the contemporary needs and markets, a foreign technology/ solution modified/value added to suit the local context, or it may be in the form of a completely new innovation. It is generally carried out to add value, to increase the life-cycle or usage of the available resources and/or products, to reuse or recycle the available products/materials, to create new opportunities and above all to improve the quality of life of the people involved. By their very nature of development, these solutions/ideas would have inbuilt considerations of many of its usability, practicality (in terms of its production/fabrication), ecological, cultural, and sustainability aspects of design.

Majority of these solutions/ideas, as they are developed to solve specific needs of the person or a group/s and not for any commercial purpose, would therefore be found scattered in the community. These solutions, as they will be mostly in the form of appropriate modifications/refinements or improvements in the existing products, will fall under the category of incremental and 'bottom-up' type of innovations. Due to the very nature of these innovations, they all will require further, critical interventions and hand-holding efforts for their protection (in terms of IPR, etc.), promotion and developments. Connecting this informal and indigenous knowledge of the innovator to the formal knowledge of the researchers/academics/industry needs delicate and empathetic hand-holding. Replication and/or commercialization of the solutions demand different expertise and mindset, than the ones generally associated with the innovators.

Any innovation involves risks, and demands patience and perseverance. The government and the NGOs involved in these tasks therefore, need to be willing to share these risks and be prepared for their long term involvements. Also, innovation is primarily a team work that thrives in creative environments and a culture that encourages experimentations and positive critique. Team synergy based on complementary expertise and strength of each of the members, and innovator as its central member, will greatly increase the chances of its success. A cluster based participatory approach that brings together the grass root innovators from the region/locality and the scientists/researchers will therefore be more suitable here.

While, interventions and supports in terms of marketing, management, engineering and finance are visible, the design interventions, that are so crucial today to develop these innovative ideas into marketable solutions are found missing, or are at best

inadequate. With global outlook, sensitivity to local needs and aspirations, and capability to hand-hold the innovator/industry, designer can help convert these innovative ideas into market success. Design, it is now recognized, is the core of innovation, and thus the key to any business success. By the very nature of its profession, design helps bring in the much needed empathetic understanding and holistic vision to connect and integrate all the various efforts towards a positive outcome. Designer would, while utilizing the unique strength of the innovation/idea, help connect these indigenous innovations to the users' aspirations, and in the process help overcome those typical constraints of resources, skills etc. He/She would thus act here as a catalyst to bring in the much needed new changes and new vision.

Indian economy demands different solutions, the solutions that are 'people centric' - people not as consumers but as human beings – a solution that generates new employment opportunities utilizing the existing skills of the people, improves the standard of living while preserving the values of traditional society (Mehta 2003). These necessitate developing a product design methodology that addresses this unique need to en-cash the abundant ingenious and indigenous resources available in the country, encourages sustainability in all its forms, and the one that is focused primarily on improving the quality of life of people involved.

Over 50,000 indigenous innovations and indigenous knowledge practices, documented by NIF, over the last seven years, could form an excellent base to build further interventions efforts. These ideas/innovations could be categorized to understand their levels of innovations, type of further interventions required, their practicality and replicable aspects, their market and business potentials, etc. While providing necessary support for their protection/IPR, developing an idea-bank/ website of these innovations with necessary technical details and market and business potentials of each of these ideas will help connect these innovators/ innovations to the interested investors/entrepreneurs. Systematic, networked and institutionalized interventions involving design, technology, marketing, management and finance specialists, along with the innovator and local participation will help increase the rate of successful transition of these innovations into markets. Incubators that can provide these much needed hand-holding supports to the so far isolated individual/innovator to quickly get varied expert inputs, information and resources are thus the need of the hour. Increased rate of conversion of these indigenous innovations into market success will thus, help foster innovative attitude in the community, leading to economic and social developments at all levels of the society.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

UFOs

Unidentified Future Objects

A suggestion on civilization brought from creative bottom-up instances

Mendoza Andrea[1].

Abstract

"*If an alien from outer space were asked*
why on Earth cities exist,
he or she would no doubt answer that
its inhabitants use those to move around,
mainly to practice the art of shopping"

BAS DE LEEW[2]
UNEP - Head of the integrated resource management unit

Constraints at all levels from time and space to tolerance and creativity affect contemporary cities/citizens.
Within this urban ambit where material and immaterial resources are limited, the aim of this paper is to give account of the promising value that a bunch of subjects and their bizarre objects, (who's value at this point of time, and space is almost invisible) can be taken to other layers of society; subjects who by chance more than by choice, don't go performing the art of shopping on planet Earth.
The paper describes who these dwellers are, focusing on the solving "technologies"/artefacts that these dwellers invent and re-invent on everyday basis and that come from non-conventional tactics backed mainly on their primal creativity.

Introduction

Have you ever seen an UFO?

Science fiction movies[3] tell that nowadays, and since long, aliens live infiltrated among our societies and that they have produced many of the episodes having place along centuries in planet Earth, from NY blackout in 1977 to the microwave oven, liposuction or even the discover of fire and the invention of the wheel.

Now, what if we gave those fictional plots a try, and started looking closely, on the streets to the non-conventional subjects and their objects? What if "aliens" are really not about to come, but are already here? And what if, as fiction tells, aliens are not "them" but, we, ourselves? What could we find out when walking out on that whirling dimension called modern urban public space?
Apparently we could find hundreds of strange artefacts with which certain individuals seem to be fulfilling their daily needs all over the world, individuals that with their bizarre inventions seem to be key in the development of our revolving civilization.

In addition, we may find that those emerged objects populating our streets, don't come from far galaxies but are artefacts with which simple people who by social, political, economical or even religious circumstances have had to (as Anthony Giddens suggests[4]) invent and re-invent on daily basis their lives.

These "aliens" who hereafter we will refer to as SOLOS (Self-Organized-Livelihood-Subjects), with heir self-arranged artefacts give account of a self-organization and talks about a self-regulation capacity, which as a value spreads in their surroundings as a kind of mutual regulation among societies.

In order to make a living and a life Solos, those subjects that in struggling situations choose for positive although difficult ways to give solution to their needs by providing a solution/service/answer to others, invent artefacts which for the purpose of this paper are named UFOs: Unidentified-Future-Objects.

Aims

Toolkits, guidelines, methodologies, sets of though criteria, complexity organizers… the aim of this paper is not to give recipes. On the contrary it intends at suggesting different research paths that not necessarily derive in design interventions, this because in order to act, it is first necessary to modestly stop and think.
In these revolving days this could seem as a privilege, and indeed, it is.

The aim of this paper is:

-–To invite those interested in changing urban mainstream conditions to be acquainted of the promising value that a bunch of city dwellers located -and moving- in different parts of the world happen to have as mere valuable capital; a capacity to organize daily lives on self-basis by adopting spontaneous, unedited and at times bizarre mechanisms to fulfil their basic needs.

---

[3] e.g. Cocoon, the Abyss, Mars Attack, and or Man in Black in which actors affirm that the steel operas at Queen's World Exhibition, the NY big blackout in 1977, the microwave oven, the liposuction, etc., are just things invented in other galaxies and given by tourist visiting planet Earth in exchange to get entrance permit. Muller Jurgen in Cinema degli Anni 90. Taschen GMBH. Page 478

[4] Giddens, A. (1991), *Modernity and Self-Identity*, Oxford: Polity Press, 1991

This acknowledgment is of utmost importance at this point and state of the world hence Solo's existence has been banalized, whereas they could be blueprint for the emblematic and unsolved match between primal needs and needs that come from consumerist societies.

Taking off

As Christopher Alexander did in his text "the city is not a tree[5]" here we will try to exemplify how Solos and their UFOs activate the dynamics of a city:

It's early in the morning. A large tray covered with a white tablecloth seems to be floating on an Istanbul street. Two wooden legs hang from it; two human legs push, shovel, move randomly under it. Legs belonging to a street vendor who happens to be selling "Simits", a typical Turkish pastry usually eaten for breakfast, pastry that he carries on the tray.
The vendor seems to be driven by a radar, being sensitive to any slight vibration of potential customers.
Even with the tray on top of his head he is able to "see" a woman who behind the veil curtains watches him from the second floor of a building. He detects her, looks up and tries to make eye contact to offer her the Simits.
The woman feels embarrassed and walks away from the window.

In the meantime a man walking down the street has seen the vendor and buys some Simits to take away. A young woman getting out of her apartment drops by the vendor and buys a bag of Simits before riding her car.
Minutes later the street is void again. The food vendor might has reached the Bosporus' port where he might have unfolded the wooden support he was carrying, built up an ephemeral table and stayed there selling the Simits until midday. The passer-by should have eaten the Simits while sitting on the minibus on his way to work and the woman should have eaten them while maybe driving, putting some making up and talking over the cell-phone".

Quotidian, simple, everyday actions. Events that talk about a society but also about a quality, a tradition, a mode and a mood to solve daily needs with not necessarily main stream solutions. The consumers here described could neither do the Simits themselves because it is time taking, nor prepare them because the Simit's recipe is something that was not passed to them from one generation to the other.

The object described here, which is a kind of articulated one formed by the tray, the tablecloth, the wooden support, the Simits and the guy, is actually a subject/object entity.

---

[5] Alexander Christopher, the city is not a tree
"In Berkeley at the corner of Hearst and Euclid, there is a drugstore, and outside the drugstore a traffic light. In the entrance to the drugstore there is a newsrack where the day's papers are displayed. When the light is red, people who are waiting to cross the street stand idly by the light; and since they have nothing to do, they look at the papers displayed on the newsrack, which they can see from where they stand. Some of them just read the headlines, others actually buy a paper while they wait.
This effect makes the newsrack and the traffic light interactive; the newsrack, the newspapers on it, the money going from people's pockets to the dime slot, the people who stop at the light and read papers, the traffic light, the electric impulses which make the lights change, and the sidewalk which the people stand on form a system - they all work together".
http://www.patternlanguage.com/leveltwo/archivesframe.htm?/leveltwo/../archives/alexander1.htm

Briefing, these urban "objects" have neither been identified as mirrors for people having their lives ruled by mainstream ways of production/consumption, nor have been detected by the radar of those working on the city subject, who could target them not as informal-immigrants-burdensome vendors, but as possible bottom up creators that could bring about solutions starting from behavioural instances for the here, for the now, and for the future.
These solutions, let us be clear, would not mean to make designers "improve" Solo's ways of being and doing or pushing design to fall into an old discourse of using discarding material to add more objects to the already saturated material culture environ. As said this reflection is been made as part of Design Research Studies and as such invites at thinking on the way that design and associated disciplines, could prompt citizens to spark their inner primal creativity such as Solos already do.

Cities, a resource

Solos field of action stands in what according to Hans Rosling[6], (Swedish expert in human development), is the 60% of the Planet's population. People who are not beggars but trashing about on daily basis to get a living within a radius of income which goes from 10 to 20 dollars a day[7]. Therefore, they don't miserably dwell in the marginal parts of the cities because as said, they have pierced contemporary urban spaces.

Reflections on the future of contemporary cities have been addressed from the most fictional to the utmost realistic scenarios; but it was not until the last decade that it started been seriously taken, meaning passing from just envisioning what a better planet or cities could we build up or what apocalyptic almost cinematographic catastrophes should we avoid, and started acting. Dozens of roundtables[8] gathering brilliant characters from all over the world have met in all conceivable places to start making sure that policies were put into practice.
Many of these actions have been prompted by top down organisms, official leaders and/or by disciplines strictly bonded to the city such as Architecture and Urban Planning; but now it seems that the subject "city" needs that fiction and reality convene.
Here is to mention what Anna Tibaijuka, (executive director of United Nations-Habitat program) recalls on the '2007 State of the World report[9] regarding struggles to change our cities. Tibaijuka:

"*Charles Dickens, Emile Zola, Jacob Riis, and Edward Mayhew were instrumental in improving the urban policies of their day. Today, researchers and authors […] help sensitize the larger public to the major issues of our time".*
In the UN-Habitat documentary called Slums, she adds: "*The first solution is awareness, about the magnitude of the urban challenges […] democracy, solidarity, equity and to see [people] as an asset*[10]".

[10] Quoted by Hans Rosling in UN-Habitat film on slums.

Her position goes in line with what Richard Florida[11], expert in creative cities, have said about the last book of Charles Landry (another city specialist) called *The Intercultural City*[12]. Florida reads: "*there can be no truly creative or competitive cities without first having curiosity, compassion, conviviality and co-operation*.'

All these nouns: compassion, equity, sensitivity, creativity, go in hand with the arty approaches embarked on design studies because, as Andrea Branzi[13] states: "Art is what really pierces society".

Nowadays legitimated disciplines have realized not only the importance but imminent necessity of looking beyond the boundaries of each official rank of knowledge in order to simplify, because what is simple is what the folk actually gets, and Art in its many forms being it cinema, photography, sculpture, public art, etc., is in its interlinked approaches, a way of translating scientist's findings into folk's language.

UFOs

What basically differentiates a filmmaker's envisioning from any vision coming for instance, from design, is that design is called to act on non-fictional basis. But, could fiction be a resource, a way to depict improving scenarios regarding urban lives in planet Earth?

A primary response could be found in Ron Burnett[14], who states:
"*I have been involved in Cinema Studies for over forty years. At that time cinema studies were not considered to be a legitimate discipline […] the work of filmmakers like Jean-Luc Godard, Ingmar Bergman, François Truffaut and Italian directors like Antonioni, Bertolucci, Fellini and Pasolini combined with an explosion of creativity in experimental cinema [opened] a window and often a mirror through which individuals could reflect not only on art, but also on their status and identity within western societies. Unlike other activities, the cinema's links to popular culture, encouraged new ways of thinking about hitherto dominant notions of high culture. Simultaneously, pop art was transforming the modernist trajectory in the visual arts incorporating everyday objects and sign systems into artistic visualizations and representations. […] This convergence along with the scholarly work of McLuhan, Innis and Carpenter in Canada, Christian Metz, Roland Barthes and Claude Lévi-Strauss in France […] were part of an intense period of creation and reflection on the status of cultural forms and their impact*."

As seen, regarding cities improvement various disciplines not just urban planning architecture or politics but ethnography, psychology, economics, literature, filmography, photography, public art and design have step into the city's discourse. For instance the Roman collective Stalker (homonymous of 1979 Tarkovskij's film leads "transurban" actions by crossing on foot interstitial zones of cities such as Rome, Milan, Turin, Paris, Berlin and Miami to develop an analysis and intervention methodology on those pieces of urban space in continuous but unconscious transformation.
When practicing what Stalker calls "transurban" crossings, and that we for the purpose of our research adhered as deriva, (urban drifting for other authors[15]), many

[15] e.g. Baudelaire's flâneur, or urban drift carried out by Dada, Situationism and Psychogeography. See http://devenirnomada.blogspot.com/

of the so far invisible or unrecognized urban objects, subjects and situations in the grid of the city start rising. What we would like to highlight here is that if one is keen to acknowledge them, the fact of identifying these objects may give a key to build up not only the future of the cities but to re-think its here and now.

On this regard (*deriva*) I will recall the peer reviewer of this paper who in his/her assessment presented a great knowledge regarding the *deriva*; he named a list on how can it be applied:

"… urban drift:
- a collaborative platform for contemporary urban strategies
- networks initiating and supporting urban interventions
- hybrid urban praxes
- opening up and communicating architecture to a wider cross cultural audience
- inventing and presenting urban survival strategies
- inventing time-based architecture (projects that take account of time factors) permanent, transitory, temporary and ephemeral
- urban transformation and the reanimation of lost, forgotten, and hidden city spaces
- responding to drift-inspired random movement
- trans-cultural collaboration-
-the city as a medium (scavenging; remapping; re-sampling the city through light, sound, and text; life as a survival form of urban nomads; the reinvention of spaces; intervention; curating, refocusing, making aware or explaining urban conditions (misconceptions, realities, and myths)
- working with the city's second skin (virtual worlds, gaming, and computer gamers whose lives have been transformed by the emerging genre of Massively Multiplayer Online games (MMOs)
- facilitating a mobile and fluid urbanity
- reading the city as text
- deciphering psycho-geographies of the space for better possibilities to refine interrelationships
- the creation of urban situations
- looking for, reassigning functions and values of peripheral urban spaces
- process-driven urban design
- building and reducing urban voids
- animating urban life
- evolving knowledge about the insert something artificial into what is real will distort reality
- container cities; city in a state of flux; but modular; viral; transportable and translatable sometimes but not always elsewhere;
- drift via text; smart materials; mobile technologies; and new hybrid cultures in urban design; soundscapes; multiple identities, etc."

We would just add that it was not clear to our peer reviewer the fact that we are here trying to address which is the possibility that urban drifting has as a possibility to be given to citizens of go and recognize, with a arty-some approach, the primal creativity that their urban dwellings display and then, having acknowledge it, go back home to, take what they find out there as instance of what a civilization may be so that consequently they feel prompt to awake and activate their primal creativity, the one with which we all given our human condition are entailed. In so doing valuable worlds from Solos practices could, according to us, emerge.

Now, there is to say, not to conclude, that art do and will play an important role in the long term run for design because as said, art is what really has, is and will, pierce the

social tissue (Branzi 2007[16]) hence is a strong prompter of behavioural changes in people. In words of designer Bruce Mau[17]:
"The future of art will be to recover optimism and beauty. Which, I think it largely abandoned in the 20th century. There are some historical reasons that make sense with that".

I would also like to add that the title of this paper "UFO" has not been lifted from "UFO Belgrade", as the peer reviewer suggests, but still, having gone to know explore what it is/was, UFO Belgrade seems very appealing and worth seeing for those interested in the peripheries of city's contemporary discourse.

Time, an ephemeral dimension

The ephemeral although permanent presence of objects such as the one of the Simits, are platform to set three different, but interlinked conversations.

Firstly, individuals assembling artefacts like the one of the Simit's example, have somehow a capacity to "travel" in time.
Like subjects of a fictional movie, they seem to fluctuate between past, present and future in an almost… candid way. At times they look like coming from a post-catastrophic world in which resources of the planet are gone, but they came back successfully because thanks to their flexible minds, their nomad and low consuming rate lifestyles they could survive. Other times, they look like coming from the past bringing with them a rich source of knowledge, traditions and wisdom that contemporanity has forgotten and that is of precious value to our present generation.

Secondly, the Simit's example brings to the floor the afore mentioned discussion that Giddens posts[18] as the necessity to daily invent and re-invent our living ways and thus overcome the challenges of contemporanity by constantly updating our biographies, in other words, it is a call to activate our primal creativity everyday.

On a third moment there's the role of artefacts as pre-political solutions. To enter this third moment, we contradictorily bring a politician to talk about it.
When asking[19] Antanas Mockus, former Mayor of Bogotá, Colombia if, in order to get citizens acting together as a whole what planet Earth may need is a sort of alien invasion…, which kind of invasion should it be? Mockus answers that:
"*who has to invade us is the Other the one in which we are not enough thinking nowadays*".
Solos then match with what Mockus calls the: "Time Machine experiment".
Mockus:
"*I have proposed in various conferences the topic of the Time Machine, meaning: you take our grand-grandsons and imagine that those grand-grandsons discover a time machine and have the possibility to come back and show us the planet we are leaving them and so they try to correct us, to persuade us, to make us think in the other; […] it is possible that the most alike people to whom the grand-grandsons could be identified to, are Solos, so positively what we need is learning to look ahead by looking back* […] *Citizenship culture looks for organizing the transition to an accomplishment of the law, sometimes even modifying the law…*" meaning rules

coming from the relations that systematically, as Christopher Alexander has proven, are already set into motion out there, on worldwide-streets.

Where then stands Design?

What could happen to design if in the near future the urban-daily objects with which humankind fulfil urban-daily primal needs were not bought, but created and re-created by "users" themselves? What if given contemporary limits citizens of/in/for/with the world started activating their inner creativity to give solutions to their needs?
Breaking, stretching, bending, crushing, cracking, folding the stuff around us (as Bruce Mau's suggests in his Incomplete Manifest) is what, maybe we could be triggering citizens to do, triggering them to observe, to learn from what others are already putting into practice, to arrange their daily lives in such a way that this arrangement can derive in a mutual social arrangement.

In a world where the discussion on human permanence in the planet points out to imminent-catastrophic insights, it seems that not only for the sake of future generations, but for the here and now, what we need is to focus on the possible positive suggestions of such fictional insights, and identify the positive potential objects, subjects and behaviours that could improve life conditions in the cities of planet Earth.
How can /could this be done?
By prompting an appropriation of the urban realm in non-Solos citizens by means of a jointure art-design, meaning, by using for example:
a. activating or being platform for the above mentioned strategy of *deriva* to prompt primal creativity in non-Solos audiences.
b. by giving room to design so that their fixed categories can move gently and independently from mainstream and or too perfect design tactics, as B. Mau's[20] suggests:

"If you think about design independent of form and visual practice, and you push it through to designing what we need… in terms of "what are the possibilities", whatever form they take[…] and, use the visual to articulate those possibilities […] ultimately to think, ok, what are the capacities we need to develop to solve this problem or to meet this need… It'd change fundamentally what the categories of design are".

The End

In the movie man in Black[21] they say that:
"On average, there are 1500 aliens on planet Earth, and most of them are located in Manhattan"…
Solos, instead, are not, or not just located in Manhattan; they keep on arriving/emerging in big metropolis in order to infiltrate themselves in the public realm and thus make not just a living but a life. Important is that whereas one can disagree or ignore the fictional existence of aliens and their invasions in movies, the existence of Solos and their non-professional creativity is real, they do exist, and are part of the engine which daily starts up the dynamics of this complex transition that the planet is experiencing.

[20] http://www.stockexchangeofvisions.org/vision.php?id=295. Last access May 24, 2008.
[21] http://www.imdb.com/title/tt0119654/

To conclude, there is to say that Solos, their invented artefacts and behaviours are instrumental in prompting a change in the perception of contemporary needs, being those basic or not.
Solos' solutions are not apocalyptical, rather are portraits of what is presently going on and could be seen as depictions of a positive alternative to shift our linear schemes of mere production, consumption and behaviours related.
Like that, we, as designers, have the capacity to create, recreate and prompt primal creativity in other layers of society.

Because of their infiltration capacity, their invisibility, their weird artefacts, their somehow abilities to anticipate events bringing back forgotten knowledge and practices and specially because they don't practice the art of shopping in planet Earth, it seems that ignoring these Solos would not be the solution to actually improve our societies or prevent urban dwells from worsen, because if we look closer, Solos may be "bringing a message" from that other space in which they dwell, an urban space that we all cross everyday but that somehow we are forgetting how to navigate in.

At this point, we can almost assure, that you have seen an UFO (Fig.1) in your life, the question now is:

Are you ready to ride on it?

Fig. 1: Palermitan Solo riding his UFO

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

A vision of an *urban countryside*.

*Service Design as a contribution to the rururban planning**

Anna Meroni[1], Giulia Simeone[2], Paola Trapani[3]

Abstract

This paper aims to present, from a Service Design perspective, a scenario of sustainable development for a critical and crucial context: the *rururban* territory i.e. the *periurban* area that lies between a town or city and its rural surroundings.

It is here that urban and rural dynamics meet, creating unique opportunities (or risks) to improve the quality of everyday life and make a decisive step towards sustainable territorial development.

This approach, uses Service Design skills to help us visualise empty or pending urban spaces as a rich, multifunctional territorial resource, where virtuous local interactions among actors create a network of services that can support urban planners and architects in giving shape to the territory.

The paper presents an Italian research project developed for the Agricultural Park South, surrounding the southern part of the city of Milan.

* This paper s the result of a collective work, but, for the proposes of this publication, A. Meroni has written the paragraphs 1-6, G. Simeone has written the paragraphs 3-4, P. Trapani has written the paragraph 2-5.

1. Background: *rururban* territory and virtuous networks

The so called *rururban* territory (Donadieu, 1998), i.e. the *periurban* area that lies between a town or city and its rural surroundings, is a critical context for the sustainable development of any urban area. These areas are subject to urban expansion where formerly separate cities and towns merge into vast urbanised zones: *periurbanisation* may be described as a process that integrates rural areas into systems organised around cities, and such a process has heavy spatial and social consequences, resulting in what Gottmann called a *megalopolis* (Hugo and Champion, 2003) The way this comes about is crucial for the development of a region. It is here that urban and rural dynamics meet, creating unique opportunities (or risks) to improve the quality of everyday life and make a decisive step towards sustainable territorial development.

According to the European Spatial Development Perspective, the kind of *urban-rural partnership* is a key issue: to define the nature and structure of this partnership, a multidisciplinary approach is needed, crossbreeding contributions from the disciplines of finance and economics, urban planning, geography, sociology, agronomy and landscape architecture (Landry, 2000; Viljoen, 2005)

Recently, Service Design has also taken up this debate, and this territorial application looks extremely promising for this new discipline. Collaboration would appear to be particularly promising with the so called *Scuola Territorialista* (Magnaghi, 2000), which seeks to valorise territorial heritage (environment, urban settlement, culture and society) as the only possible and fundamental approach to producing a lasting enrichment of an area. According to this approach, places are the result of a historical co-evolution of human settlement with environment, nature and culture, whereas the recent functionalistic approach tends to consider the territory as a kind of technical support for activities organised independently from the local means, resources, potentialities and qualities.

In such a framework, the concept of sustainable development not only refers to the reproducibility of natural resources, but also to the way in which urban systems are established; to the coherence of productive systems with local resources and entrepreneurship; to the development of capability and self government by local communities.

Service Design contributes to this approach by observing local social innovations, meaning local virtuous and promising activities in different areas of doing, and interpreting them as forms of interaction and exchange of benefits that call for proper (or better) infrastructure and support. Virtuous and promising activities are those able, in everyday life, to bring individual interests into line with social and environmental ones (Manzini and Meroni, 2007). In different ways and for different motivations, such behavior often means *radical changes* in the way practical problems are solved, and would appear to represent a positive step towards sustainability, drawing the interest of an increasing number of people. It has been argued (Meroni, 2007) that since such bottom-up initiatives, along with the Creative Communities that activate them, are deeply rooted in local territory, they can be considered the starting point and the stimulus for a new generation of collaborative services (Cipolla, 2004) within a scenario of Diffused Social Enterprise (Manzini and Meroni, 2007). In other words, Creative Communities together could mature into a form of social organisation where a larger number of people are enabled to organise themselves to achieve results that interest them, while producing sociality and environmental quality.

Because of the common interest in understanding the link between people and places, and between virtuous initiatives and promising models of settlement, this Service Design-driven approach to social innovation can also conveniently integrate the urban planning approach of the *Scuola Territorialista.* Its contribution consists in offering another disciplinary viewpoint and

methodological toolbox for generating a new paradigm of urbanisation which grows out of an understanding and enhancement of local virtuous initiatives, rather than a techno-functional ratio, in a vision of connected and symbiotic networks.

Given the previously discussed critical state of *rururban* territories, where open spaces tend to be inundated with building or treated as residual gaps, the combined approach to territorial development of Service Design and territorial Urban Planning could lead to an experimental one, where local interrelations become dominant and generative, so that even empty or pending urban spaces are seen as rich, multifunctional territorial resources, where virtuous local interactions create a network of services fulfilling ordinary needs and, at the same time, producing sociality and environmental quality.

In such a collaborative pattern, after an initial phase of identification and understanding of local best social innovation practices, the Service Design aim would be to outline corresponding *service models* to be utilised in generating a *scenario framework* for the development of the territory: a scenario that, in seeking to facilitate virtuous interactions, would foster an urban planning strategy able to support Diffused Social Enterprise.

2. Social innovation and experimental projects

This essay presents part of the results of an Italian research project, founded by the Italian University and Research Ministry (PRIN, Miur, 2006 - 2007) for the Agricultural Park South, surrounding the southern part of the city of Milan, in region of Lombardy. This area is an emblematic example of the previously described situation, currently suffering from highly speculative pressures and a lack of vision in terms of a possible sustainable partnership between the town and the productive countryside. The aim of the research was to construct a theoretical and instrumental foundation for a new way of designing urban settlements.

In view of their specific areas or interest, the cases of social innovation here considered can be partially gathered under the umbrella of the so called “solidarity economics networks” (EQUAL, 2007) and are mainly related to three fields of activity: 1) the production, exchange and consumption of food; 2) leisure in the area between town and countryside. 3) the innovative housing and hospitality system in the *rururban* areas.

They demonstrate the presence in the Lombardy Region, and in the Milan area in particular, of a lively humus of activities, already creating a virtuous, but still fragile, network in the territory: numerous examples of solidarity purchasing groups, community supported agriculture, farmers’ markets and direct sales, organic and quality food production, agritourism initiatives for proximity leisure, innovative housing and working typologies. Even though these virtuous initiatives are currently working, they are the result of a sort of *early stage heroic effort*, and lack any real supporting system and any effective transversal connection.

Besides this emerging local reality, it is useful to observe some experimental projects in various parts of the world that exemplify how to use the Service Design approach to integrate the competences of the various disciplines working on territorial development. We will briefly discuss two cases where the approach and field of application are of particular interest:

_ Dott2007 (*Design of the time 2007*) is a national initiative of the Design Council aiming to explore what life in a sustainable region (i.e. North East England) could be like and what role the Service Design discipline can play in achieving it. Spotlights are on five aspects of everyday life: movement, health, food, school, energy. Dott2007 promotes a “less-stuff-more-people approach”, where services help the community to share the load of everyday activities: eating better food, caring for sick or aged people, looking after children, going on holiday, washing clothes and so on. It is a matter of providing instruments to develop personal visions and scenarios, rather than teaching people how to live.

_ VEIL (*Victorian Eco Innovation Lab*) is devoted to research, innovation, creation and testing of fruitful long-term (typically 25 year) scenarios for sustainable solutions: concepts for sustainable products, services, built-up environments and lifestyles in the Victorian region of Australia. The project promotes an interdisciplinary research environment: an evolving 'think-tank' referred to as *the Hub*. It matches different contributions in constructive speculation; calls on the university design program to re-invent the future; presents new products, services, systems and life-styles to be tested in real everyday life; drives investments and social tastes to expand the request for eco-innovation; helps professionals to develop a successful career dealing with these issues; matches the best research with government policies. These long-term visions and eco-innovation ideas are also taken up as '*design studio*' topics for the university design schools (and as student competitions). At the end of these design studies, the students' work is sent back to the VEIL, and the most promising ideas are discussed in a *post-production workshop*, involving students, hub members and professional designers. Here, the projects are revised in order to make them suitable for communication to the general public and media, and then discussed.

Both examples show some common points that can be considered essential in a Service Design driven approach to sustainable development:

- they present a high degree of multidisciplinarity;
- they involve the different local actors in a co-design process, and put them in direct relation with each other;
- they stimulate a self-help attitude and develop community capability by providing enabling tools and creating the conditions for the birth of a flexible socio-economic system;
- they rely on the strengths and on the opportunities offered by the local territory.

3. The scenario framework: hypothesis and objectives

The real problem of defining a urban identity of *periurban* areas is the apparent lack of profitable and practicable alternatives to production sites, housing or offices. However, increasingly supported by current reality, the researchers hypothesised the profitable feasibility of developing existing small agricultural concerns in a local network, taking into account local resources and opportunities offered by the local territory.

Work was based on two main hypotheses:

- only by using local resources (Mirata and Ristola, 2007) and activating collaborative and open services (Cottam and Leadbeater, 2004) is it possible to make real, tangible and effective improvements in quality of life and environment.
- local collaborative patterns, involving both local inhabitants and enterprises, can lead to powerful social innovations able to radically change settlement models, by changing underlying practices (Latouche, 2004).

In this conceptual framework, the role of Service Design is to interpret, activate and develop such collaborative local enterprises, in order to provide them with a more favourable ground to flourish (EMUDE, 2007). This means, first and foremost, creating a network of interconnected and complementary *service models* able to develop a different partnership between town and country. To use the tools and the language of the discipline, this partnership typology defines the *scenario framework* (Ogilvy 2002) that challenges the overflow of urbanization by presenting sustainable alternatives: *periurban* areas are seen as places where the *network economy* meets the *collaborative service pattern*, giving rise to a vision of an essentially *multifunctional urban countryside* where:

- the food system aims to increase regional self-sufficiency through local food sale and the de-mediation (Meroni, 2006) of agricultural production. This still remains the most important function of periurban agriculture (Petrini, 2005);
- relationships between rural areas and the city are strengthened in terms of material, economic and cultural flows, and rationalized according to a sustainability assessment;
- enhanced agritourism activities add a new perspective to proximity leisure ;
- locally focussed, regional economies generate income and improve labour opportunities (Fleury, 2005);
- closed loop systems use better and cycle the results of rural activities within a logic of service symbiosis (Mirata and Ristola, 2007);
- good practises and *soft policies* can play a significant, structured role;
- traditional and new communication technology fosters the constitution of collaborative communities;
- agricultural activities can inspire new urban lifestyles by promoting the diffusion of technologies that allow urban farming (green walls and green roofs, simplified hydroponic and aeroponic systems), ease the spread of a new generation of urban cultivators and, at the same time, increase the quantity and quality of urban green (public and private)

4. The scenario for the Agricultural Park South

The work presented here is an action research project conducted by a multidisciplinary team, in 2006-2008 under the auspices of the Italian University and Research Ministry. Its aim was to lay a theoretical and instrumental foundation for a new way of designing urban settlements, through the proposition and visualisation of a scenario of sustainable development for the great *periurban* area of the Agricultural Park South.

This area, made up of different kinds of field partially rented out to farmers and partially owned, is managed and overseen by the local authority for the Province of Milan.

It is an area currently in decline as small farmers abandon the fields, and the soil is overexploited by agro-industrial production. It is also subject to aggressive building programmes and, as their contracts expire, leaseholders fail to invest in new infrastructures and services. Even the small producers are not stimulated to invest money in the agricultural business, which is no longer profitable in a mass distribution scenario. Despite this situation, the previously described solidarity economics network (a mix of Creative Communities and Creative Entrepreneurship) has emerged, and seems to open the way to a sustainable development.

The project has taken this virtuous situation as a starting point from which to develop a coherent system of interconnected territorial service and actor networks, mutually reinforcing and producing business and society.

This system consists of eight *service models*, which we will describe briefly, that take their inspiration from the observed reality. Per se, they are not yet networked or multifunctional, but they are the basis of the entire system.

The collective Park brand

What shared identity can we attribute to this park which is able to characterise its activities? What does this identity entail?

The answer is a brand that denotes the short chain initiatives and activities that are the result of networked collaboration between different actors (eg: food box subscription with products from different local farms; agritourism hospitality combined with other leisure and catering services etc.)

The authority issuing this brand could be a consortium of producers, or the local authority for the Province of Milan, which wants to promote and support the quality of Milanese local products. The products awarded the brand must be the result of collaboration among different local producers; there must be a set percentage of products/services distributed at local level; the products/services must be produced and delivered according to eco-friendly production techniques (biodynamics, biologic and integrated systems…).

Farmers' market: the market for the Park's produce and services

How can the Park and its produce be brought into the city? How can the city feed on its territorial produce? Where can a trip from the city to the countryside start?

To enable short sale from the producer to the consumer, the Farmers' market can be placed in dedicated areas within the most important street markets in the city, following a weekly rota. Organized by a consortium of local producers, it can support the de-mediation of both product and services, encouraging access to the park from the city.

Local product and local services can be sold side by side as in a new kind of street market, where people can find "packages" to enjoy the territory (bicycle rent discount, restaurants), last minute offers of surplus produce and a refreshment point, providing take away food and ready to eat snacks, made with local produce.

Public green procurements: green purchasing

How to transform an administrative protocol into a landmark for aware consumers and enlightened producers? How to organize local windows for the exchange of high quality produce and services?

The Consortium of Local Producers can be the promoter and the provider of this service. It can create touch points between virtuous producers and critical consumers through the realization of critical mass and the organization of shared platforms for goods exchange based on the model of group purchasing organizations. The solution works like an auction where the discount of the products increases with the increasing of the amount of people who join the auction, so building critical mass. Consumers can join the service either through a *digital window* or a local agent, who is a resident of the Park, paid by the service provider.

The food box subscription

How to supply the city with local produce through a convenient and advantageous service? How to give commercial continuity to the producers?

The food-box is a de-mediation service promoted by a consortium of producers, or by a bigger farmer and his network of small suppliers. It is conceived to be accessible in terms of costs, because of the cut in long distance transport, and in terms of convenience, because of the regular home or near-home, delivery. The consumer can personalize his/her purchase by choosing the products he/she wants, how much and how often according to his/her needs.

Visitors' centre: the Park Points

What could a "visitors' centre" look like in an agricultural park? What is it possible to find there? Who takes care of it?

Park Points are welcoming place, located at strategic points in the Park. They combine physical access to the territory with access to its knowledge and its produce. Here it is possible to find an info point and local produce on sale at the same time; or it can also be the starting point for special routes and itineraries and offer agritourism hospitality, etc.

This service is like a mirror of a Farmers' market: it is a territorial agency for the park within the Park itself, and it also sells produce from the closest farms, whereas the Farmers' market is a place where the visitor/consumer can get in touch with services and information to visit the Park and where he/she can buy local produce. A Park Point can also work both as a welcoming centre and as a logistic sorting hub linked to the Farmers' market and vegetable orders.

The rural cultural centre (at a historical building)

How to create an active cultural place in a Park? Where is it convenient to place it, what is it possible to find there, what is it possible to do? Who takes care of it?

The idea of a Cultural Centre is to enhance the value of local biodiversity through activities carried out by scientific researchers (from Universities) and experienced local farmers.

It should bring together a seed savers' association, a botanical multimedial library and a botanical garden, working together. It a place of knowledge and study of local cultivation and traditional farming techniques and is also a consulting window for local producers on advanced farming techniques (advanced organic and biodynamic cultivation, the use of indigenous species etc.). Since this is intended to become a point of attraction in the park, it should be located in a building of historic or other particular interest.

Horticulture

How is it possible for an amateur to enjoy taking care of a vegetable garden in the Park? How can the Park be made more beautiful, vital and healthy with the help of amateur gardeners?

The service transforms available fields on the farms into amateur allotments to cultivate as small vegetable gardens. Amateurs can pay a rent to the host farm or a fee as part of the association that organizes the service. The garden is hybrid space where individual and collaborative activities are connected, as for a *time bank*. When a farmer needs help in his/her activities he/she can rely on an internal exchange of favours and products, managed on a credit system. .

The design of the service facilitates the internal exchange system, which needs to be organized and balanced to make collaboration as friendly and easy as possible.

Urban indoor/outdoor agriculture

How is it possible to enjoy cultivating a vegetable garden in the city? How can 0 mile fresh and biologic vegetables be produced?

Advanced building and gardening technologies can help urban farming: from great metropolises to smaller towns several solutions like green walls and green roofs, simplified hydroponic and aeroponic systems, are getting footing in urban environments to fulfil the need of citizens to cultivate their own food.

The service is intended to give advice on implementing such solutions, based on fixed parameters like the season, the space and the energy available, light and water requirements and so on. It can support users in setting up and maintaining their own vegetable gardens.

5. Service structure and organization

These eight *service models* are quite consistent with each other, but a deeper analysis is required to understand how they can overlap, integrate and share resources so to create a symbiotic network.

In order to do this, a frame of analysis has been developed breaking the services down into assessable elements (Jegou, Manzini and Meroni, 2004) The different elements (the minimum material or immaterial self coherent constituents needed to deliver the services) have been clustered under the following categories:

- Logistics and infrastructures
- Material goods
- Immaterial goods
- Human resources
- Communication

All the eight service models have been analysed using these criteria, so as to understand how they overlap and complement each other, giving rise to possible synergies or closed loop systems. Taking the Farmers' market (FM), the Horticulture (H) and Park Points (PP) as examples, it emerges, for instance, that:

- FM and PP can benefit from sharing logistic systems, means and storage: a well equipped PP would appear to be a convenient collection and transit point for the FM;
- since PP and H, both need an accessible location, they can often be merged. Additionally, the two services both need to attract people for working and for leisure, so the amateur farmers can play an important role in animating and making the PP work:
- FM and H call for similar management actions and tools, so they can share the same system of managing work credits/debits.

By repeating this analysis over and over again a conceptual map of possible integrations emerges, where it is possible to see:

- an overlapping of the elements: potential economies of scale and convenience in joining the services
- complementary elements: potential economies of scope and convenience in linking the services.

Using this method it has been possible to establish guidelines that make a convenient multifunctionality in the agricultural service system feasible.

6. Conclusions: networking and multifunctionality

The services described here propose a vision where agricultural activities, and particularly food production and exchange on a local scale, become the means of sustainably developing *rururban* areas. They rely on direct relations (de-mediation) between producers and consumers, and their collaborative nature blends the roles of the actors, highlighting the need for a local rural-urban production partnership to produce territorial value.

They become profitable precisely because they use the local resources to best advantage: as a matter of fact, the availability of such resources and the possibility of having direct control over them, as far as quality and quantity are concerned, is the distinctive and key factor that enables small business to use them in a beneficial way, making the difference in the market. This allows small enterprises to create the distinct features in their offer that attract the critical consumer; controlling these resources is the way to activate a quality market beside the mass one.

Nevertheless, without a network strategy able to share and complement assets and resources, they are unlikely to have sufficient power to influence the way the territory takes shape: only when and if these services become self-sustaining, will they be capable of creating a social and economic territorial humus that can counter the building speculation.

In order to support their diffusion, Service Design aims to make them more accessible and affordable for a larger target of users and, at the same time, more practicable for a larger group of producers (Manzini and Jégou 2003). In such a framework, the network strategy is a way of increasing both options and benefits to users and effectiveness and convenience for producers.

The functional basis for building the network is the need to share or complement the main elements that constitute the services. From a social and relational perspective, the key point is to enhance actor perception of a coherent community where everybody contributes to collective success.

This approach can lead to a feasible concept of multifunctionality, where activities become conveniently manageable by the actors, not wasting working capacity, but rather increasing it. In these terms, the collaborative aspect of these services is also a way of relieving the farmers or the associations in charge of the territory, of the burden of delivering several services. A self help group of amateur farmers can, for instance, cultivate a field on the farmer's property with a relatively autonomous attitude, using equipment in exchange for labour. A group of professional farmers can run direct sales more easily by managing turnovers and sharing logistics. A group of experienced agricultural enthusiasts can effectively help the less experienced in approaching the cultivation of native species, or processes, much better than a consultancy.

The emerging network (an articulated model of *Community Supported Agriculture)*, a way to exchange or pool resources and competences, can be seen as a web of interconnected and complementary services in the territory, which operatively tends to concentrate around crucial points where, for the convenience of the enterprise, several service models can coexist. We can call these points *territorial service ganglions*, because of their crucial role in making the whole system work. They result from the sum of different overlapping and complementary opportunities, where food production, exchange, hospitality, leisure, cultural and social activities create a unique mix of functions, adding value to the territory even simply by avoiding its exploitation for building.

The *ganglions* are the key points of the system, with a multifunctional role. They can be seen as the result of the functional optimisation of business and the convergence of social and human energies around an epicentre of entrepreneurship, which could be a community or a business with the social innovator characteristics previously mentioned. In fact, management of the *ganglions* calls for actors with a distinctive and outstanding entrepreneurial attitude: farmers, associations or other enterprises that, like the *creative communities*, are already notably active in the territory and whose current activities will be enhanced by this new role.

A *ganglion* manages considerable flows of goods, resources and persons, gathering together several smaller activities. Because of the availability of adequate resources and infrastructures, and its strategic location, it plays the role of strategic operational support for businesses gravitating around it: it can better express its own potential as territorial enterprise, by making it possible to activate a win-win alliance with smaller businesses in geographic proximity. Back to the example of a possible convergence of Farmers' market, Horticulture and Park Points, a *ganglion* can be a Park Point endowed with a logistic platform for gathering the product for the

Farmers' Market, at the same time selling part of them, and hosting a community of amateur gardeners.

The possibility of activating synergies or sharing with other businesses in close proximity is, moreover, a way to create virtuous circles that also valorise the offer of leasehold-farmers unable to benefit from huge investments in adequate standards of service. This dynamic can activate an *economy of reciprocity* where services and goods are exchanged outside traditional market rules, creating a flexible local system.

For all these reasons the *ganglions* are the means by which *soft policies* (bottom-up rules and behaviours self-imposed by local communities in order to increase quality) are implemented in the territory, and are also crucial points where institutional policies and local Authorities (Landry, 2000) could really and effectively support them in producing a sustainable local development of *urban countryside*.

Visual explanations of ecological cycles in science learning material

Annegrete Mølhave[1]

Abstract

This paper discusses the anlaysis framework and critical review of visual explanations – eg diagrams – of ecological cycles. It focuses on visuals from English and Danish biology and chemistry textbooks [1930-2008] for 14-18 year olds. Diagrams of ecological cycles [eg carbon-, nitrogen- and water cycles] are common elements within such textbooks.

Given the current focus on sustainability, as well as carbon and nitrogen emissions in the environment, these visuals are essential in developing public understanding of such important scientific concepts. The review finds, however, that imprecise categorisation of information in diagrams may cause ambiguous messages about circulation of matter within cycles. The review method is then proposed as a generative tool to define practical design briefs.

1. Visual explanations of ecological cycles

A visual explanation is a visual artefact predominantly in pictorial and schematic mode aimed at describing in detail a specific content. This paper discusses the anlaysis framework and critical review of visual explanations – eg diagrams – of ecological cycles. It focuses on visuals from English and Danish biology and chemistry textbooks [1930-2008] for 14-18 year olds. Ecological cycles [eg carbon-, nitrogen- and water cycles] are cyclical networks in which matter is recycled in a continuous sequence of processes. Diagrams explaining these are common elements within such textbooks [see figure 1]. Given the current focus on sustainability, as well as carbon and nitrogen emissions in the environment, these visuals are essential in developing public understanding of such important scientific concepts. The review finds, however, that imprecise categorisation of information in diagrams may cause ambiguous messages about circulation of matter within cycles. The review method is then proposed as a generative tool to define practical design briefs. The work presented here is part of graphic design PhD-study which aims to identify the rationale informing the transformation of information into visual explanations of ecological cycles in reviewed material. The visual content analysis is complemented with 24 semi-structured interviews with designers, editors, and authors at 3 publishers in UK, 3 in Denmark, to investigate the design process and rationale for transformation of information.

Structure of paper

1) Visual explanations of ecological cycles
2) Visual survey: description of methodology and sample
3) Theoretical framework for visual syntax and review criteria
4) Review of information categorisation in sampled diagrams
5) Conclusion – visual review as a conceptual design tool

2. Visual survey: description of methodology and sample

Three textbook collections were searched for visual explanations. Denmark and the UK were chosen to enable comparison between two different sized commercial publication markets:

- National Textbook Reference Collection, Institute of Education, London,
- Curriculum Resource Collection, Institute of Education, London,
- National Textbook Collection, Denmark's University of Learning.

609 books were searched. Pages, which include visual explanations of the three cycle subjects, were collected, resulting in 260 examples. The extent of the collection is as follows:

Books

Danish publisher*	23
UK Publisher	134
Total	**157**

* Translations: 1 Japanese original and 2 UK originals.

Author-teams

Danish*	19
UK	105
Total	**124**

*Includes 3 Danish editors overseeing translation.

Publishers

Danish	9
UK	48
Total	**57**

Curriculum levels

14-16 years	167
16-18 years	74
Other*	25
Total	**260**

*Includes primary, university, popular science *etc*.

Visual explanations/Cycle types

Carbon	97
Nitrogen	83
Water	48

Other*	32
Total	**260**

* Includes e.g. oxygen cycles.

Organising the sample according to year, publisher and type of visual revealed the ubiquity of one diagram type: a linking diagram in which objects are linked by arrows. Each time [260 instances] a single or groups of visuals is used to explain the cycles, this diagram type is included.

When other types of visuals complement the diagrams, they follow a narrow path of exploration in terms of both media and themes. Only 12 non-pictorial visual explanations such as graphs and charts occur across the three cycles.

In particular, the carbon cycle explanations are not supplemented with pictures until the 1980s; however, the nitrogen cycle includes earlier examples. The most common feature here is a visual explanation of root nodules eg a photo. During the 1990s the nitrogen-related themes expand towards the farming context, but lightning is a repetitive feature as well. A recurring feature in carbon cycle examples is photos of decomposition or decomposers (earthworms or fungi). Very few visual references are made to global warming.

This indicates stagnation, within educational publishing, in exploration of visual modes and theme of these cycle subjects. Further scrutiny of diagrams produced by the individual publishers reveals several patterns of repetition of whole diagrams or individual visual elements such as:

- straight re-print
- re-use in different titles
- questionablly close reference to other material
- re-use of individual graphic elements ie pictorial objects.

In terms of developing graphic design practice, this apparent stagnation is regrettable.The linking diagram is a thoroughly established convention for visually explaining flows and interrelations within systems. As such the diagram structure itself is not questioned here. The success of the linking diagram is partly due to its simplicity in using arrows, text and possible pictorial objects to show complex systems. The simple combination of graphic objects, however, increases the demand for precision when applying complex information to the elements. Imprecise categorisation may create ambiguity. This issue has been highlighted by several authors (eg Tufte 2006, Bertin 1983). Most appropriate to this study, Stylianidous et al (2002) tested students' reading of images in science textbooks. They found that students had difficulty interpreting different meanings [polysemy] applied to pictorial similar objects such as arrows.

To investigate the precision with which information is categorised in the diagrams, a set of review criteria was established based on theories of visual syntax, as now discussed.

3. Theoretical framework for visual syntax

When transforming textual information into a visual explanation the designer engages directly with the compositional rules of visual language – visual syntax. As in verbal syntax, basic units – here graphic objects – and their interrelationship create the meaning. The review applies

Engelhardt's (2002) theoretical framework for analysing visual syntax in the diagrams, because it expands on the detail handled in Richards' earlier model (1984/2000-1/2002).

Following Engelhardt's approach to decomposition of graphic representation a linking diagram such as figure 1 consists of:

'A *graphic space* that is occupied by it, and

A *set of graphic objects,* which are contained within that graphic space, and

A *set of graphic relations* in which these graphic objects are involved. '

(Engelhardt 2002, 14).

For the following review, analysis of *graphic space* is excluded in favour of detailed analysis of graphic objects and their relations. Engelhardt defines three basic graphic objects: *text*, *shapes* and *pictures* (2002, 119). Two types are thus present in the above diagram: text and shapes [arrows], which are involved in a set of simultaneous *object-to-object relations.* These include:

- Node/connector roles
- Arrow types/meaning
- Verbal semantics and syntax
- Visual attributes: Type hierarchy, colour and shape

Nodes, connectors and labels

According to Engelhardt graphic objects applied in linking serve two syntactic roles: *nodes* and *connectors*. 'A connector is a graphic object in the shape of an arrow, band or line that is anchored to two other graphic objects (nodes), connecting them.' (2002, 40). Thus where arrows commonly are perceived as dynamic objects (Richards 1986, Bertin 1983, Tufte 2006), Nodes take on a more passive role by *being* connected.

Engelhardt further states that an object may serve the syntactical role of a label, if anchored to another object. semantically, the meaning of the lable 'specifies information about the labelled object. (Engelhardt 2002, 34). For precise distinction between word objects in reviewed diagrams, nodes are here defined by their position between an arrowhead and an arrow tail.

The diagram analysed here thus consists of five nodes and six connectors [arrows]. Thus two overall categories of information are established through the visual syntax: 'DECOMPOSERS…' SOIL…, PRODUCERS…, CONSUMERS… and sunlight – the node category – are *connected* by decay, water and salts, die [twice] and eaten – the linking category.

Arrow types

Arrows are the most common type of shape in the 260 reviewed diagrams. Engelhardt (2002, 42) defines two types of arrows, according to the concept they represent:

A *connector* – an arrow leading 'from a *source object* to a *target object*'.

Movement arrow – 'physical *movement through space* of an object'.

He further expands the connector with two types (2002, 102-103): *physical* links and *conceptual* links. The first type occurs eg in wiring diagrams, the latter frequently in cycle

diagrams, eg in figure 3, ‘decomposers…’ and ‘soil…’ are conceptually linked by the process ‘decay’. Hence each type of arrow represents an individual type of information.

There are four conceptual links in this diagram: ‘Decay’, ‘Die’[twice] and ‘Eaten’. These are events that conceptually connect the organisms in the nodes. Eg decomposers and consumers are conceptually linked through the event of death.

‘Water and salts’, however, are substances that move from the soil through the roots of the plant. Thus this *connector* arrow may in fact be read partly as a *physical link* ie the roots of the plant, and partly as a *movement* arrow. In the latter interpretation, the arrow represents the movement through space of salt and water, from the source object – the soil – to the target object – the plant.

The sixth arrow qualifies as a connector, by being anchored to the ‘sunlight’- and ‘producers’-nodes. It may however, simultaneously be interpreted as a *movement* arrow, ie sunlight moving towards the plant. In this latter case, the movement is *of* a *source object* to a target object, rather than *between* the two. Thus Engelhardt’s movement arrow may be further distinct between movement *of* a source object and movement of a third entity *between* a source and a target object.

In summary, the visually similar six arrows represent a set of three arrow types – hence information categories: 4 conceptual connectors, 1 physical and 2 movement arrows each representing a different type of movement. As an additional ambiguity, two arrows may each be interpreted as dual types.

Given the visual similarity of the arrows, the arrow labels become increasingly important for interpretation. This will be discussed next.

Verbal semantics and syntax

Besides the nodes, words appear as *labels* in the diagram. These are anchored to the arrows through spatial proximity.

Within the reviewed diagram several types of word categories exist. These may be distinguished according to the concepts they refer to – semantic categorisation, and according to grammar – their verbal syntactic structure.

The nodes

In terms of meaning, three nodes, ‘DECOMPOSERS bacteria and fungi’, ‘SOIL minerals and humus’, PRODUCERS green plants’ ‘CONSUMERS animals’ refer to an established taxonomy of biological organisms. This taxonomy is, however, visually categorised similarly to soil, a related but distinct concept. Furthermore, the latter node’s sub-groups are distinct types of information [a mini-taxonomy]. ‘Minerals’ is chemical- and ‘humus’ organic matter. Sunlight, the fifth node refers to solar energy, a third type of concept. In terms of syntax, the nodes all represent entities by use of nouns.

Links

Imprecise labelling of arrows adds to the above confusion. Semantically the verb ‘eaten’ is transient, whereas ‘die’, and ‘decay’ are intransient verbs, which can be used without an object. ‘Decay is, if read as a noun, also a process ‘Die’ and ‘eaten’ represent two different object/subject relations. Producers are ‘eaten’ by consumers, but producers also ‘die’ and in reality are then ‘eaten’ by decomposers. Thus two processes are included in the latter arrow, one of which remains implicit.

‘Water and salts’ are distinguishable from the other labels semantically by referring to entities rather than actions, and by their verbal syntax as nouns.

By omitting a label on the arrow leading from the ‘sunlight’ node this arrow is open to interpretation. The origin of the graphic arrow symbol, from archery, and its omnipresence as representation of direction (Gombrich 1983, Westendorp 2002) increase the likelihood of this arrow being read correctly as a movement arrow, the node [sunlight] thus moving towards the plant. If read as a conceptual connector the implicit process is photosynthesis.

If the latter two arrows are read as movement arrows, these combinations thus refer to a *transfer* of matter or energy, rather than the *transformations* embedded in the other four arrows.

From this analysis three general semantic categories may be identified. Present are processes, energy, and organisms/material. One category commonly found in the sample’s other diagrams is excluded – the explicit mention of ‘matter’ eg Carbon. Two overall types of processes happen to two types of entities: transfer and transformation of energy and matter. In addition to this, the 6 arrows represent 6 explicit and 3 implicit information categories. Of further concern is the noun syntax of ‘water and salts’. If read as a movement arrow, the similarity in verbal syntax to ‘decay’ may cause the latter to be interpreted as a movement arrow, the process thus physically moving through space, rather than conceptually linking decomposers and soil.

At both the syntactic and semantic level ambiguity is increased due to the similarity in visual attributes of the graphic objects in the diagram. This issue will be discussed next.

Visual attributes: Type hierarchy, colour and shape

Visual attributes may be applied to Individual Graphic objects or groups. Word-based objects and shapes have separate conventions for attributes based on similar principles.

Visual attributes

These were formally defined by Bertin (1983) and later refined by Engelhardt to include: colour, shape, direction, texture, size, value, and position. Variables can be applied to ordinal, numerical or nominal groupings created between graphic objects.

As the arrows in the diagram are the same colour and shape, they create visual association. Their direction follows the spatial position of the nodes in an organisation that does not reflect the physical reality. E.g. soil is positioned above the animals. As mentioned in the analysis, in reality the arrows represent distinct categories of information on several levels. In this case the symbols, which represent different types of information may, however, be read as synonymous.

Typographic variables

Words may be distinguished through the following typographic attributes.

Category	Variables
Type style	Regular Italic Bold Underline

Case	Upper and lower case
Orientation	Horizontal or variable
Size	One size or ordinal hierarchy

Each of these attributes may be applied to associate or disassociate one word or sentence from others. Additionally, the ‘size’ and ‘upper/lower case’ attribute creates a hierarchy. In the reviewed diagram a hierarchy is created in the nodes through application of uppercase. The second level of these hierarchies is confusingly similar to the arrow labels and the ‘sunlight’ node.

Implications of analysis

The deconstruction of a diagram undertaken served as part of an initial analysis of the entire diagram sample. By breaking down the information into visual syntactic, verbal semantic, and –syntactic layers several instances of imprecise information categorisation were identified.

Review level	**Options**	**Applied in Mackean 96**
Visual syntax	Nodes and links	Nodes and links
Arrow types	Four types	3 types
Semantic level	Four overall groups	3 present
Verbal syntax	Limited by grammar	Consistent nodes, inconsistent arrow labels.
Visual attributes – arrows	7 variables	Colour and direction
Visual attributes – typography	4 variables	Upper/lower case

Hence information is categorised across six different levels in this diagram. Apart from the simple visual classification of node and links through words and arrows, inconsistencies were found within each level. This imprecise visual categorisation of information may distort the central message about what is being recycled; and how, where and when it happens. Part of this problem is the marriage of simple graphic objects and complexity in the information conveyed by them. Thus the analysis raises a question of how the information may be simplified by complementing with other types of visual explanations.

Based on these findings, review questions and criteria were defined for the three levels of analysis, as will be discussed next.

4. Review of information categorisation in diagram sample

The analysis and review of the diagrams seeks to evaluate the consistency in information categorisation within each level of review categories as well as consistency in their interrelations.

Presented here is the review of the sub-groups including text and arrows only. This choice demonstrates the complexity of applying information to the simplest graphic object combination.

The following questions are applied for the review:

Nodes and links

What semantic groups are included as nodes?

What semantic groups are included as arrow labels?

Are semantic concepts applied consistently within nodes and arrow labels?

Verbal syntax

Is the application of verbal syntax consistent within nodes and arrow labels respectively?

Arrow types

Which types of arrows are included?

Are any arrows dual types?

Visual attributes – shapes

Which visual attributes are applied to the arrows?

Are they applied consistently?

Visual attributes – typography

Which visual attributes are applied to the arrows?

Are they applied consistently?

Description of sub-sample for review:

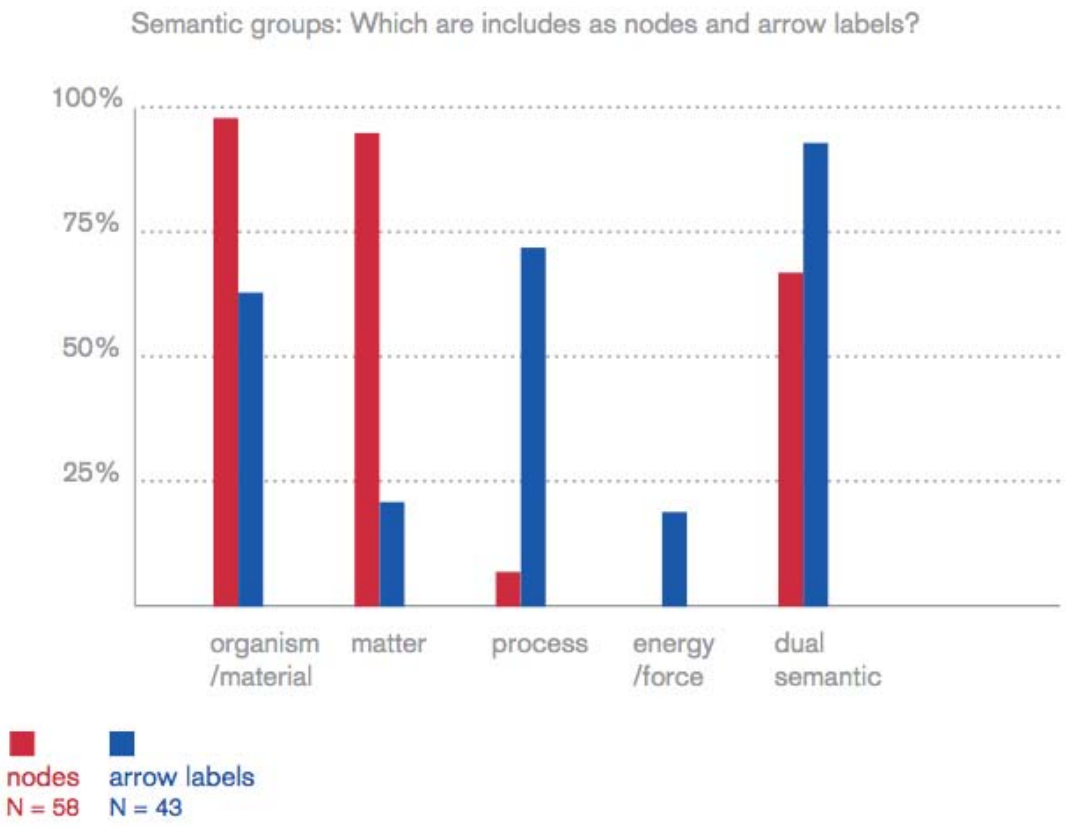
The overall diagram collection has been categorised according to the types of basic graphic objects [text, shapes and pictorial] included. I will here present the findings about the most simple combination, the group including only arrows and text. This sample includes 60 diagrams, raning from 1935-2007.

Description of matrix method

Each diagram was analysed and the data plotted in a matrix, comprising 1 column per diagram and one row for each review criterion. 17 diagrams include only unlabelled arrows and 2 diagrams include labelled arrows but no defined nodes. Thus the matrix includes 43 link columns, 58 node columns.

Findings

Semantic groups – which are included as nodes and links



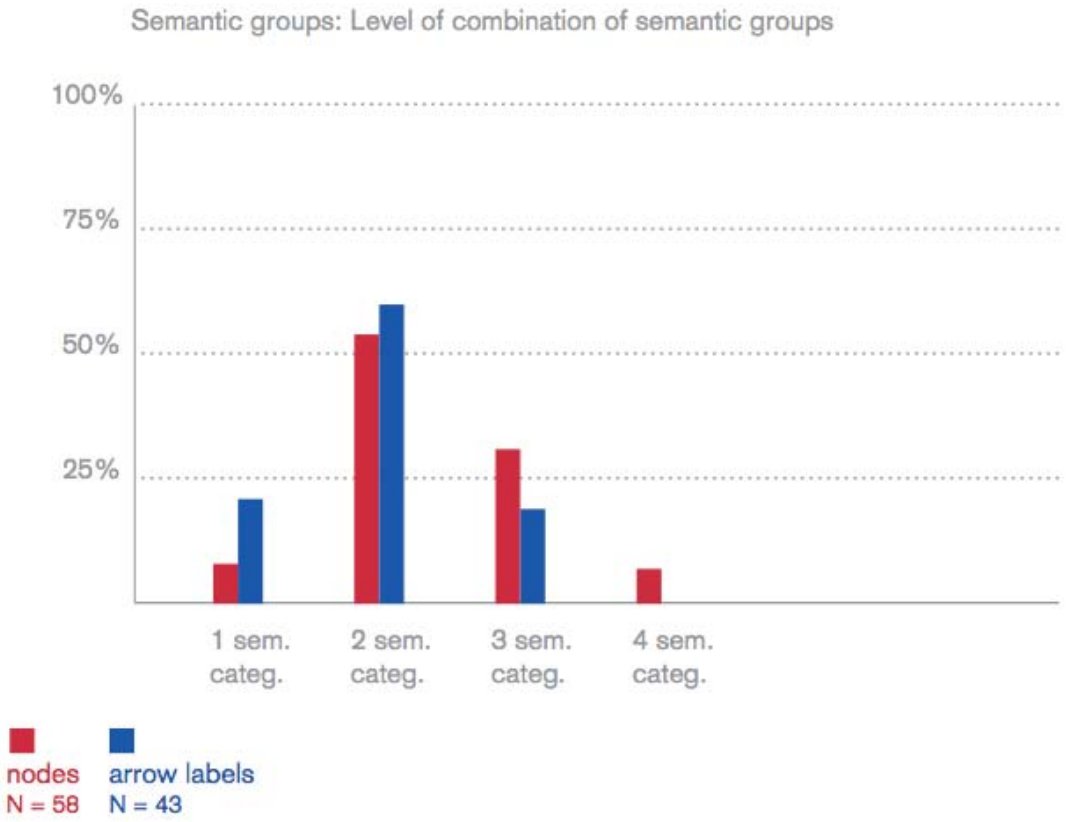
Nodes

By far the most common semantic group included as node is organism/material, appearing in 98% of the diagrams; this reflects the static nature of these elements. The high proportion, 67%, of the diagrams, which include dual semantic categories, is of some concern, as two concepts are here applied to one graphic object.

Links

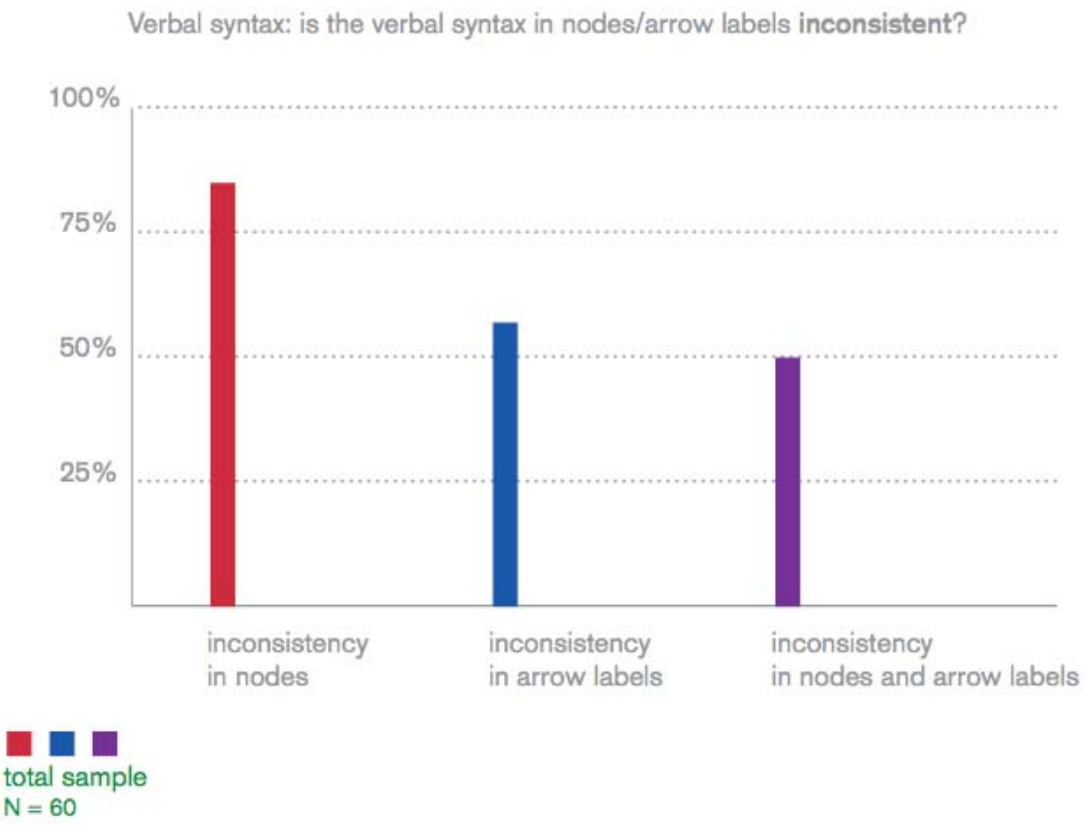
'Process' appears in linking positions in most diagrams, closely followed by organism/material; these two are often applied together e.g. 'respiration of plants'. Interestingly, matter is present in linking objects in only 21% of the diagrams. Thus matter is frequently categorised as a passive element e.g. 'stored 'in an organism, rather than actively circulating in the cycles. Notably 93% of diagrams with labeled arrows include at least one instance of dual semantic information in a label. These arrows thus represent two different types of information. Further scrutiny of diagrams that include 'process' in arrow labels revealed that each one of these represents the process with a noun e.g. 'photosynthesis'. This creates two ambiguities: if read as a movement arrow, photosynthesis is thus an object being transferred; secondly, the process is spatially positioned outside of the node, or organism, in which it takes place. I.e. photosynthesis happens in 'open air' between the atmosphere and a plant, rather than inside the latter.

Semantic groups – level of combination of semantic groups



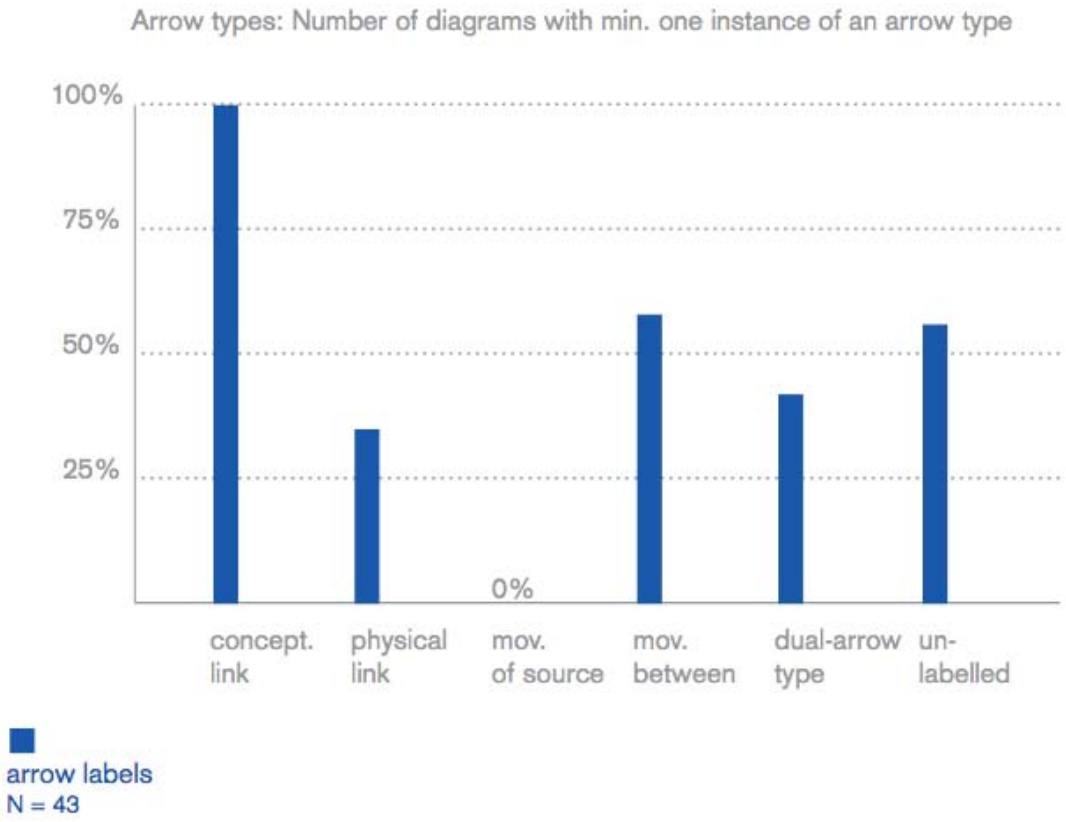
Only 21% of diagrams include only one semantic group in the arrow labels whereas 8% of the node groups are consistent. In both groups, the combination of two semantic groups is most frequent.

Verbal syntax – is the verbal syntax of nodes/labels applied inconsistently?



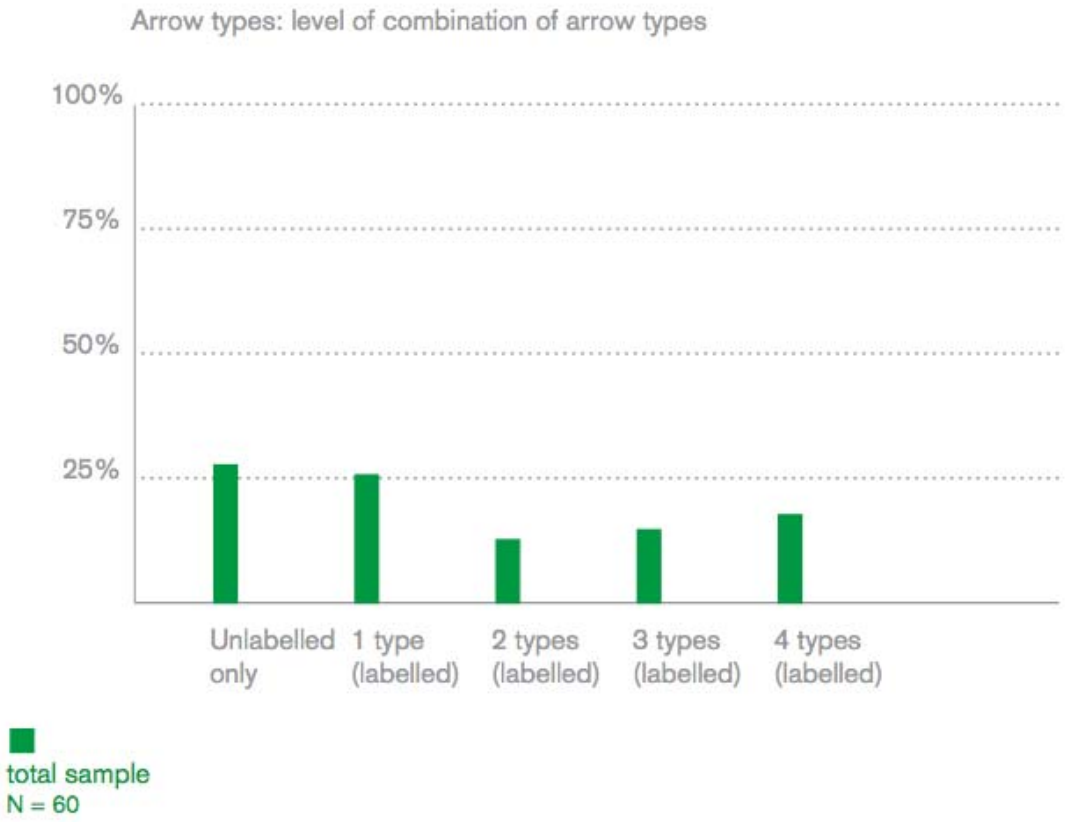
A worrying 85% of the 60 diagrams are inconsistent in use of verbal syntax in nodal position. Less ambiguity is seen in the arrow labels; however, 50% include imprecision in both arrow labels and nodal verbal syntax.

Arrow types – which types of arrows are included?



The most frequently included arrow type is a conceptual link occurring in all of the 43 diagrams which include labelled arrows. No diagram includes movement of a source object; however, nearly half apply movement of entities between nodes. In 42% of the diagrams at least one instance of dual-arrow types was found, creating additional ambiguity. Similarly worrying is the 56% of the diagrams which include one or more non-labelled arrows. This latter imprecision leaves the interpretation entirely up to the reader to resolve.

Arrow types – level of combination of arrow types



The 17 diagrams with non-labelled arrows are left open for the reader to define the type of connections involved. A quarter of the diagrams include only one type of arrow. Instances of combining 2, 3,or 4 types occur with roughly the same frequency.

Visual attributes – arrows

Only four of the 60 diagrams apply visual attributes other than the ubiquitous direction variable. Here texture distinguishes nitrification- from denitrification processes (Godwin 1948), chemical methods from biological process (Daniel 1954), or line width is applied to indicate quantities in flow (Palmer 1954, Kolb 1963). Thus the the designer is overlooking an opportunity to apply a range of visual vocabulary to increase the precision, hence succeeding in getting the basic concepts across to the reader. This missed opportunity is similarly evident in the application of typographic detailing.

Typography

Most diagrams apply different typographic treatment using a range of variables in nodes and arrow-labels. Below follows an overview of the 14 different combinations of typographic attributes present in the sample.

	Italic	Bold	Underline	Upper/lower	Direction	Size	No. variables
Regular only							1
1						•	1
2		•					1
3				•			1
4	•	•					1
5					•		1
6				•		•	2
7				•	•		2
8		•			•		2
9					•	•	2
10		•			•	•	3
11	•				•	•	3
12				•	•	•	3
13		•		•	•	•	4
14		•	•		•	•	4

If no typographic detailing is applied increased scrutiny is demanded from the reader to distinguish nodes from arrow labels. This treatment thus increases the effort needed to disambiguate if several semantic categories are added to the node and link categorisation. In older examples, direction is commonly applied to distinguish horizontally positioned nodes from arrow labels, which follow the arrow direction. Contemporary examples rely on horizontal typographic direction. This increases the demand for other attributes to emphasise the difference between nodes and arrow-labels. Like upper/lower case combinations, size may be applied to create emphasis on nodes or in some cases hierarchies within the set of nodes. Individual elements emphasised with size is commonly ‘nitrogen…’ or ‘carbon dioxide…’ ‘…in the air’, ‘plants’ or ‘photosynthesis’.

Analysis of the typographic styling revealed that only 2/60 diagrams are consistent in typographic styling of the semantic and verbal syntactic information types: Daniel (1954) and Atkinson (1964).

Generally, the content in the diagrams thus appears analysed to the extent of forming node and connector categories but stops short of distinguishing different types of information within these elements.

Overall only three of the reviewed diagrams were identified as consistent in their categorisation of information (Daniel 1954, Atkinson 1964, White 1939). These all include nodes and unlabelled arrows and one semantic category. When several semantic categories are applied in either nodes or arrow annotations, an illogical and ambiguous sequence appears. This may include one step being an organism *eg* 'plant', whereas the next step is a facilitator of a process *eg* 'bacteria'. Thus, whilst the linking diagram accommodates sequence and stages in a process it appears that the three semantic categories of the cycles are more complex to explain in this diagram.

Implications of review

Linking diagrams, as reviewed here, consist of 2 graphic objects: words and arrows. The complexity of information needed to describe ecological cycles, however, increases the demand for precision with which information is applied to these objects. This analysis identified six levels in which information can be categorised when applied. Several points of concern were found due to polysemy or imprecise categorisation of information, resulting in ambiguous messages. Of particular concern is the polysemy created by the 67% dual-semantic nodes and 93% dual-semantic arrow labels. The inclusion of non-labelled arrows among labelled ones creates further ambiguity. In terms of the actual cycle subjects, the majority of the diagrams represent matter as a passive element stored in organisms or entities. Processes, on the other hand, due to their noun syntax may be wrongly interpreted as objects circulating between organisms.

Given the high level of ambiguities found, the above-mentioned uncritical repetition of diagrams and their elements in textbooks is worrying. The stagnation in visual exploration is further evident in the omission or imprecise application of visual attributes. To address this stagnation, the review presents a method with which practical visual exploration may be approached. Based on the review findings, a set of design briefs may be defined. These are centred on three themes as will be discussed next.

5. Conclusion – visual review as a conceptual design tool

When utilised as a generative design tool, these research findings enables construction of a design brief that will increase the precision and coherence of the visual explanations. As such the concise analytical findings produce systematic underpinnings for a practical exploration. Three themes are identified for such future activity:

1) **Types of linking within elements – based on arrow types**
   The four arrow types, conceptual and physical linking, and two different types of movement may be explored to create understanding of interrelations within the elements of the cycles. Such exploration could focus on matter as the circulating element.
2) **Semantic groups**
   further visual scrutiny of the semantic groups could be explored. This includes differences between matter in storage and circulation, and transfer and transformation processes. Starting points for these would be external factors' effect on the concepts eg time, energy, force and location of the elements.

3) **Visual attributes**
   Current application of visual attributes touches upon quantities of flow. Several other quantities such as time or amount in storage could similarly be explored.

Thus it is suggested that a simple, one semantic, linking diagram is complemented with visual explanations of the cycles' behavioural aspects. The latter focusing on basic combinations of information categories. Given the identified rarity of other types of visual explanations, the possibilities of applying the existing visual vocabulary of information design remain wide open.

This review focuses on 14-18 year olds in formal education. Ecosystems are however communicated daily to general audiences eg in newpapers. Here frequent use are made of diagrams applying the same compositional principles as reviewed here. Discussing visual explanations, Edward Tufte (1997, 10) noted that 'Since such displays are often used to reach conclusions and make decisions, there is a special concern with the integrity of the content and the design.'

Increased demand in reader effort to disambiguate the message may thus affect the motivation to understand the subject at the very heart of our wider social learning process. This, in turn, highlights that skill and precision is crucial when applying information design's tools and visual vocabulary, regardless of the context.

DESIGN VISIONS PROPOSALS AND TOOLS

Product service systems and non-market oriented approach

Methodological and ethical considerations from a design perspective

Nicola Morelli [1], Wolfgang Jonas [2], Juliane Munch[3]

Abstract

Contemporary social and economic changes are forcing firms and institutions to focus on local and highly individualised solutions. The challenge is not only to provide local and highly individualised solutions, but also to propose strategies to transfer and reproduce the solutions in different local contexts. This would be possible by using forms of *codification* of the most relevant components in local solutions.

The codification refers to local organisational knowledge and to the way local components interacts with the others. This paper will illustrate how this process was developed in a concrete case. Through this case the authors analyse the possibility to build something similar to a source code for initiatives based on social interaction and investigate the process of construction of such a code.

1. Introduction

The project reported here is part of a strategy to link teaching activities to applications in the real world and to design research. The actors are:

- **The students of the 8th semester Industrial Design at the School of Architecture and Design** in a Danish University: the project was the theme for a 3 weeks workshop on concept development.
- ***Focus Folkeoplysning***, (FF) a Danish organization that provides vocational education.
- **The authors of this paper**, who, in the last few years, have been working in different institutions, on themes related to system design and service design.

The opportunity came from a loose cooperation between FF and the University aiming at a new service to employ people with low employment opportunities. FF had developed the concept of the service (a meal delivery system for people working in the city centre) to the first embryonic stage and is now planning to develop the project to a running phase in a few months. The idea of the cooperation between the organisation and the university came from the discussion about designers' role in planning and developing innovative services, which is an ongoing discussion not only in Denmark.[4]

This theme is close to the more general question of relocating the role of designers beyond the traditional link with material products. This theme has been the main research focus for the authors (Jonas 1994; Jonas 1996; Jonas 1997; Morelli 2002; Morelli 2003; Morelli 2006; Morelli 2006; Morelli 2006).

The project is also consistent with the authors' research on applications of design methodological approaches to innovation in social systems, outside the traditional market-oriented context for the design discipline (Morelli 2003; Morelli 2006)

The project

Active labour market policies in Denmark and Scandinavia are based on an approach aimed at enhancing unemployed people's residual capabilities (Esping-Andersen 2002). This approach, often labelled as *active welfare* (Møller 2002; Sabel and Zeitlin 2003; Vandenbroucke 2003) or *open welfare* (Cottam and Leadbeater 2004) makes it possible to decrease the level of people dependence from the welfare system, thus encouraging the re-integration into the labour market. FF´s initiative in this area consisted in a program to employ people with different social and behavioural problems in a café, which is in most aspects similar to any other café. Here unemployed people have a regular working routine and a continuous social contact with clients. This is an opportunity to learn new skills for a good reintegration in the labour market.

The new service proposed as a theme of a workshop with design students is a meal delivery system for people working in the central areas of a city. Businesses in those areas can rarely afford a canteen for their employees. Their employees must buy their own lunch and often have very limited choices, influenced by reduced time and dietary factors. The new service is meant to connect them with small cafés and restaurants offering good quality food, to satisfy their needs and optimise the time for their lunch break. The service should serve a limited area of the city and use bicycles as the only means of transportation. As in the café, the service will employ people with low employment capabilities in five main functions: logistic, payment, IT, delivery,

[4] Several design education institutions in Denmark are focusing on service design. Service design is now a consolidated subject in design education in several Scandinavian countries and in UK. Recently service design has also been the theme for exhibitions and conferences promoted at the Danish Design Centre. System Design at the School of Art and Design at Kassel University, Germany, one of the partners in this project, is developing solutions for people; in this approach the distinction of products, services, infrastructures is a secondary one.

marketing and bike repairing (in total about 15 people). The cost of the service is meant to be very low („as much as sending a postcard“) compared to the normal cost of the lunch, decided by the meal provider. The meal provider, in turn, will contribute to the service with a small amount of money per each meal. The local government is paying the salary (the normal unemployment benefit plus a small activation contribution) plus a small amount of money per employee to support the service.

2. The research question

The project's approach to social innovation is based on the direct participation of local actors in the development of innovation. The project is supposed to generate a broad structure in which FF will organise the practical and operative aspects of the service. The assumption is that local actors (providers, customers) have context specific knowledge for generating local solutions. This kind of knowledge is often hard to transfer to system developers. Rittel (Rittel 1984) characterized this situation as a *symmetry of ignorance:* Knowledge is asymmetric: users are domain experts who understand the practice (they know implicitly *what* the system is supposed to do) and system developers know the technology (they know *how* the system can do it).

By transferring the responsibility to develop the system directly to users it is possible to capture essential knowledge that would be critical for the development of highly contextualised solutions. This condition however, would also reduce the possibility that those initiatives be reproduced in different local contexts.

This means that many of such initiatives remain isolated cases and little space is left for their broader diffusion, notwithstanding their high potential to offer concrete solutions to present crises of welfare systems. An important research question arising from this context is therefore whether those initiatives can be totally or partly transferable[5].

The reproducibility / transferability of those initiatives would be possible by using forms of *codification* of the knowledge needed for their planning and/or development. Codification implies the modularisation of the most relevant components included in a project (related to knowledge and processes) and a certain level of standardisation of such modules. In this sense codification implies a reduction of the reach and qualitative complex characteristics of local solutions into a simpler, but nevertheless more reproducible solution that could generate economy of scale or scope. [6]

The code to develop in this case includes all the organisational knowledge related to the project components, the modules and the interaction among them. Its reproducibility depends on the capability of local actors to understand and use it to generate their own context-related solution. Likewise software systems, local product-service systems can be built upon a *source code.* This contiguity, however, should suggest a set of relevant research questions:

- -Is it possible to generate anything similar to a source code for initiatives based on social interaction and innovation? What can the source code for open welfare look like? Which are the aspects of codification that contribute to the reproducibility / transferability of this kind of design interventions?
- - A further question concerns the capability for designers to contribute to generating such a source code, that means to design and represent the processes involved in initiatives of social innovation, as well as they are able to design and represent the outcome of industrial processes. Can the services in this context be compared with services developed in a normal business context? Do designers need any particular

[5] The debate regarding the question of transferability in design research is just beginning, see for example Chow (Chow 2006).

[6] It is clear that the challenge in this project is highly complex, because the knowledge to be codified does not concern a product, or a process of transformation of material parts, but it rather relates to social structures and contexts, organisational and cultural components, which are by nature harder to be trapped in a code.

knowledge to operate in the context of social services? Are the criteria to evaluate efficiency of those services the same as those used to evaluate the efficiency of market-related services? Are there special methodological requirements for the social approach as compared to the business approach?

The hypothesis is that codification is possible on the problem side (dealing with the complexity of the situation to be improved) as well as on the solution side (dealing with the contingency of the form of the new situation):

- - On the problem side we provide a methodological concept, which enables designers to systematically understand and represent highly contextualized situations and to specify processes in order to transfer these situations into preferred ones.
- - On the solution side we provide a platform concept that supports highly specialized and complex Product Service Systems in a certain field of application by using basic solution elements.

The authors suggest that, when appropriately designed, the intervention in this area may generate good opportunities for innovation. In fact the project proposes a perspective shift in the way of doing business in this area, which raise the level of social intervention to the status of a normal business.

3. Designing for social purposes

A framework of designing for social purposes

Since its first contributions (Papanek 1973) (1979)[7] the debate about a social role for designers has pointed out the need for a new approach of design to social and environmental issues, challenging the dominant logic of economic rationalism that is orienting mainstream design activities. The most recent emergence of macroscopic phenomena, such as globalisation, massive migration, population ageing and new cultural patterns are increasing the demand for new solutions to improve social quality.

The traditional approach to social intervention is based on a *relieving logic* (Manzini, 2005) that replaced products and services informally offered by families, neighbours, social networks (*informal economy*) with a set of product or services offered by a *provider* to a *consumer*, on the basis of an economic exchange. In this sense the logic of public intervention on social problems did not differ from a market driven logic. However this logic is probably very expensive in the long term, because the separation between a *server* (the institution or the private company) and *served* subjects (the citizens) considers the latters as passive receiver, thus reducing their capability to solve their own problems in the future. Furthermore this logic undermines the social cohesion that an informal economy inevitably creates.

The problem of social quality, in other words, requires a revision of the traditional logic and possibly the definition of a new approach to social action.

Design and social quality

The capability to work on local contexts emerges as a spin-off of the same phenomenon of globalisation: new technologies make it possible to reduce market segments to extreme customisation. Furthermore global companies are recognising the local capability of generating context-related solutions as a critical competitive factor (Becattini 2004). Global companies are challenged to become an active part in local networks including institutions, companies, and customers. This is changing the conception of the social role of business organizations:

[7] These are the two milestones of this debate. Papanek view was opposing market driven logics to socially oriented design, thus considering the two logics as antithetic and incompatible. The Ahmedabad declarations proposed a different view of design as *a powerful force for the improvement of the quality of life in the developing world*; thus proposing a view in which local and traditional cultures could be supported, without ignoring *the power that science and technology can make available* to them. A critical comparison of the two approaches has been proposed by Margolin (Margolin 2006)

- Rather than providing products, those organisation are now supporting local networks of stakeholders, and
- Rather than providing finited relieving solutions, they are providing semi-finished platforms, including products and services, that will enable people to create value according to their individual needs

This contextual condition would redirect the design agenda: Rather than finished material products, designers will be required to produce scenarios, platforms and operative strategies that enable small companies, local institutions, cooperative groups, association and individuals to produce their own solutions.

The long tradition of cooperation between design and industries generated an *operative paradigm*[8] (based on reproducibility of knowledge, division of labour, optimisation of resources), that can be useful to support designers working in the new context. A relevant design problem, in this context is to *industrialise* local and highly individualised solutions, that means making them *transferrable* to different contexts, in order to solve similar patterns of needs.

Design and morality – a kind of relativisation

The new perspective outlined above, together with the challenge for designers to redefine their role and activities, raise the question whether there should be a special moral code for design. Should design be a critical discipline? (Jonas 2006) argues that design (as a discipline) is *uncritical*, because it has to be. Since we are confined to the observation of observations (2nd order cybernetics), it becomes delicate to evaluate the representations of reality by comparing them with reality itself. Pure criticism, whatever that might be, is not really useful in the process; the pivotal point is missing. Critical theory, the favourite toy for some intellectuals, is broken. Criticism will be replaced by performance and appropriate methodology and the focus on the communicative process. Social systems (Luhmann 1984) are systems of communications (groups, teams, neighbourhoods, companies, social movements). System and service design is aiming at intervention strategies regarding desired outcomes. But design itself cannot define these purposes. Design can be "critical" only in the sense that it provides and illustrates different choices and puts them to discussion among the stakeholders. It has no criteria that enable decisions as to morally "good" or "bad" solutions.

We should think of replacing normativity (criticism) by "teleology" (purpose orientation) and effectiveness. Rosenblueth et al. (Rosenblueth, Wiener *et al.* 1943) re-introduced the concept of teleology into science. The critical attitude should better be transformed into an ironical attitude (Rorty 1989). Imagination, provocation, intervention, etc. are essential elements of design´s role in increasing the variety of choices for people.

Design (as a discipline) is *amoral*. The claim for ethics as a major criterion in design seems to be a symptom of immaturity. We need a moral disarmament of design in order to become acceptable to other disciplines. Ethics should be kept implicit in the process. (Margolin 1998) criticizes Simon´s (Simon 1969, 3rd ed. 1996) definition of design as "transforming existing situations into preferred ones" as "deceptively catholic". But can there be a more challenging and responsible task than this? "Humanistic" attitudes are not really useful in a time where the "human measure" is an increasingly inappropriate criterion. Only by dropping rigorous concepts of humanism will we be able to work for real people in their individuality. It makes no sense at all to work for "mankind" or for "the environment".

Design teams, companies and individuals are definitely *responsible* for what they are doing. Responsibility is only possible if we do *not* retreat to moral positions. There was the time when designers thought they would transfer real problems into real solutions. Today we know that these are just denotations indicating the starting point and the endpoint of a project. It is

[8] Arbnor and Bjerke (Arbnor and Bjerke 1997) introduce the term *operative paradigm* to indicate a toolbox of *methodical procedures* and *methodics* that can be used to apply a methodological approach to a specific study area.

more appropriate to talk about transferring system state 1 into system state 2, always having in mind the **complexity** of state 1 (perspectivity of defining / designing the "problems") and the **contingency** of state 2 (there are many possible "solutions"). Contingency is inherent in the process. Responsibility is required to deal with this perspectivity in a democratic manner, to support, for example, error-friendliness of solutions or innovations.

Designers cannot act as moral guards but rather as scouts, sometimes as jesters, hopefully as respected partners in a network of disciplines and stakeholders. Appropriate methodology, especially regarding communication, is essential.

4. Methodology

The need for accelerated and systematic innovation suggests to adopt *design as the generic process model of innovation***.** Since innovation is knowledge intensive attempts at operationalization have to integrate the scientific and the designerly process. Furthermore a successful approach has to reflect the involvement of the designer / researcher in the process.

The emerging paradigm of "research THROUGH design" (Jonas, 2007) provides a methodological and epistemological concept for the relation of "problems" and "solutions", that means for problem definition (dealing with complexity on the problem side), project formation (dealing with the process), and solution generation (dealing with contingency on the solution side). The challenge consists in the efficient operationalization.

General overview

System design at Kassel University is using an instrument for systematic problem solving and innovation, which is being developed for designers and design researchers and their collaborators (Hugentobler, Jonas, & Rahe, 2004; Münch, 2005)9. It helps to reduce complexity and uncertainty during problem solving and research, while increasing efficiency and effectiveness when collaborating with partners and clients. Moreover, the instrument provides a terminology, which improves the transferability of design processes (and possibly solution elements) towards new / similar / comparable situations. The instrument is acting from a design research perspective and is based on the assumption that this perspective encompasses social innovation processes as well as technological and market oriented R & D and innovation.

The approach distinguishes and addresses situation, process, methods and tools, and thus exceeds existing models (2005), (n.d.). It assists design researchers and their collaborators and clients to

1. Specify / categorize (problem) *situations,*
2. Match *process* patterns to the specified situation and define the *role* of design researchers in the process, and
3. Select *methods / tools* related to the process.

Theoretical background

The instrument is underpinned by a generic process model, which consists of a hypercyclic combination of the *macro-cycle (domains of knowing): ANALYSIS – PROJECTION - SYNTHESIS* (Nelson 2003) and the *micro-cycle (learning steps): research – analysis – synthesis – realization* (Kolb 1984), linearized into a "toolbox" (Tab 1).

[9] This is done in close cooperation with Deutsche Telekom Laboratories (T-Labs) Berlin, where this project is directed by Dr. Rosan Chow under the title "t.bag". The longer-term aim of the t.bag approach is the development of an integrated knowledge and communication platform for research THROUGH design. The outcomes are Product-Service-System (PSS) models in the widest sense.

	research	analysis	synthesis	realization
ANALYSIS				
PROJECTION				
SYNTHESIS				
COMMUNICATION				

Tab 1 Hypercyclic model of a generic design process, linearized into a "toolbox" (Hugentobler, Jonas et al. 2004), (Münch 2005)

T.bag starts with the problem specification and a systemic model of the problem situation. From that a preliminary proposal for a specific process is derived, based upon the generic process model and using methods and tools from the toolbox (this is pre-rationalization). The proposed process can be modified according to new and changing insights and requirements any time, so that t.bag has the function of a communicative / reflective tool during the process. The final process can be documented and stored in a project archive for further evaluation and use (this is post-rationalization). The growing archive will feed the toolbox and generates new knowledge regarding the appropriate use of methods for the configuration of processes. Prototypical processes for certain situations may emerge, so that transferability of processes will be a longer-term effect of the use of t.bag (Chow and Jonas 2007).

The approach is made operable by applying a number of descriptive concepts: project dimensions, project domains, project constraints and process types, which are used for stepwise specification of a situation, which needs to be improved, i.e. for the definition of a problem-solving or innovation project.

- Project dimensions comprise:
  - *System:* scope of contextual factors to be considered: market, society, environment, etc. (degree of complexity),
  - *Research:* scientific standard to be considered (degree of scientific knowledge input),
  - *Future:* projective time space to be considered (degree of uncertainty), and
  - *Implementation:* executive opportunities (degree of realisation).
- Project domains describe the project focus and comprise:
  - *Technology,*
  - *Business / market,*
  - *Human values.*
- Project constraints specify further conditions and comprise:
  - *Schedule,*
  - *Budget,*
  - *Human resources, etc.*
- **Process types** are derived from the hypercyclic model / toolbox (Tab 2):

ANALYSIS				PROJECTION				SYNTHESIS				
												1 a "complete" design (research) process
												2 a futures studies process (without synthesis)
												3 a "normal" design process (without proper projection)
												4 a "risky" design process (not properly grounded in what IS)
												5 an analytic process (inquiry into "the true")
												6 a projective process (inquiry into "the ideal")
												7 a synthetic process (inquiry into "the real")

Tab 2 Rough categorization of innovation-, design and design research processes:.

Operationalization

The following describes the operational steps in more detail. They can be considered as a conversation between stakeholders, which tries to clarify the situation in order to design an appropriate initial process plan.

(1) Specify problem situation

- Identify the overall process by determining the values of the project dimensions
  - **System** dimension: high in this project, because of the specific complexity of the client´s system (employees, social aspects, market situation) and the uncertain contextual conditions.
  - **Research** dimension**:** low in this project, just existing knowledge.
  - **Future** dimension: short to medium terms (2-5 years).
  - **Implementation** dimension: low to medium, a concept / feasibility study, serving as a pool of ideas for the working prototype.
- Decide on the **project domain**

In this project: User values with a side glance at future business opportunities. Users are the end-users as well as the client´s employees.

- Specify **project constraints.**

This is a students´ project with emphasis on SYNTHESIS, tight timing, no budget.

(2) Match process patterns to specified situation

- Select **process type**

The determination of the project dimensions and project domains helps to select a process type, see fig. 3. This project would correspond to type 1: a "complete design (research) process".

- **Match** process patterns to the specified situation and process type.

Once a situation is specified in terms of dimensions, domains and constraints and the process type is selected, it can be matched to more detailed process patterns. Specific methods and tools to be used can be selected (Tab 3).

timeline	Week 1		Week 2	Week 3
Project phases	**ANALYSIS** mainly existing data	**PROJECTION** future images, contextual uncertainty	**SYNTHESIS** detailed concept of the PSS and exemplary realization of product proposals	
Methods used	Sensitivity modelling / analysis	scenario-building ("quattro stagioni"), essential in order to explore uncertain future contexts…	Business concepts Use-cases Prototyping User studies Quick&dirty concepts	
Project characteristics	- Design (user values) emphasis - Emphasis on usable concepts - Systemic emphasis, system model necessary as a basis for understanding the system´s dynamics and sensitivity,			

Tab 3: More detailed process pattern of the project, derived from the situation and the process type.

(3) Select specific methods /tools to be related to the process

Methods and tools are categorized by means of the underlying toolbox structure. In combination with the information available from the considerations above, i.e. the detailed process specification, it is possible to select appropriate methods for an optimal process. This is the link between the four levels of the approach as shown in fig. 1. The result is a preliminary project structure including the methods and tools to be used.

5. Process

The process consists of the 3 main steps of ANALYSIS, PROJECTION and SYNTHESIS according to the generic model. Analysis and projection have to be packed into 4 days, so that no further field research was possible. Because of the high systemic dimension of the situation it was decided to put the main emphasis on the system analysis and the exploration of uncertain (future) contexts. Both provide a kind of basis and guideline for the more detailed design efforts in the synthesis phase.

Starting point is the well-known interface concept of designing as put forward by (Alexander 1964) or (Simon 1969, 3rd ed. 1996): design creates the fit / the interface between the inner system (the artefact) and the outer system (the uncertain context). The inner system is the PSS to be designed, the outer system is the social / market / urban context in which the service has to be viable. This is also comparable to the logic of SWOT analysis: matching the strengths and weaknesses of the system with the opportunities and threats of the environment.

ANALYSIS and PROJECTION

Sensitivity analysis (Vester 1999) creates a systemic model of the situation by building an effect system out of the relevant factors determining the situation.

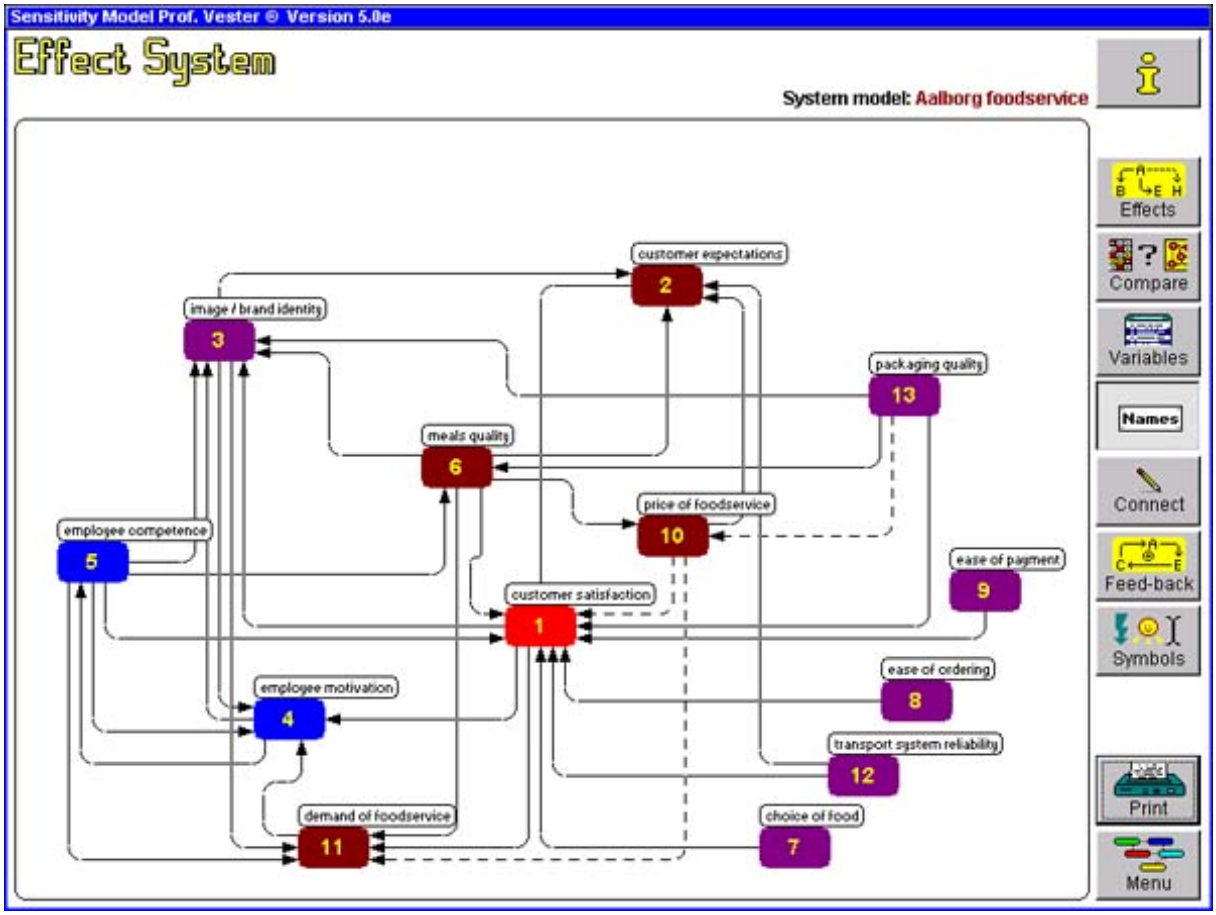

Fig. 1: Effect system of the meal delivery service

By means of cross-impact analysis it is possible to gain valuable insight regarding the systemic roles of the variables:

- - active factors (e.g. 5 employee competence, 13 packaging quality, etc.) have a strong impact on the rest of the system and may be used as levers for intervention,
- - reactive factors (e.g. 1 customer satisfaction, 3 image / brand identity, etc.) serve as indicators showing the state of the system, they are normally not useful for direct interventions,
- - critical factors (e.g. 4 employee motivation, 1 customer satisfaction, etc.) have high influence on the rest of the system and are – at the same time – influenced by the system, they have to be handled with much care,
- - neutral (e.g. 10 price of foodservice) and **buffering** (e.g. 13 packaging quality) factors contribute to the self-regulation and stabilization of the system.

Sensitivity modelling is not a solution machine but serves as a communication platform structuring the debate among stakeholders and contributing to a common understanding of the situation and its dynamics. And, of course, this contributes to structure and purpose-ortientation of the further process: **Motivation of the employees**, **customer satisfaction** and **reliability** of the service turn out to be essential for the system.

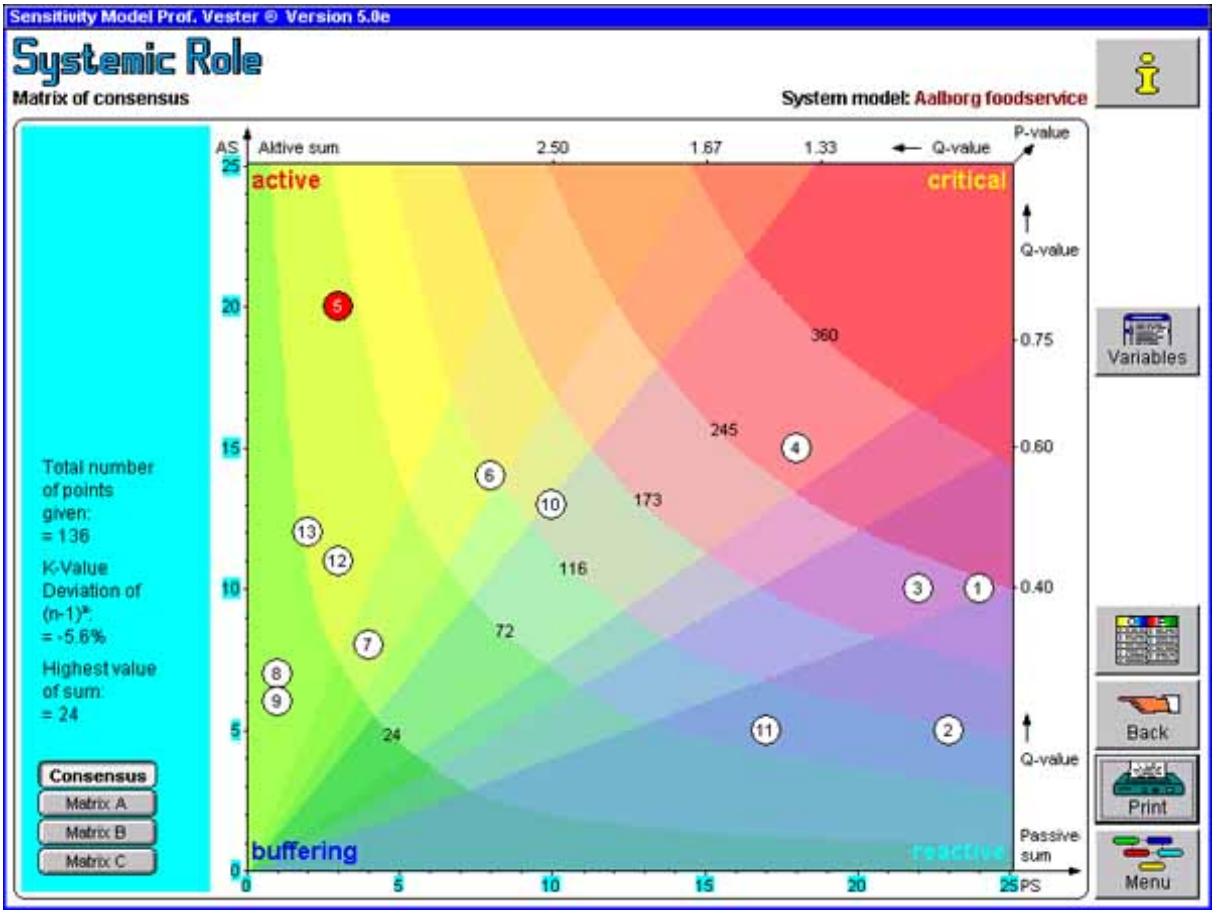

Fig. 2: Systemic roles of factors of the meal delivery

Another essential outcome of ANALYSIS is the definition of activity / solution modules for the foodservice: **logistics, delivery, payment, marketing / PR, and bike maintenance**.

PROJECTION

Projection normally deals with possible future states of the system´s environment and the viability of solutions with respect to these conditions. Here it is not so much the future state but the present situation of customers´ demands in the local context that is unclear. So we have to ask: what are the external uncertainties that influence success or failure of the service?

We use the scenario approach "quattro stagioni" (Schwartz 1991) to describe 4 extreme contextual states. The main purpose of this step is to make possible future contexts explicit. Increased awareness of future uncertainty contributes to the transferability of solutions into new contexts. With reference to the debates in the ANALYSIS phase we decide to use the dimensions:

- - time flexibility of customers (fast food – slow food)
- - food preference of customers (simple food – complex food)

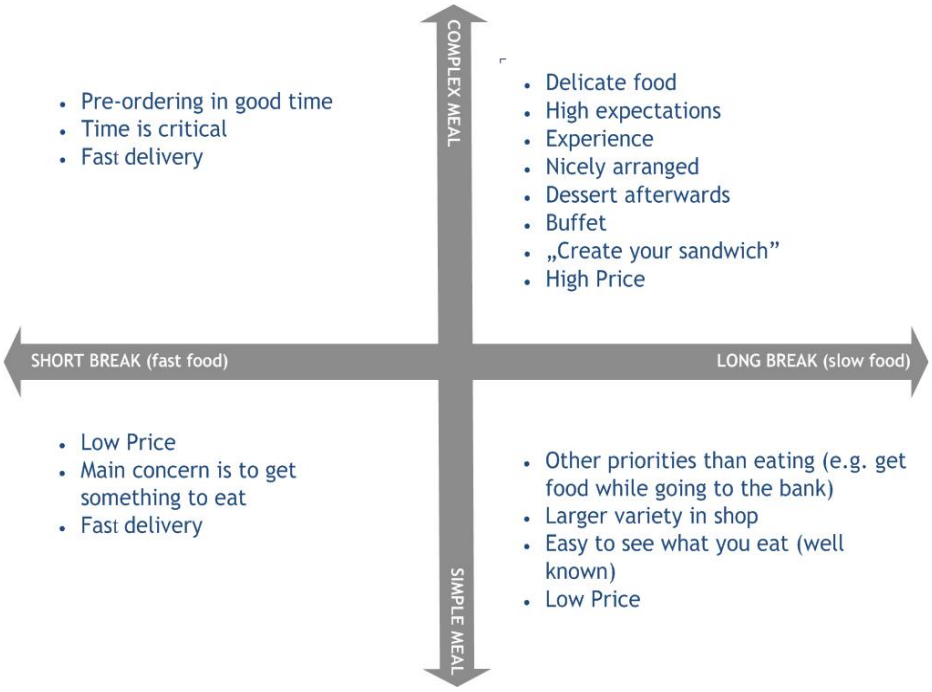

Fig. 3: "Quattro stagioni", 4 different scenarios for the service

In a final step we try to match the activity / solution modules to the scenarios:

- - If we are uncertain about the future context, then we should aim at a robust strategy, which is usable in different contexts (a horizontal row, explorative scenario approach).
- - If we are certain about the future context, or if we are determined to be successful in the chosen scenario by all means, then we should aim at specific / taylored strategies aiming at the desired state (a vertical column, normative scenario approach).

	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Logistics				
Delivery				
Payment				
Marketing / PR				
Bike mainten.				

Tab 4 Strategy development for the activity fields related to the scenarios (Jonas 2000; Jonas 2003; Jonas 2005).

SYNTHESIS

The systesis consists in the development of the four scenarios outlined above into details.

Each scenario defines a business concept on the basis of the most critical factors identified in the "4 stagioni" method and in the sensitivity analysis (Fig. 4).

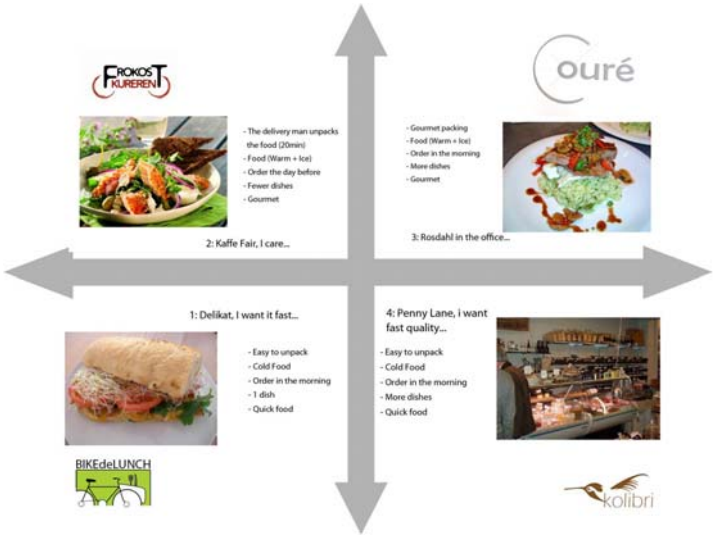

Fig. 4: Overview of the four concepts deriving from the 4 stagioni method

Requirements

Each concept, identified with a name, defines a platform of actors, interaction, information and business flows that needs to be defined in details. The requirements are therefore organised on the basis of the 5 activities fields described in Tab 4:

Logistic aspects depend on bicycle transportation and customers' expectation about delivery time. Those aspects concern the identification of a *served* area, a number of food providers that can be associated to each concept, number and efficiency of the couriers (the project does not assume the courier to be in perfect shape every day)

Delivery aspects include ordering time, food choice (more variety can affect delivering time) and the collection of food from local shops or restaurants

Payment-related aspects: delivering people should not have the responsibility to collect the payment, this has several implications on the organisation of the payment system.

Marketing/PR: delivering people are not specialised in this service, and in some case they have problems in their social relation with other people. This requires more attention on strategies to address customers' expectations and on the interaction between customers and delivery people.

Bike Maintenance: The service has its own bike repair workshop, that should also able to provide assistance in case of emergency.

Concept development tools

A progressive definition and detailing of the service, starting from the broader frame outlined in the "4 stagioni" method, is organised in order to address different design aspects:

- The development of a modular architecture for the service
- The analysis and design of time-related aspects
- The organisation of an efficient system configuration on the basis of a high variation of individual choices; and
- The organisation and design of infrastructural elements of the system

A modular architecture

Being based on bicycle transportation, the service must cover a limited area of the city centre and use only local resources (food providers, restaurants). The methodological approach

used for the organisation of local activities and the exploitation of local potential is based on a modular architecture, in which each module refers to an autonomous actor. Each actor holds the knowledge needed for providing a part of the service. The main organisational task is to generate a *solution platform* that allows multiple solutions, by specifying sequence of events, interaction among modules, physical and financial flows.

Those platforms allow for a distribution of *engineering power* among the modules of the platform. Each module will be appropriately designed and organised at the local level (e.g. each food provider will autonomously decide upon its offering), while the system organiser will negotiate the connection of those modules through an appropriate modelling activity that simulates the behaviour of the system in time and space. The system organiser should also propose elements essential elements for the coordination of the activities , such as time planners, bicycle transportation, a web page for ordering and daily menus.

According to this methodological approach the first stage of the project consists on the identification of the actors (food providers, service providers and customers) on the basis of their geographical location.

Addressing time-related instances

Likewise architectural design, the concept development process can start from larger scales (platforms) and, in a second phase, be articulated into details (products and interactions)

Unlike architectural design, though, the definition of the details in service design cannot be based on synchronic representation, because of the critical relevance of time sequences and events in phases such as logistic and delivery. The whole system should be organised around a very short “time window” for delivery: lunchtime.

An event based method, such as use cases, can effectively address time-related instances of the service. Use cases are used in service design to specify the sequence of events in a service (Morelli 2002). Each use case represents a simple instance of the service and focuses on a specific actor (the courier, the customer, the IT unit). The time sequence specifies each phase of the service, elicits requirements concerning the actor’s experience (front office) and the system behaviour (back office), finally, use cases facilitate the coordination between individual time plans.

Planning variation of individual choices

The focus on highly individualised solutions requires that different scenarios be defined, that address individual choices. The scenarios consider different actors’ behaviour, different organisational instances and emphasise their implications on the system.

Scenarios are particularly relevant in the organisation of meal ordering. Individual preferences could be combined (thus creating cumulative orders from people working in the same building, or people with the same dietary requirements) and with organisational instances (e.g. the availability of meals or food providers that satisfy that choice). By grouping those instances, different ordering scenarios can be adequately addressed, that improve the efficiency of the service.

Planning the infrastructure

Use cases and scenarios bring the development process to a level of definition that is adequate for the specification of the material tools and the technological elements that will support the service.

In this case the service is not supposed to introduce any particular innovation at the product level: bicycles, communication tools and personal equipment are off-the shelf products;

minor adaptations are required (e.g. bicycles, packaging, invoice system), to facilitate delivery logistic and payment-related requirements.

Outcomes

The design process brought about four detailed concepts for the “Frokost kureren” service proposed by FF. In fact frequent meeting with FF personnel made it possible for this organisation to be an active part in the development process. Although some of the concepts proposed were not perfectly adequate to this specific initiative the four framework concepts were useful for the company to focus on the problems and develop new solutions.

The focus on the problem site emphasised issues related to:

- an adequate time plan to organise the logistic-delivery system, with particular focus on critical phases, in which several functions are overlapping;
- different demand patterns;
- an adequate coordination of the offering from different meal providers
- a marketing and communication strategy consistent with the effective capabilities of FF personnel
- By focusing on the solution space FF was able to:
- Identify an approach to coordinate time related instances in the logistic and delivery system (e.g. use cases and scenarios)
- Identify different solution frameworks to address different demand patterns (i.e. different ordering or membership scenarios)
- Identify the elements that would support the interaction between different actors (e.g. booking systems, online menus)
- Define an adequate qualitative level for the service according to the available resources (PR, service identity, interaction between customers and service).

After the workshop the service was started for a test period. FF chose to work on a mixed concept, considering a limited number of meal providers for customers with long break (a scenario similar to the lower right quadrant of the 4 stagioni method). The service is still in the test phase because of the difficulty for the personnel to guarantee an adequate level of service.

6. Conclusions

The research questions addressed the issues of

codification / transferability: whether is possible to generate anything similar to a source code for this kind of initiatives and what form for the source code; and

differences / similarities of business- and social processes: whether criteria and procedure for designing services in a socially oriented context are different from market oriented services

Transferability of the approach

The relevance of this project in the debate on design research lies not only on the design process for this specific solution, but also in the definition of strategies to “codify” the design process, in order to transfer elements and procedures to further projects in different contexts. This paper proposes the question of transferability both on the problem space and on the solution space, thus proposing a methodology for handling the problem and an approach to structure the solution:

- The methodology / methods toolbox as described and applied above provides a framework and guideline to deal systematically with highly contextualized design situations. In spite of the situatedness of every new problem t.bag contributes to the collection and refinement of prototypical process patterns.
- The articulation of the solution into an architecture composed by modular elements creates a platform for different combinations that can provide highly individualised PSSs.

Business design processes vs. social design processes

When working on local projects, socially oriented design processes and business processes are both focusing on contextual conditions; in this sense the difference between the two approaches is minimal. In both cases, the processes introduce conditions that are “external” to the design activities, and do not bring about fundamental changes in the design process, although they do imply a different approach. Designers will need to abandon traditional top-down and business centred approaches and increase their sensitivity for social contexts. The design team should individuate a network of local actors that will co-develop the solutions.

Designers, with their methodological approach to innovation and their aesthetic expertise will keep their role as change-agent even in local and highly individualised solutions, but the “symmetry of ignorance” requires a modest attitude for designers, in order to withdraw from the previous control position and become a moderator in the innovation process.

By focusing on mechanisms of activation of local social and business resources, this project points out at the big opportunity for innovation in design activities. Whether coming from business or socially oriented processes, such innovation changes the perceived role of designers in the development process, though it does not change his/her level of responsibility for their action.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Contribution of Design to EU Projects and Programs in Italy

An experience on the use of a "design-oriented approach" in an EQUAL project. Compared outputs.

Manuela Morra[1], Antonio Ilic Vitolo[2]

Abstract

This research buds from the experience of Altronde, a team made up of two professional "service designers" aiming at using design tools (especially service design) as a strategic, methodological and creative contribute to the development of welfare initiatives oriented toward social and environmental sustainability.

This paper aims at presenting our point of view: we believe that design is a significant contribution within EU projects and programs. It can facilitate the methodological and creative process, giving a support during the needs analysis and the project's outputs orientation.

This paper contribute to define how design can work into an EU project or program and how it can interface with stakeholders and their traditional approach.

[1] Altronde (Italy), Partner, m.morra@altronde.org
[2] Altronde (Italy), Partner, a.vitolo@altronde.org

1 Introduction

This research aims at introducing guidelines useful to understand how design and creativity oriented competencies can be helpful to project processes relative to European programs and calls, oriented to welfare and local development.

The suggestions are the result of our professional experience as service designers participating to Equal project “Palcoscenico”.

The paper consists in three main parts: the first one shows the context, namely the EU programs and the project we worked on. The second part deals with the most relevant contributions that, according to our own experience, designer can provide to EU projects. In the third one we identified the most critical factors in achieving a “design oriented” approach. The last part gives some suggestions to both designers to understand how to face such a context and to the stakeholders to realize which are the main advantages of such a creative approach.

2 The context

2.1 EU projects in Italy

Since 1957, through the ESF (European Social Fund), the European Union has been financing projects helping citizens improve their own competences and increase their working opportunities: occupation is the first mean through which EU grants prosperity and welfare to Europe and its citizens.

EU projects aim at reducing the differences among European regions and among member states as regards life quality and prosperity. Therefore, they are useful to support social and economic cohesion by creating a larger and high quality occupation and by giving citizens the opportunity to develop the necessary competences. (Equalitalia, Portal of the Community initiative EQUAL).

European Social Funds are available by presenting operative programs created by the partnership of different organizations. Operative programs establish the ESF action priorities and the objectives for a period of seven years (i.e. 2007-13).

Projects need to be focused on general targets and be characterized by a high quality level resulting from the idea, which should be good and properly organized, and the partnership, who should grant highly qualified stakeholders.

As to the period 2000-2006, the main objectives were:

- to promote development and structural adaptation of weak regions: Campania, Calabria, Puglia,Sardegna, Basilicata e Sicilia
- to support districts with structural difficulties in order to reconvert them economically and socially.
- to develop new professional training systems in the fields of education, training and occupation.

In particular, five sectors were considered as priorities:

- The development of occupational policies
- The promotion of equal opportunities in acceding to labour market;
- The promotion and improvement of professional training and education
- The promotion of qualified workforce, of innovation in work organization.
- The realization of specific actions aiming at improving women’s access and participation to labour market. (Equalitalia, Portal of the Community initiative EQUAL).

A note about project partnership.

European funds are distributed at communitarian, national and regional level. Most of them are distributed through calls, mainly addressed to project partnership, namely groups of public and/or private actors.

These programs are enacted by several typologies of organizations, such as national authorities, education and training organizations, ONG and voluntary associations, social actors, etc. Partnerships generally identify a lead partner and distribute the roles.

Considering the high number of participating people, the management system is very complex. The organization phase is often the most critical for the Italian partnerships: it requires great part of the resources to the detriment of outcomes quality.

2.2 EQUAL projects

As an ESF community initiative, Equal is a platform aiming at finding new ways to reach European strategy objectives of occupation and social inclusion.

The role of Equal projects is to generate meaningful changes in specific problems to be solved, through an investment in terms of innovation and experimentation. Equal actions can and must experiment with new ways, tools and methodologies which have to be more effective and face people's and organization's problems in specific areas and topics. (Equalitalia, the Portal of the Community initiative EQUAL).

What makes the initiative different from the main ESF programs is the fact that it provides examples of best practices in terms of innovative approaches. It also pays great attention to active cooperation between members states, in order to grant the sharing and diffusion of the outcomes all over Europe. Therefore, projects have to include activities which are necessary to spread and apply what has already been tested.

Projects are realized in a period of 2-3 years and consist of 3 actions:

- Action 1: Setting up of the Development Partnerships and of a transnational co-operation
- Action 2: Implementation of the work programmes by the Development Partnerships
- Action 3: Thematic networking, dissemination of good practices and impact on national policy. (Equalitalia, the Portal of the Community initiative EQUAL).

A critical note on Equal projects efficacy in Italy

Some critical points about output typology and Equal outcomes have emerged from the 2005 Equal national report. Equal programs seem to operate as reinforcement/substitution of ordinary actions, rather than as an innovative way to develop them.

Equal programs have a high number of addresses, but not for long treatments.

There is a great difference between the number of the addresses involved in the encouragement actions and the ones involved in structured and direct actions. From the 77 Development Partnerships' final reports it emerges that 2440 people per DP have been involved in informational and promotional actions, while only 349 people have been involved in motivational actions. The numbers lowers in more structured actions 75 (training and services to direct users). (Ismeri Europa 2005)

This report shows the tendency to develop supporting offers (informational and cultural), rather than to give direct answers to the needs, in spite of Equal trend to emphasize experimentations and actions directed to final users.

2.3 Palcoscenico project

Palcoscenico is the project we have been involved in as consultants.

P.A.L.CO.S.C.& N.I.CO. is an acronym for "Piano di Azioni Locali per la Costruzione di

una Sensibilità Collettiva e una Nuova Identità della Conciliazione" which means "Local Actions Plan for the Creation of a Common Sensibility and a New Identity of Work-life balance".
Its main purpose is to realize initiatives and services aiming at reducing working time or organizing it in a different way, and also at setting it free through measures supporting the balance of working time and personal life.

Another purpose is to spread out a new idea of work-life balance as something referred not only to women, but to everyone.

The institution client is Regione Campania and the DP is made up of Provincia di Napoli (lead partner), Comune di Napoli, ARCI Napoli, D&S Group cooperative and OBR, the Bilateral organization for professional training in Campania.

The objectives are achieved through three main actions:

- A communicational action plan regarding the entire district of Naples, through a differentiate and integrated use of mass-media, in order to involve both local actors and citizens.
- An Agency for the Work-life balance to realize work-life balance services and initiatives.
- An experimentation action in five areas of Neapolitan district where to activate initiatives involving directly local administrators. The action includes a needs analysis and the suggestion of intervention models. In one of the areas the project managed to activate an action for the creation of a work-life balance service. (Equi-Palcoscenico, Palcoscenico project web site) .

2.4 Who we are: Altronde

Through "strategic design" and "service design" methodologies, Altronde offers consultations to firms, and public administrations to find and develop solutions and services characterized by a highly innovative content and a "sustainable" orientation to the purpose of producing benefit for life quality and environment.

Altronde transfers part of the designer's competences – already present in the productive and industrial fields – to strategic sectors in order to create actions referred to welfare politics. Creativity, vision, design method and management of complexity: if focused on solving a problem, they all are effective in creating satisfactory solutions for a specific welfare request in a specific context.

Altronde deals with increasing the value of bottom-up solutions, which are models to be repeated in several contexts, if properly interpreted and re-designed.

Our goal is to create effective and user-oriented services as part of the answer to a problematic context. Services are meant as pleasant experiences where the user plays an active role. They also represent a chance to inspire responsible behaviours and social fabric regeneration processes.

Our designed services materialize through new lifestyles or new ways to solve daily problems: elderly and children care, management of urban green, house maintenance, new mobility systems, food networks, etc.

2.5 Altronde's part in Palcoscenico

Altronde's partners participated to Palcoscenico project as consultant.
Firstly we had to support the design of services within the IV Municipal Corporation of Naples, where the Partnership aimed at supporting local administrators in designing and activating a service for children care. Then we were asked to design the PALC (local action plans for the Work-life balance), namely documents proposing intervention models in terms of services to citizens and workers, on the base of a needs analysis.

We have probably been involved in the project because, in the light of a previous experience (Equilibra), the Partnership felt the necessity of designing concrete actions of Work-life balance, in the form of services to the citizenry.So, Altronde's initial role was to address project outputs to citizens and final users solving some of their direct needs.

In particular, we cooperated with two of the project group partners: the Social Cooperative "Donne e Sviluppo" and OBR, the Bilateral organization for professional training in Campania. With the first one, our task was to analyse and design concepts for the Vesuvian area. With the last one, and the Group "Piccola Industria di Napoli", our task was to analyse and realize projects for the IV Municipal Corporation of Naples.

1 Analysis of the contribution of design in the EU welfare projects

3.1 The critical definition of the project specific target

The most important elements that design can improve concern the targets of the project and the shape of the outputs.

The design typical creativity, related to complex projects, can be useful to help give appropriate shapes to the solutions, so that these ones can fit in the reference context, according to the available resources.This is a skill that less creative expertises aren't inclined to deepen: as shown in the report above, the trend is to propose easily manageable indirect solutions, based on either communication or training actions or governance models .

This kind of output is acceptable considering the competences or the skills of expertises generally involved in EU programmes. These expertises do not have the tools to develop citizen-oriented solutions.

When we started devoting ourselves to the project, as service designers, we thought that the project was mainly aiming at establishing services for community benefit, work-life balance. We also thought that the resources of the funds could cover also activation fee.

Actually we discovered that project, only in its experimental part, took into account the development of solutions aimed at the final users. Besides the economical contribution was provided only for the planning part.

Our expectation about the project output, was in opposition to an approach, directed to the formulation of planning and governance tools (Local Action Plans of work-life balance) and to the supply of informations and consulting services (agencies of work-life balance).

Later on we had to lead our efforts from a feasibility planning (activated for only one territory) towards a design of intervention models, intended as ideas to be developed in specific local contexts.

The proposed actions (PALC and agreement protocols) have been therefore addressed mainly to institutional agencies (Local Authority) rather than to companies and citizens, thus extending the planning chain and the times.

It has therefore been considered appropriate, to privilege actions aiming at the awareness and diffusion on the territory of a culture of the work-life balance, through a communication plan:

"all the time you want".Such an action was developed to stimulate awareness on work-life balance issues.

Other EQUAL projects, realized in other contexts, led to the real experimentation of services in support of the family. Such services have been addressed to the weakest people in the families, such as as: the eldest /youngest/disabled people. Other services are instead directed to the conciliatory needs of the employees. This initiatives have integrated pre-existing services, creating new work opportunities, especially for women. By offering family-friendly services it has been provided an innovative response to the existing and real family needs. Among the good practices it is worth noticing the service activated by the Municipality of Perugia, which puts into practice the service design approach.

The Babysì service was intended to create an association of mothers and baby-sitters that manages care services addressed to 6-months-old to 10-year-old children. The service links the present initiatives in the territory by promoting the regularization of employment in this field. The model succeeded and was added by the Region Umbria in the draft "three-year plan of the system integrated of social and educational services for the early childhood 2008-2011". (Territori concilianti 2008*)*

One of the difficult aspects was that the project was affected by financing, laws on which the solutions should have been based. The problem related to this approach is that the project will offer "prepackaged" and generally incomplete solutions, which are not suitable to the context.

Therefore, a well planned design chain, which is intended to tackle beneficiaries' real and concrete problems, must start from a complete and accurate analysis of the existing situation. The solutions that are able to cope with the problems must be created subsequently.

Design may be a tool to optimize the planning chain.

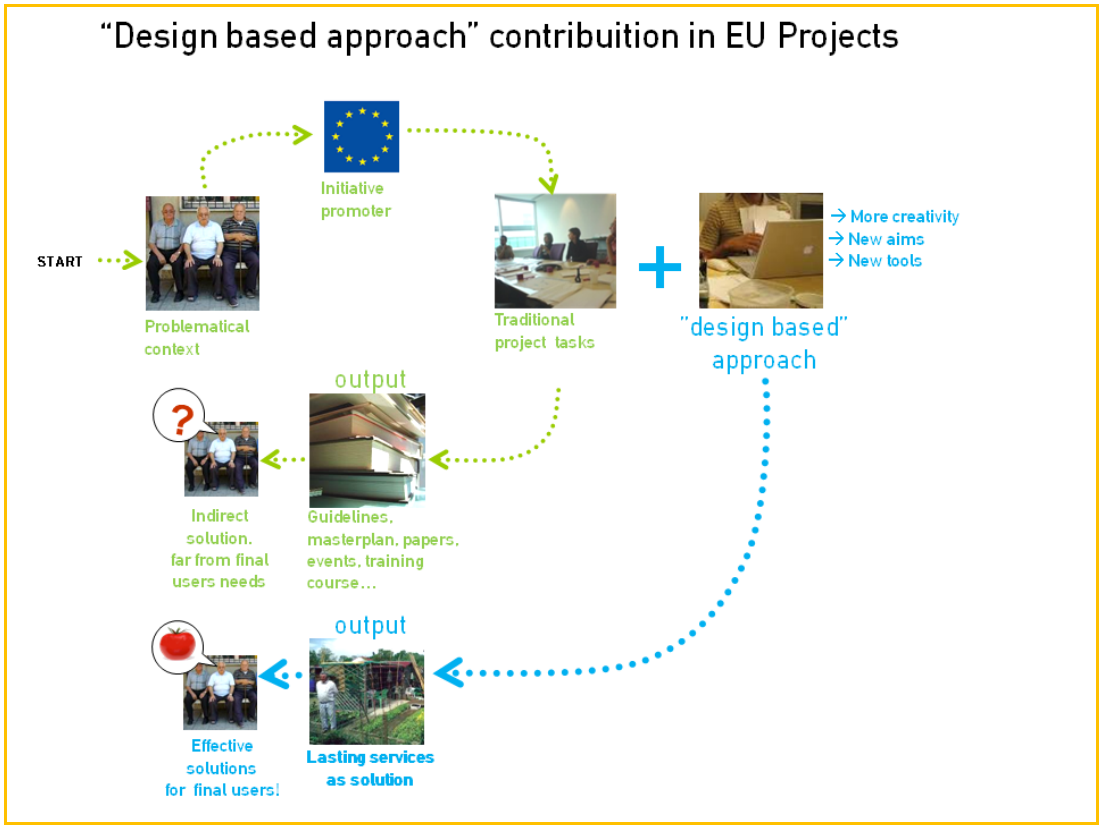

Fig. 1: "Design based approach" contribution in EU Projects

	Development Partnership vision	Designer vision (Altronde)

Main objectives	- design governance model - make informative front office and initiative - make a “guide” to help local administrator to build services	**build services for citizens to improve work-life balance.**

Table 1: Comparison table, Palcoscenico project objectives

Defining methodology and work tools

A strategic factor of design that can be crucial in EU projects is definitely the methodology, namely how to deal with the working activities and what tools use to achieve the goals.

To tackle our tasks we have focused on the effectiveness by creating a path, and some tools which would let us achieve the goals. To identify the work-life balance needs the development partnership had established an articulate path consisting in "territorial forums" and "focus group".

- “Territorial forums” were a series of meetings with groups of local administrators, who should have clarified what the issues, the items of intervention and resources were.
- “Focus groups” instead should have been meetings attended by representative of the partnership and the third sector actors to decide the intervention plans.

These instruments have shown little effectiveness; in fact it has been difficult to organize meetings, which could be involving for a sufficient number of people to take significant decisions.

Another problem was related to the results of these actions; in fact they were effective till they dealt with the general level of the topic.

Also for the actions of context and work-life balance mapping, the reference actor had developed a form of approximately 120 questions that the Provincia di Napoli should have sent to all the local assessorships and competence offices. Obviously, not even one filled-in questionnaire has been handed back. It is likely that the questionnaires have not even been delivered to the city council.

For the planning of actions and services, Altronde has developed a path divided in three main stages:

- Territorial analysis: providing a full overview of the characteristics of the territory, of the needs of their respective catchment areas and their quantification. The methodology used in the context analysis phase has concerned a first research realized through the web (macro-analysis) and a more detailed deepened (in-depth) investigation based on interviews and comparisons with reference actors (institutional representative) and people who work or live in the territories.
  Output of general analysis phase has product some synthetic mappings which were showing:
  - critical and promising factors recorded in the territories
  - context mapping (services, associative realities, …)
  - general map of the problems expressed by the interviewees
  - general map of the promising factors
  - general map of the proposals

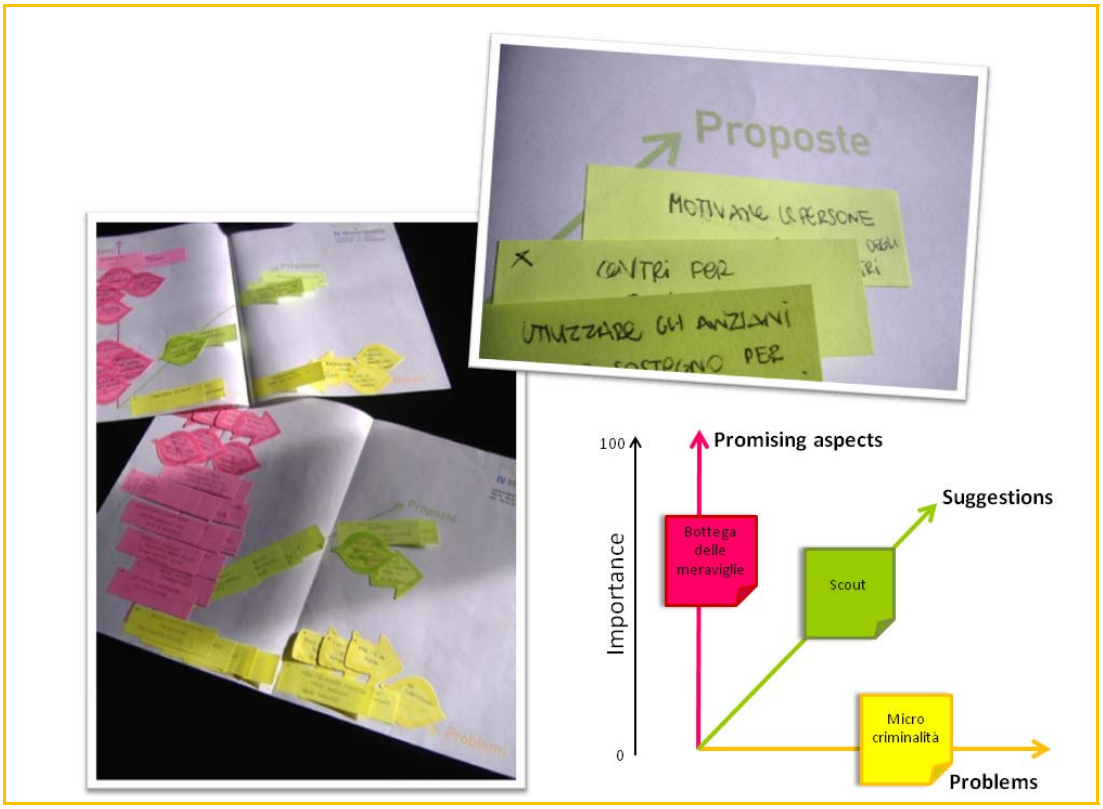

Fig 2: **Problems / Promising aspects / Suggestion Map**. We designed a viewing information system for the dialogue/survey with the reference actors (qualitative analysis).

- Research on the themes of work-life balance and analysis of case-studies: a research has been started to find what the visions on work-life balance were and how they adapted to to the Italian society. The collection of case studies, characterized by innovation, was instrumental to gain new knowledge and know-how both from the successful and unsuccessful cases.
- Designing phase: design inputs have been identified leading to the formulation of the various "operational models" related to the different territorial contexts. By operational models we mean service ideas describing in a synthetic way the service being offered and the needs it was addressing, the interaction system with the user, and an organizational chart showing the stakeholders map.

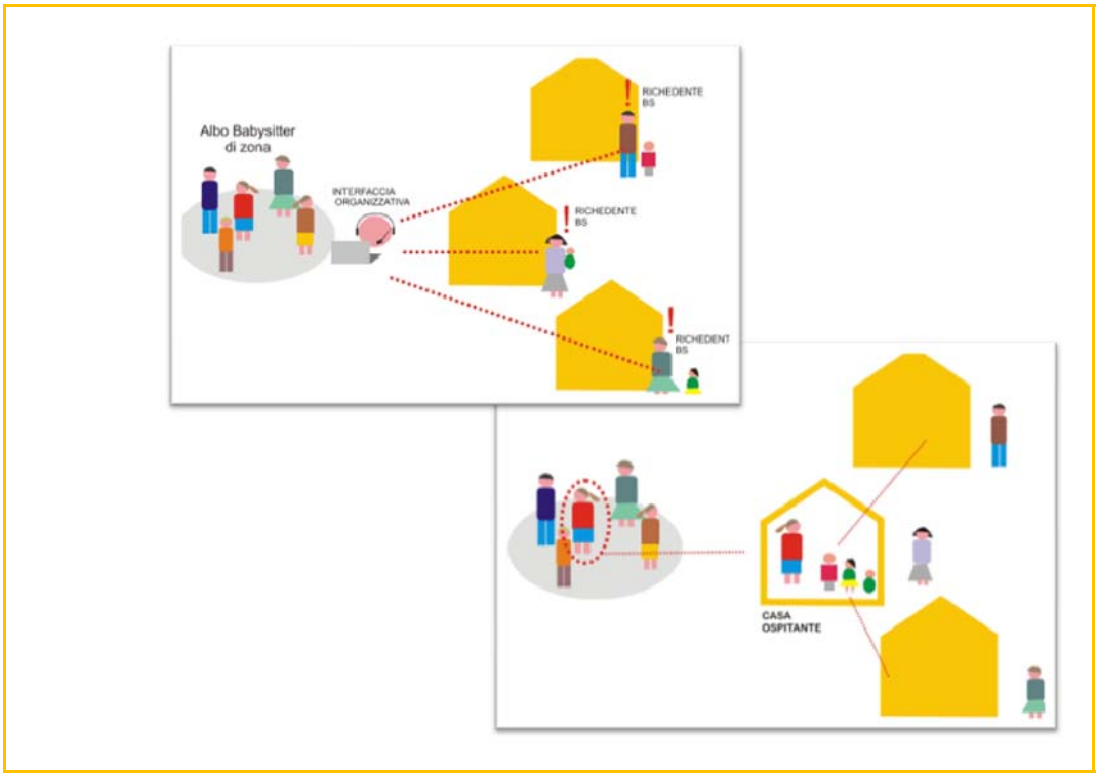

Fig 3: **A Service Map**. The concepts are displaying through "service maps" that identify the fundamental aspects in a graphic, simple way: role of the actors, interactions between users, material and immaterial elements, resources, places,....

- Guidelines: for each phase we built some tools (mostly maps) which supported the collection and management of information and also to share with the other actors of the project. We always tried to facilitate the tasks of the other actors by submitting collaboration requests easy to fulfill (limiting the transfers, the necessary time and within the range of their expertise).

	Development Partnership	Designer (Altronde)
Tool	Focus group: meeting with group of local administrator and stakeholder.	**Personal interview** organized on 3 topic : problems, promising aspects and proposal.
Efficacy	The organization and management was very difficult. The actors presences was insufficient. Generally discussion turn from original goals.	Great number of interviewed people. Accurate information functional to project development.

Table 2: Comparison table, Palcoscenico work's tools for work-life balance needs analysis

Communication and simplification of language for a shared vision of the project.

If a citizen was asked to read a project of an EU program, he probably wouldn't go further than the tenth page. However he would already be confused. This happens because the world connected to this type of planning often seems fond to a complex aesthetics.

Simple things – very often the most effective – are often distrusted. It seems that creating difficult logical-conceptual processes is necessary to give dignity to the work. Of course, this approach influences the communication of the project which is a complex system in itself because of the amount of actors.

Another factor to consider is time that often actors of the project lack of because they are generally very busy. Not all of them manage to read the whole material or comprehend it completely. At worst they give a different interpretation from the author's one.

An effective visualization involves also the characteristics of concreteness and tension toward the outputs. A visual map of the logical path followed by the designer to reach the final result makes clear and facilitates the creation of common ground that is the first step towards the "common vision of the project ".

To make each work stage more effective we elaborated it as a presentation. This way, we are forced to consider its communicative value as a fundamental aspect.

This process helped us designers simplify and summarize the results from time to time, focusing on the final goal and not on the single stage. The presentations helped the other actors read the work, which, through the synthetic text combined with images, encouraged the reading and the faster perception of the salient points.

	Development Partnership	Designer (Altronde)
Tool	**Typical report** The accountable actor planned a document in which must be present an introductive part on territories and a second part with the list of initiatives and services functional to work-life balance	**Contest presentation+mapping system** A presentation with a large use of images and catch phrases summarizing complex information . We designed territorial mapping system. Maps supplies typology of information with geographic references too.
Efficacy	Report was developed in a didactic way. It result very hard have a brief vision of the contents.	Main information was suddenly clear trough the mapping system.

Table 3: Comparison table, activities for communicating territorial analysis results

The involvement and playfulness in the project activities

We developed some work phases through methods involving all the participants: the planning team members or interviewees. We also chose a light and funny approach.

It is possible to lighten the mood, especially in group activities, through two levers: the language and the tools.

The language: it is important to use a "light tone", which must suit to all the activities and the communicative artifacts. The lightness stands in language simplification and in the pleasantness of discussion experiences.

Realizing a simple and clear introductory speech to submit to an interviewee, providing him with material on the project and editing its graphics: all these elements can be simple actions that may encourage interaction with other actors. The use of both titles and funny and unusual images delights who is listening.

The tools: when the way to reach the goals must be defined, it's highly productive to develop work tools stimulating the involvement.

The involvement is useful both at a higher level (the methodological one) in which the identification of participation activities take place, and at a more practical level, namely in all the discussion actions (whatever the referent) in which it is always useful to set up the activities in an interactive way.

We tried to develop interactive tools aiming at stimulating the discussion and the contribution of everybody. For example, in our presentations, we used address specific questions to the present people in order to stimulate their participation in decision-making.

	Development Partnership	Designer (Altronde)
Tool	Multiple Form: a tool to conduct a census about work-life balance activities and initiatives. It is e-document send by e-mail to local administrator offices. To compile the form was necessary to mark voices among about 200 boxes	Answer tab: We used colored "post-it" to mark (in real time) the answer on a visual map divided by 3 axes: problems / promising aspects / suggestions.
Efficacy	The document doesn't introduce in a appropriate way the project. The used language was hard and burocratic. The reader perceived the form as promissory to fill out.	We introduced personally the project Palcoscenico. The interviewed people resulted involved and intrigued by colored post-it on the tab. Viewing in real time their answers people gave a correct vision. Often interviewee required news about project development and local analysis.

Table 4: Comparison table, tool to obtain information on the interviewee's territorial context

3 Critical factors to design and designers

The following chapter deals with the most difficult points to cope with when adopting a designer approach and the obstacles to the work of creative figures within traditional working teams.

3.1 Project language dimension

We believe that within project activities, a design oriented approach needs the presence of creative professional figures. However, very often they lack in relevant training or experiences in this field. So we believe that one of the main obstacles to a design-oriented approach is the kind of language used by the traditional actors of the world of European projects.

The vocabulary used in the project activities documents are often neologisms defining typologies of solutions or tools to use within the project.

This kind of micro language is likely to be better understood by actors dealing with welfare and local development than by the ones who do not posses these competences or do not know

the internal dynamics of a project. In this case creative figures could feel disoriented in consulting the project documents.

We ourselves needed a long time to really understand the various aspects of the project and the true meaning of some activities we were hearing of.

3.2 Managing politic and interactive dynamics

Design is a cultural mean which affects output quality, whatever the field it is applied to.

Within the management system of a project, the higher is the position of the design, the most its potentialities will increase.

In a project like Palcoscenico, the designer can provide his support in designing and realizing a simple presentation trying to improve its quality and making it more communicative and effective.

However, at the same time, the contribution of designer can be more incisive by focusing on the goals and the means to reach them and by providing a new point of view based on creativity. This quality should make a difference between the designer and the other members of the team.

The designer can also offer a critical and innovative view of the project, thus providing the members and actors of the partnership with some things to ponder.

Naturally, it's up the project managers to define the role of design and of the creative figures. Instead, the designer must be able to manage his competencies in such a complex context, to understand the interactive dynamics and to find the place to express his own opinions and ideas.

The actors leading the management of EU projects are generally numerous. In a group, each one has his/her own point of view: this generates contrasts due to technical discussion and many other reasons, such as temperamental incompatibility.

Internal conflicts affect the efficacy of a working group, but the strength of the choices depends on the active participation of each member.

In this scenario the designer must be able to act diplomatically, trying to give his own technical contribution without being influenced by working team internal contrasts.

As to our personal experience within the Palcoscenico project, the first difficulty was to provide our contribution to two partners having two different visions of the objectives to be achieved. This contrast caused confusion over the kind of support to offer and the output to get .

Another difficulty was to define the nature of our contribution to the project as services designers. The other members of the team immediately noticed our skills in communication, especially in making all the work more noticeable. In fact, since the beginning we were asked oversee the reporting of the meetings: we caught the main points and interpreted them as project tools.

The communicative action must be not a limit. During the project activities we showed that our contribution could also be a methodological and content resource. It is not easy for the ones who work in EU projects (sociologists, economists, educators, administrators) to understand the possible contribution of the designer. They usually adopt a different approach and have a different opinion about what the design activities are.

Naturally, the designer should not be considered as the solution to all the problems, but as a tool to address activities and outputs towards the real objectives.

The designer's vision of the project must match the other actors' visions and activities.

3.3 Managing normative aspects and feasibility of the solution

Our role within the project was to develop service models useful to public administrations as guide to effectively build the initiative.

Project teams usually pay great attention to normative feasibility of the proposed solutions. The most innovative and complex ones are generally distrusted because legal and organizational tools are not completely known.

It is therefore necessary for the designer to provide his ideas with some legal and organizational references with the help of more competent members of the team.

Sometimes feasibility aspects are much more important than the idea itself. In describing the idea to the project partners, it can be more productive to focus on how the service can be activated and supported financially and organizationally than to dwell too much on qualitative and evocative aspect of the service.

In order to grant continuity to his ideas, the designer has to try and realize the set of measures reinforcing the path toward the creation of the proposed initiative. It can be useful to adopt creativity also in this part of the project through “unusual” resources. For example, when we designed the “map of stakeholders”, we suggested the involvement of private firms as sponsors, or of low budget resources (associations and civil service).

Some proposal have been considered not very feasible or too complex because we have not been communicating enough about the organizational aspects.

4 Conclusion

This chapter will be showing the results of Palcoscenico project and, within them, which were the contributions provided by Altronde. We have tried to compare the output of this project with those of the previous project achieved by the same partnership

Presentation of the project results and contribution of Altronde

Palcoscenico project was born from the experience of the EQUAL project Equi.libra, developed between 2003 and 2005. In this project a set of actions were promoted and activated. The concrete results were the training of 15 “work-life time balance” agents and the experimentation of actions of organizational processes in 10firms.
But these attempts often clashed with a context in which the proposed actions did not have continuity in time because they were colliding with organizational and cultural problems within companies and the realities involved.

“Palcosc&nico” represented the desire to operate in processes of change about the specific issue of work-life balance. The project wanted to carry on the experience and make it sustainable by expanding the action and the number of interested actors. The project began focusing on different goals that have given rise to several actions:

- the creation of an action to increase awareness and information on the issues of “work-life time balance” from which a communicative campaign was born.
- the creation of a “work-life time balance” agency with front offices providing citizenry and local organizations with consultations for the actuation of work-life balance initiatives. The agency also offers guides for the development of services (PALC).
- the experimentation action in which a stakeholder started to activate the construction of some initiatives and services aiming at satisfying the work-life time balance needs.

We believe that our participation to the project enriched the different actors orienting and awakening them towards a different and final user-centred planning approach.

We believe that our contribution as designers within the project provided two kinds of contribution: a practical and a cultural contribution.

The practical contribution consists in the development of the analysis and design output (local context mapping and service ideas), with a considerable amount of information and ideas which can be easily read by anyone.

The cultural contribution consists in the emphasis we gave to the possibility to address to the final users this kind of design: we focused on their real needs by developing services designed to satisfy their needs with direct actions.

4.1 Suggestions for the designers (to work in a European project)

- Try to play the role - within the team - of the ones who's task is to address the works toward the real objectives;
- Try to design new creative tools and methodologies for the purpose of increasing activities efficacy. This is suitable from the analysis and comparison phase till the development of solutions and services.
- Study and delve deeper into the issue of the project developing the feasibility of own ideas.

4.2 Suggestions for the Development Partnerships (to have a design oriented approach)

- Try to simplify, making the path of the project more fluid. This kind of approach is suitable both for communication and language and for definition of objectives and activities;
- Make the project activities more informal and easier, searching for elements to make the participation to the project more satisfying.
- Encourage the integration of creative figures in the working teams and try to increase their value by giving them a strategic role within the project.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design stories for a sustainable society

Case studies of responsibility in practice

Judith Mottram[1], Paul Atkinson[2]

Abstract

Three design projects tackling the energy challenges facing contemporary society provide the focus for this paper. The projects include the design of an anaerobic digestion facility and associated greenhouse capacity; a light-industrial wind turbine; and street lighting. They originated without client brief from a small company in Leicester, UK., and embody elements that constitute a model for responsible design practice. The stories of these projects are distinguished by the way they highlight the necessary conditions for creativity - knowledge at and beyond field boundaries, combined with a vision of and strong motivation for change. As such, they suggest how designers might engage with the challenge of sustainable and responsible practice and verify models of the conditions for creative innovation.

1. Introduction

The focus of this paper, in common with several earlier studies of designing, is upon a small design consultancy, rather than upon design within a manufacturing enterprise. In contrast to earlier work, this study looks at three projects by the same company, to explore whether market sector or product scaling impacts upon practice, thinking or strategy. Cross noted that most studies of 'designer behaviour' have used novices as respondents (Cross 2003). Methods used include video recording or protocol analyses of designers at work, used to model design thinking or to explore design creativity (Kavalki & Gero 2002; Ball, Ormerod & Morley 2004; McDonnell, Lloyd & Valkenburg 2003), but interviews do appear to form a key approach to eliciting information about the practice of professionals in the field (Roy 1993; Cross 2003). Whilst this paper makes no claims for the expertise level of Atkinson Design Associates, the sustained practice of the company over 25 years is considered to enable the enquiry to claim some insight into the nature of the practice, which has received no external recognition for their specific contribution to the sustainability agenda.

The research method for this current study draws upon the approaches of Roy and Cross, although previous collaborations provided enough familiarity for an initial modelling of a design process where 'vision' was an important tool or stimuli for practice. Preparatory reviews included scrutiny of some previous literature on design case studies and on the modeling of creativity and innovation across disciplinary fields. The initial framing of the hypothesis was that issues such as the sustainability agenda could provide a driving principle for design thinking. It was anticipated that stories, framed as metaphors and held up as exemplars, would be a powerful part of the communicative processes employed within design practice driven by an absent meta-client.

The use of strategies for design development, and the role of specific subject and boundary knowledge was also of interest, and their fit into models of research-informed design or design-led research. A standard interview schedule was the basis for three conversations about discrete projects. The resulting transcripts were subject to a simple coding exercise using headings derived from the hypothesis. The analysis reflects on existing models of design thinking and practice, is necessarily interpretive, but draws upon the distributed understandings of the field.

While not engaging formally with narratological methods as part of a design process, the analysis did explore storylines within the interview transcripts. This builds upon the four main roles that stories might play within a design context, as reported by Turner & Turner (2003): giving the audience a progress account, providing an 'index' to previous events, identifying different perspectives or 'competing rationales' for an object, and as a 'socially constructed meta-story of the process'. The similarity of narratological theory to the approach taken by Wenger (1998) in the research that led to his discussions of 'communities of practice' is also noted.

2. Interweaving stories

The coding of the interview transcripts identified that the respondent tended to use a number of interweaving stories to structure his answers. He tended to give long and fairly coherent responses of between 600 and 1200 words, to quite short open questions, indicating a ready propensity to articulate his memory of events. The repetition of the stories about Concorde and Fiat (LS5 and AS4, and LS6 and AS3) clearly provide important touch-stones for current activity. The respondent did query the labelling of the narrative strands as stories, concerned that a story might be perceived as 'not serious'. However, the extent to which analogues are used to model indirect responses to direct questions was then accepted as justification for the label. Table 1 below indicates the stories in each project account:

Lighting	Turbine	Anaerobic
Collaboration (LS1)	Design Idea Development (TS1)	Project Description (AS1)
City Trials (LS2)	Finance (TS2)	Anaerobic Process (AS2)
Carbon Trust Funding bid (LS3)	Potential Private Investor 1 (TS3)	Fiat Panda (AS3)
Project re-shaping (LS4)	Potential Private Investor 2 (TS4)	Concorde Lighting (AS4)
Concorde Lighting (LS5)	Potential Commercial Investor 1 (TS5)	Finance (AS5)
Fiat Panda (LS6)	Potential Commercial Investor 2 (TS6)	Clients (AS6)

Table 1: stories about design projects

While the stories in the account of the Lighting project were essentially sequential, LS2 is resumed after LS3, and is used to lead gently into LS4. LS3 is reintroduced after LS6 while Atkinson is summarising the thinking in terms of key or core principles that permeates all three major projects covered by the interviews. He had been talking about how, in relation to the lighting project, 'the whole design ethos is to chase carbon out of products', which meant that the 'design principle is like falling of a log. 90/95% of this project is grounded in common sense and the reduction of CO^2…so it's not inventive, it's following common sense'. He then went on to say,

> If you look at the three projects, they share absolutely common stimuli. In the case of anaerobic, it is to develop a process that maximises methane production because by doing that you maximise renewable electricity against the competitors in the market place. In the case of the wind turbine it's to deliver a serviceable machine within reach of human scale that can be rugged for twenty five years and be cost-competitive against other renewable technologies in the wind economy. And in the case of lighting, … You work with a brilliant lighting engineer, the remarkable work of Berman and his conjecture and the rest is fiercely logical, … ultimately, the products look good …, but that isn't the driving energy behind the project (forgive the pun). The issue is carbon. Non-carbon, low carbon.

Following this short account of the key principles driving his professional objectives, the reintroduction of the story about the Carbon Trust funding bid acts as an exemplar story to illustrate the problems faced by the company in relation to raising funding to support their sustainable initiatives.

Against a similarly regular introduction of new stories, there was slightly more interweaving of stories in the account of the Turbine project. The fragment on the Anaerobic project followed TS2 on finance, and was used to explain the difference in terms of scale of elements within the project while stressing their similarity. Progression to the other stories about the potential investors followed sequentially, Towards the end of that story (TS5), Atkinson referred back to TS1, TS2, TS3 and TS4 before moving on to TS6 which referred to contemporaneous events. Prompted by a question on the business perspective of the project, a brief response picking up the initial project development story was punctuated by an emphatic statement denying the existence of

any underpinning business logic propping the project up. This was followed by an equally strong assertion of the climatic rationale for the project:

> The design logic is that Britain benefits from a highly advantageous wind climate in relation to the rest of Western Europe. So if you look at wind modelling, especially in northern Britain and Scotland, the wind energy available for this island sitting in the ocean is approximately twice the net energy available for the whole of the rest of the European continent. So Britain is a good place for wind energy

The justification for the design solution was given by the following question: 'if we can generate energy and renewable electricity from wind energy much closer to the planet, can we indeed build multiple micro-turbine infrastructure out of view of the general public?', explaining the rationale to counter objections to large-scale turbines. What appears to be indicated by the structure of the narrative is core principles and design thinking being used to alleviate anxiety about an unsupported business model.

The stories in the account of the Anaerobic project are essentially sequential, but with the opening and second stories about the project framing and the system of the anaerobic process itself reappearing between AS5 and AS6 and AS8 and AS9 respectively. This looping back again served as a vehicle to reassert some of the core design principles about the project. When first talking about the project inception, Atkinson referred to the base-line drivers for the project: to build new and sustainable employment opportunities for a post industrial community, to start dealing with the waste close to its generation and to engage intelligently with a raft of new legislation including the Animal By-Products Regulations of 2005. When talking about funding (AS5) he referred again to the base-line principle of how the project could impact upon employment when challenging the agricultural consultant's advice on budget modelling (2nd emergence of AS1):

> We'd always put £10 per employee per hour into the business plan and they seemed to think we could shave that in half and pay minimum wage, which completely contradicts the ethos of a modern industrial company using modern industrial methods and paying people honourably for a fair days work and adding value to the economy through their activity rather than being a new, British, agricultural sweat shop

When talking about existing anaerobic digestion systems (AS8), he notes they were all 'conceived, designed, developed, commissioned and built prior to the ABPO legislation' but were antithetical in nature to the current project in 'their nature, their dimension, their capital spend, their scale of infrastructure'. He returns again to the anaerobic system (AS2), describing taking waste only 15 to 20 miles from its 'arising', and the logic of a dispersed multiple micro-technology solution and the proximity principle. The story of the system was maintained through answers about competitor products and the design process – the solution and its modelling provided the vehicle for talking about design office activities:

> generating engineering layouts and plans, plan elevation, play layouts, side elevations, side section analysis, trying to build an architecture that would sit close to landscape. We set again I think a self-imposed criteria, of could we make anaerobic digestion succeed within a roof ridge architecture of 6 meters… so the whole architectural model could sit discretely within the land, or on the landscape, rather than being a.n.other monumental British stupid shed. That the building should be smart, not stupid, should look good, not bad

The stories of the Fiat Panda Designer (AS3, LS6) and previous work for Concorde Lighting (AS4, LS5) appear in both the account of the anaerobic project and in the account of the lighting project. The narratives seem to operate as an analogue for the principles which underpin Atkinson's design ethos. Like the Panda designer, he wants to deal with the system and its manufacturing, as well as the end product. He also has a measure for realising those principles through the Concorde lighting project, which had outperformed in profit to the manufacturing company compared to any other product. Atkinson's analysis of how this happened is as follows:

> that the product was good for the market, the customer, the people in the trade fair and the international distributors network that buy it and sell it, but it was great for the blue collar worker… the best workers out of 300 workers in the factory all wanted to make that fitting, they all enjoyed touching it assembling it and putting it in boxes.

The penultimate story in the anaerobic account was presented in response to a question about whether tools or methods like scenario analysis, backcasting or brainstorming were used in any conscious or formal way as a part of the design process. The response was contained in a story of 1000 words, which detailed two projects Atkinson had participated in when teaching on Industrial Design courses. This story operates as an analogy for a descriptor of his underpinning design principles, and suggests that such analogical models could be more successful than explicit engagement with scenario building or other design methods. His brief to the students was to design a furniture programme, but the students also had to find a real building and identify a prospective occupant:

> Concurrent with finding themselves an architecture they would also invent a business, and by inventing a business I didn't give a damn whether their business employed 15 people and was in the fashion industry, because the boy had a girlfriend who was studying fashion at Northumbria at the time, or that they would run an insurance company.

As well as identifying the company, the students were asked to flesh out the company business plan:

> what was the core business activity of the company, did it employ 20, 30, 40, 50, 100 people? did it have a front desk, did have finance, did it have marketing, what were they doing, what were they selling, which service were they providing?

The responses of the students included inventing company structures and descriptions of hierarchy and management profile and then 'they would then spend the rest of the 6 week project, conceiving, designing, developing and manifesting a furniture solution for that architectural interior to sustain that business model'. The work produced by the students was considered to be exceptional and the basis for this is believed to be that:

> the furniture had meaning, the kids had a population to match, through visual expectation and functional expectation. So the furniture project could succeed because they were matching the hypothetical customer invented by themselves, with a real building, found by themselves

Atkinson recognised that this process could be called 'sophisticated scenario building', but then recounted another education project consciously using a scenario-building model. He described that project as 'kind-of shallow, thin, super-theatrical assessment of cause and effect, or need and demand', and asserted that a brief 'could only succeed if you put enough flesh on the bone'. As single cases, these vignettes seem to be operating more as an analogical means for responding indirectly to the question about the use of tools and methods, rather than as judgements upon the teaching methods of two institutions.

This use of stories to provide an analogous description or vehicle for accommodating the aberrant behaviour of other parties sits slightly outside Lloyd's framing of the roles taken by stories in design as reported by Turner & Turner (2003). Some of the Atkinson stories sit within the model of progress accounts, detailing the way in which an idea or scene unfolded, but the characterisation of the players lifts the stories beyond that simple functional role. There is an element of indexing in the use of the Fiat and Concorde stories, in terms of providing a benchmark, used to re-affirm core design principles. The comparative notion of competing rationales is hard to identify, apart perhaps from where embedded in characterisation. The sketches of the waste operative with personal vested interests, or the council waste manager as 'an interesting man … never seemed to be there, never replied to phone calls,… always seemed to be on holiday, or vacation, or leave, and drives a very, very large Mercedes', enable a value position to be asserted by the narrator.

3. Character modelling

Characters in the stories are personalised beyond the ‘flat’ characterisation one might have anticipated in an interview situation, and enables this embedding of value judgements. Such values assigned to the individual players in the stories tended to be positive, extolling personal attributes such as honour, intelligence, humanity. The two potential private investors in the Wind Turbine are each depicted in such a manner. One was ‘a quite brilliant industrialist… had a fantastic reputation in the aerospace industry’. He declined the investment opportunity within three or four weeks on the basis that the forecast 20% returns were modest in comparison with his recent investment in a Japanese company he had recently acquired. He was described as ‘very open, very sincere and we were disappointed but thanked him’. The second potential private investor was also a retired industrialist. The transcript includes a 200 word account of the story of his ‘beautiful apology’ detailing the family persuasion for him to fully engage with his retirement, rather than investing in the Turbine project.

What seems to be happening is that Atkinson is humanising some of the inexplicable contradictions or disappointments that arise within his stories. In talking about a previously successful investment recipient from the first potential commercial investor for the Turbine project, he recounts one vignette about dispatching the obstructive lawyers then reaching agreement, and a second about meeting a competitor who ‘was a decent guy but I don’t think (he) fully understood the implications of our proposal’. In the anaerobic account there are both positive and negative renderings of specific players in the narrative. While one participant in a due diligence meeting was described as making ‘a series of highly contentious and highly disruptive remarks’, including one that directly opposed the fundamental principles of the project (‘why didn’t [the company] simply ship the shit to China for the same gate fee’), he still managed to cast some positive connotations on the company chief executive who aborted the meeting:

> the female chief exec who should have been running the meeting, walked into that meeting 2 hours and 45 minutes after it started, with a sincere apology to the room, so 14 people stood up and bowed, and thanked this remarkable woman for attending her own meeting...

However, the ensuing story of how the meeting played out rolled on to leave the meeting over in the next fifteen minutes. The meeting ‘was disbanded unceremoniously by a female sales exec who wasn’t that interested in waste management anyway’, to enable her to work on the deal she had brokered while the due diligence meeting was being undertaken. Atkinson closed the story by summarising that ‘the circumstances for failure of due diligence were about as corrosive as they can be’, and seamlessly moved on to a positive story about an earlier project with an investor.

4. Design process

When talking about the practical aspects of designing, Atkinson tended to frame responses in terms where the design decisions are the result of evaluations. On the Lighting project, he describes the original need to draw a scientist onto the team to resolve ‘a real technical difficulty…’ arising in resolving the lighting requirements for a series of display units. The solution was to take the ‘highly disadvantageous point of illumination at high level’ and complement it with ‘lighting from the back and beneath of the display to balance the lit conditions’. The lighting scientist Atkinson drew on to solve the problem ran a software program for 26 hours to analyse the complexity of the ambient lit conditions for the cabinets, and thus determine the lighting needed in these other locations. The strategic recognition by Atkinson and the scientist of the potential to work together on future projects arose from this sharing of knowledge between them. In talking about the opportunity evaluation to take on the street lighting challenge, Atkinson notes the state of the field:

> The optical systems are poor, the lamp technologies are thirty years out of date, the science that underpins the photopic debate is in our terms discredited, new understandings of human biology determine that the scotopic dynamic is relevant and the photopic dynamic is redundant, the practice that is commonplace worldwide throughout the second half of the twentieth century is irrelevant, and that there are massive new opportunities for energy saving

This analysis of opportunity then drives the practical combination of prototype development and testing, including an ‘elaborate tap dance of making near replica but not recognisable designs’ as they couldn’t use the prototypical form in the city trails.

The most extensive discussion about the evaluation of materials occurred in the account of the Wind Turbine project. Atkinson noted the scale of drawing and model-making included:

> draughting and drawing, a lot of three-dimensional model-making, a lot of autocad, sizing, re-sizing, restructuring, a lot of inventive step in new structures, … every project we look at invites a new analysis of best-fit and fitness for purpose, so the most recent studies look at a dozen different technological strategies to make this damn thing, including alloys that, alloys this, alloys the other, steel this, steel that, steel the other

As well as talking further about material selection, the account makes extensive reference during this 1000 word section (from nine minutes of interview), to wind speed, rotor performance and the energy generation models produced by the combinations of variables, and to how the design scaling of the rotors might impact upon the rural landscape situation that could provide the first implementation of the turbine with the second commercial investor. The notion of chasing carbon out of designs was considered for the whole supply chain, exploring the implications of different materials for scale and embodied energy.

The principle that the projects under consideration were ‘industrial’ design projects was explicit in Atkinson’s analysis of a competitor turbine project. Despite being ‘shocked and distressed’ to find ‘essentially our proposition being developed by the University of Illinois’, the ‘laboratory lash-up’ added to their determination to succeed. Atkinson noted that he was keen:

> to engineer a machine that arrives in a box, a big box, and is engineered ruggedly to hit structural objectives at the maximum and unit cost at minimum. There is no evidence of that thinking within the American project

5. Knowledge

The project accounts indicate that knowledge from beyond the domain of design was actively sought to resolve design problems, and then the familiarity with those new knowledge fields was used to stimulate the development of new thinking. The chance encounter with Berman’s 1992 paper on scotopic sensitivity stimulated thinking which built upon previous experience on luminaires with Concorde Lighting. His increasing familiarity with the upcoming legislative framework on energy, understanding of embodied carbon and propensity to recall facts and figures, provides a convincing context for innovation.

Knowledge of the legislative context was key factor in all three projects. In Lighting, it was noted particularly in relation to the Health and Safety and Law and Order responsibilities of town and city councils and the law enforcement agencies, for the Turbine project in relation to materials recycling. For the Anaerobic project, the legislative background on waste management generally, and the aftermath of the UK Foot and Mouth outbreak in 2001, stimulated the conceptual framing of the project. ‘17 or 18 converging legislations’ determined ‘that this issue will get dealt with’. The respondent noted that ‘the key underpinning information that we had beyond common sense that we could see with our own eyes was that there was this monumental national problem’. When questioned on sources of information used in the design process, Atkinson talked more about process rather than information. He noted:

> common sense is very helpful. Designers generally make conjecture, and then set out to test that conjecture, or they build a hypothesis of a theoretical model and they set out to test that theoretical model, and we do that more or less every day that we work. Its certainly true of a classic industrial design project, where the client comes to you and says, 'this is our dilemma, this is where our competitors are going, we need one of these, we're quite uncertain about what one of these means, that the key characteristics of one of these is this, this and this', and at that point the client has thrown you a design brief and your challenge is to understand the forces acting upon the market and contemporary products available in the market, and to design a better product. But every sketch you make is a hypothesis, it's an attempt to address one or some or all of the criteria embroiled in the client brief

What appears to be evident from the three project accounts is that accessing relevant deep and current knowledge from the domain of the problem is part of Atkinson's core design process. By engaging with information about issues and past work in the fields of energy production, waste management and optics, the design company appears to have developed the intellectual basis on which to make design propositions which embody an incrementally more fundamental re-working of problems than existing solutions.

6. Design models

A closing interview session covered generic issues relating to all three projects. The key topics were publicity and project dissemination, the company business model, and awareness of environmental standards, environmental policy toolkits, and design models. Through this latter section, the stories are primarily 'progress accounts', with a strong emphasis on design process and core principles.

Atkinson's account of the design of a corporate headquarters, a response to querying absent clients for sustainable projects, noted how they prompted a technical sales representative to use a 'green' ticket to argue for the specification of a high quality product with particular aesthetic qualities over 'a really cheap petrochemical product'. This story was also responding to the apparent irony of presenting the headquarters project as being primarily about aesthetics – 'the most beautiful headquarters interior we've designed in the practice 25 year history' – after visual attributes had been only occasionally mentioned in the preceding discussions of the Turbine, Lighting and Anaerobic projects. In terms of design scope, this interiors project was described as:

> a study in space, light and management proximity and management dynamic, you know, with ergonomics thrown in so a little to do with science and a lot to do with perception… we're trying to build a corporation that is optimistic and forward-looking rather than pessimistic and backward-looking, and the environment should sustain that collective psychology

The same sort of values and principles that motivate the sustainable projects forming the main focus of the interviews appear to be fundamental elements of the design strategy for this underpinning commercial commission focused on improving a corporate environment.

While Atkinson recognised his projects did share characteristics with the model of the relationships between product strategy, product development, production and tools for environmental improvement (ESTO 2000, 8), he found that model 'fiercely convenient and fiercely linear'. He noted that in the projects discussed the design team went 'back to the beginning three, four, five and six times on each of the three projects'. This looping back was considered unusual in mainstream product development, which more often emphasised 'simply getting the product to market commercially tomorrow, you know, the feed and drink of design activity, or decorator activity'. This looping often incorporated stakeholder reviews where:

> the chief exec. or the board…or head of marketing or head of technology… and they review the intuitive work – the conjecture by the design team – and they say 'oh my God, you've got to be kidding, you can do that. If you can do that, can you do this?

What Atkinson did feel was missing from the model was 'the politics of the public purse, the politics of pubic difficulty, corrupt officers, the politics of learning and reviewing policy in light of that learning'.

It was apparent that Atkinson was not familiar with the toolkits and checklists developed to support sustainable product design. There was an element of cynicism about the usefulness of such tools, with a strong indication that deep knowledge and a clear value agenda were far more important for driving change. Reflecting on the projects covered by the interviews, he felt the proposition that small and medium-sized enterprises (SMEs) need to be provided with toolkits and checklists to support sustainable approaches to design was immature. He noted that one cannot just talk to stakeholders at the commencement of a project, but this must be embedded as an ongoing part of the process: 'you have to have a form of that, not using jargon – but hopefully sincere language – at every stage, and as for brainstorming techniques, we, we call that thinking'. Essentially, his perspective was that 'Its just design that is targeting CO^2 or CO^2 reduction, so it isn't consciously an eco activity'.

The problematic aspect of encouraging sustainable design was seen to be the same as getting design embedded or understood within the management philosophy of a company. It was seen as:

> all very well going forwards with a rule book on eco design, but if your client is unwilling or unable, you're going to have real problems, so you can write the manuals if you want to, but I don't think government has begun to understand how difficult these issues are.

The centrality of design between technology (engineering, materials, science) and human-centered values (sensation, appearance, touch) was stressed when discussing the modelling of the industrial context for design as presented by Rust, Roddis and Chamberlain (2000). Atkinson suggested that their reworking of Heskett's positioning of design should be reviewed again, stressing the importance of communication, not marketing, as the vehicle for human-centered analysis, moving design to sit across the junction of the two axes, and bringing in Finance as a distinct element as the conduit for a synthesis of human values, 'the currency, the underpinning enabler'.

7. New models or an idiosyncratic case?

The outcome of the interview analysis is a reframing of the original hypothesis. Instead of stories primarily providing metaphors and exemplars, the narratives could more correctly be described as being analogues providing abstract models of design principles. These are not analogues in the mode of Ball, Ormerod and Morley's concrete solution elements (2004), but rather they appear to be descriptive models which embed the principles underpinning design process, through a mechanism where the specificity of past solutions does not constrain creativity. These stories also carry characterisations of players in the story, which enables their behaviours to be accommodated. The interviews also confirmed that the absent meta-client functions as a driving design principle.

Given that the initial interview schedule had purposefully excluded some of the issues focused upon by previous work on expert designers, the fit of the data resulting from this project to earlier models is rightly partial. However, there is a reasonable match between Cross's general model of creative strategies (2003) and the cases under consideration here, despite Atkinson's discomfort with its simplicity. Roy's earlier identification of characteristics of creative processes in design (1993) had identified constructive discontent, idea and technology transfer between applications, practical experimentation and attunedness to market potential as notable aspects of the expert designer. All these factors are evident here, although the features of his second case

(introductions to markets by a third party, the use of biological analogies and visual brainstorming) were not so notable.

The cases described in this paper also provide some confirmation of the models of design thinking described by Owen (2006), although the collaborative nature of the projects in their more mature stages begin to combine design thinking with other modes of operation. Owen summarised the characteristics of creative thinking identified by Fabun, Arieti and Csikszentmihalyi, and added to this his own list of the additional features other than creativity, that he saw as characterising design thinking. He noted the balance these features had with science thinking - when conceived as a pair of approaches they would have significant potential to influence policy decisions at strategic, governmental levels. Atkinson's work falls into Owen's category of 'conditioned inventiveness', where tangible solutions for specific applications are developed. There is an element of 'what'-focused (scientific) enquiry underpinning the modelling of solutions for specific sites in relation to turbines, anaerobic and lighting, as local conditions are modelled to determine new challenges for either the technological process or for the material considerations of the possible design solutions.

The focus on having a client is one factor that clearly differentiates the cases reviewed – in Owen's terms design thinking has a 'human centred focus', unlike science and technology who share with the arts the characteristic of explorations proceeding 'where discoveries direct'. He does note that 'environment-centred concerns' have given design thinking 'a second, omnipresent and meta-level client: the environment', which today has to operate as an overriding qualifier for any activity in the field. This meta-client was clearly the main driver for the cases reviewed here, although the business model has flaws. The extent to which science-thinking adopts this client and its concerns, within a functional business model and as an operational value and measure, depends upon whether science could adjust towards making and inventing rather than finding or discovering. It might require intentional collaboration with the thinking skills of the designer, possibly as exemplified by these cases.

Atkinson rejected the idea of toolboxes to support 'eco-design' by SMEs. This suggestion arose from the European Commission's work on the systematic incorporation of environmental factors into product design and development (ESTO 2000). ESTO concluded that best practice will embed new methods in policy, with communication and feedback, supported by toolbox of databases, software tools, manuals and checklists or protocols. However the current case studies suggest that motivational factors and ability to apply knowledge across known schema's might be more relevant. The challenge may be to train procurement beyond the design field to respect what design can bring to problems, rather than just to operationalise existing observed processes. ESTO also had a very different conception of how design might link with university expertise. They saw the university as developing methods or tools which although not tested in industrial practice might be implemented there (ESTO 2000, 42).

In terms of building a future vision that learns from the case studies presented here, some fundamental assumptions embedded in the European Commission's work may need further review. It saw the challenge for developing eco-design in SMEs as enabling access to new markets for environmentally sound products. While large companies would not need 'further government support to apply eco-design', environmentally-orientated public procurement and fiscal instruments might impact upon their behaviour. This point was forcefully made by Atkinson on several occasions during the interviews. He indicated that a significant resource for grappling with future challenges is the knowledge and vision of the company MD, with motivation to apply his expertise to projects that could make a difference to the world in practical ways. This case also saw an active engagement with the region's universities and businesses, in contrast to the normal conception of the knowledge transfer flow from the university sector.

Cross (2003) pointed out that the relevant first principles are not evident 'until a problem frame has been established', but the meta-client of the sustainable agenda can be conceived to act in a similar omni-present manner to idioms like 'form-following-function'. However, the ability to operate successfully with such broad first principles while engaging strategic process knowledge appropriate and pertinent to the specific problem, is likely to require the expertise

arising from time spent within the disciplinary field. While verification of the specific skills sets and strategies for expert designing is still being modelled on the basis of few case studies, there does appear to be some congruence with generic creativity models in relation to the role of expert knowledge within and at the boundaries of a field, such as described by Lubart (1995), Csikszentmihalyi (1996) and Weisberg (2006). The role of vision and conviction and a context in which to operate meaningfully also accords with the conditions for creativity as identified by these commentators on the generic act of creativity, and such models can usefully be reconsidered when reviewing how to give future designers the tools of their profession.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Shifting Trajectories

advancing cosmopolitan localism through participatory innovation

Mugendi M'Rithaa[1], Bart Verveckken[2], Rael Futerman[3]

Abstract

The central question that this paper seeks to address is whether indeed Africa can 'leapfrog' into a truly sustainable future by using extrapolated scenarios based on evidence from the elective creative community at the FabLab in Cape Town, South Africa.

The FabLab offers an ideal forum for key actors (from government, industry, academia and the civil society) to evolve a unique form of cosmopolitan localism which in turn could inform future design pedagogy and other public policy initiatives.

Whereas the discourse on sustainability is arguably new on the African continent, the (potential) role of design as a catalyst for sustainable socio-economic transformation is promising. This argument locates the vision advanced by this paper within the theme of "Changing the Change".

1. The Beginnings of a Global Phenomenon

Neil Gershenfeld (2005, 12) defines a fabrication laboratory or FabLab as "a collection of commercially available machines and parts linked by software and processes… developed for making things". He describes the humble beginnings of the FabLab phenomenon as a result of overwhelming interest and enthusiasm from students in response to a course he introduced in 1998 called *"How to Make almost Anything"*. The viral profusion of the FabLabs is nothing short of a global phenomenon.

Gershenfeld (ibid) observed that the principle motivation for students' participation was personal (as opposed to professional) interest, and that a fun element characterized the creative atmosphere therein. The unique technical and pedagogic features of this interaction formed the blueprint for what eventually became FabLabs. Some key lessons emerge from these early experiences:

- **Never underestimate the power of imagination.** The impressive and totally unexpected results from students with limited technical, or engineering knowledge was abundantly evident- an experience shared by Victor Papanek (1995) when teaching six and seven year-old children some of the design subjects he taught to university students.

- **Change is inevitable.** The new challenges demanded a totally different approach to pedagogy with teaching methodology shifting from a traditional 'just-in-case' to a more proactive 'just-in-time' paradigm. This created the catalyst for students to invent "a new physical notion of literacy".

- **People are the most effective and sustainable agents of change.** A demand-driven learning process akin to "an intellectual pyramid scheme" emerged whereby students enthusiastically passed on emerging knowledge to other students. Deepuck Chunilall (2007) described this form of peer teaching as "each-one-teach-one".

The FabLab's premise is that "the most sustainable way to bring the deepest results of the digital revolution to developing communities... to enable them to participate in creating their own technological tools for finding solutions to their own problems" (Mikhak *et al* 2002). Each FabLab is initially equiped with the same basic design and modeling, prototyping and fabrication, testing and monitoring, and documentation tools (ibid). Personal fabrication is facilitated in a non-prescriptive manner by promoting access to personal fabrication facilities and opportunities.

Gershenfeld (2005, 8) describes the plan of the FabLabs as one that seeks "to put control of creation of technology back in the hands of its users". Further, Gershenfeld (2008, 14) believes that "emerging technology can help build better communities". This scenario concurs with the creative communities as defined by Manzini (2007a). Indeed, any vision of sustainable living must transform consumers and users to being co-creators within their given contexts.

2. The AMTS FabLab in Cape Town

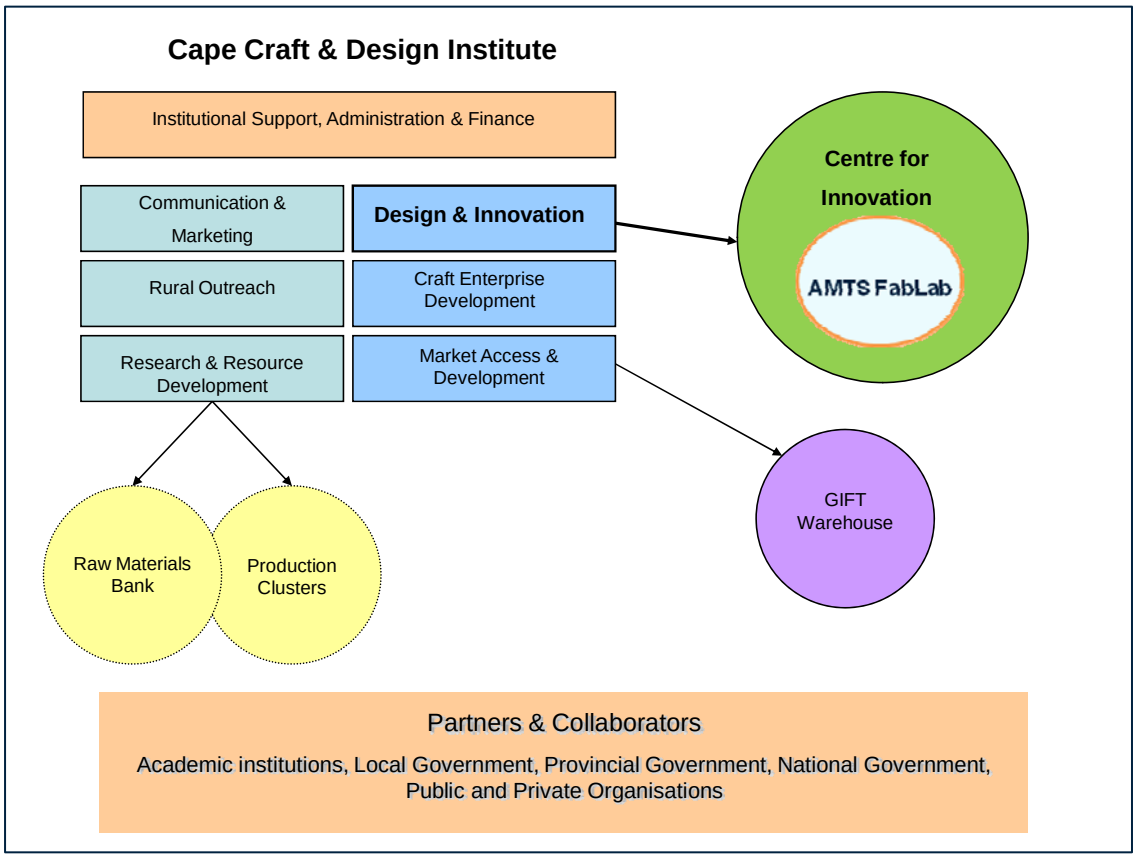
The Advanced Manufacturing Technology Strategy (AMTS) FabLab is run by the Centre for Innovation, as incorporated by the Cape Craft and Design Institute (CCDI) in Cape Town, South Africa. The AMTS FabLab (hereinafter refered to simply as the FabLab) distingusihes itself within the global network of FabLabs as the only one with a specific focus on the craft industry.

According to Erica Elk (2008), the Executive Director, the CCDI was established in November 2001 with a mandate to develop the craft sector in the Western Cape Province. The CCDI has identified the following three primary objectives:

- Provide support to the craft and hand-manufacturing Small, Medium and Micro Enterprises (SMME) sector
- Inform and lobby for an enabling policy and regulatory environment
- Act as a catalyst within the tertiary education environment (Elk 2008).

It has three core functions: Design and Innovation; Craft Enterprise Development; and Market Access and Development (Elk 2008). The design and innovation function inform the Centre for Innovation, and by extension, the FabLab (see Fig. 1). Various partners and collaborators support the functioning of the CCDI financially and strategically. These include an academic institution (the Cape Peninsula University of Technology), local government (the City of Cape Town), provincial government (the Provincial Government of the Western Cape), national government (the Departments of Trade and Industry; Arts and Culture; and Science and Technology) as well as a number of public and private organisations.

Fig. 1: Operational schematic of the Cape Craft and Design Institute *(after CCDI 2008)*



According to Elk (2008) the craft sector has been identified nationally and regionally as a major job creator. Thomas (2006, 60) also highlights the potential contribution of craft production in the (informal) economy, particularly when linked to export markets. The CCDI adopts a sector development approach complimented by rural outreach to facilitate the entire craft sector (as opposed to a limited business focus) (ibid) and believes that a community grassroots approach supports the socio-technical transformation imperative in South Africa, thereby facilitating

empowerment and ensuring sustainability. This is done by actively supporting open-networking and shared resources. The CCDI plans to consolidate its impressive track record of success by:

- establishing a greater number of academic links with CPUT for pedagogic input
- supporting formal research activites within the craft sector for better documentation
- expanding the existing database (of close to 700 members of the crafter sector).

The CCDI holds a monthly forum on the first Wednesday of every month where on average 70 to 100 members of the craft and design community maintain contact, exchange ideas and best practices. The forum is informative and educational and provides networking opportunities. Elk (2008) reports of countless instances of spontaneous partnerships that have formed out of such meetings. A monthly newsletter reaches over 3000 people, including service providers and retailers (ibid).

Alan Alborough (2008), a renowned fine artist and Manager of the Centre for Innovation, emphasizes the need to sustain access and stresses the importance of using the Linux open-source software as it is freely available to anyone with acess to a computer thereby ensuring inclusiveness among co-creators. Gershenfeld (2005, 15) also argues that open-source software forms the basis of a proprietary business model. Indeed the principle of 'access' is one of the key elements of the FabLab charter. C.K. Prahalad (2005, 18) adds further elements of 'affordability' and 'availabilty' to compliment that of 'access'.

Alborough (ibid) endorses a view supported by other commentators on the value of maintaining sustainable collaborative human networks (Gershenfeld 2005; Johansson *et al* 2005; Prahalad 2005; Thackara 2005; Manzini 2007b). He seeks to effect the mandate for promoting design and innovation through a number of activities:

- extending the outreach programme effectively targeting historically disadvantaged communities for inclusion as well as accommodating non-English speaking users
- strengthening links with community primary schools to encourage young innovators to access the FabLab from an early age
- increasing the percentage share of the number of crafters and members of the general public accessing the FabLab.

Deepuck Chunilall (2007) has an engineering background and is the FabLab Manager. Chunilall (ibid) reported that there were 9 FabLabs in South Africa, 1 in Ghana and about 50 globally (there were only 15 world-wide six months earlier). He sees the viral spread of FabLabs globally as a result of robust networking within the global galaxy of FabLabs- a powerful expression of what Ezio Manzini (2007b) describes as "cosmopolitan localism".

Chunilall describes the FabLab as an innovation incubation centre. To sustain an effective collaborative network, the FabLabs in South Africa hold quarterly meetings. Chunilall also attends the international weeklong meeting/symposium that brings together representatives from FabLabs across the world. Here, members exchange best practices and present interesting case studies based on their own contexts. To this end, the FabLab in Cape Town is unique in the galaxy of FabLabs due to its focus on the craft sector, and the specific involvement of design students (Elk 2008).

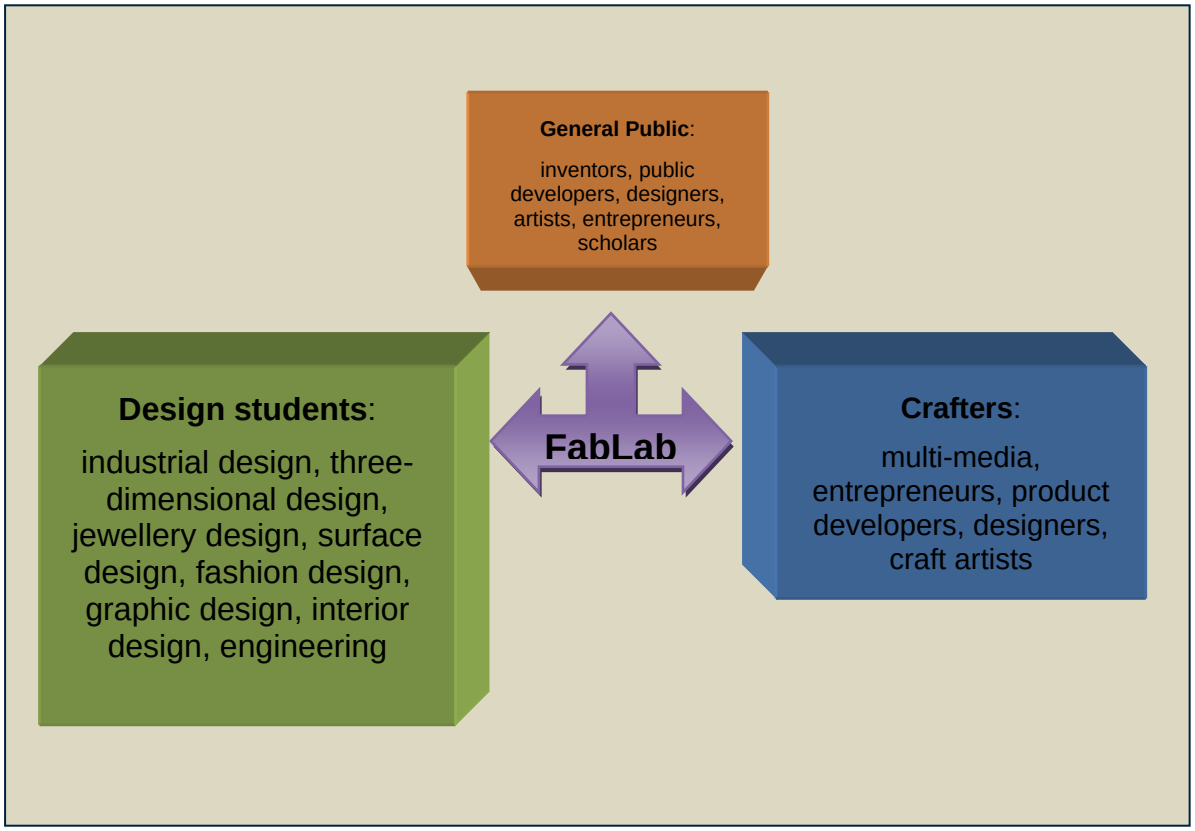
The intimate link between the CCDI and the FabLab is particularly propitious when one considers the potential impact of combining traditional craft techniques with design methodology. Gershenfeld (2005, 6) was pleasantly surprised to learn that "starting out with skills more suited to arts and crafts than advanced engineering, … [students] routinely and single-handedly managed to build complete functioning systems". The common features of craft and design praxis after all include distinct acts of conceiving, designing, and producing an end-product.

3. Everyone's Invited

The AMTS FabLab in Cape Town is open on weekdays from 9 am to 4 pm, and from 9 am to 12 noon on Saturdays. The public are free to use the facilities on Mondays, Wednesdays, Fridays, and Saturdays whereby they can participate in technology demonstrations which are held twice a day- an average of 12 tech-demos per week or 48 per month (Chunilall 2007). Dedicated workshops are run on Tuesdays and Thursdays by prior appointment through the Centre for Innovation (Alborough 2008).

FabLab assistants and facilitators typically work about three hours a day for four to five days every week. During this time, they interact with about 25-30 visitors a day or roughly 150 users per week. The vast majority of these visitors are design students (almost 70%). These students are drawn from the disciplines of industrial design, three-dimensional design, surface design, fashion design, graphic design, interior design, and engineering (CCDI 2007). The majority of these students are from the Faculty of Informatics & Design, working on "curriculum-based and project-related activities" (CPUT 2007, 5). Crafters (multi-media, entrepreneurs, product developers, designers, and craft artists) make up about 20% of those using the facilities, whilst the remaining 10% are drawn from the general public (made up of inventors, public developers, designers, artists, entrepreneurs, scholars, and an assortment of other individuals) (ibid). Visitors range in age from youth in their early teens to the occasional senior citizen. Fig. 2 illustrates the three major constituencies interacting at the FabLab.

Fig. 2: Interactive constituencies at the FabLab



Interviews conducted with four FabLab assistants/facilitators (all in their mid-twenties) give useful insights on the nature and dynamics of interactions between various users. Johan Johnston (2008) is a design student and describes the typical user of the FabLab as "an industrial design student creating proxy models for their projects". Johnston has been using the FabLab for about fourteen months and interacts mainly with design students from disciplines such as industrial design, jewellery, fine art and fashion design. He describes his main form of interaction with users as one of providing assistance with software layouts and settings, problem solving involving materials, and integrating various materials to make models. The only major challenge is in maintaining fidelity of files when he has to convert Computer–Aided Drawing (CAD) files to Linux software.

Sandile Cele (2008), a product developer, has been using the FabLab since November 2006. Cele enjoys the brainstorming sessions, and states that that open-source software is a great idea as it ensures accessibility to anyone with a computer. He interacts mainly with crafters and design students. According to Cele, the relationship between design students and crafters is mutually beneficial as the two constituencies share experiences. This view is shared by David van Staden (2008) and Chris Jones (2008). Jones observes that the design students routinely help out and share their technical and design skills with the crafters. The crafters in turn share their typically superior knowledge of fabrication. The summary of the FabLab assistants/facilitators' responses are captured in Table 1.

Table 1: Summary of FabLab assistants/facilitators' responses

NAME	INTERACTS WITH	EQUIPMENT USED	MATERIALS USED	SOFTWARE USED	FABLAB VISITS
Sandile Cele	students, crafters	laser cutter, milling machine, vinyl cutter, embroidery machine	cardboard, vinyl, Perspex, card, paper	Linux 'open source'	4 days/week
Johan Johnston	students	laser cutter, milling machine	Perspex, other plastics	Linux 'open source', other CAD software	5 days/week
Chris Jones	students, crafters	milling machine	Perspex, other plastics	Linux 'open source', other CAD software	4 days/week
David van Staden	students, crafters, general public	laser cutter, milling machine, vinyl cutter,	cardboard, vinyl, Perspex	Linux 'open source', other CAD software	4 days/week

4. From Economic Passivity to Participation

The world that we live in is fraught with contradictions. Whilst a privileged minority enjoy a life of conspicuous consumption, the majority of the earth's inhabitants barely eke out a subsistence existence. Gershenfeld (2005, 13) speaks of the gaping "digital divide". Various design commentators propose socially responsible design as a sustainable strategy to foster

development in developing and majority world contexts (Whiteley 1993; Papanek 1995; Sandhu 2002).

According to David Fick (2006, 17) “Botswana and South Africa developed the strongest investment climates in sub-Saharan Africa between 2003 and 2004”. South Africa accounted for 38% of sub-Saharan Africa’s gross domestic product in 2004 (Fick 2006, 166). This would appear impressive for a country with an annual growth rate averaging 4% for a population of 48 million. However, upon closer scrutiny, evidence emerges that this ‘success’ is not shared amongst all the country’s citizens, particularly when seen against the official development policy that perpetuates a form of ‘economic dualism’ (Frye 2006, 2). The president of South Africa, Thabo Mbeki (1998 cited by Frye 2006, 5) refers to this problem as the “two nations” paradox. The first one enjoys world-class socio-technical privileges whilst the second more populous one is underdeveloped and characterised by lives of abject poverty. Frye (2006, 2) argues that the ‘two economies’ discourse amounts “to two starkly disconnected communities” with separate economic ‘prescriptions’.

As intimated earlier, the so-called ‘first (or mainstream) economy’ as a major generator of products and services positions South Africa as the largest economy in Africa, therefore enjoying relative free reign in running its own agenda (Fick 2006; Frye 2006; Boon 2007). On the other hand, those in the abject ‘second (or informal) economy’ incur what Prahalad (2005, 11) describes as a ‘poverty penalty’- where the poor pay a higher premium on everything in comparison to the rich. At the bottom of this economic pyramid unemployment runs as high as 42% of the working-age population (Fick 2006, 166). Frye (2006, 3) lays the blame squarely on the government by arguing that “poverty and unemployment are a direct result of the current growth path patterns of ownership of the means of production, and the methods of production favoured by business”.

The well-meaning government initiatives of the now defunct GEAR (Growth, Employment and Redistribution) and the current ASGI-SA (Accelerated and Shared Growth Initiative of South Africa) have failed to make any significant impact on ameliorating the plight of those in the ‘second economy’ (Frye 2006, 1, 3). The latter are seen to be a burden on the system wherein attempts at ‘distributive justice’ through taxation have failed to offer redress. South Africa would do well to emulate other majority world contexts enabling their people to capitalise on what Prahalad (2005) describes as ‘the fortune at the bottom of the pyramid’. This would be a more sustainable option, instead of the present practice of relying solely on the profits of the so-called ‘first economy’ to eradicating (or at least reduce) poverty. Prahalad (2005, 7) points out that wealth creation is more sustainable as an economic policy strategy than ‘distributive justice’.

To effectively target poverty in the context of design for development, there is need for a multi-dimensional view of sustainability - economic, environmental, social, and institutional (Thomas 2006). Further, designing for poor markets requires far greater technological innovation and sophistication than one would expect for the so called ‘richer’ markets (Prahalad 2005; Thomas 2006, 57). Design for development requires fresh strategies for intervention (Thomas 2006; Margolin 2007). Such strategies would benefit from an integrated holistic and multi-dimensional economic development plan- one that believes in the creative potential of its entire people. A creative and empowered people are more likely to co-create their own futures.

The FabLab vision on design and innovation intrinsically supports this premise and the need for proposed interventions to be context-responsive taking cognisance of people’s aspirations. Whiteley (1993:119) further argues that “a product or process which does not grow out of the habits and customs of a country or region is unlikely to be successfully integrated into the society’s culture”. *The New Model of Socially Responsible Design* (Davey *et al* 2005) locates the design agenda at the core of all public sector engagement. Davey *et al* (2005, 2) define SRD as “the use of design to address social, environmental, economic and political issues” and further argue that “SRD interventions, whether focused on the individual or wider society, move beyond economic considerations to embrace ethical, emotional and humanitarian values”. The geopolitical realities in South Africa (and indeed on the rest of the continent) demand a more

proactive grassroots approach to design activism if the quality of life for the vast majority of its peoples is to be enhanced.

To catalyse the expected growth of creative communities, locally pertinent concepts such as *ubuntu* - a home-grown concept of mutual support and communal solidarity (Boon 2007), and *batho pele* (literally meaning '(putting) people first') lends themselves readily to an anthropocentric ideal. *Ubuntu* variously means: "morality, humaneness, compassion, care, understanding and empathy" (Boon 2007, 25); or "humanness" (Fick 2006, 168). Boon (2007, 3) believes that in embracing *ubuntu*, Africans celebrate their cultural diversity and "a vision of harmony, prosperity and success". *Ubuntu* can be viewed as the impetus to create new forms of elective communities of like-minded people sharing a common vision.

Designing in a complex environment often presents a blend of seemingly insurmountable challenges alongside historic opportunities (Thackara 2005). Johansson *et al* (2005, 977) propose a vision of 'distributed economies' that would ameliorate the above scenario by "introducing and making proper use of a collective team spirit where improvements will be shared by a collective community that has familiar ambitions and values". This would ensure wealth creation by a larger number of people and strengthen the sense of community.

A vision of sustainability would have to take into account the potential of 'distributed economies' (as opposed to 'segregated economies') that effectively promote entrepreneurship and adopt labour-intensive production means, thereby stimulating innovation and creating sorely needed sustainable employment opportunities. The resultant economic empowerment and concomitant reduction in poverty (and related social ills) would make Africa a better place for all.

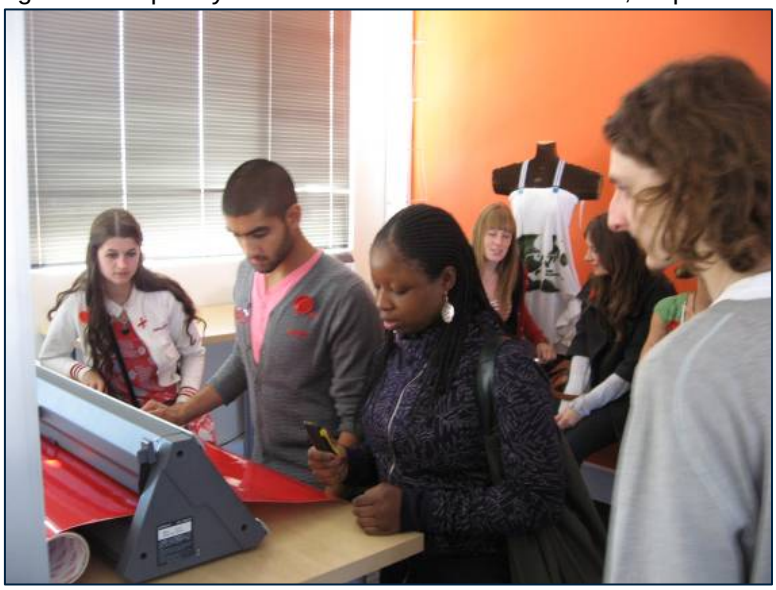
5. Advancing Participatory Innovation

Speed is not everything. There is strong evidence to show that slower, locally-situated, and need-based response strategies translate into more sustainable endeavours (Gershenfeld 2005; Johansson *et al* 2005; Manzini 2007a). The popular saying that "there is no hurry in Africa" could turn out to be a *really* good thing for a continent grappling with various developmental imperatives.

Elements of 'distributed economies' such as small-scale local production, are innately more accessible and promote economic diversity and sustainable development (Johansson *et al* 2005). Gershenfeld (2005, 16) also endorses quality over speed, and personal fabrication rather than mass production. Further, grassroots and participatory design initiatives empower people by helping them to take control of their own production, consumption and distribution means.

The opportunities and potential offered by the FabLab for all stakeholders are vast. Papanek (1995, 210) recommends that "design education should be introduced into nursery, primary, and secondary schools instead of limiting it to vocational and occupational studies at post-secondary level". Participatory innovation sessions at the FabLab (such as in Fig. 3) compliment this strategy by collaborating with community schools to expose young minds that are ripe for "discovery and self-knowledge" to innovative processes (Papanek, 1995, 211).

Fig. 3: Participatory innovation session at the FabLab, Cape Town



6. Conclusion

The central question that this paper addresses is whether Africa can 'leapfrog' into a sustainable future through elective creative communities such as the one described. The FabLab at the Innovation Centre of the CCDI has been in operation since June 2006. Given the relatively short time it has existed, we expect that the full impact will become visible when the students and crafters who presently spend their time in the FabLab realise their full economic potential. The effect of the collaboration between design students and crafters is already evident in the successful products the CCDI takes around the world on shows and exhibitions.

It is clear from the interpretivist perspective adopted in this paper that the FabLab infused with the spirit of *ubuntu* is a potent force to facilitate the kind of processes that are thought to contribute to global sustainability. As far as we know, the unique combination of the technologically advanced FabLab and handcraft sets a unique scene where the spirit of Africa can flourish and provide sustainable economic models within the changing world economy besides improving the quality of life for people living in their local reality. This approach, coupled with an inspired brand of design activism promises sustainable livelihoods for all involved.

The FabLab is a space where people from the two segregated economies can meet and work together as equals and learn from each other. The crafters are given an opportunity to experiment with advanced techniques. This often leads to improved and more consistent technical quality of their products which gives them an advantage in the market place through product differentiation. Through the use of open-source software products can be refined and new possibilities can be explored. The interaction with people from 'the other economy' gives the design students an expanded view and a better understanding of the world they live in and stimulates their imagination and creativity. The technology available in the lab has become the channel for communication between two worlds. The specific focus of the Cape Town FabLab on craft, through its link with the CCDI, has lifted its purpose of personal fabrication to social transformation.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Changing Perspectives on Design Education

The change in the design apprenticeship using the methodology of scenario building associated with sustainability concepts at the Universidade Federal do Rio de Janeiro (BRASIL)

Marina de Arruda Nicolaiewsky[1], Beany Guimarães Monteiro[2]

Abstract

This research's main goal and motive is to help find ways to improve design education in our university. It consists basically of an analysis of opinions of 71 students about their knowledge and apprenticeship of design and sustainability at the Industrial Design Undergraduate Course of UFRJ. It also aims to find out if the new methodology applied in the Product Project Development III (PPD3) class - scenario building associated with sustainability concepts (Manzini, 2003), which started in mid 2006, has changed the students' perspective on their role, as designers, towards the transition to world sustainability.

1. Introduction

The issue of sustainability in design education is being broadly discussed by design researchers worldwide. There seems to be a general consensus that "[…] the transition towards a sustainable society will require a long and complex process of collective learning. A process in which every social actor will need to play a role, assume new responsibilities and acquire related new capabilities" (Vezzoli, 2003).

It is also well known that institutions of higher education focus on highly specific and specialized knowledge and skills, building upon what students learned previously. "Education for sustainability, however, cannot follow this 'normal' pathway because much of what students have learned in their previous education does not fit into the paradigm of sustainability." (Juárez-Nájera et al, 2005).

Therefore, we realize that "[…] there is the need for rethinking and transforming learning processes and dialogues" (Bergea et al, 2005). Reinforcing this line of thought, Second Nature.com, a website on transforming higher education, states that:

> "Higher education could have the power to lead in this endeavor by exercising its role in training future leaders, teachers and other professionals and in producing wisdom needed to face the challenges of an increasingly complex world. A transformative educational experience would be essential in creating the shift in thinking, values and action necessary for a healthy, just and environmentally sustainable society".

According to Manzini and Vezzoli in *La formazione di una nuova generazione di progettisti, L'architettura naturale: La cultura del progetto sostenibile*,1998:

> "[…] environmental issues have now penetrated society, education and systems of production. In particular, new educational curricula (with an overt environmental emphasis) for designers have begun to be developed and implemented. But this is barely a beginning. A whole new generation of designers still needs to be educated and employed. Designers have a crucial role to play in the radical change required to achieve a sustainable society and design educators must recognize this as a primary goal."

However, we need to recognize the difficulties encountered when trying to remodel values and thoughts of teachers and professionals of design, already so used to their own way of doing things, and, most of the time, reluctant in accepting change, especially the radical and internal ones. We must, then, start to understand the role of the students in this process of transformation of their education, and of society in general. "Educational campaigns led by students can result in significant energy savings by changing behaviors and purchasing decisions. Students are effective advocates on college campus, able to reach their peers and high-level decision makers" (Greencampus.com).

By any means, it is reasonable to conclude that both, instructors and learners, should try to work together in "modifying the educational process in order to emphasize active, experimental and collaborative learning and real-world problem solving in campus and in the larger community" (Second Nature.com). In this context, John Thackara states that "[…] active learning happens when we participate in projects that are meaningful to us and engage the real world. We need to believe that the task we are about to tackle is important and meaningful." (Thackara, 2006, p.

148). Design education, having, theoretically, a participative and meaningful character, should show its capacity to blossom the students' pro activeness needed to promote change. However, this is only going to happen when the design, or the choice of the project to be developed, is decided by teachers and students together.

According to Manzini, in his text *Design, ethics and sustainability*:

> "[…]as social actors endowed with specific design knowledge and specific design skills: the knowledge that enables them to understand the full, macro-picture of how things have changed (and are changing), and the micro one, of local context characteristics and on-going dynamics. They should use theses skills to propose solutions and/or scenarios; formulate effectively whatever emerges from the collective design group discussions; and develop the ideas on which partner convergence has been verified." (Manzini, 2006, p. 6)

This shift in their roles, the activity in partnership between those with and those without *light*, is the main factor that we must recognize to begin the sustainability march.

With this research, we intend to answer some issues about the teaching of sustainability in Industrial Design Undergraduate Course at UFRJ and its role in the change of the students' perceptions on their social-environmental responsibilities, as future designers:

- Does our University have an active role in the education of sustainability?
- If so, how and when does it happen?
- Does that happen because of subject PDD3 and its scenario building methodology?
- Does this apprenticeship really change the way students see themselves and their profession?

2. Methodology

Questionnaires

The questionnaires used on this research had 11 essay questions about design in general and about issues concerning sustainability and sustainable development. The students were required to answer the question writing 5 lines maximum, without consulting books, teachers or websites, and with no fixed time frame when answering them. The student participants had volunteered and could leave unanswered questions, for free will or ignorance of the subject. The questions used in this research were as follows:

1- In your opinion, what is design (product design)?

2- Why is this an important profession nowadays?

3- How would you explain the concept of Sustainable Development?

4- How would you explain the term Life Cycle Analysis of a product?

5- What does design and world sustainability have in common?

6- Do you know the area of design called (If so, explain it)

a) eco-design

b) design for sustainability

c) social design

d) universal design

7- Do you think sustainability should be a design specialization or that it should be integrated to all areas of design?

8- If you can, write down the names of 5 Brazilian designers that you consider outstanding professionals.

Each question was carefully chosen in order to fulfill a certain purpose. The first two, being related to the students' opinions, were meant to make them think about their profession and, therefore, were not included in the result analysis. The questions 3, 4 and 5 meant to check the students' knowledge on the new issue of sustainable development in the world and in design. The four questions of number 6 aimed to, at the same time, open freshmen's' eyes to the existence of such areas of design and to find out how many of them knew how to define those areas. On the seventh question, concerning the sustainability issue as being a specialty or not in design, being required a Yes or No answer, the objective was to obtain an statistical result, which could represent a sample from the design course students. That kind of information would be useful for the group of teachers that is currently studying design curriculum modifications. Finally, question 8, which posed the greater difficulty for the students, was chosen to show, even for the senior ones, how little they knew about design in their own country.

Besides those conceptual essay questions, it was required for the students to do a self-evaluation test of their knowledge on each subject by answering the question: "How well do you know this subject" by marking the space beside each question, in which the participant could choose between 'Well', 'So So', 'A Little' and 'Nothing'. It should be pointed out that due to the liberal characteristic of the present research, the students were allowed to leave questions unanswered. Although it is not possible to explain why some students had chosen not to answer certain questions, the blank answers were considered in the graphs' construction.

However, it should be emphasized that, as this research is being conducted by a senior student, tutored by her former PDD3 teacher, having the students do a self evaluation test counterbalances any bias on the result analysis.

In addition, although being given less importance, the main ideas of the answers were corrected (question 3 through 6d), being evaluated as 'Correct', 'Reasonably Correct' and 'Incorrect'. For the correction of those essay questions, conceptual answers worldwide known were established, as follows:

3- How would you explain the concept of Sustainable Development?

Development that meets the needs of the present without compromising the ability of future generations to meet their own needs. (http://www.un.org/esa/sustdev/)

4- How would you explain the term Life cycle Analysis of a product?

Life Cycle Assessment (LCA) models the complex interaction between a product and the environment from cradle to grave. It is also known as Life Cycle Analysis or Ecobalance. If you want to be more precise, you need life cycle assessment (LCA) to quantify and balance the impacts of products. (http://www.pre.nl/life_cycle_assessment/life_cycle_assessment.htm)

5- What does design and world sustainability have in common?

Sustainable consumption questions, not only products and services,but also the way that needs and wants are defined and/or fulfilled. Within this framework, designers have an important role to play: They form a bridge between the consumer's cultural sphere and the world of production and they have the potential to be important actors in the product development process. (Manzini E, Vezzoli C. La formazione di una nuova generazione di progettisti)

Do you know the area of design called: (if so, explain it)

6a) eco-design

Ecodesign is a design management process which minimises the negative environmental impacts of a product, package or service while optimising its performance. (http://edcw.org/about-us/what-is-ecodesign/); *and The environmental impacts of Energy-using Products take various forms, such as energy consumption and related negative contribution to climate change, consumption of materials and natural resources, waste generation and release of hazardous substances. Eco-design, which means the integration of environmental considerations at the design phase, is arguably the best way to improve the environmental performance of products.* (http://ec.europa.eu/enterprise/eco_design/ecodesign.htm)

6b) design for sustainability

Designing for sustainability requires awareness of the full short and long-term consequences of any transformation of the environment. Sustainable design is the conception and realization of environmentally sensitive and responsible expression as a part of the evolving matrix of nature. Design for sustainability is closely linked to wider concepts such as sustainable product-service systems, systems innovations and other life cycle based efforts. (http://www.d4s-de.org/manual/d4sChapter01.pdf)

6c) social design

It's design for the greater good. Social design is design for everyone's sake. (http://www.design21sdn.com/design21/about) *or social design is sometimes defined as a design process that contributes to improving human well-being and livelihood. Social design thinking within the design world joins developing human and social capital with new products and processes that are profitable.* (http://en.wikipedia.org/wiki/Social_design)

6d) universal design

The design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design. (http://www.design.ncsu.edu/cud/about_ud/udprinciplestext.htm)

The 'correct' answers were those which resembled the standard concepts. The ones evaluated as 'reasonably correct' were those which captured the essence of the answer and the 'incorrect' ones were totally mistaken, misunderstanding terms (which was the case with Life Cycle Analysis of a product and Product Life span)

Participants

The research participants were 71 students from the Industrial Design Undergraduate course, Product Design, from Universidade Federal do Rio de Janeiro (UFRJ). The UFRJ Industrial Design course can be completed in a minimum of eight semesters, in 4 school years. It consists of a basic program in which the students are educated in drawing, art and model construction for one year. In the following 3 years, the students design one product each year in a subject called Product Design Development (PDD), which is accompanied by secondary subjects as

ergonomics, math, social sciences and model constructions, among others. This research concerns chiefly the students who have already taken the PDD3 course, in the fifth semester. In that particular subject, since 2006, a methodology in which concepts of design for sustainability has been applied, through scenario construction (Manzini, 2003). In order to enhance the perception of the importance of an active role, seminars are sponsored by older students, who have already taken the class and wish to spread out their knowledge to others. Hence, using methods like identity and scenario building (Jégou, 2007 and Manzini, 2007), storyboards, community research in addition to constant concern on friendly materials and processes, students then become conscious of their projects' value, importance and limits.

The questionnaires were given to students from several semesters throughout the course, in order to reach the student who had recently got into the university, the student who was taking the PDD3 class and the one who was in the process of starting his final graduation project. In order to find out how that particular subject could really introduce the concepts of sustainability on design students, we have decided to include also the graduating and recently graduated students, who did not have the opportunity to take the PDD3 course the way by which it is taught now, that is, emphasizing design sustainability. For sake of writing simplicity, we will refer to the group of graduating and recently graduated students only as 'Graduating'.

In total, 18 students from the first semester, 24 from the third, 7 from the fifth, 15 students from the seventh semester and 7 graduating students have answered the questionnaires. The main problem in getting greater similarity on the number of participants of each group resided on the unwillingness of the elder students to participate on the research, and also on the difficulty of finding them at the University campus or even on the internet.

Non-structured and informal data acquisition

As already mentioned, the second part of this research consists basically of an informal and random data acquisition on students' opinions about the education of social and environmental responsibilities of design in the curriculum of the course. Those data were collected in March and April 2008, by means of interviews, discussions and a round table at a design event, organized by students, called MegafônicasRJ2008.

3. Results

The results from the questionnaires were analyzed by observing bar charts obtained from the collected data (Fig. 1).

Self Evaluation

When comparing the self evaluation charts from different semester students, it can be observed that the older students feel safer about their own knowledge. Clearly, the first semester students (G1) declare they do not know most of the issues; the students in the middle of the course (G3) apparently see themselves as having medium knowledge on the questions presented, while the seniors (G5) found that they knew a lot on the issues brought up in this research.

This trend can be noticed visually by the prominent colors in the charts. While the light blue color, corresponding to knowing ‘Nothing’ about a subject fades away as the semesters approach the end of the course, the turquoise blue, which represents how ‘Well’ you know something, grows gradually until it is the dominant color in the graduating students chart.

Similarly, the colors burgundy and yellow, which represent, respectively, knowing ‘So So’ and ‘A Little’ of a question, show very interesting trends. Both reach their maximum by the middle of the course (G3 and G4) and decrease towards the graduating class (G5).

That result reveals clearly the objective of an undergraduate program, which is to prepare students gradually and systematically through the 8-year course. It should be pointed out, however, how trust grows among the students between fifth and seventh semesters. While the fifth semester students are still reluctant to admit the extent of their knowledge, the seventh semester ones seem more certain of their answers. This can be verified by the greater amount of “A Little” and “Nothing” evaluations in the fifth semester charts, while in the seventh semester graphs the “Well” and “So So” answers prevail, with very few “Nothing” answers.

In the results analysis, the “No answer” concept was not considered, since it would be difficult to figure out the reason for a blank answer. However, the “No answer” option was included in the graphs for statistical purposes.

About the Self-evaluation of the conceptual questions

The conceptual questions, from 3 to 6D, are related to the subject Product Design Development 3 and to the methodology of scenario building based on sustainability concepts. Therefore, it is important to consider those questions separately in order to evaluate the importance of PDD3 for the students, especially the ones taking it at this semester (5^{th} semester), the ones who took it a year ago (7^{th} semester) and the graduating students who took the subject when it did not focus on sustainability. Also, it is important to point out that the difficulty of the questions increase throughout the questionnaire, as there are more answers stating “A Little” or “Nothing” on the last questions, in all graphs.

When evaluating specifically those three last classes, some consistencies and surprises may be perceived. Some questions show an increase on the students’ knowledge along the semesters, as is the case of questions concerning the importance of design to sustainability and eco-design definitions. On the other hand, in relation to other questions, it seems there is no increase of information among the classes, demonstrating that all students found them difficult to answer. That can be apprehended by observing the charts maximum of each question. The questions 5, 6A and 6B show a clear knowledge increase throughout the semesters, inferring that eco-design is being relatively well discussed at the University; whereas questions 3, 4, 6C and 6D show hardly any knowledge growth among the classes. Concerning questions 3 and 4, statements of “A Little” and “So So” are more commonly found, showing the difficulty in defining specific terms as Sustainable Development and Product Life Cycle Analysis. Finally, in respect to questions 6C and 6D, the majority of answers stated “A Little” in almost all classes, except for the sophomores, in which the concept “Nothing” was prominent, showing clearly a lack of discussions related to some areas of design such as social and universal design.

About Self-evaluation of question 1 (In your opinion, what is design (product design)?)

This question refers to the students' personal opinion on product design, so it is not related to the subject PDD3 or to its methodology, but to the design course as a whole. Since the way one defines design cannot be corrected by a third party; the question can only be evaluated through the self-evaluation point of view. In this case, the results are consistent, as the unawareness on the subject decreases throughout the semesters. It is interesting to emphasize anyway that even the students who have been 2 or 3 years at the university find it difficult to safely draw a concept on their profession. That fact is shown by the predominance of "So So" concepts in all charts, except for the graduating students who answered "Well" more often.

About Self-evaluation of question 8 (If you can, write down the names of 5 Brazilian designers that you consider outstanding professionals.)

This question is also not related to the subject PDD3, but to the personal capacity of each student to be updated about their profession, to identify new tendencies and who is the leading team of professionals in their own country. The results of the question show a clear lack of awareness about design out of the university campus. The charts show a little increase in knowledge thru the school years, but in a very slow pace. Even the students who are probably already working could not mention names of Brazilian designers. Maybe this could be explained by the fact that people in Brazil do not really know what a designer is, and which are his attributions and activities. Very few magazines, papers and news on Brazilian design are published, causing an absence of models and examples for the students. Anyway, it is an issue which will need further investigation.

Hetero Analysis of the Essay Questions

This analysis has shown basically that the graduating students have scored more right answers than students from other years. There was also a great increase in right answers between the fifth and seventh semesters, but there was no such increase between the students of first and third semesters.

The behavior of each class was analyzed through the charts G6 to G10, by observing the concept with the greater percentage in each graph. For example, the question 6A, about eco-design, probably one of the easiest questions due to the great disclosure of the subject at the university and in the design world itself, has reached the greatest percentage of "Correct" in classes of first, fifth, seventh and graduating semesters (shown, respectively, in graphs G6, G8, G9 and G10) and "Reasonably Correct" for the third semester class (G7). Observing the graphs, one could verify that the "Correct" concept clearly increases thru the semesters, being the greater percentage only 3 or 4 times in the graphs of the first 3 classes, and scoring 7 times in the last 2 classes. Whereas the concept "Reasonably Correct" decreases throughout the years, not being found in any of the questions of the graduating class. It is interesting to point out that the concept "Incorrect" is very seldom found in any of the graphs. This is explained by the fact that most of the students would prefer to leave a blank answer than taking the risk of getting it wrong. That is why we could not find out which was the most incorrect of all the questions answered. The only question in which there was at least one mistake in each class was about Sustainable Development. Additionally, only twice the concept "Incorrect" surpassed the others in one question. Those were the cases of Sustainable Design for the 3rd semester and the question on Product Life Cycle Analysis for the sophomore class. Both cases could be excusable since those concepts are not discussed in the subjects in the first two school-years of the course.

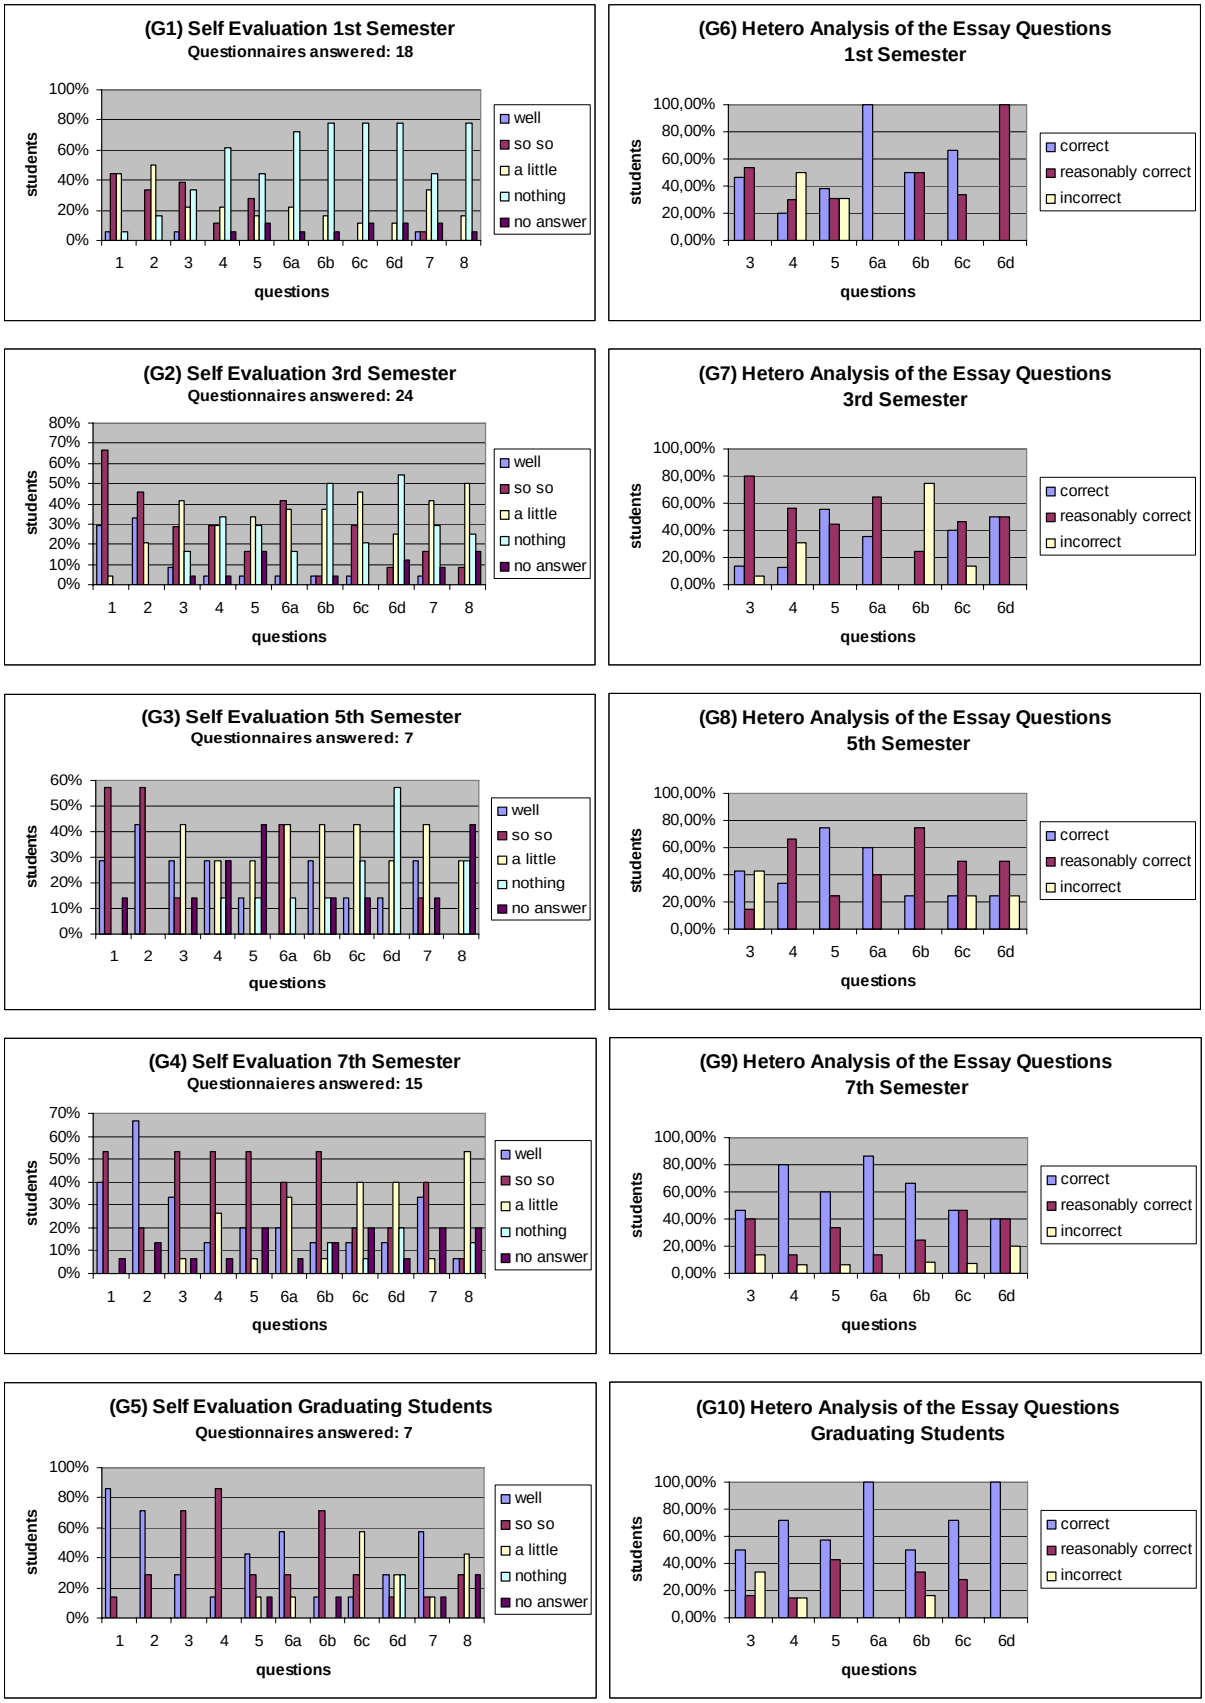

Fig. 1: Self Evaluation and Essay Questions Analysis Graphs

Informal Data Acquisition

When the students were questioned about the socio-environmental responsibilities of professionals and students of design and how those issues were taught at the university, the students' answers were quite similar:

- I know almost nothing about it. And the little I know is not enough to be used in my projects. There is a lack of those topics in our course at UFRJ.
- We know it exists, but it's difficult to use it in a design project. This is because there is not a specific subject about it. We hear more about it when we are taking PDD3, in the fifth semester.
- The environmental and sustainability issues should be natural in our profession because they belong to design. And it is not just a matter of materials, recycling, reusing – we should be studying everything that is involved.
- Of course, eco-design should be included in our curriculum. It should start from the beginning, since day one.
- Well, that was the first step, to know it exists and that it is necessary. Now, we need to start learning how to apply this in our life and our profession.

When asked about the results of the PDD3 subject and its methodology of scenario building, they answered:

- That subject made us look around. Instead of designing a specific product, we were supposed to design it from the environment point of view and not from just a need, that is, to see the necessity from the environment. In other projects, you picked a product, or the teacher chose it for you, and you saw through the particular product what was necessary to be done. You didn't see the environment and decided what to do from it.

- I thought that the methodology focused on the user, and not only him, but on his activities. The product was focused in an integrated way. The other methodologies, in other product design subjects, were not focused on the user. You thought about him at one moment, but not in the context of the environment of that product, so it was all very loose, things didn't relate to one another. The scenario methodology creates a link between the elements. I intend to adopt that methodology because I think it is richer in possibilities. To learn that was very good. Now, for me, sustainability and design are inseparable. But this awareness came a little too late; I would be grateful if I knew about it in the first semester.

- Designing a project based on the construction of a scenario, reaching a target problem and, from that scenario, create a new product was interesting. I thought it was cool to make a scenario first, because it indicated a certain way to make a product, it was not making it without a purpose. There are other subjects with some ideas on sustainability, but in PDD3, it was more emphasized during the classes. This has changed my way of thinking and believing. Before, I knew nothing and thought I knew. Now, I know that I don't know much and that is a step forward. I know how big the problem is and how difficult it is to find a solution. Sustainability is today my main objective in life. I am going to use this concept in everything I can, not only in relation to design, but to everything.

From those examples, one can see that it is almost unanimous the unawareness on the issues of sustainability and the need to have it more disseminated in the design university course. Although it might seem that those opinions were chosen just to show this tendency, in reality, almost all students have demonstrated the same worries. Something that would corroborate to this assumption is the fact that from the 56 students who answered the question "Do you think sustainability should be a design specialization or that it should be integrated to all areas of design?" 54 stated that sustainability should be integrated. Answers like "It should be integrated to all areas of design. Concerns about the future of our resources and our planets is a feeling one should always have, independently of motive, being related to design or in any other situation." or

“Integrated to all areas. They should brain wash all students in that matter because people must convince themselves of the importance of their actions and realize how they affect the environment and how the environment affects them.” were very frequent.

4. Conclusions

From the data analysis above, it is possible to draw up some conclusions on the teaching of sustainability in the industrial design course at UFRJ and its implications on the students’ opinions. It is clear the design course at UFRJ fulfils its purpose of educating students over the school years, as there are not many inconsistencies in relation to a greater knowledge of the students in the last semesters if compared to the initial course students. In most cases, the graduating students evaluated their knowledge about design and sustainability as satisfactory, as well as having been well graded on their essay questions. Notwithstanding having presented some misconceptions on certain issues investigated in this research, it was evident that the course is capable of bringing up design professionals relatively up to date. When comparing the students who are taking the PDD3 class, the one who have taken it and the graduating students, who had not taken PDD3 with the sustainability approach, it was difficult to understand the origin of the differences of results in those classes.

Probably, for the students who are taking the class now, everything is still very new and the concepts had not yet settled down when they answered the questionnaire. Those who had taken the course a year before (7th semester student) had possibly got an internship to work in the area, attended seminars on the subject, having thus more chances to study on their own and to use their knowledge in their work. On the other hand, the graduating students, who never studied through that approach, maybe learned it another way. Although it is hard to identify which, one could imagine that the graduating students who volunteered to answer to our questions would be those who, coincidently, were the most interested in the area and that is why they had chosen to participate in a research of interest to them.

Anyway, one may point out some deficiency in teaching of specific areas of design and sustainability. Because industrial design at UFRJ has an artistic background, being part of the School of Fine Arts, and also a technical one, approach used by most teachers, few are the moments in which the students are confronted with themes like social design, universal design or design as a product-service system. Besides, even eco-design and other concepts of sustainability are still viewed by some influent professors as inferior and hippie approaches.

In spite of this, it was possible to observe, mostly by the informal data acquisition, a growing movement from the students, recognizing the need to discuss those questions more often and, most importantly, the need to include them in the curriculum of design course. It can also be concluded that, although there is great awareness, at least among the students, about the importance of teaching sustainability, sustainable development and eco-design, it is not clear how to put into practice those ideals.

Therefore, about the issues this research aimed to answer, one could sense that the university’s role towards sustainability education is only partial, since most of the knowledge is being searched elsewhere; the subject PDD3 has achieved its purpose of modifying the students’ perception, at least on the importance of studying those issues in this profession. Unfortunately, it was not possible yet to evaluate how much of this knowledge is modifying the perception of the students about themselves and how it is affecting their relation, as designers, with the world in the direction towards sustainability. Anyway, we must recognize that the first step has been taken;

however, in order to conceive designers more conscious of their role in this transition period, we must walk faster now.

Again, we should emphasize the relevance that co-design has in this process, reminding that its main issue is to go from fulfilling consumer needs to identifying user demands (EMUDE project). In this context, Dr. Mark Brietenberg, in his text on Interdisciplinary Innovation, questions himself on:

> "How can we plan in advance to insure the best possible collaboration among students and faculty? […] Interdisciplinary design projects can be exciting and rewarding experiences for students, offering new ways of thinking and the potential to produce innovative outcomes. Rather than simply putting different faculty and students in the same studio and hoping for the best, it is necessary to think of the project as educational experience design, where we apply the same research, processes and validation we use as designers."

We hope, then, with this research, to have come closer in understanding the ways we can design our educational experience in order to further the limits of reach of the students towards the faculty's, and vice versa.

DESIGN VISIONS PROPOSALS AND TOOLS

Product Design Influencers and Triggers in Micro and Small Enterprises in Kenya

Case Study of Sofa-makers in Gikomba Market, Nairobi.

Lilac Osanjo[1]

Abstract

Key words: Design process, micro and small enterprises, design based research

Products consumed by the majority of Kenyans are produced by the micro and small enterprise (MSE) sector. The MSE sector is important to the economic development of the country because they supply goods and services to most of the population. However, MSE products have inherent weaknesses that include poor product quality and inappropriate raw materials. Designers are concerned about these poor products. However, focus on gaps in the product design process has not impacted on MSE design practice. This research takes a different path and focusses on the entrepreneurs who are the producers. The purpose is to establish the factors that influence design in MSE entrepreneurs with a view to improve the quality of products by embracing modern design concepts.

[1] University of Nairobi, School of The Arts and Design, Lecturer, email:lilac.osanjo@uonbi.ac.ke

1 Background to the Problem

Good products promote healthy, efficient and ecological lifestyles and are a result of sound design practice. Today, people require products that make them feel and look good. Within the home environment, furniture that includes sofa reflects the personalities, tastes, and financial status of their owners (O'Neill 1971: p 23-24). Furthermore, sofas are focal points used in identifying and positioning other furniture in living rooms. Sofas have their origins in Europe and spread to African countries during the late 19th Century. Today, nearly every urban household has sofa and the demand for them continues to increase.

Design is intertwined with quality of life in that it manifests itself in products, fashion, food, drugs and other things that we use everyday. There are many working definitions of design many of them specific to fashion, graphics, interior or other disciplines. The Oxford Dictionary uses words such as purposeful, artistic, skillful, conception, invention, planning, sketching and *opposed to chaos* to define design activity. Because of its relationship and interdependence with quality of life, design professionals have been challenged to champion and provide leadership and embrace design concepts (Vil-Nkomo 2006, and Viljoen 2006). And, today design concepts are anchored on sustainability; in the 1990s the Hannover Principles stressed the need for design that was *ecologically, economically, aesthetically and ethically responsible* (McDonough 1999). Other design concepts include Design for the Real World advocated by Papanek (1972) and the Appropriate Technology movement of the 1970s. With increased competitiveness and Globalization, companies large and small, public and private are more aware of the need for design. Unfortunately, both large and small companies do not pay enough attention to design research and process (Donaldson 2006 p 143). The micro and small enterprise sector producers particularly, seem to be highly profit driven at the expense of acceptable design practice.

Micro and small enterprises (MSEs) are economic entities employing between one and fifty workers per enterprise. Micro enterprises employ up to ten workers while small enterprises employ up to fifty workers. The business activities of MSEs include trade, service provision and manufacturing in both rural and urban centres. Between 1993 and 1999 the MSE sector recorded an average growth rate of 7% according to the MSE Baseline Survey. Out of a total of 1.3 million MSE, 13.4% were engaged in manufacturing, 64.3% were engaged in trade, another 14.8% were in the service sector and 7.7% were engaged in other activities (ACEG 2005 p 1). In the ensuing years, the MSE sector continued to record growth although in 2008, the growth rate may have been affected by campaigns and political unrest. The MSEs contribute substantially to the economy because entry into the sector is relatively easy: the sector provides goods and services that support agriculture that is the mainstay of Kenya; it provides employment in both rural and urban centres - 74.2% of the Kenyan labour force (ACEG 2005 p 2), serves to arrest rural to urban influx of job

seekers, supports medium and large enterprises and is a breeding ground for the small and medium enterprises.

The growth of the MSE is not without problems in regard to policies that are poorly formulated; the legal and regulatory in which some existing laws and regulations impede growth; limited access to financial services; a weak environment for co-ordination and transfer of technology and low demand for goods and services due to dumping and overproduction. MSEs have a limited access to relevant marketing information and their competitiveness is weak due to poor product quality, packaging, advertising and distribution (ACEG 2005 p 6). In response, the Government of Kenya has set out to formulate the Micro and Small Enterprise (MSE) Act that will provide the legal framework for the implementation of MSE policies. Strong MSE Sector Associations have been proposed that can lobby government on MSE needs, supplement efforts in training, marketing, technological development and transfer, information collection and dissemination, environmental management and provision of other support services.

Poor quality products from MSE have been attributed to training, lack of information, and competition among other things. Professional designers attribute poor products to gaps or oversights in the product design process. Donaldson (2006 p 152), attributes the poor products to poorly defined needs at the initiation of the design process. MSEs derive designs from five sources that includes imitation of foreign-based products; imported designs; original basic design and specialty design. Nearly all products purchased by the average Kenyan consumer are imitations of foreign-designed products (Donaldson p 152). From observation MSE sofas are no exception and are reproduced from European sofas. In the process of reproduction MSE entrepreneurs fail to infuse design and thereby create sofas that are flawed.

This report is compiled after the first phase of research into the MSE sofa design practice. Case study approach was the main research method (Yin 2003) because of the need to capture as much baseline data as necessary. Data collection was undertaken through observation using field notes, photography and sketches. In-depth interviews covering diverse topics were conducted. Each enterprise was visited at least three times on average and each visit lasted one hour. During the field visits, customers who came to make orders were interviewed. Secondary data was complimented with information from experts and government officials. Experience with MSEs at different levels provided useful insight into the research approach. Qualitative data collection and analysis was found to be most appropriate for this phase. However, quantitative methods that include semi-structured interview guides and questionnaires will be designed for the next phase of research.

1.2 Research on MSE product design

Research into the reasons and causes of poor products from MSEs has been undertaken by economists, social scientists (Donaldson 2006, Ngethe and Ndua 1996 and Abuodha, 1995) and design professionals (Mwasi 2006, Onyango 2003 and Osanjo 2003). Omissions and gaps within the product design process has been the focus for research.

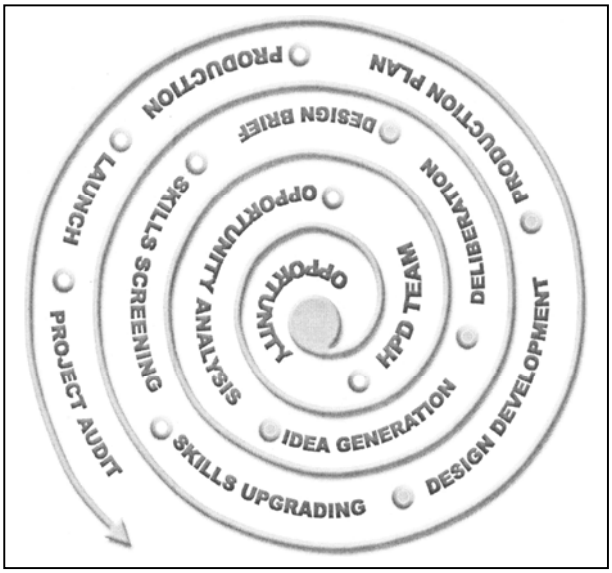

Figure 1: Hybrid Product Design (HPD) Method

Source: Mwasi (2006 p 3)

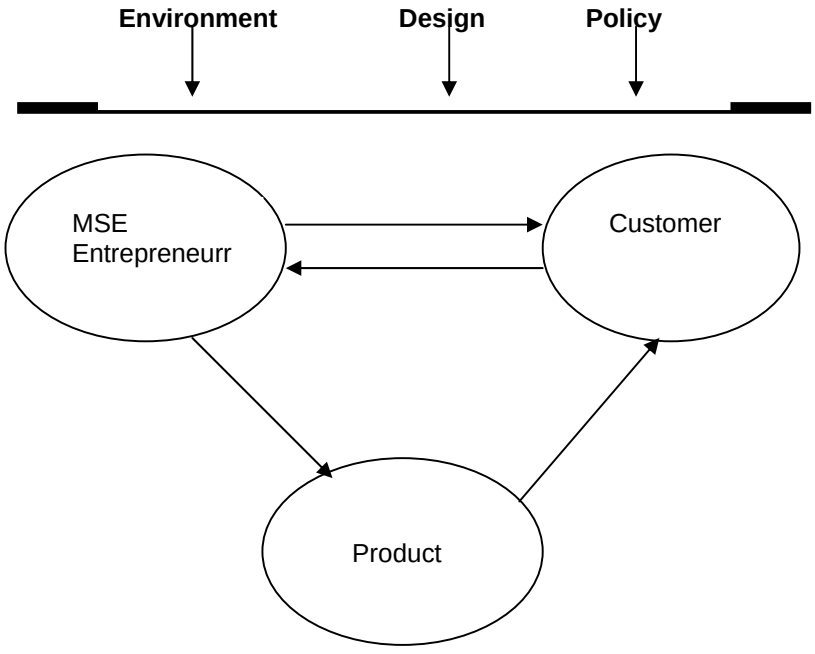

Figure 2: MSE product design environment
Source: Osanjo 2008

This has always led to a proposed product design process. Donaldson (2006 p 136) in his case, for example, used David Ullmans' mechanical engineering design process as a point of reference for MSE product design. And yet, we know that It is difficult to equate the MSE product design process without clearly identifying the parameters. While MSEs operate at the middle and lower income group levels of the population, mechanical engineering and professional design practice are both undertaken at a higher and more sophisticated market strata. The proposed Hybrid Product Design (HPD) method proposed by Mwasi (2006) and outlined in Figure 1 exemplifies the MSE product design problem. The HPD method highlights some of the issues that underlie MSE product design research. The method is based on shared responsibility as shown by the constitution of a *design team*. Yet, it is known that one of the characteristics of the MSE sector is that they have less than 10 employees who have minimal technical skills. Within the furniture making, the entrepreneur wears many hats at the same time; they are the artisan, manager and marketer- essentially making them a *design team* that is essentially a one-person team. The HPD method is elaborate and requires design skills for successful implementation. These design skills, the MSEs do not have (Abuodha 1995 p 45).

The present MSE product design practice shows a market system in which the MSE entrepreneur and customer share information and trade in sofa without consideration for design, the environment and any Global trends. The dis-connect between stakeholders and MSEs product design practice is illustrated by the thick black line in (Figure 2). One of the objectives of this research is to establish whether or not this is the case for MSE sofa designers.

This research deviates from the poor product as a unit of analysis and focuses attention on the MSE entrepreneur. The purpose of this research is to determine the ability of MSE entrepreneurs to design acceptable sofas that will answer to the needs of the people, the designers and the world at large.

1.3 The Problem Statement

The research problem that is being addressed is that products from MSE are characterized by poor quality. The MSE chairs are unstable and easily fall apart, the wood and raw material used is of poor quality (Donaldson 2006, Onyango 2003).

- There is little research on design in Kenya, and no in-depth study has been undertaken on MSE entrepreneurs who create the products. The design based research so far undertaken by design professionals focus on MSE product design process and not enough attention has been paid to the entrepreneur.

- There is no framework for appropriate MSE product design practice that engages design in the process. This framework will begin to breakdown the barrier that prevents entrepreneurs from embracing design.

The concern on how to tackle this research problem invariably directed the research at MSE products that are widely consumed and that have not received much design attention – the sofa. Sofa making is undertaken in all urban centres but this research was based in Nairobi because of the concentration of sofa makers and the convenience for back and forth movements during this phase of field work. Gikomba Market was the selected site because it is a major source of sofas for the middle and lower income earners in Nairobi and that represents a substantial market.

1.3.1 Gikomba Market

Gikomba Market is situated to the Eastland of Nairobi (Figure 3) that is inhabited by the middle and lower income earners. The market is the source of various goods and services including fresh food produce into and out of Nairobi. Sofas and other furniture activities are tucked away on the banks of Nairobi River that passes through the market. The open space is dotted with electric woodworking machines such as lathes and band saws (Figure 4). This type of activity gave rise to the famous "*Jua Kali*" (Kiswahili word for *hot sun* in reference to the open air work space) identity for MSEs.

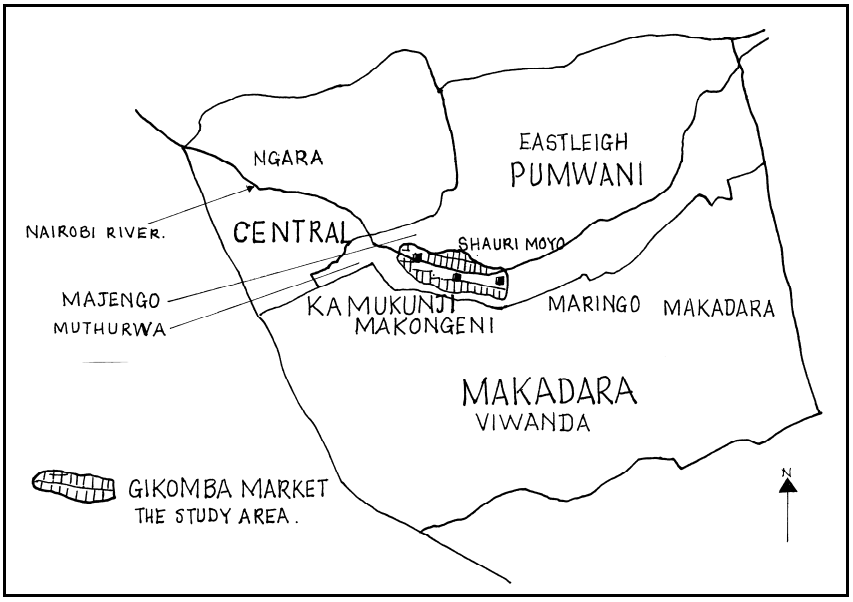

Figure 3: Closeup sketch of Gikomba Market – the study area.

Figure 4: Artisans working on sofa frames within Gikomba Market.

1.3.2 Gikomba Sofa Making

Sofa making in Gikomba Market can be traced to 33 enterprises that produce an average of 8 five-seat sofa sets per day. This translates to 264 sofa sets each day from all the enterprises. Each month, the enterprises produce 5990 sofa set frames. The frames sell between $84 (Kshs 5,000) and $50 (Kshs 3,000) per each depending on style and wood used. The sofa styles change periodically and the sofas bear names that reflect political, social or other environmental phenomenon. The economic significance of sofa making is that on average, the entrepreneurs have a turnover of $2.9 million (Kshs 17.9 million) per month between them.

Sofa making is a hierarchical or pyramid activity in which there are three individuals who have design advantage over other entrepreneurs. This group of three is what this research identified as *cell* members. Operating mysteriously, the *cell* members are difficult to identify on casual observation. Most of the MSE entrepreneurs belong to the second and third group of entrepreneurs who are the carpenters and the "*hammer and nail*" group. These are individuals who have the technical capability to piece together wood to make sofa frames.

2 Preliminary Findings

Data collection from Gikomba Market is very challenging because of insecurity, the nature of MSE activities and Gikomba Market itself. Some of the materials such as Mahogany wood that the entrepreneurs sometimes use are illegal and therefore, they do not want to release information that is discriminating to their activities. Sofa making has rapidly expanded and presently, a single sofa can pass through at least seven micro enterprises before completion. Each enterprise makes design decisions that affect the overall design. The role and effect of these enterprises will be investigated in the next phase of research because it is difficult to determine who is responsible for the design flaws in the MSE sofa. Over a period of six months, the research has been able to identify the *cell* members and compile the following data.

2.1 Cell Members

The *cell* members are the single most important to any changes in sofa design process that involves Gikomba Market entrepreneurs. An in-depth case study of each of the *cell* members was undertaken including Mutei who is shown in Figure 5. *Cell* members are owner/managers of their enterprises and several others that are rented out. They have been working within the Gikomba Market for between 17 and 20 years. They are all technically able to replicate sofa design from pictures or shop windows. The *cell* members own heavy duty machinery such as lathes and band saws and have an average of 8 permanent employees. *Cell* members engage in apprenticeship training for individuals who wish to enter the sofa making industry. They are also officials of some of the

Welfare Associations that operate in Gikomba Market such as the Gikomba Jua Kali Association. Investigation covered aspects of their lives, education, motivation, and insight into sofa design (challenges and opportunities). Most of the information gathered so far in this research was provided by the *cell* members.

Figure 5: Mutei, one of the *cell* members, at his work station.

Source: Osanjo 2008

Figure 6: Buffalo sofa design from the MSEs in Gikomba Market.

Source: Osanjo 2008.

- *Education*: All *cell* members are secondary school drop-outs, forced out of school because of lack of school fees due to the death of a parent or the effects of poverty. One *cell* member was lured out of school by his uncle who was working within the furniture sector and promised training and employment.

- *Training*: *Cell* members underwent apprenticeship training for between six months and two years within medium furniture making firms before starting out on their own. Training covered all aspects of carpentry, management, Art and Drawing. They do not have certificates for the training. The third cell member inherited his uncles' workshop after training and working with him.

- *Motivation*: The knowledge gained and the money they earned from their labour was strong motivations for the *cell* members to stay on

and expand their business. It has never occurred to them to leave Gikomba Market and venture into any other business. The returns on investment have been good and the profits have enabled them buy vehicles, land and open other outlets within Gikomba Market. They work in Gikomba Market every day unless there is a good reason to be away.

- *Marketing*: The *cell* members do not engage in marketing activities but their businesses continue to grow mainly due to customer referrals and consistent presence over a long time.

- *Sofa Design*: According to the entrepreneurs, everyone needs to look at his or her interests in the sofa. It involves two people - the consumer and the entrepreneur. The consumer wants to save something on the *price*, and the entrepreneurs want a reasonable *profit*. Pricing can take one of three forms; *high price* for those who cherish value and uniqueness, the *fair price* that is charged to most customers (this is the customers preferred price), and "*special customer*" price (a price charged according to the individual customers' special needs).

2.3 The causes of bad sofas from MSEs

Asked to specifically outline the issues that affect sofa design and production, *cell* members stated that:

- most entrepreneurs do not value standards;
- European dimensions are not adhered to by the entrepreneurs;
- entrepreneurs do not value their customers and
- entrepreneurs use wet wood in making furniture frames-*often knowingly*.
- The premature break away from apprenticeship training also causes the entrepreneurs to produce bad sofas.

2.2 Sofa style selection

Sofa style selection is the responsibility of the entrepreneur and the customer. Ideas come from customers, pictures and shop windows. Table 1 shows the source and highlights the issues that arise from this style selection method.

No.	Source of Idea	MSEs	Issue
1.	Customers	The customer explains and entrepreneur sketches. Entrepreneurs reproduce the sofas that customers want without questioning.	What the customer wants may not be what is appropriate for them. Customers are mostly limited to what they can see and find in Gikomba Market.
2.	Observation from display and shop windows.	The customer identifies the design they want from a window or shop display. The entrepreneur is then taken to see the design and asked to replicate the sofa.	In the process of replication the entrepreneurs may not have the material or adequate resources to undertake production. Especially because they are charging up to 3 times less than medium and large shop prices.
3.	Journals and Magazines.	The entrepreneur collects journals and magazines from the big stores and newspapers.	Their source of design ideas is limited to what they are exposed to.

Table 1: Sources of sofa styles

The MSE sofa *design team* of the customer and the entrepreneur agree on details, discuss price and production starts. The issues in Table 1 arise because of the *design teams'* limited sources of ideas and design. The importance of customers in the sofa idea is consistent with observations made by Donaldson (2006 p 139) who observed that MSE product manufacture began with *ill-defined needs*.

2.3 Customers role in MSE sofa design

MSEs depend on customers who come to them. This is consistent with other researchers (Donaldson 2006, Onyango 2003 and Osanjo 2003, 1994). A randomly selected sample of fifteen customers who were found in Gikomba Market were asked to state what they were looking for in a sofa, 10 out of 15 customers said they wanted the "*new design*" implying what was in fashion, 4 of them were looking for "*they could afford*" while the rest were open to suggestions from the entrepreneur. From this it can be concluded that MSE customers are concerned about "*fashionable sofa*."

Customer preference dynamics is illustrated with the Buffalo Sofa (Figure 6) that is one of the popular and fashionable sofas. Although copied from a magazine, it is re-named Buffalo after the wild animal because of the “horn like” stuffing running on the back rest. The price range is between US$250 to US$1,000 for a 5-seater set. Even at the higher price, the MSE Buffalo sofa is three times cheaper than a similar “looking” sofa bought from a medium or large outlet.

- ***Fabric selection***: Fabric selection needs careful scrutiny because fabric is available in its original form, and a cheaper version that uses mainly plastic material is also available. Whereas the prints for the fabric look exactly the same, the “feel” is different. The customer can opt for the more expensive, longer lasting, value guaranteed fabric but, more often selects the cheaper version mainly because they all look the same.

- ***Names or identity***: Sofa preference by customers can be influenced by name given to the sofa style. Political names such as Lucy (named after the wife of the President) appeals to some customers. ODM (named after the Orange Democratic Movement-one of the local political parties) has been a popular sofa with certain customers especially during campaign period.

- ***Comfort***: Comfort is not a major concern for customers. Asking customers to take a seat on the sofas that were on display in the showroom during field work, it was observed that customers do not pay attention to the comfort in the seating process and sitting posture. All the fifteen customers trusted that the sofa was good. Either that or the customers had faith in the entrepreneur to produce an appropriately comfortable sofa without stating the need explicitly.

3 Stimulating acceptable MSE design practice

Stimulating acceptable design practice is a factor of identifying the influencers and the triggers that are in existence and providing ways of infusing acceptable practice into the system. Experience can be drawn from other MSE programmes such as entrepreneurship. Stimulating entrepreneurship in MSEs, Gibb (1988 7a) suggested bottoms-up systematic approach that involves MSEs themselves identifying opportunities that support and motivate them. This approach guarantees commitment of the MSEs to the selected course of action. This entrepreneurial approach is often best done by non-governmental organizations led by individuals or groups capable of making things happen. Implementation involves formation of small business associations, local trade associations, sector groups and business cooperation of all kinds. Small business networks at local level and linkages with professional components of the environment including designers and trainers, will build them to be major industry leaders (Gibb 7 b). With this in mind, this research reexamines some of the enablers or influencers that can form a basis for improved MSE design practice.

3.1 Apprenticeship training

The *cell* members provided an outline the ideal growth path for a sofa entrepreneur entering the MSE sector. The average age of individuals entering the MSE sector is estimated at 14 years. For the first two years they should be directed by a *master*, this can be a *cell* member. During these two years they undertake small projects with the *master,* this includes cutting wood, familiarizing with equipment, safety and general duties. At the end of the two years, the trainee graduates to an apprentice and begins to earn some wages. As an apprentice, they should take some responsibility for their activities and they can begin to understand workshop management, pricing and sourcing of materials. After this stage they can be absorbed fully into operations. This process is very similar to the present informal apprenticeship training in Gikomba Market that takes between three and six months. During apprenticeship, the trainee pays a fee of about US$30 (Kshs 2,000) per month. The entrepreneur-to-be should not be in a hurry to wean-off his *master*. This is the critical stage in the development of the entrepreneur in so far as product design is concerned. Premature weaning, forces entrepreneurs into meeting "survival" needs and thus starting their own enterprises. In the process, they set the stage for bad sofas. Inferior quality of products is an outcome of artisan's limited skills and access to tools and machinery that Kabecha (quoted by Donaldson) refers to as "*product-process mismatch*" (Donaldson 2006 p 19).

3.2 Associations

Within Gikomba Market there are several associations mostly addressing welfare issues. The Gikomba Jua Kali Association is the largest with an average of 70 members. The association was set up to promote the growth of the members by providing training, marketing opportunities (such as product exhibitions), access to finance and other government support. The association however, has been riddled with problems and most members have fallen behind on payments.

3.3 Non-governmental organization (NGOs)

NGOs are well placed to facilitate product design and development as they have resources, access to modern technology and information (Donaldson 2006 p 146). In the case of furniture makers in Migori (1995 p 45) in which I was involved, the micro and small entrepreneurs were mobilized into a cohesive group and made to identify their priorities for growth. Arising from this was the Jua kali workshop that was donated by Intermediate Development Group (ITDG). The workshop provides the entrepreneurs with access to heavy duty machinery that otherwise they would never be able to afford on their own. As a result, the furniture makers are able to turn and shape wood into appealing designs for beds, chairs and tables. Access to machinery and equipment can be said to contribute to improved product design.

4 Emerging issues for Design Based Research

The information so far collected begins to formulate into relationship that will answer the research problem at hand. The problem of this research fits well into what Rittal described as the *wicked problems of design.* Wicked problems are social system problems which are ill-formulated, where information is confusing, where there are many clients and decision makers with conflicting values, and where the ramifications in the whole system are thoroughly confusing" (*quoted from* Buchanan 1995 p 14).

Design based research focuses on the development, articulation and communication of design knowledge that is found in people, processes and products. Drawing from scientific and social research methods, design based research embodies, "*things to know, ways of knowing them and ways of finding out about them*," (Glanville, 1999, Cross 1999 and others). However, in complex systems, where there is relatively little data to build upon, it is difficult to separate and isolate variables. And the researcher is left to isolate the variables as part of the investigation. They are always present as active agents (Glanville 1999). Influenced by social, epistemological and other factors, the researcher, continues until the system begins to perform as desired or required into a pattern.

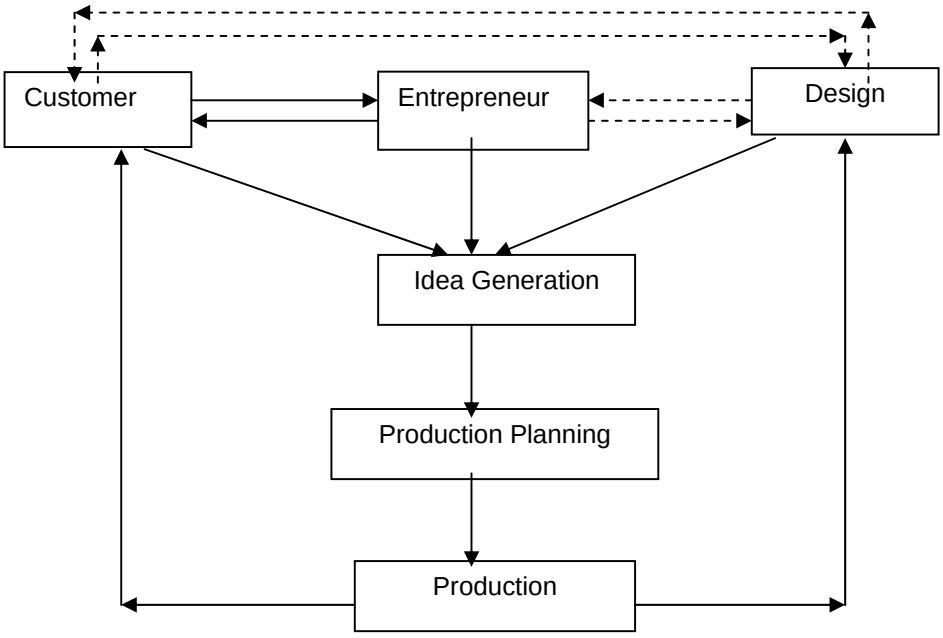

Figure 7: Framework for MSE design practice
Source: Osanjo 2008

The framework for MSE design practice (Figure 7) that is proposed for further investigation isolates design from environment and policy and places it at per with the existing *design team* –namely the entrepreneur and the customer. The dotted lines will replace the barrier identified earlier in Figure 2. Apprenticeship, association and NGOs will be explored as ways of infusing design concepts into

the design practice. Confirmation of data so far collected and instigating quantitative methods into the research by use of semi structured questionnaires and in-depth interviews are on-going. The research sample will also be expanded to include more entrepreneurs, NGOs, administrative officials, customers and design professionals.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design for disassembly and reuse for renovation of housing in Flanders

Case Study for existing (high-rise housing) buildings

A. Paduart [1], S. Elsen 2, W. Debacker [1], C. Henrotay [2], W. P. De Wilde[1], H. Hendrickx[2]

Abstract

Conventional existing building structures are not designed for change. Transformations in buildings, required to answer variable factors of the everyday life, often cause demolition of buildings. The enormous amount of waste produced during renovation and demolition processes causes serious environmental issues. The combination of disposal problems, pollutant impacts and the loss of materials and energy resources, requires building strategies taking life cycle design of building products into account. To increase the building's transformation capacity building systems have to focus on building systematisation and development of building methods providing adaptable structures allowing reconfiguration, reuse, or recycling. The aim of this paper is to specify decomposition characteristics of buildings, which determine the reuse potentials of the building in the framework of the existing building stock.

1. Introduction

Production of daily used goods requires high amounts of finite resources such as petroleum products, rocks, minerals and fresh water. As the world's population is continuing to grow, the depletion of the earth's material and energy resources will continue to increase, leading to degradation of our natural environmental and human health. The building construction world is a sector that is responsible for a high contribution to the consumption of these natural resources. New construction, maintenance and renovation of buildings account for 40% of the total world's materials flows (Roodman and Lenssen 1995). It is even more alarming that barely 20% of the world's population, i.e. the richest countries, is responsible for the consumption of 86% of world's material resources (Fernandez 2004). Moreover, gradually the rest of the world is catching up now, causing even further environmental issues. Subsequently, the balance between nature and human activities can no longer be guaranteed. Building activities have clearly disturbed the rational consumption of our natural resources and of its equal worldwide distribution.

The high contribution of the building environment can be explained by the current static design applied in traditional buildings. Conventional existing building structures are primarily not designed for change (Webster and Costello 2005). Transformations in buildings, required to answer variable factors of the everyday life and changing society needs, usually cause demolition of building parts or even demolition of the entire built structure. An enormous amount of waste is being produced during these building processes and renovation interventions - an amount that is still increasing, as building activities increase over the years. As a result, for example, the construction and demolition waste in Flanders (Belgium) represents the largest fraction of the total waste disposal (EuroSTAT 2007). This tendency has been observed in several other European countries. In recent years, the proportion of construction materials being reclaimed and reused has been falling (BRE 2006). The combination of increasing disposal problems, resultant pollutant impacts and the loss of materials and energy resources, embodied in traditional building products even worsen this situation.

Bearing these problems in mind, do we continue to design in the same traditional way and do we keep on wasting precious materials possessing unexploited benefits by encouraging early recycling (down cycling) and landfill? Or do we think ahead and incorporate features into our design which would allow building elements to have optimised lifetimes by introducing reconfiguration of building structures, reuse of building elements and components and ultimately recycling? In order to achieve this, the traditional perception of the building and its structural configuration has to change.

It is clear that an alternative way of designing should be introduced into the design of new buildings. But what about the existing building stock? The number of new buildings constructed annually in developed countries barely corresponds to 1,5- 2 % of the existing building stock. This means that at the current construction rate, it would take from 50 to 100 years to replace the current stock of existing buildings entirely with new buildings (Sustainable Construction Task Group 2004). Since the existing building stock will remain with us for decades, the importance raises of the building stock as economic, social and cultural capital that should not be wasted.

2. Aims

Designing adaptable buildings incorporating reconfiguration and reuse is fundamentally different from conventional design methods. Conventially, the designer first conceives elements and systems for a building, and then specifies the materials and components needed to achieve the desired building performance and quality. When designing for reclaim of products and materials, it becomes essential to identify the source of suitable design methods, materials and building products before detailed design can begin (Addis 2006).

The key to the strategy for reconfiguration is not attempting to predict what kinds of forces may act on the building and when they may appear, but providing mechanisms by which the

building may respond to any combination of circumstances at any time (Fernandez 2004). In order to increase the building's transformation capacity to respond future's needs, building systems have to focus on further building systematisation on the one hand, and development of building methods that provide adaptable structures through potential disassembly on the different building levels on the other hand. Bearing the revealed environmental issues in mind, features have to be incorporated into the design, which allow disassembled building elements to have optimised lifetimes by introducing reuse of the building elements and components.

The aim of this paper is to specify decomposition characteristics of building structures, which determine the future reuse potentials of the building, its components and materials, in the framework of the existing building stock. Through a case study for renovation of social high-rise housing, the possibilities for reducing waste production and materials and energy consumption are being explored, by means of introduction of disassembly and reuse strategies.

3. Increase of sustainability through design for disassembly and reuse – a 4Dimensional Approach

3.1 From fixed to decomposable structures

Designing adaptable buildings incorporating reconfiguration and reuse for new buildings as well as for existing buildings is primarily different from traditional design methods. A short term view on the construction world has to be combined by a long term and holistic view.

4 Dimensional design (4D) refers to a design attitude providing artefacts with a long term vision (Debacker 2007). Therefore, the fourth dimension, i.e. *time*, is being integrated in the first stages of conception of a building and its components. Time is not only related to the wear and tear of the artefact, but also to changing and evolving circumstances which will affect it. In this sense the artefact and its components must have the potential to adapt to these unexpected changes. Consequently, 4 dimensional design considers an artefact as a materialised answer to a process of changing events. In spite of the unpredictability in accordance with great uncertainty how governing circumstances will evolve, the artefact may not be a static result of a pre-programmed end state. This design strategy conceives building artefacts that support evolving processes in life and society instead of predetermined designing for a specific situation.

This design strategy therefore prevents unnecessary construction and demolition waste production and maximises the potential energy embodied in materials, by taking into account buildings' life cycle on three different levels - material, component and artefact and introducing adaptability, reuse and recycling (Debacker 2007).

It is important to understand that recycling only partially addresses the construction and demolition waste problem, because it can use up considerable resources of material and energy in re-processing and transportation. Reuse is therefore the most desirable option,because it is the most effective in reducing the demand for resources and reducting waste (Webster 1995). However, nowadays one of the main obstructions to reuse building elements and components is the difficulty in separating materials and components from the remnants of the building. Often the only remaining solution of demolition leaves materials broken and unsuitable for anything other than land filling, combustion or recycling (downcycling) of the identifiable materials. The alternative for this *cradle to grave* cycle is to give the three levels of the built environment (excluding urbanism) - materials, components, and entire buildings - several lives before they must be disposed. Different possibilities for recovering materials and components in the built environment can be considerd through (Figure 1) (Crowther 2002):

- relocation and reuse of an entire building - when for example a temporary building is needed that can later be reused elsewhere for the same or similar purpose;
- reuse of major parts of a building - renovation of a building;

- reuse of components in a new building or elsewhere on the same building;
- reprocessing of components and materials into new components - recycling of materials into new materials.

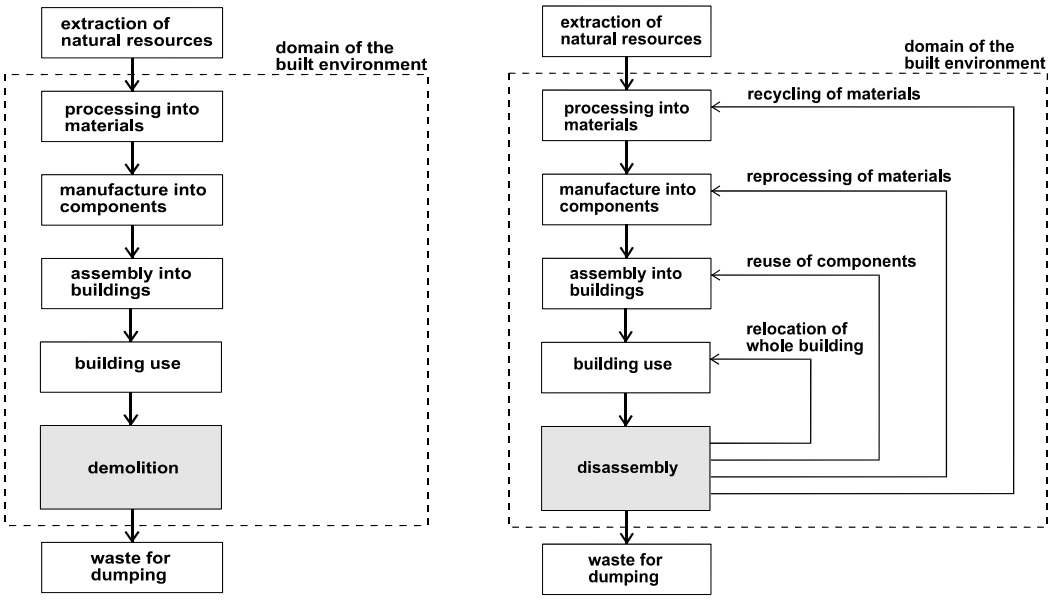

Fig. 1: The *cradle to grave* flow of resources in the built environment against different possible reincarnation scenarios (Crowther 2002)

The 4 Dimensional Design Strategy (Debacker 2007) and the Design for disassembly approach (Crowther 2002) are two strategies that take such an approach into account and can therefore be applied to increase the future rates of material and component reuse. Both consider an individual product as an assembly of functional components with multiple life spans, rather than a specific finalised artefact with singular longevity. These components can potentially be deconstructed and reconstructed into different configurations, shifting the emphasis from 'product longevity' to 'component longevity'. This approach creates potentiality to adaptable, reconfigurable and reusable building systems.

As a result of the fundamentally different nature of these design approaches, to achieve adaptable buildings considering reuse, emphasis lays on particular detailing for easy disassembly in accordance to the choice for suitable materials. Therefore, as an example, a possible 4 Dimensional Design approach for detailing will be discussed in this paper for a case study of existing high-rise buildings in Flanders.

3.2 Design for disassembly

Every building part performs a different function and has a specific life cycle span. "Faster-cycling" components such as, for example, dividing walls in the current building design can experience conflicts with "slower" building parts such as the structure of the building, when they need to be adapted. This explains why much of the construction and demolition waste does not arise from the demolition process itself, but from upgrading and maintenance processes such as refurbishment, organisational changes, and components reaching the end of their service life (Morgan and Stevenson 2005). These processes generate unnecessary amounts of waste, because in most cases not only the component needs to be repaired, but several adjacent and connecting elements have to be removed. Steven Brand (1995) therefore introduces a conceptual framework for dividing a building into different lifespan layers (Table 1), with different

functions, characterised by their anticipated need for modification. The separation of constructions in these six shearing functional layers proposed, allow one layer or system to be changed over time without affecting the other layers (Morgan and Stevenson 2005, Brand 1995):

- The *Site* is defined as geographical setting, the ground on which the building sits;
- The *Structure* is the foundations and load bearing components of the building, those parts that make the building stand up;
- The *Skin* of the building is the cladding and roofing system that excludes (or controls) the natural elements from the interior;
- The *Services* of the building (electrical, hydraulic, data, etc.);
- The *Space Plan,* the internal partitioning walls and systems;
- The *Stuff*, the furniture and other non-attached space defining elements.

Brand also gives an indication of the life expectancies of the different proposed building layers (Table 1). Besides Brand, a range of other writers and researchers have also suggested times for the service life expectancies of different parts or layers of buildings:

LAYER	***Structure***	***Skin***	***Services***	***Space plan***	***Reference***
LIFESPAN	*30-300 (typically 60)*	*20-60*	*7-15*	*3-30*	*(Brand 1994)*
	50	*50*	*15*	*5-7*	*(Duffy 1989)*
	40	*15*	*3*	*5-8*	*(Cook 1972)*
	50-75	*25*	*8-10*	*2-8*	*(Durmisevic and Brouwer 2002)*

Table 1: Life spans of building layers in years

There is significant relevance in these time related building layers to the concerns of design for disassembly. It is at the interfaces of these layers of different service life expectance that disassembly will need to occur. Facilitating such disassembly will allow buildings to develop over time in an environmentally and socially responsible way. An understanding of time related building layers will assist in understanding where and when to design for disassembly (Crowther 2002).

However, the functional levels discussed by Brand do not have consistent life cycles. This can be illustrated with technical installations, mentioned as one of the six main functional levels. There exist six main installation services: electrical supply, water supply, sewage system, ventilation, air conditioning, and heating, all having different functionality and changing rates. As a result, these constitute six additional functional levels (Durmisevic 2006). Therefore, fixing the number of changing functional levels is misleading as a concept for the design of adaptable structures that rely on disassembly of changing physical levels and materials.

The performance of a particular construction with respect to disassembly (and transformation of the structure) can however be measured by two criteria for disassembly according to Durmisevic (Durmisevic 2006): *independence* and *exchangeability* of materials. In other words, a building product can be dismantled if it is defined as an independent part of a building structure and if the interfaces with other parts are demountable. When considering independency and exchangeability of building materials, three elements of configuration design can be optimised

during design process, in order to provide higher disassembly potential of designed configuration (Durmisevic 2006):

- Material levels: This is an element of configuration design that deals with functional decomposition and allocation of functions into separate materials, which respond in a different way to changing conditions. These materials have separate lives, which lead to differential movement, differential durability, or incompatible materials;
- Technical composition: Technical composition deals with hierarchical arrangement of the materials, and relations between materials;
- Physical integration: Physical integration deals with interfaces that define the physical integrity of the structure.

On material level, the hierarchical levels of building composition/ decomposition can be defined as:

- The *building level:* represents the arrangement of systems, which are carriers of main building functions (load bearing construction, enclosure, partitioning, and servicing);
- The *system level:* represents the arrangement of components, which are carriers of the system functions (bearing, finishing, insulation, reflection etc) - the subfunctions of the building;
- The *component level:* represents the arrangement of elements and materials, which are carriers of component functions, being sub-functions of the system.

Therefore, in an attempt to design open/dynamic configurations, effort should be made to separate different building functions by use of separate subassemblies for each function on the building level, system level, as well as component level.

Different strategies have been studied for possible application in designing for disassembly (Addis, 2006, Durmisevic 2006, Crowther 2002, Sassi 2002, Thormark 2001). Examples of principles having relevance to the process of design for disassembly are shown in Table 1. They are divided in *building*, *system*, *component*, and *element* issues (Figure 1).

	Principle	Ref.
BUILDING LEVEL		
structure	- design bearing structures which can be strutted and adapted safely and easily	(Addis 2006, Addis and Schouten 2004)
services	- minimize the amount of mechanical services - strategic routing with a minimum of interpenetration between other layers	(Addis 2006, Morgan and Stevenson 2005, Addis and Schouten 2004)
disassembly	- allow for parallel disassembly rather than sequential disassembly so that components or materials can be removed without disrupting other components or materials	(Crowther 2002)
SYSTEM LEVEL		
transparancy	- building systems need to be visible and easy to identify	(Webster and Costello 2005)
regularity	- buildings systems and materials need to be similar throughout the building , and laid out in regular, repeating patterns	(Webster and Costello 2005)
COMPONENT LEVEL		
durability	- lengthen the life span of building components by patchable detailing	(Morgan and Stevenson 2005)
handling	- design easy to handle components - more easily dismantling can be achieved when structures are composed of a small number of larger members; larger members tend to resist damage more easily during the deconstruction process and can be removed more quickly from the structure - limit the amount of components and fixings - avoid special dismantling tools	(Morgan and Stevenson 2005)
limitations	- minimise the number of different types of components and fixings - this will simplify the process of sorting on site and make the potential for reprocess more attractive due to the larger quantities of same or similar items	(Crowther 2002)
connections	- materials should be easily separated into reusable components: use indirect connectors and dry-jointing	(Morgan and Stevenson 2005, Addis and Schouten 2004)
access	- place layers of elements with more frequent cycles close to the surface connections have to be at reach	(Morgan and Stevenson 2005, Brand 1995, Addis and Schouten 2004)
standardise	- use common, standard shapes and connections; minimize the number of different member size	(Webster and Costello 2005)
materials	- choose materials which allow above mentioned principles	(Addis 2006, Morgan and Stevenson 2005, Addis and Schouten 2004)
tolerances	- provide realistic tolerances to allow for movement during disassembly; the disassembly process may require greater tolerances than the manufacture process or the initial assembly process	(Crowther 2002)

Table 2: Design principles on building, system and component level for disassembly

3.3 Design for disassembly and adaptive reuse of existing buildings

Given that many buildings are being removed from sites due to redevelopment or their inability to remain useful within changing needs of users, the introduction of design for dissasembly in existing buildings prevents economic factors (such as labor costs) to encourage destructive demolition and disposal of buildings.

When considering the designer's brief for a new project, there is a natural hierarchy of waste minimisation to consider :

Hierarchy of Building Resource Management Goals
1. Adaptive reuse of existing building incorporating Design for Disassembly (DfD) for future adaptation
2. Design for Disassembly (DfD) for adaptability and longevity of new buildings
3. Reuse of building assemblies
4. Reuse of building components
5. Remanufacture of building components
6. Reuse of building materials
7. Recycling of materials
8. Reclamation of energy from building elements, components or materials
9. Biodegradation of building materials
10. Landfill sequestration for future resource/ energy recovery

Table 3: Building resource Management Hierarchy (Morgan and Stevenson 2005) (Thormark 2001)

Adaptive reuse of existing buildings, particularly as a result of performance upgrading, has been identified as having an important impact on sustainability of the built environment (Bromley et al. 2005, Sustainable Construction Task Group 2004). Ronald Rover's research (2004) concludes that the existing building stock has the greatest potential to lower the environmental load of the built environment significantly over the next 20 to 30 years. Furthermore, Peter Bullen (2007) adds that older buildings contain many materials that possess lifecycle benefits not originally realised during their initial occupancy. Adaptive reuse of existing buildings bypasses the wasteful processes of demolition and reconstruction, therefore contributing to the environment and becoming an essential component of sustainable developments (Dept. of Environment and Heritage, 2004).

Therefore, it is essential to develop corresponding renovation strategies of waste minimalisation and reuse for existing buildings. The application of principles discussed in Table 2 will be illustrated in a case study of a buildings system design, introduced for adaptive reuse of existing high-rise buildings. This case study will explore the possibilities for waste minimalisation and reduction of materials and energy consumption through disassembly and reuse strategies for renovation.

4. Case Study

4.1 Design for disassembly and reuse for existing (high-rise) buildings

A feasibility estimation of the described design approach for existing buildings is being evaluated through detailing of a fictional renovation project for high-rise buildings in Belgium (Elsen 2007). The Chicago building, a 27 floors high-rise housing building situated in Antwerp (Belgium), represents a large number of similar high-rise housing buildings in Flanders, built to answer the rising prices of the building plots in the 1970's. As a result of the rigid construction design applied on this building, efficient, qualitative and adaptable living has been obstructed after several years of use.

Under the present circumstances, the inability of meeting changing inhabitants' needs will often cause demolition of this type of buildings, although the structural systems would still meet the present requirements. Considering that structural systems generally account for wel over 50% of a building's mass, a renovation approach (reuse of building parts) is more preferable then total replacement of the buildings (Webster and Costello 2005).

To prevent the mentioned waste and energy issues and to answer the environmental concerns in the future, a dynamic concept is being introduced in the renovation intervention. Through design for disassembly a tool is supplied to support the natural evolution of the inhabitants needs, allowing structural changes and taking reuse of building components in consideration. Through a separation of *support* (including the collective facilities) and *infill* two main independant layers are being created. Therefore the originally building is stripped down to the bearing structure, existing of concrete floor slabs and bearing walls. The created empty plots, function as a support for the infill of various dwelling types. Those infilling dwellings can be transformed within the main structure according to changing requirements.

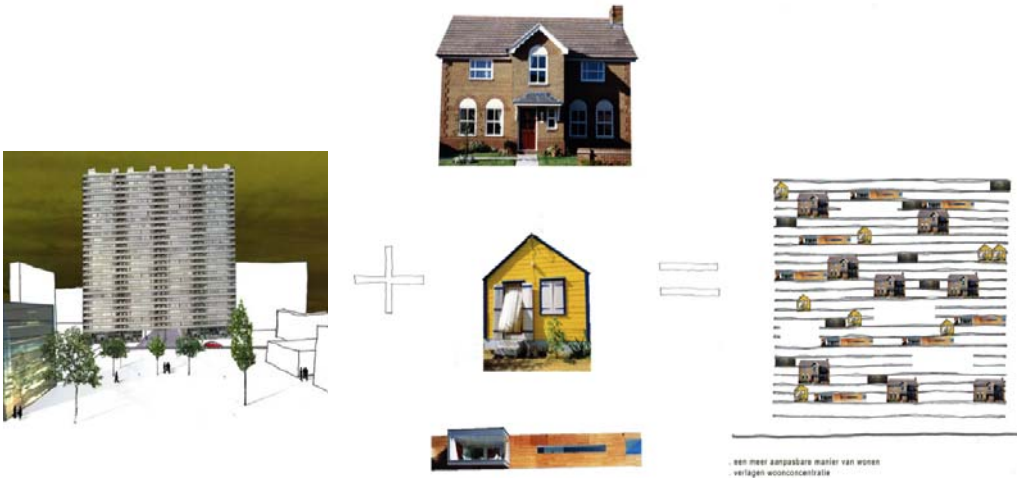

Fig. 2: Dynamic transformable concept for Chicago Building, Antwerp, Belgium (Elsen 2007)

Despite the unadaptable character of the removed ancient infill, it does incorporate a minor level of reuse and recycling. Flooring materials (tiles, floor boards), timber and metal window frames and doors, staircases, sinks, basins and baths, radiators (mainly cast iron), light fittings and miscellaneous furniture and fittings can still be salvaged (Addis 2006).

The new infill proposal includes the described layering using Brand's six S's system of Site - Structure - Skin - Services - Space Plan - Stuff (Brand 1995). This layering enables the different participants of the building to intervene in specific construction levels, without influencing the functioning of other layers. The created levels on scale of the entire building are:

- the bearing structure (floor slabs and bearing walls);
- vertical circulation facilities (stairs, elevators);
- technical services (electrical supply, water supply;
- public space;
- infilling dwellings.

4.2 Proposal for an adaptable renovation building system

The introduced technical *Services* and the assemblies composing the *Skin* layer (thermal insulation, acoustic) of the infilling dwelling construction system can not be combined and may not be fixed to the main existing structure. Indeed, this would obstruct the adaptation or reconfiguration of the dwellings during their operation life. To prevent this, the introduced construction system is characterised by a further layering, inside the existing bearing structure:

- skin;
- services;

- space plan;
- stuff[3].

The *space plan* proposition for the created empty plots structure interconnects adjacent plots, separated by the bearing walls, through introduction of new openings in these walls. These openings enlarge the potentialities of the former structure: larger building plots can be acchieved, allowing houses to expand, reconfigure or contract to neighbouring plots. These reconfigurations can be required when changes occur in the socio-economical situation of the inhabitants.

To allow to answer these various scenarios occuring during an inhabitant's life process and to answer the ecological issues discussed in this paper, the proposed construction system for the infill of the building takes adaptability, disassembly and reuse into account in its initial design. More specific, this construction system allows to built up the '*skin*' layer of the dwellings, by means of combinations of a minimal number of functional basic elements with multiple life spans, applying the 4 Dimensional Design approach. Three types of basic elements can be discerned (Fig.4):

- *line elements* (one-dimensional): steel profiles
- *plane elements* (two-dimensional): insulation and covering panels
- *volume elements* (three-dimensional): corner elements that enable the assembly of a three dimensional frame structure

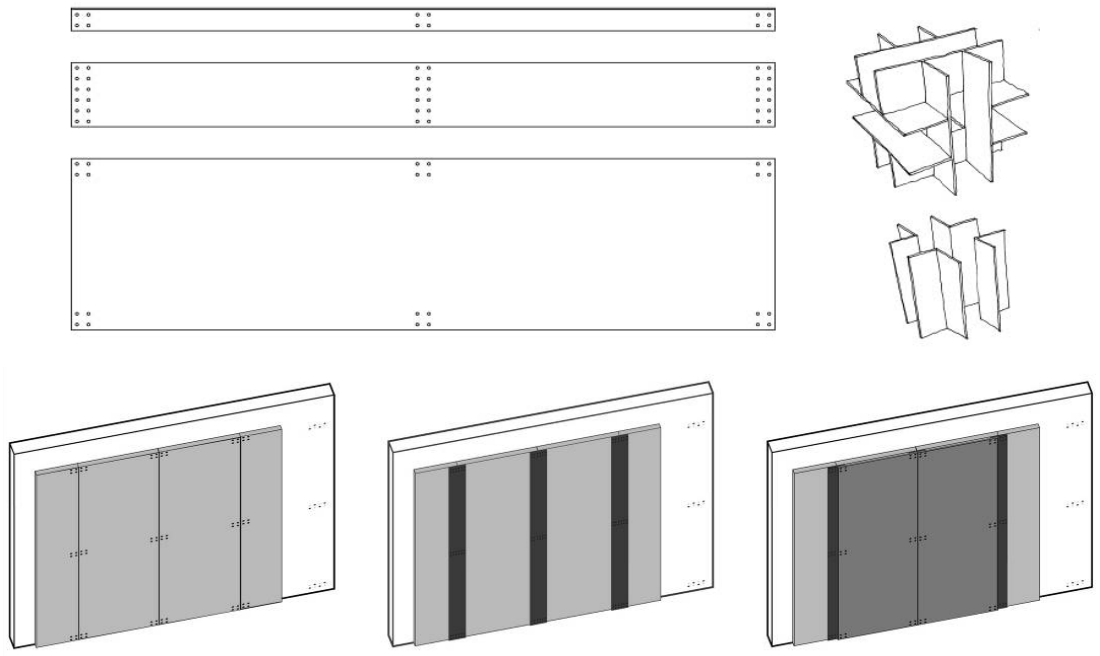

Fig. 3: Basic elements of the renovation construction system composing the *Skin* layer of the infilling dwellings (Elsen 2007)

Although in today's economy steel is hardly ever reclaimed, but rather separated from other materials and recycled, it has a great potential for reuse (Webster and Costello, 2005). Therefore

[3] In this case study, the layer *Stuff* has not been included as it consists of non-built artefacts such as furniture that are not attached to the building system.

the existing concrete bearing structure is combined with steel framing for the infill. To ensure disassembly and adaptability, attention is given to the nature of the connections: mechanical fasteners (bolts) are being used with integrated tolerances to simplify deconstruction and adaptation operations. Through the three types of basic elements a surrounding skin can be achieved, providing satisfying thermal and acoustical quality, comfort and safety.

To prevent technical services to restrict the realised housing flexibility, supply and drainage of water, and supply of electricity and heating also has to be conceived in an adaptable and accessible way. The designed service distributing system takes into account the restricted storey height. A shaft distribution system is opted, providing all services through a specially designed standardised unit (Figure 4). These units are provided on a fixed point on every single plot on the building space plan. As a result, for all possible dwelling plan scenarios possible access is given to all technical services. Also, flexible heating elements can for example, be introduced between the covering panels and the insulation panels if necessary (Figure 4). Those heating elements can also be relocated or taken away if necessary.

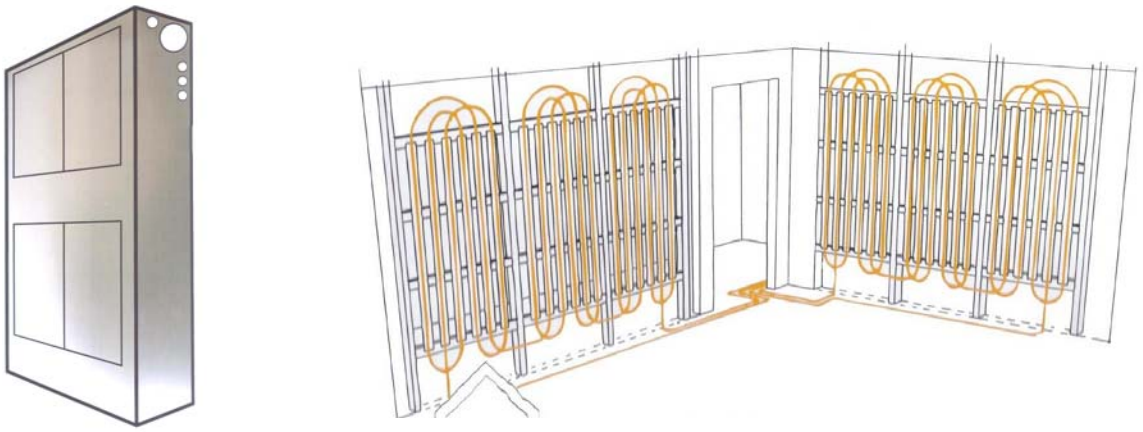

Fig. 4: Technical services: standardised service unit and adaptable wall heating system (Elsen 2007)

4.3 Living as an constantly evolving process through scenarios

The approach for the renovation of the Chicago building, that combines a support - infill system with the use of an adaptable and reusable construction system, endorses transitions of plot and housing configurations. The illustration below (Figure 5) depicts the adaptability of the dwellings and the plot structure through the execution of a succession of scenarios (a quarter of a floor plan is shown).

An initial housing configuration, providing three housing types for family compositions of 1, 2 and 4 persons can be easily converted to new configurations, answering changing needs or dealing with varying number of inhabitants.

Clearly, the introduction of openings inside the building structure considerably enlarges the potential of the existing plot structure that used to be very rigid and unadaptable as a result of its static design. The different introduced space plan scenarios now create the opportunity to answer to changing needs of the habitants in a non- destructive way.

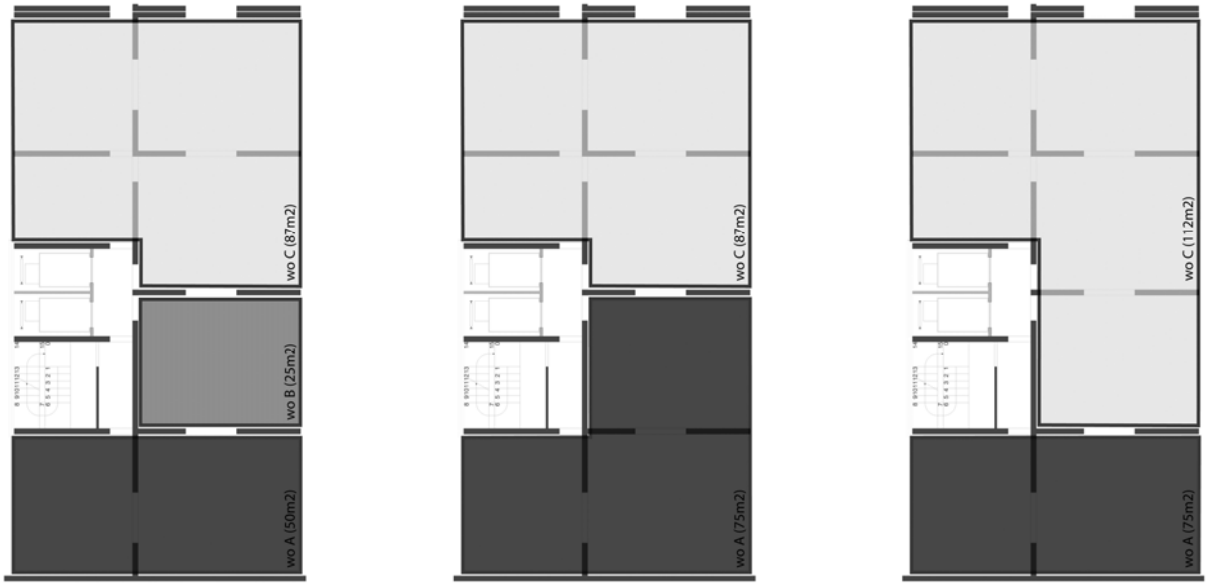

Fig. 5: Adaptive reuse of the Chicago Building: three possible space plan scenarios (Elsen 2007)

4. Conclusions

To allow and to facilitate building transformations in the future, the traditional perception of the building and its structural configuration has to change. Even if buildings can not foresee the uncertainties that the future might bring, social acceptance of failing buildings being demolished and new built without taking reuse in mind has to be undermined.

By adopting concepts as design for disassembly, systems of a building are becoming more responsive to modifications and changes of use. At the same time, the technical composition of a building becomes transformable, which is a precondition for reuse and recycling of building components.

New buildings as well as the existing building stock have to be considered in this research field. Changing housing conditions and requirements concerning quality, comfort and safety of dwellings are always to be expected. Renovation interventions that help to achieve these standards cannot longer be seen as isolated actions, generating great amounts of refurbishment waste after each taken action. The existing building as well as the new interventions and their interrelations have to be assessed, before and after renovation, aiming to provide potentialities for a better use, maintenance, but also further interventions, which will certainly take place in the future.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

NEW ARTISANSHIP FOR NEW COMMUNITIES

Frugal Design as the way of the artisan in the new world

Jogi Panghaal[1]

Abstract

In their practice artisans have managed to not only address the needs of their buyers but also create models of product quality that are distinct and unique from the machine made cheaper products which have stolen their traditional buyers. New projects show that artisans can regain their buyers by clearly understanding the nature and role of craft practice in contemporary world. It is by combining tacit knowledge of the artisan with the explicit knowledge of the designer and buyer that a fresh strategy can be evolved which will ensure that artisan can sustain his practice and maintain his control over the quality of his product and continue to service his buyers.

[1] Independent Designer, Teacher & Researcher, India , panghaal@mac.com

1. Context

India has by a conservative estimate about 11 million to 14 million artisans for whom practicing artisanship is essentially a livelihood issue. This community of artisanship is spread more or less evenly across the country with few exceptions. Within the community of this artisanship, though there are wide differences of histories, cultures, social status, skills and levels of prosperity of artisans depending upon their locations (geography, remote or close access to raw material, market) and presence of enabling infra-structure (government policies or NGO liaison offices, Banks).

As much as there are differences and diversities in artisan communities there are also some common threads that connect them. This vast community of artisans has served various needs of communities of India over the years particularly in the rural areas. Even though India is urbanizing rapidly, over 60% of its population still resides in about 600,000 villages. In the course of serving community's needs, artisans have articulated and informed the forms of all the products and services that one uses in a day today life in India particularly in rural regions.

These processes of making and informing a product or service have been born largely in the challenging environments of scarcity of resources and inability to afford and source these from the market. This has resulted in the artisans working closely with nature and its materials, processes and its laws. The form of products and services that have emerged from this engagement with their natural resource fields and sites exhibit a certain quality, of frugality, a 'certain goodness, a certain beauty and a certain search for truthfulness'.

This frugality of form and economy of movements of its making, when situated or embedded in the day today life of a community of users, produces very elegant and appropriate solutions which are often sustainable and also have a great presence of quality in them. These, in fact, do represent an image of a desirable life style that is, both sustainable and achievable.

Artisans engagement with different natural contexts has given rise to development of a huge range of diverse product forms and other cultural artifacts besides development of range of skills and tacit knowledge among artisans. This reservoir of diverse product forms and accompanying skills that addresses our daily needs is not only a local or a global cultural resource but also an essential keeper of quality among the communities that it serves.

This frugal design has a light presence on earth but also a constant reminder to a community of their true calling. It culturally re-enforces a common idea of quality in all its members. It is from their appreciation of this quality that they derive a common idea of identity. What is significant here is that even the poorest person in a community has an idea of quality that is culturally embedded in him and puts him in the same league as a less poor person. It is important to state here that we were not looking to work with poor person for any altruistic reasons as such but investigating the nature of quality as it resides with communities who are at the so called bottom of the pyramid.

In this sense, quality is, perhaps the embodiment of what Prof Ikujiro Nonaka has called in another context, ‘values of truth, goodness and beauty’.

Artisans are part time farmers or the other way around. For most artisans either agriculture or craft is a supplementary income and they cannot do without it. Craft sector is the biggest employer after agriculture in India. With its capacity to create employment with low capital investment and high value addition, it also is a sector that every government wants to promote. India exports crafts worth $3.5 billion a year (2005 figures) with a growth rate of 10% every year since 2000. It is thus a significant sector for Indian economy. But its larger impact is in the local, informal economy of India.

Artisan products are sold in the local haats or local bazaars. With increasing penetration of cheap machine made products into the rural regions, their traditional markets are diminishing by the day. They need to find new markets. In a democratic set up as in India, they have managed to create a stake for themselves as voters and have managed to get governments to initiate several steps to address their situation. Many policy decisions have been affected that address their concerns. Public sector organizations in the sector like the Development Commissioner of Handicrafts (DCH) facilitate design intervention projects among other things.

Artisan communities are largely illiterate but are very knowledgeable. They own a huge repository of tacit knowledge, which is subjective and experiential in nature, and as Prof Nonaka says it cannot be expressed in words, sentences, numbers and formulas. It is this knowledge that has been used to inform the craft forms over the years. Tacit knowledge happens, learns, adapts, adopts and changes with situation but it is very much the product and fixture of that particular place where it originates. It cannot be transported. With tacit knowledge artisan is able to make for the local intimate area and scale but for a distant and a new market he needs to learn to make it differently For that to happen he needs a partnership with explicit knowledge workers who can help him to use his skills, capabilities and sensibilities and reposition these to design a product or services that find new users and new markets.

2. Project

Bastar is a tribal district in the forested areas of Chattisgarh state in Central India. It is believed that Iron forging techniques and bronze metal castings techniques through lost wax process have been practiced there for nearly 2000 years. It’s an area rich with iron ore mines. There are about 1000 Forge Ironsmiths and about 800 Bronze Casters in Bastar.

Objective of my project which I called Designshala (a home to learn to design) was mainly to develop a series of new products for domestic and personal use in Wrought Iron and Bronze Castings that would address the needs of new buyers and also ‘train’ artisans in ways to learn about new users for their products. A total of 70 artisans worked in phases over a year to make nearly 100 objects each in wrought iron and bronze castings. There were both men and women among artisans, men significantly more than women. Two designers worked together with this group of artisans right through the year.

3. Process

We started by inter-acting closely with artisans and their families and experiencing the ‘quality’ of their lives and their self made object forms with them. It meant looking critically and appreciatively into their habitats, their food and drinks practices, dance forms, healing traditions, listening to their stories, songs and epics, watching their performances in theatre and dances, studying their dresses and traditions. It meant participating in their rituals and ceremonies and listening to their mythologies. Above all watching them make craft objects with their tacit knowledge.

Their core values of goodness, beauty and truthfulness seem to be created with this tacit knowledge and in which every body collaborates fully.

We looked at the material of the crafts that we were focusing on and observed closely how artisans played with it to discover attributes and values of sensuality of the material. (In the nature of ‘you make material but material makes you too’) the speed of slowness or haste. Physical movements of the body to make these products was also observed with efforts always to minimize waste of human energy in sloppy movements.

One of the key observations at this early stage of project is to determine the speed at which products are being made. The beat of making of a product can lead to very meaningful decision making. More beat a product has, more time it has taken to make it and slower would be its embedded speed.

Designshala was an open event in a public space that constantly attracted visitors among whom were students, tourists, a large number of them Indians and some foreigners. There was a constant dialogue between them and artisans mediated by designers.

Designs developed in a manner of shared ideas with their tentative playfulness with materials yielding interesting forms, which were than persuaded to lead to a particular agreed direction.
At every stage, ownership of the evolving form rested with them. They did not do any thing that they did not understand. This meant that they were always working as creative partners in this and not as cheap labor.

What seemed to happen was that tacit knowledge did create the initial start of form making in the material after which designers drew on papers and modeled in wax or clay to create a situation where artisans were able to come out of their own thinking and practicing domain and look critically and reflectively at what designers had done.

This led to opening up the whole issue of the craft and visualizing the entire process of making of craft in simple images. This helped to generate conversations on sustainable practices in terms of use of resources and in terms of finding alternatives to some of these unsustainable practices.

Tacit knowledge helps artisans to make products that largely adhere to sustainable production of them but there are problems when disproportionate success of a particular product leads to rise in its demand. At this stage one needs to collaborate with other explicit knowledge workers like designers and determine how much is the correct,

appropriate and sustainable scale of production. Like what has been said before, too little demand is a disaster but too much demand is a disaster too. Here strategic design choices are critical.

Economy of means of doing things has been a major element that has been the bedrock of sustainable practice. With new product development it created new challenges for both designers and artisans. But with practice and experience we were able to create and observe new body movements, as economical as before to make our new products. Their tacit knowledge helped them to relate to designers new challenge and this new series of products also helped them to move to another and a new level of tacit knowledge.

Tacit knowledge seemed to become explicit knowledge even for artisans through the processes of drawing and modeling that designers were using to visualize the product in greater detail. This helped artisan to look at their own creation and practice in a critical and reflective manner, which led to creation of better levels of skills, practices, forms and new product proposals and designs. More importantly it led to creation of new knowledge both in the tacit knowledge domain and in the explicit knowledge domain for both artisans and designers.

This was an interesting process, which seemed to suggest important roles for persons with explicit knowledge skills. By using certain simple communication devices like words, story telling, drawings, sketches, it is possible to co-create products with artisans like co-authorship of a story. Where these artisans can continue to be creative masters of their professional domain and yet be in an evolutionary mode in the manner in which they grow in their own domains.

The ‘site’ or ‘field’ of the body of a crafted product than is where the evidence of transformation of tacit knowledge to explicit and to a new collective tacit knowledge seems to be seen to be happening.

It was the open source nature of the workshops that led to potential buyers being drawn into lengthy conversations with artisans. Their conversations again led to situations where there was an equal give and take between artisan and potential buyer where both moved from their stated positions of maker and buyer to that of joint creators. New knowledge about the role that artisan can play in their lives and for artisan to know that there are new kind of buyers for his works. This was often difficult to navigate for both but necessary for artisan to understand that new buyer demands a different kind of engagement which is that of co-creation.

It is evident that an active play and creative engagement between tacit knowledge workers and explicit knowledge workers would help both. It is important that this relationship survives in a knowledge economy and a knowledge society. Tacit knowledge comes from the bottom of the pyramid communities and it is important that it continues to be valued and used to make innovations that would gain them new market share on one hand and also continue to give them a central role as active participant in their own development stories by continuing to create more tacit knowledge.
It would also help the buyers to exercise the real choice to connect to the real stories of frugal nature of doing things.

Products of artisanship are not just numbers and volumes. These are individual items, each different from the other. Today's buyer has to be open to make major shifts in looking at craft items as they are, distinct from machine made items. Two universes are totally different from each other but they help us to appreciate the other. They help us to locate their boundaries, their property, their attributes. There is a need for a wider social conversation on this so that artisans are not stressed to make things in a manner that can only be machine made and vice versa.

Designers need to be sensitive to their own biases of aesthetic models as their education naturally inclines them towards western sources and perhaps machine made aesthetics more than it does towards hand making aesthetics. The designer's education looks at quality from the industrial shop floor and it tends to ignore the complexity, richness and plurality of the aesthetics of the hand made solutions. Designers tend to flatten and homogenize the diversity of form of artisan's products, texture, color and sensuality that his tacit knowledge has given him to embed in the product.

It is important for designers to be open and work creatively along with artisans to discover the local and tacit elements of design in the craft of a region. This perspective will help to keep the diversities of the forms and visual languages alive. It is also important for designer to be sensitive to the frugal notions of design whereby certain economy of means, materials and methods gives rise to a very distinctive look and feel of the products and services. This is perhaps the core of sustainable design perspective in our communities.

4. Tools

1. Story telling in the local languages was most extensively used to create an atmosphere for all to imagine new characters. Often development of new characters in a spontaneous manner led to new story making.

2. Photos, drawings and models were used as a process to trigger idea movement and also shown as the material of the designer as much as craft materials are materials of artisans.

3. Actual samples from market or buyers or from other producer groups was also used to trigger critical reflection, new ideation and development of new stories

4. Songs, mythological dramas were often used to create a sequence of events where it was needed to know the order of things.

5. Visit to potential users home was most interesting as they could see their/others products being used in actual context for which they had made it. It also leaves them wondering for new product ideas and a new tacit knowledge.

6. Visit to monuments, ancient sites with remains and museum to check on the local vocabulary of form and materials was useful whenever mediated by designers. It was clear that designers were constantly interpreting explicit knowledge to artisans in a tacit manner to communicate subjects better.

7. Exposure to new materials and new tools and techniques was arranged with mixed results. Some ideas were picked up as others were ignored as impractical and inefficient in the context that we were working in. Its possible that in a different context their choice of what they accept and what they reject would be different..

8. A detailed brief was made and the bigger picture of what we were setting out to do in a year was shared with artisans.

9. Workshop was open to visitors and in a public space. This encouraged a whole lot of people to visit us and share their ideas with us even as they observed the workshop.

10. Exhibitions of the final products were organized in a show and tell mode for buyers where skill demonstration and role of artisans was paramount. This was also an open invite for potential buyers to come and co-create products of their concern.

11. Detailed visual documentation was made with still digital camera to share it with future workshops participants.

5. Issues

1. Keeping the **livelihood** of this vast number of artisans intact is one of the biggest challenges. To do this in the face of homogenizing nature of globalization is even bigger challenge. This must be taken on by mobilizing the participation of all who can bring new knowledge and expertise to help mount effective challenge. Fortunately artisans are open to change, open to learning and to creating new tacit knowledge. Like mentioned before, it is perhaps important that we have both, handmade and machine made universes of doing things surviving side by side. Both can inform each other and evolve independently. They provide real choice of quality, sensibility, diversity and sustainability to the world. Perhaps artisan need to reinvent himself as an artisan equipped with new knowledge of sustainability.

2. Artisan practice contains an aesthetic which is very special and different from what machine made aesthetic provides. Artisan is excluded from a creative process if his aesthetic is always marginalized and he has to constantly adjust to the new governing aesthetic of the machine. Designers need to be sensitive to this and they can play a positive role if their visual vocabulary included references to the artisan aesthetics. This would make designers practice **inclusive for artisan**.

3. When designers work with artisans they bring in their **explicit knowledge skills to the domain of tacit knowledge skills** of artisans. In the course of their partnership each domain learns from the other. Tacit knowledge become explicit knowledge and together these two knowledge systems produce another level of tacit knowledge when artisans work with it. This onward spiral of new knowledge creation should be allowed to have its full continuous play. New ways need to be found to harness the movement of tacit knowledge as it contains the native wisdom of a particular community that has been co-created by all its active members over the years.

4. In a scarcity hit regions of the world, creativity has been used to not only develop products and services that are **frugal** in nature but also the manner of their making shows an economy of creation, (in materials, tools, energy including human). When we shift to an economy of easy availability of resources every where, any time there is a real possibility of the loss of economical ways of doing things, of frugal design, which is inherently sustainable and perhaps desirable.

5. Hand made universe is actually handmade, slow and sustainable if scale of production of objects is within the appropriate **scale** of the handmade. If the order of things move into numbers that rival machine made production number, than we have to reconsider the choice of handmade to address that particular order. Real artisanship that produces quality needs time, skills, appropriate tools, appropriate scale of production and discerning users.

6. Finally artisan demands **recognition, respect and dignity** for having first created a physical example of an idea of certain quality in our midst and in our communities and his willingness and eagerness to take that idea further into our common futures.

seven plates for table, in bronze, 10cms dia. Each plate has a boarder from a tribal field.

Six versions of cow on the road in Bronze, size length 14cms, height 7cms

A field in the plate, bronze cast, 30cms dia. Theme was to bring the feel of fields in a plate to an urban household. To be used as a fruit bowl.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Creative Communities for Sustainable Lifestyles

Visions of sustainable ways of living in Brazil, India, China and Europe...

Lara Penin[1], François Jègou[2] and Sara Girardi[3]

Abstract

The project Creative Communities for Sustainable Lifestyles (CCSL) proposed to enlarge and adapt the notions of creative communities and promising cases for new models of sustainable lifestyles at a worldwide scale, comparing some European experiences with ones observed in emerging countries.

The paper will discuss the CCSL results, first regarding the nature of the local initiatives and how they are positioned within the worldwide arena of social innovation phenomenon.

Second, the specific design capabilities useful to the diffusion of these initiatives. A design exercise with design students in the three countries has generated a set of scenarios of localised collaborative services providing valuable insights for the construction of a rough map of need-areas and possible local penetration of promising cases.

1. Introduction

The EMUDE research[4] has exposed the phenomenon of diffused social innovation, specifically under the form of collaborative everyday life creativity (the *creative communities*) in Europe: groups of active, enterprising people inventing and putting into practice original ways of dealing with everyday problems, and by doing this, offering insights of new possible sustainable ways of living. But could these initiatives of collaborative everyday life creativity be considered a global phenomenon, present not only in the mature industrial economies but also in emerging ones? Can diffused social innovation be considered as a global phenomenon?

This was the starting point for the project Creative Communities for Sustainable Lifestyles (CCSL)[5], being to enlarge and adapt the notions of creative communities and promising cases for new models of sustainable lifestyles at a worldwide scale, comparing some European experiences with others that can be observed in growing urban populations of emerging countries.

CCSL project has proposed to investigate this phenomenon in three emerging countries (Brazil, China and India) focusing on what could be the similarities and differences between those *creative communities* and the ones in Europe. In particular:

- Considering creative communities in different countries: what are the similarities and differences between them? In particular: what can Europe learn from emerging countries, and vice versa?
- Considering creative communities in emerging countries: do these cases indicate a direction for sustainable lifestyles? In particular: do they indicate sustainable lifestyles for the growing urban population of emerging countries?
- Considering creative communities as successful cases of grass roots innovation: how have they been improved and replicated? What kind of specific initiatives have been promoted?
- Considering the issues involved in improving and replicating such cases: could the communication and design capabilities that have been applied in some European cases be usefully adopted in the context of emerging countries?

CCSL has conducted research activities based on partnerships with local institutions[6] through a research process based on the identification and documentation of local initiatives and the interpretation of these initiatives in terms of their *service ideas*, through an open dialogue with local experts in the three countries.

In parallel to that, CCSL has proposed a design exercise, targeted at design students in Brazil, India and China, aiming at the interpretation of local based collaborative services. The aim was in one hand, explore potential new roles and capabilities that designers might develop and apply in this new field, and in the other hand, explore how some service ideas that were found to be recurrent worldwide, could be proposed for replication in these courtiers.

Local cases and previously collected cases in European context (EMUDE) were presented to the design students, who carried out a contextualisation exercise of their assigned

[4] EMUDE has been a Special Support Action promoted in the framework of the 6th Framework Program (priority 3-NMP) of the European Commission. EMUDE was coordinated by INDACO, Politecnico di Milano and developed by 10 research centres and universities and 8 European schools of design. EMUDE was concluded in April 2006.

[5] CCSL project was coordinated by Politecnico di Milano and Strategic Design Scenarios and promoted by the Sustainable Lifestyle Task Force, funded by the Swedish Government within the United Nations 10 Year Framework of Programmes on Sustainable Consumption and Production (Marrakech Process) and endorsed by the United Nations Environmental Program. CCSL ran from October 2006 to November 2007.

[6] CCSL partners were: Technology & Social Development Laboratory (LTDS) at Rio de Janeiro Federal University (UFRJ) in Brazil; SRISTI/HoneyBee, The Society for Research and Initiatives for Sustainable Technologies and Institutions and the National Institute of Design (NID) in India (Ahmedabad); and Institute of Civil Society (ICS), Sun Yat-sen University and the School of Design, Guangzhou Academy of Fine Art (GAFA) (Guangzhou) in China.

service ideas and the development of a scenario building process aiming at creating and visualising potential localised scenarios of sustainable ways of living.

The CCSL research process and its results can be discussed in two levels:

First, the appreciation of the nature of local cases and how they are positioned within the worldwide arena of social innovation phenomena. Exploring the creative communities concept through non-European contexts, has led to the acknowledgement that in these emerging countries, **there are groups of people who organise themselves to solve everyday life problems or to open new possibilities in the new urban environments, and in so doing invent and practice sustainable ways of living,** even though if terms like “community” or “creativity” have different meanings from the ones adopted in the definition of creative communities in Europe.

Results of these initiatives are *collaborative services;* but are they different in emerging countries from those found in Europe? As it will be seen, CCSL has revealed that, in one hand very similar *service ideas* are found worldwide, even if motivations and social meaning can vary from place to place, whilst their results are similar. In the other hand, local conditions and particularities have established a connection between creative communities and their collaborative services to initiatives definable as micro-entrepreneurship.

The second level of the discussion of results refers to partial or complete visions of sustainable lifestyles that emerge in each country resulting from the conducted design exercise. These activities have led to an outline of which kind of service ideas are more likely to be adopted in each of the three contexts; and which instead would not and why. This process allows delineating a (rough) map of need-areas and possible penetration of promising cases in Brazil, China and India.

The nature and quality of tentative visualizations produced by the different scenario building exercises with students in Rio, Ahmedabad and Guangzhou permit to better focus some concrete examples of solutions and picture the way they could be embedded in the current local culture and concerns.

2. Main results

The first level of results, deriving from the experts workshops conducted, are related to the nature of local cases found and how they are positioned within the worldwide arena of social innovation phenomena, summarized here bellow.

Good Ideas Spread Worldwide

Creative communities and collaborative services are deeply rooted in their specific contexts, but their ***service ideas*** can spread worldwide. In practice, this means that, in different contexts, a ***service idea*** can be roughly the same, though its motivations and social meaning may be slightly different from case to case.

C*ollaborative services* are organizations that produce results for all participants, i.e. forms of service. In other words: *collaborative service* is a service that, to exist and be effective requires some form of community. Every creative community, considered in its complexity, is by necessity deeply rooted in a local social and physical context. The same is true for the corresponding collaborative service. But for this service, as for every service, we can recognize and outline a kind of structure that is less context-specific, which is called *service idea*. More precisely, it is the system architecture and the partner’s positions and motivations that characterize a service and enable it to exist and, perhaps, be effective.

The importance of the notion of service idea is given by the fact that it permits to separate what can be reproduced (because non context-specific), if the conditions are given, from what cannot be reproduced (as the creative communities and their related collaborative services).

By comparing creative communities cases collected in Europe and emerging countries we have indeed verified, here and there, initiatives belonging to the same clusters of services, accepting that their motivations and social meaning change, they are:

- **purchase groups**: groups of consumers who organise and manage the purchase of healthy and fresh produce in bulk, directly from producers;
- **community supported agriculture**: direct trade networks between producers and consumers, connecting urban and rural people and helping to sustain small-scale, organic agriculture;
- **urban vegetable gardens**: groups of people who organise urban farming, raising crops in their backyards or in public areas, obtaining fresh produce and greening the city;
- **child socialization:** places for children to meet and play in an open-minded social atmosphere, often favouring interaction among parents and becoming a meeting place and reference point for the entire neighbourhood;
- **local exchange trading systems:** mutual exchange of services, professional and non-professional skills among the members of a community;
- **community care for the elderly:** groups of senior citizens who can re-create their social circles, share everyday life tasks and get involved in productive activities;
- **community nursery**: small-scale home-based nurseries;
- **car-pooling:** alternative use of individual cars organised by groups of people who live or work in the same area, or who use similar routes in town.

Creative Communities in emerging countries are related to micro-entrepreneurship

If in one hand, we observed that the same service ideas appeared equally in both industrialised and emerging contexts, on the other hand, something different, specifically related to emerging contexts has appeared: cases linked to micro-entrepreneurship, revealing a new sub-system of grass-roots social innovation in everyday life.

This finding causes an important change in terms of the point-of-view we have used so far to analyse Creative Communities initiatives: EMUDE has always looked at the cases from the final user point-of-view (*demand*). Now, for emerging countries, we also have to consider the point-of-view of the *offer in order to grasp the complete meaning of the initiative*. While in Europe creative community initiatives are mainly demand-based (emerging from a specific demand for services from the end-user), in emerging countries, a different mix of more supply-based motivations appear, emerging from the offer of specific services that groups of people organise and put forward on a micro-entrepreneurship basis: small, localised, productive activities, which have a direct impact on the quality of life, offering a source of income that guarantees the inclusion of groups of people in the economy.

Collaborative services and micro-entrepreneurship are sometimes even opposed in emerging contexts and regarded as potentially competitive. Groups of people organizing on a private basis to co-produce a service for themselves could be seen as a possible threat to employment. In India for instance, the dynamism of micro services pushed by overpopulation and unemployment in cities tends to discourage enabling solutions.

However, it is important to interpret micro-entrepreneurship within contextual conditions and circumstances. In Brazil for example, it is often connected to existing networks and

supporting initiatives from civil society organisations working through some community-based approach.[7]

Not all cases of micro-entrepreneurship in emerging countries can however be considered as creative communities, opening up a grey area, a blur between near but different concepts. In Brazil, India and China, the expression "creative communities", when explained as *grass roots social innovation*, is often considered as a part of other, existing and relatively consolidated arenas of discussion and fields of actions:

- *The development of under-developed communities*. In this case the common denominator with our concept of creative communities is the collaborative dimension. But the communities being considered here are mainly traditional ones, and the contexts where these actions take place are mainly rural (such as villages in India) or very poor (such as the Brazilian *favelas*).
- *The promotion of new (profit and non profit) enterprises*, meaning the results of creativity and entrepreneurial capacities of individual people. In this case, the common denominator is the high degree of entrepreneurship in solving the problem. But here the focus is on individual capabilities rather than in groups of people who collaborate to solve common problems as it occurs in creative communities,
- *The promotion of charity-oriented organisations*, relating to organisations where someone voluntarily does something for someone else. In this case, the common denominator with is the promotion of social value. But here the relationships mainly consist of someone helping somebody else who is in difficulty, without demanding anything in return. Instead, in creative communities, relationships are based on some form of reciprocity where everyone involved is active in different ways.

The meaning of "community" changes deeply in the different contexts.

In the European experiences the communities we refer to are "intentional communities": new social organizations emerging from a long process of individualisation (and, largely, as forms of reaction to it). *Vice versa,* in emerging countries, the communities we refer to can be seen as a balance between continuity with still existing traditions (families, villages, neighbourhoods, etc.) and the innovation needed to face radically new conditions of life (and the challenges of sustainability, not just environmental, but also social and economical). In each country, this balance can be different, but in each one of them it will result in the up-dating of traditions, i.e. the use of conventional social organisations as building blocks for new forms of social network (in the framework of which collaboration, mutual help, sharing and, more in general, community building can be up-dated and re-interpreted).

The very interpretation of the terms *creative communities*, *social innovation* and *sustainable lifestyles* is key for understanding the different socio-cultural meaning of these initiatives in each context.

Community is the most critical term, appearing in Brazil as to replace the word "favela" (shanty town), for politically correctness purposes (R. Bartholo, UFRJ, Brazil, pers. comm. 05/02/2007). In India, *community* tends to have a connotation of traditional rural communities, as well as referring to one particular religious faith, whereas in China, there are different historical interpretations, including the delimitation of an administrative area by the government (Alice Lau, ICS, China, pers. comm. 24/01/2007).

The discussion of the role of creativity in contemporary society (and in a knowledge economy) is today very diffused worldwide (and in Brazil, India and China too). However, it has to be said that the notion of creativity normally used in the public discussions is quite far from the one we adopted when defining the concept of creative communities. As far as creative

[7] For example social incubators and other initiatives based on the solidarity economic approach have an important role in encouraging and supporting micro-entrepreneurship and community-based solutions aiming at re-establishing social fabric and wellbeing.

communities are concerned, the creativity we are referring to is not the creativity of experts (i.e. workers in creative industry) but it is the *diffuse creativity* that characterizes contemporary societies when oriented towards inventing collaborative solutions to everyday life problems and opportunities[8].

Particularly in India and Brazil, experts have pointed out for one of the possible reasons of this different interpretation, basically related to the understanding of creativity as an individual quality rather than a collective one. In India, (social) creativity is commonly linked to the notion of "juggard" (copy/hack culture) (A. Srinivasan, IIT Delhi, India, pers. comm. 02/03/07), which demonstrate a strong individual creativity but tends to stick to the "fix-it" level (S. Mehta, NID, India, pers. comm. 06/03/2007) and therefore very much referring to grass roots inventors (Honey Bee, India). In Brazil, “the notion of *creativity* has been given recently an individualistic emphasis: *creativity* as an attribute of the individual freedom”(R. Bartholo, UFRJ, Brazil, pers. comm. 05/02/2007).

Cases of social leapfrogging

In emerging countries, collaborative behaviour patterns still exist in different traditional forms (inside families, villages, neighbourhoods, etc). At the same time, main stream thinking on modernization, following the patterns of existing mature societies, considers that these living traditions are condemned to disappear, swept away by an “inevitable” individualization process.

On the contrary, through the *creative communities* perspective, we assume a different idea of modernization, where new forms of cooperative behaviour, creative communities, appear as cases of *social leapfrogging*. That is, as cases of social innovation where groups of people move directly (or, in any case, very fast) from traditional forms of collaborative behaviour to new ones, responding to needs of contemporary everyday life (avoiding the phase of extreme, unsustainable individualisation that characterizes existing mature industrial societies). We have assumed that in emerging countries, creative communities can be seen as a non linear evolution towards modernization, i.e. cases of *leapfrogging in the social development process*. However, these “leaps” require some ideas on where to leap: a new idea of wellbeing that must be perceived as better than the one achieved through a more linear process. If this is true, the kind of wellbeing that creative communities generate has to be perceived as better than that proposed by the normal “modern” solutions[9]. This means that this community-based and context-related wellbeing must be attentively and effectively communicated. And wider visions of what life could be like, if it were widely accepted and diffused must be produced.

In other words: effective communication and scenario building are crucial to give these promising cases the possibility to last over time and to spread. ***New design tools and new sensibilities must be developed to make it possible.***

3. Design Exercise...

One of the questions of CCSL was: considering the issues involved in improving and replicating creative communities cases, could the communication and design capabilities that have been applied in some European[10] cases be usefully adopted in the context of emerging countries?

[8] The EMUDE research has proven that the creativity of professional creatives, and that of creative communities are different. Nevertheless, it proved also that creative communities can generate a favourable context for the development of professional creativities.

[9] We must add here that, today, the perspective of creative communities must also be perceived as better than another (very dangerous) existing proposal: the one based on ultra-conservative ideas on identity and traditions.

[10] In Europe, associated to Sustainable Everyday project and EMUDE research, a number of events were held to promote the social debate around creative communities and collaborative services: seminars and publications and traveling exhibitions. For details, see www.sustainable-everyday.net

Most of these collaborative services observed are deeply local and nearly private initiatives: they are known only by the group of people that organize them. They have anonymously developed among a small community of users/producers who, very often, being quasi self-sufficient, do not feel many reasons to publicise to larger audiences what they are doing. This lack of visibility prevents these cases to be promoted (we hardly notice them around…) and slows down their dissemination (not being seen, they do not inspire replication…).

It results that, in order to promote them and express their potentialities in terms of seeds of possible sustainable lifestyles, it is crucial to improve their visibility. That is: to communicate effectively and to use them as starting points to build scenarios of sustainable everyday life based on the hypothesis of their possible larger diffusion and replication.

New roles for design emerge here: designers can help in giving visibility to creative communities initiatives assuming the role of becoming "project agents" of new sustainable solutions, conceiving and developing advanced solutions of collaborative services.

In this framework, CCSL proposed to design schools in Brazil, China, and India[11], to host a design exercise with students aiming at generating a set of scenarios, (the creative communities scenarios) of how life could be like in a society where creative communities, and the ways of living they propose, could spread in their culture. This design exercise, organized as three days workshops, introduced the participants to the notions of grass roots social innovation and collaborative services in the perspective of sustainable ways of living.

Participants were asked to re-compose these scenarios of sustainable lifestyles inspired by the promising initiatives collected by EMUDE and CCSL. To compose the new scenarios, they were exposed to samples of characteristic solutions, presented through a set of stimulation cards (each card containing an aspect of a collaborative service). This starting material has focused on three clusters of initiatives: new food networks, community housing and neighbourhood care.

The first design step was to "localise" service ideas, translating them into their own socio-cultural and economic structure, articulating these sample of solutions into new services for food (new food networks reconnecting urban consumers to the food they consume), housing (now co-housing models) and neighbourhood care (new forms of living and being in the public urban space).

Participants were asked to experience interaction with a tentative product-service system playing themselves the role of users (act-in) in their own scenarios. For that, they have produced a visual description of their context of life (the city, the neighbourhood, the house, its spaces and artefacts, etc). This process of visual documentation of the context of life of their user was used as a baseline for the following scenario building activity, through the construction of short visual narratives (photo-story) describing a character using a collaborative service. They have questioned his or her personal characteristics, motivations, expectations to take part in the service. At the end the selected narrative should capture the meaning of the service in user's daily life through a series of five to eight scenes. As a final instance, external users were interviewed after observing the results so to investigate in depth the potentialities and barriers for dissemination of the different collaborative services.

The results of these visualizations express in a concise and highly communicative way, new possible collaborative services that reflect contextual cultural norms and socio-economic systems in the countries where they were developed and provide interesting insights in terms of potentialities and barriers for proposing collaborative services in Brazil, India and China.

4. Tentative (partial) visions...

[11] The schools involved were COPPE / EBA Technology & Social Development Laboratory (LTDS) at Rio de Janeiro Federal University (UFRJ) in Brazil; the National Institute of Design (NID) in India (Ahmedabad); and the School of Design, Guangzhou Academy of Fine Art (GAFA) (Guangzhou) in China. In Brazil, a second workshop was conducted independently of CCSL at the School of Design UNISINOS University.

In the light of the main results described in section 2, we propose here a second level of interpretation of CCSL results, through the discussion of what emerges as the main characteristics of the collaborative services proposed by the design students in each country.

The results of these exercises are presented in the form of photo-stories (as described in section 3): a sequence of pictures carefully produced to represent a progression of events that constitute the proposed service (see figures 1, 2 and 3). We argue that the interpretation of the proposed services can provide valuable insights regarding the kind of service ideas that would be more likely to be adopted in each of the 3 contexts, helping on the construction of a rough map of need-areas and possible penetration of promising cases. Even if the photo-stories cannot be interpreted as such, since the solutions developed are too much influenced by the input clusters (the stimulation cards) and therefore do not pretend any generalization, they provide us with insights of collaborative services in each different cultural context.

India: From "service communities" to "promoted participation"

The different adaptation of the three service clusters by the Indian students seems to be characterized by a shift from a community that collectively set services for themselves to a collectivity that is participating to a collaborative service initiated and coordinated by a promoter.

In a 'spontaneous service society' like India where every opportunity to provide services is immediately implemented providing added value and employment, the hypothesis of collaborative services is first seen as a threat to income sources: a food purchase group organized and operated by families living in the same neighbourhood sounds a rather complicated and risky solution when the same service could be very efficiently provided by any of the vendors selling fruit and vegetable on carts in the street. The community most of the time pre-exists. People leaving in the same place, colony[12] or neighbourhood are a *de facto* community and it does not seem to be too complicated for them to become a collective employer, grouping to get for instance an organic food delivery service from the existing streets vendors.

This is the case for almost every aspect of urban everyday life, from food (street vendors, providers at your doorstep), to mobility (abundance of rickshaws and auto-rickshaws in contrast to poor infra structure of public transport), to clothing care (the washing wallahs, collective laundries) and beyond. In the " wallah" culture, there is almost always a service provider at your doorstep (Soumitri, G.V. and Srinivasan, A 2003).

If these services are frequently based on low resource intensity and avoid individual ownership of a range of goods/artefacts such as washing machines, automobiles, etc, they frequently rely on underpaid occupations. In effect, they relate to a severe demand for job opportunities and income generation in the urban environment (considering sheer migration flows from villages to the cities in recent decades, millions of poor and unskilled people moving into urban areas in search of livelihoods).

In solutions imagined by the Indian students, the collective gardens are characteristic examples of an evolution from these "services communities". The general scheme remains the same: a single operator on one side and a community of families on the other side. But the single operator is not anymore an employee performing the complete service: he becomes the promoter animating the initiative within the community. In one of the students' scenarios, an elderly retired man wishes to revitalise the use of traditional Ayurvedic medicine (see photo-story in the visualization section below). His motivations to come out with this new activity are related to the opportunity of regaining social and family acceptance and recognition through a new occupation. For that, he starts planting an Ayurvedic garden on the roof of one of the colony's buildings and involves other tenants in the enterprise. The community around is not then anymore a passive employer: promoting a vegetable orchard (see photo-story on www.sustainable-everyday.net/ccslproject) they collaborate to the initiative guided by the elderly: they take part to

[12] Residential neighbourhood typology in India.

the gardening activities, they help in harvesting, cooking, making preserved food and organising a collective meal... They participate in the solution guided by the initiative of the solution promoter.

In the ayurvedic garden scenario, where the retired man finds an innovative way of animating the community (and creating social value), the street vendor is out of scene. One could argue that in this new scheme, he looses his role as provider and ultimately his source of income. After all, the retired man living in a colony comes from a middle class person, and the street vendor probably comes from a less privileged social position. They are not equivalent social actors, when it comes to having access to similar infra-structure that allows for example the retired man to have a roof top available for his ayurvedic garden. It might not be the case for the street vendor to have access to such a space.

A challenge for the spread of collaborative services in this context derives from the complexity and diversity that characterises the Indian society, notably its deep social inequality. It will have to consider how to reach social actors such as the street vendor. If instead of a private rooftop, he could count with a public space, then it could become a solution that caters this public, favouring social aggregation and generating social value.

Even if challenging in some aspects, the perspective of integrating collaborative services and micro-entrepreneurship opens up interesting opportunities. Another scenario proposed by students proposes a similar situation, but here the social roles are not so marked (as in the case of the elderly wishing to regain his social status). It is just a group of people who decide to organise a purchase group to obtain organic produce. In this new food network solution, street vendors could play an important role, even becoming the promoters of a direct food chain. Their work would gain an improved value and more guarantees since it becomes systematised and part of an organised scheme.

China: From "institutionalized collectivism" to "open collaboration"

The adaptation of the initial set of cases proposed by the Chinese students seems to be strongly influenced by the past forms of institutionalised collectivism that constitutes a positive background for implementing new forms of more open collaboration.

During the past decades China experienced many forms of institutionalised collectivism that at the citizen level induces everyday life solutions based on the sharing of goods, use of collective spaces, local-based forms of organization, etc, experiences thus similar to the set of cases showed to the students, through the stimulation cards. A parallel of the Chinese mindset can be traced with other countries that have also experienced a long period of collectivism such as Central Eastern Europe, that react with some reluctance collective-based solutions (Vadicovic, 2008).

Although China, since the first steps of economic opening, has been showing a massive rush towards western lifestyles, consumerism and individualism, the reaction of the students were fairly positive towards the creative communities cases and their ways of doing. And they have demonstrated a true spirit of 'open collaboration' when designing their new scenarios, by proposing clear bottom-up services: tenants of a building decide to install themselves a garden on the roof terrace of their building (see photo-story in the visualization section below), a young couple decides to share their car (see photo-story on www.sustainable-everyday.net/ccslproject). But the kind of collaboration that emerged is also partly top-down The presence of the state is also required as part of the proposed solutions, for example to incentive (or allow) forms of exchange between neighbours, to subsidize initiatives of public interest such as green roofs or simply to check that installing a garden on a roof top does not threat the security of the building structure.

Even more, the solutions seem to demonstrate both a particular interest and a clear competence in organising part of the daily life on a collective basis. Great part of the motivations mentioned by the students that would lead to the creation of a collaborative solution is related to the lack of socialization deriving from the booming urbanisation process. In the traditional

Chinese society, the family is the ultimate social and economic unit, the main form of organization (Leong, 2008). With economic growth and particular rapid shift from rural to urban environment (migration from countryside to the cities) the new urban population faces a serious problem of social displacement. The disadvantage of comfortable apartments in high-rise buildings is the difficulty to make friends, especially considering that newcomers are often cut from their previous social contexts. Exchanging mutual help between tenants, sharing a car between two families is seen as a way to meet new people and make friends.

More than in the two other countries, the students demonstrated a capability to handle problems raised by collective living or sharing goods: a garden in a rooftop is nice but not all the building tenants can enjoy it at the same time. A chart is placed in the stairs enabling the families to organise its use in turns. In the same way as portrayed other scenarios, the system supporting the exchange of mutual help between the tenants in a high-rise building is part of the building infrastructure placed in the building entrance hall; sharing a car means first to agree and sign a contract between the two parties. The resulting 'open collaboration' is based on both the initiatives and the competences of the individuals to organise collaborative services.

A recurrent bottom-line present in the scenarios/photo-stories developed by the Chinese students can be perceived in the realm of “personal benefit”, in other words, solution addressing physical and mental wellbeing related to problems such as urban loneliness. Virtually all the solutions proposed offer the opportunity of socialization as the main or additional benefit for the main functionality addressed (food, mobility, etc). It emerges that collaborative services’ greatest potentiality in China can be related to this aspect of promoting socialization in urban environment, connected to the “intimate ecology” (Leong, 2008) of the self, as one important potential area in the Chinese context.

Brazil: From "spontaneous sociability" to "structured collaboration"

The adaptation of the proposed set of promising initiatives by the Brazilian students seems to be characterised by profiting from the spontaneous socializing skills of the population to set more structured collaboration and initiate collaborative services in the everyday life. This spontaneous sociability is a fundamental trace of Brazilian ethos and can be related to the notion of the “cordial man” (Buarque de Holanda, 1936), synthesis of the friendly and informal character of Brazilians, where relations of an organic and communal character based on family relations, neighbourhood, and friendship prevail over any form of impersonal or mechanical ordering.

If in one hand, this socio-psychological characteristic leads to an apparent easy and friendly social environment, in the other hand it tends to oppose to anything structured, an uneasiness in accepting and following rules that ultimately determines all forms of organizations and institutions, that after all are present also in the collaborative services. Besides, if a natural socialization seems at first sight to be an obvious characteristic of public life in Brazil to the point of becoming a cliché, it seems to operate mostly at the surface of the social life, outside, in the street. In the private sphere of everyday life, in the setting of the habitat, people tend to live on a more individual basis and even exposed to isolation and alienation.

Many of the solutions imagined by the Brazilian students try to match these two issues and make use of this spontaneous sociability to prompt a more structured form of collaboration in the everyday life. Amongst the different results of the design exercise, the most characteristic example of this attitude is probably the scenario “the sweeping band” (see photo-story in the visualization section below): the natural inclination to meet with friends and play music in an informal way is made functional, instrumental to organise the cleaning of the neighbourhood’s streets. Participants playing the music are entertaining the others sweeping the streets and gardening public green. The result is probably a not very efficient operation: the band goes up and down the streets according to the mood of the music, not cleaning systematically but enjoying a mix of both superficial and structured collaboration.

The other examples of setting up shared spaces in existing housing structures or healthy shopping and cooking groups (see photo-stories on www.sustainable-everyday.net/ccslproject) are also based on the same dynamic. A group of single students rents together a supplementary room on the same floor with the main purpose of creating a collective space or an enlarged living room where to meet and socialise, something they could not afford in their respective flats. The members of the healthy diet network connect and exchange tips through the Internet but this networking is obviously functional to the pleasure of shopping, cooking and enjoying a meal together.

This pervasive mix of superficial and structured collaboration exposes both the potentialities and limits of collaborative services in Brazil, related to the basilar dichotomy of the country's social, cultural and psychological norms. Structured collaboration will work better if at least in appearance it looks more like a game, not a rule. The relational qualities that emerge from this form of collaboration may be of a high level and contribute to the improvement of social fabric, or not. Conversely, for any solution to be successful from the point of view of its functionality and performance (as the resolution of a problem, i.e. the streets need to be cleaned) needs to rely in some form of systematization and organization capacities that depends on each participant being able to assume a certain level of responsibility and commitment.

The historical traces of "informality, innocent liberty, labor as a game, indiscipline, rejection of labor as an obligation, lose sociability and unpredictability" (Ianni, 2005) are considered to some extent, as a myth of the past but also acknowledged as the reasons for a historically weak civil society. These characteristics can however be interpreted also as positive when seen as a fluid and open social dynamic where diffuse creativity can flourish and spread. In fact, a more positive picture may be traced in the face of contemporary transformations, for example, on how society has been appropriating of new technologies and their participative and relational possibilities.

5. Conclusions...

Within the design research framework, the results offered by the design exercised have in great measure complemented and refined what has emerged from the process carried out with experts (researchers from many areas, NGOs, civil society operators, etc) in Brazil, India and China. It has been an effective approach to contextualise some service ideas into social, economic and cultural particularities of the three countries, based in the knowledge of some cities.

In these emerging countries, creative communities are found in a grey area, blurred with other bottom-up initiatives and attitudes traditionally linked with basic needs and income generation. The visualisations produced through the design exercise, have for example indicated fresh perspectives for linking collaborative services with micro-entrepreneurship, expanding the late towards a collaborative and collective model.

They have also pointed other important factors that come to play for the spreading of collaborative services, revealing non-obvious social and cultural aspects. The demand for an improved sociality among neighbourhoods, the sense of belonging to a community and creating social connections are issues normally attributed to industrialised countries, immersed in a deep process of hyper individualisation, as observed in Europe by the EMUDE research. The design process has suggested that these are phenomena that appear to have a significant weight also in the urban environment of emerging countries, even in those that are widely acknowledged by spontaneous socialization.

As in the previous European research (EMUDE), the design thinking has been decisive for the research process in CCSL, founded upon systematic collection of information, production of text and visual results. In CCSL, the design approach was valuable and decisive for contextualising service ideas and communicating them back to society, helping to give a concrete form to visions of well being, essential to promote the desired social leapfrog towards a sustainable society.

Next steps…

The results of CCSL in Brazil, India and China have opened up new opportunities to discuss creative communities and promising cases as new models of sustainable lifestyles at a worldwide scale. The next step to CCSL will be to verify if this attitude exists and is workable in Africa. And if yes, discuss what would be the form and particularities that these concepts can assume in the African continent, with a special focus on its emerging urban societies.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Transport in a systemic perspective

How can we change attitudes and behaviours in people?

Rebecca Pera[1]

Abstract

The article investigates transport mobility of an industrial area close to Turin (Torino Ovest Produce), which includes 30 enterprises with 2500 employees. The project, financed by Regione Piemonte, aims to reduce employees' private transport by encouraging the use of public and collective transport. The work highlights the need for sophisticated qualitative and quantitative research data as the basis for the implementation of an innovative systemic design methodology.

In specific the present work outlines possible answers to the following research questions: is it possible to change collective transport behaviours? What kind of marketing strategies could encourage behavioural shifts?

[1] Politecnico di Torino (ITALY) - DIPRADI department. PhD, assistant researcher and lecturer. E-mail: rebecca.pera@polito.it

1. Aim and theoretical introduction

The general goal of the work is to propose a theoretical model of alternative transport for industrial areas. The study intentends to provide an answer to a research question which has not played a crucial object for many other studies (Steg et al. 2001): which elements of a mobility system's design are particularly significant in attitude and behavioural shifts? In practice, in relation to the individual component of transport, research usually focuses on needs (depending on age, income, education level, houseld situation, etc.) and abilities-opportunities (depending on people's phisycal condition, etc) and it is generally measured with a utility-based perspective which analyzes the economic benefits that people derive from access to spatially distributed activities. Utility-based approaches assume that travellers respond to initiatives in a strictly rational manner (the increase of the prize in petrol will lead to behavioural shifts). The present thesis focuses on the "softer" aspects of the decision process (mental models, attitudes, needs) which are rekoned to be crucial in changing behaviour. Given the socio-economic population characteristics, people's opportunities and behaviours are co-determined by attitudes. These, in turn, are influenced by both affected-reasond factors (e.g. status, privacy) and instrumental-reasoned factors (perceived costs and benefits of travel) determined by the transport system (Steg et al. 2001).

This approach intends to benefit especially three categories: individual employers, the enterprises of the analyzed area and finally local community. The first will benefit economically and socially, the second will have the chance to communicate the will to be concretely socially responsible, and will have the possibility to enhance employees' belonging feeling to a community and their overall job satisfaction. Adopting a transport plan may lead to tax reductions for enterprises as well. Finally the system will be effective for the community by reducing pollution, road congestion and by enhancing road safety. The general aim is to improve quality of life. The applied outcome of the thesis will be the basis for systemic design, and will focus (this phase of the research has just begun and will be accomplished within a year) on the qualitative relations proposed in this work, which will be developed according to non-linear processes.

The paper is articulated in the following parts:

- Knowledge value on consumer behaviour in design strategies;
- Presentation of a case study (object, phases of the research, presentation of the main outcomes)
- A set of possible ideas to be developed in the design phase
- Needs, attitudes and behaviours referred to transport
- Communication strategies
- Directions for pursuing further research

2. Consumer behaviour analysis

Information and knowledge play a central role in customer orientation and are essential for the design of a product-service. One reason information is valuable is that, in general, we don't know as much we think we do and what we think we know is often wrong. One clear example of not knowing as much as we think we do is overconfidence. Typically when we forecast, we place too small a range around a forecast (view examples in Mahajan 1992). However, to focus on aspects useful for the present issue, what kind of research methods are generally applied to study consumers and gather information?

When using a scientific approach it is essential to start by an assumption: no scientific method is the very best, every research system is functional to its goals. Each research hides a thinking system that should have a scientific base, clearly declared.

Before presenting the methodology that has been designed for this study, it is advisable to synthetically present the key characteristics in quantitative and qualitative research methodologies.

In order do get to know consumers or potential ones, quantitative, qualitative and creative methodologies have been used, each characterized by shortcomings and advantages.

– **Quantitative methodologies** are substantially made of questionnaires with closed-end questions. The aim is to evaluate the presence and the extent of a given phenomenon. Therefore, representative samples of the population of interest are surveyed. Generally, however, they get interviewed on a certain matter only once. The advantages of this approach are represented by the statistical criteria used in order to allow predictive and statistically representative data concerning certain behaviours or attitudes. The limits of this methodology concern the superficial way of data collection, a factor connected with a significant need to simplify the questions in order to be understood that doesn't however allow a deep comprehension of a certain phenomenon.

– **Qualitative research** is an important source of insight and, on the contrary, are represented by in-depth psychological and motivational interview techniques, generally applied through direct meetings with single clients or groups. The advantages of qualitative methodologies consist in being able to survey in-depth a phenomenon, by identifying its causes and providing strategic instructions for planning product/service and communication improvements (these elements cannot be collected through a quantitative methodology). The limits of this approach lay in the fact that it is impossible to represent a phenomenon from a statistic point of view and, therefore, it is impossible to weigh and extend the obtained data to the population of interest (Vannoni 2002, 27).

– **Creative methodologies** are a particular version of qualitative techniques. The aim is to stimulate the ideas of a group of people (customers often) in order to identify possible new services and communication strategies. They represent a very sophisticated strategic tool, although they also have the same limits of qualitative research methodologies (Pera 2005, 177).

3. Case study: research object

Almost 30 small-medium enterprises are based in the area and great commercial and industrial expansion is forecast for the near future. At present approximately 2500 people commute everyday. The study has taken in consideration employees' means of transport and the scripts they tend to adopt (behaviours, habits, routes, stops) analyzing weaknesses and opportunities. Softer aspects have also been investigated such as motivations, beliefs, attitudes towards private and public transport.

Partners of the study

Regione Piemonte has financed a two-year research programme in which our department (Industrial Design – Faculty of Architecture – Politecnico di Torino) is project leader - transport agencies (GTT Spa, Car City Club) and local municipalities (Pianezza, Collegno) are also partners of the project, which has been coordinated by CAA (Consorzio Artigiano Autoriparatori).

3.1 Research phases

The research is structured in two years: the first is dedicated to a quail-quantitative data collection, the second, which has just started, focuses on the application of a systemic design approach to the issue. The first part has been carried out through the following steps:

First year (ended in April 08)

1. Analysis of opportunities and weaknesses of the area considering its accessibility and mobility;
2. Survey instrument: picture of employees' present mobility and propensity to take into consideration public transport and collective mobility.
3. Depth interviews on entrepreneurs and CEOs of the firms based in the area.
4. Qualitative group sessions: creative solution development with employees and transport experts
5. Design of possible guidelines related to the major attributes the system should have

Second year (by march 2009)

1. The next steps of the research are the following ones:
2. transport flows analysis from a systemic approach;
3. strategic multi-modal interchange knots;
4. technological evaluation;
5. *governance* and economic analysis;
6. multifunctional services design (number of vehicles, modalities…);
7. marketing and communication strategies.

3.2 Outcome of the study

The site's description: opportunities and weaknesses

In order to approach the topic of enterprises mobility in the most effective way it is necessary to frame the geographical area in its complex and start to describe its general accessibility. The terms "access" and "accessibility" in the literature are often used indiscriminately. Here, access is used when talking about a person's perspective, accessibility when using a location's perspective (Greus 2006, 22). Focusing on the passenger transport, we define accessibility as the extent to which land-use and transport systems enable (groups) of individuals to reach activities of destinations by means of a (combination of) transport mode(s) (Greus 2006, 201). Although the study focuses on the aspect of transport systems related to accessibility, land-use and urban policy making play a crucial role which should be also taken into account (that would however broaden excessively the present thesis). This would allow an even deeper understanding of why people (85%) use private transport and what could be planned to reduce the number.

The area under study is characterized by a land-use system that mainly comprises factories, offices, and shopping centres. The area is linked to a "nature area" (Parco Dora) whereas locations for houses, schools, leisure activities, etc. aren't present (very low diversity). The area of analysis can be easily located due to its concentration - it is bordered by two major roads (high-ways and free-ways) which allow a positive assessment of its location (studies on the location preferences of entrepreneurs and empirical analysis of firm locations in Europe have indicated distance to road and railway infrastructure as an important location factor (Bruinsma and Rietveld 1997; de Bok 2004). The area is at a 10 minutes from the centre of Turin (Porta Palazzo) by car and it is highly accessible by private transport. Other all a great availability of parking spaces within the area encourage the use of car. High car accessibility and no problems in parking spaces encourage the entry of 2000 cars a day.

Poor connections to public transport

In order to promote change behaviours from the use of car to the use of public transport it is certainly necessary an improvement of the latter.

During each phase of the research this aspect has been perceived as the most critical. The connections between the main areas from which employees come from and from possible strategic changing points (underground final station, bus stops…) to the industrial area appear very poor.

Negotiation has begun with transport agencies with the aim to ask better direct connections to the area.

Problems in pedestrian connections to bus stops

A negative perception of public transport accessibility has also been favoured because of poor pedestrian crossings, lighting, sidewalks… These elements increase risk perception, especially during certain moments of the day.

A flow analysis of the area in order to design different paths would be advisable. These should differ in regard to:

- goods flows;
- cars flows;
- pedestrian flows;
- cycle flows.

The demand of mobility: quantitative data on potential consumers

The quantitative survey intends to synthesize data useful to represent significant elements for the design of the services. Data collection has been carried out through professional interviewers who operated personal interviews, somministrating the questionnaire directly to respondents. A significant sample has been investigated (more than 10% of the universe of reference – 250 questionnaires over a total of 2300 labour force). Service demand is constituted by the following variables, which are a result of the structure of the questionnaire.

The client of the service: the majority of employees are young people: 60% is under 40 and 30% is between 40 and 50.More than half has a high school qualification (60%) and only a small group has achieved a degree (14%).

Scripts and behaviours: more than 60% of the sample arrives from the near municipalities, the remaining live in Turin. 70% takes 30 minutes and 22% less than 15. Average distance between origin and destination is 10-25 Kms. 65% of the sample goes directly to work, the remaining percentage stops during the journey to work because of children to drop off, or errands to accomplish on the way home. 85% gets to work alone with private means of transport; 15% with public transport because without alternative choice (they do not own a car).

Willingness to change patterns and modes: who travels by car perceives public transport insufficient (45%). Car ownership is associated to freedom, comfort, time-saving. Respondents declare a non-use of sustainable transport because of poor infrastructures. Public transport would be a possibility if the area was better served and if they could access to economic benefits on annual fares. 35% is willing to shift to car pooling at the following conditions: if the service is organized by their firm, if the journey takes not more than a time and half referred to the present one, and if the know the people they would share the journey with.

The demand of mobility: qualitative individual interviews on enterprises

As a result of the qualitative interviews carried out by professionals on owners and CEOs of the firms based in the area, a critical aspects seems to emerge: a medium-low perception of the problem. Mobility appears to be a problem, which however has little to do with enterprises. The possibility of perceiving mobility as an opportunity for the firm which has a way to communicate social responsibility to collectivity, to enhance employees' satisfaction and therefore productivity does not occur (with a limited number of exceptions) in the research. An extrinsic further aspect to the theme of mobility and accessibility but however relevant to the general goal of the project, is firms' low sense of being part of a system. The 30 enterprises tend to think individually instead of approaching problems and issues as a system. This is why many problems have yet not been solved (security, rubbish…): the enterprises based in the area are generally small (or medium) and this means that generally speaking there is a lack of competences/organizational/economic power, necessary requirements to approach this kind of topic.

The system in this case should also include:

- public institutions (municipalities and regional government);
- transport agencies;
- employees.

The demand of mobility: analytical-creative group sessions

We have chosen, as methodology[2] for this part of the study, a set of techniques which integrates linguistic cognitive techniques with creative/prospective ones in order to understand

[2] We suggest for further readings, the following texts:

Floch J.M., 1990, Sémiotique, Marketing Et Communication. Sous Le Signes, Les Stratégies, Presses Universitaires De France, Paris.

Greimas A. J., 1983, Du Sens II - Essais Sémiotiques, Seuil, Paris.

Greimas A. J. e Courtés J., 1979, Sémiotique: Dictionnaire Raisonné de la Theorie du Language, Hachette, Paris.

Greimas A.J., 1976, Sémiotique et Sciences Sociales, Editions du Seuil, Paris.

Pera R., 2005, Intuizione creative e generazione di idee, Utet, Torino.

values, expectations, needs, attitudes and mental models of the people under study in relation to the present issue. Participants were a mixture of employees of different firms and mobility experts (14 people). The session lasted 4 hours and it took place in March 2008 in a room offered by TOP – the public company for the development of the area.

The scientific covering laws of this methodology are drawn by structuralist semiotics and by neo-cognitive and neo-functionalist psychology, and refer fundamentally to the fact that mental models produced by respondents in relation to the topic under study, are the base from which the subjects create their attitudes and produce certain behaviours. We cannot think of this methodology as predictive of a certain behaviour, it has, in fact, a descriptive function.

The session has been organized in two phases:

Cognitive and linguistic phase

1. Individual presentation
2. Cognitive map on mobility to the area
3. Analytical discussion on weaknesses and opportunities
4. Discussion on the most significant quantitative data

Projective/Creative phase

1. Creative cards on possible solutions (car pooling, enterprises' shuttle, car sharing)
2. Collage on enterprises' shuttle
3. Collage on car pooling
4. Final discussion over the proposed ideas

3.3 A set of possible ideas to be developed

As it would not be possible to include in this presentation the application of every technique, a selection of the results will be presented. The participants have generated a number of ideas that can be grouped in three main categories: enterprises' shuttle, car-pooling, car sharing. For each category a description of the main attributes (positive values) and weaknesses will be given with a set of possible incentives and possible route flows.

Enterprise shuttle

This way of transport slightly reminds of the traditional school bus. Two versions have been proposed: the first imagines a service that picks employees up directly from home and takes them to work; the second aims to individuate a few strategic points (underground's final stop, a stop in the near municipalities, the roundabout near the area…) and link them to the different enterprises based in the area. The vehicles should therefore be small-medium sized able to be travel easily (stops should be few and not take long) and the presence of added services (air conditioned, tailored lighting, TV, Wi-Fi, possibility to book electronically ones shopping on board…) allows this mode of transport to be superior to the use of private car. The group perceives this service as highly innovative and positive also for its social benefits: home-work-home commute becomes a social moment and the vehicle could provide stimuli to the clients (a selection of books, CDs, audio-books on promotion by the shopping centres of the area). The core aspects of the service must be efficiency and reliability able to build trust. In order to provide a fast and precise service an accurate analysis of routes is required. An other attribute of the service is multi-functionality. The shuttle would benefit cost wise if used flexibly (it could be used

Vannoni D., 2001, *Manuale di psicologia della comunicazione persusiva*, Utet, Torino.
Vannoni D., 1998, *Della pubblicità, mente contesti, mondi immaginari*, Giappichelli, Torino.

by employees at certain hours of the day and to pick up customers of the commercial activities at others). The product-service provides a strong feeling of being part of a community and this element should be emphasized by communication and marketing strategies. A group of aspiration is often represented, constituted by individuals who actively make a choice, different from the majority's one. Employees are part of an ethically important project able to communicate social responsibility and sensitivity to environmental issues. The main barriers to the success of the service can be grouped in two areas:

– Cultural barriers: the object "car" still carries a strong symbolic meaning especially for individuals who have a strong need of status and ostentation.

– Economic-organizational barriers: great problems due to the average size of the enterprises based in the area for which it is not easy to face individually the issue under study. This thesis will theoretically develop the first category.

Possible incentives

A few benefits have been proposed:

– Coupons, free samples to be spent in the shopping centres of the area;

– Flexible working hours (entry and exit times) for who participates;

– Possibility to buy products in promotion by the commercial centres of the area.

Possible flows

In order to efficently design the service a number of strategic pick-up points should be individuated where employees will be collected and taken to work. Afterwords the shuttle could be used to take customers from the near municipalities to the shopping centres of the area under study.

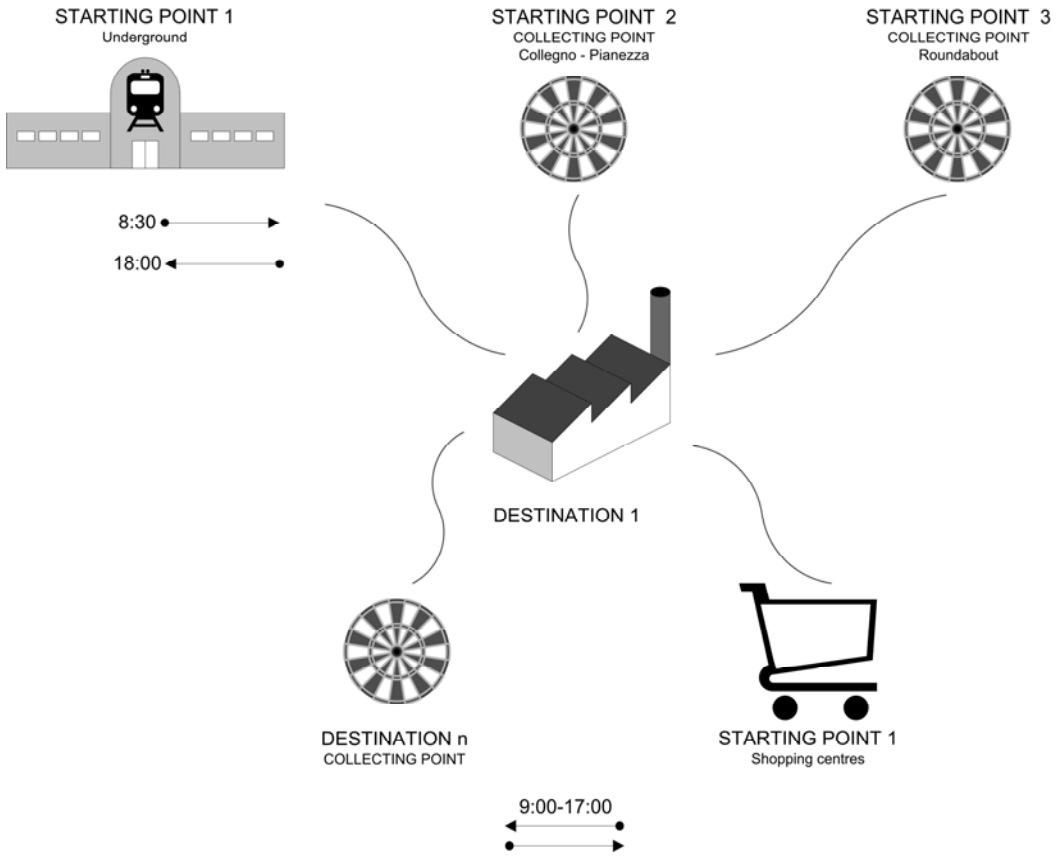

Fig. 1: Enterprises' shuttle flow

Car pooling

Car pooling intends to favour the development of automobile aggregation forms on daily routes. It allows car number reduction and related parking spaces. A cost reduction on petrol and overall pollution decrease is also evident. The goal of the session was to focus on strenghts and weaknessess of the system in order to understand and elicit how to seccesfully apply it to the investigated area. The survey has provided data that has been investigated throughly during the session. 34% would be willing to share the daily journey to work with collegues at the following conditions:

- Knowing the collegues they would share the journey with (39,3%);
- If the firm they work with organizes the service (24,6%).

The group has provided insight over the *present scenario* of individual travelling alone to work:

- Journey in loneliness;
- Higher costs;
- Stress due to traffic;
- Tiredness due traffic jams and accidents risks.

The group has imagined a possible scenario with the following benefits:

- Collegues company;
- Shared costs;
- relax;
- freedom to do something else (reading…).

The group states the need of a coordination unit able to manage the system and provide an answer to the main rigidities (travelilng only with known collegues) and manage also the economic aspects (embarassing for many). The connection between participants could be assured by the following tools: web site, e-mail, call center, sms…

Possible incentives

- Vouchers to be spent in the shopping centres of the area;
- Flexible working hours (entry and exit times) for who participates;
- Vouchers to enhance the category of insurance contracts;
- Discounts for changing ones car with an environmentally friend vehicle;
- Special parking spaces for car-poolers.

Possible flows

A possible flow is here proposed. A car pool car starts its route from a home 1, picks up a collegue at its home 2, and afterwords picks a third member up from an other strategic point (underground, railway station, roundabout close to the area…). The journey goes on dropping off one member at firm number 1, then firm number 2 and finally arrives at firm 3.

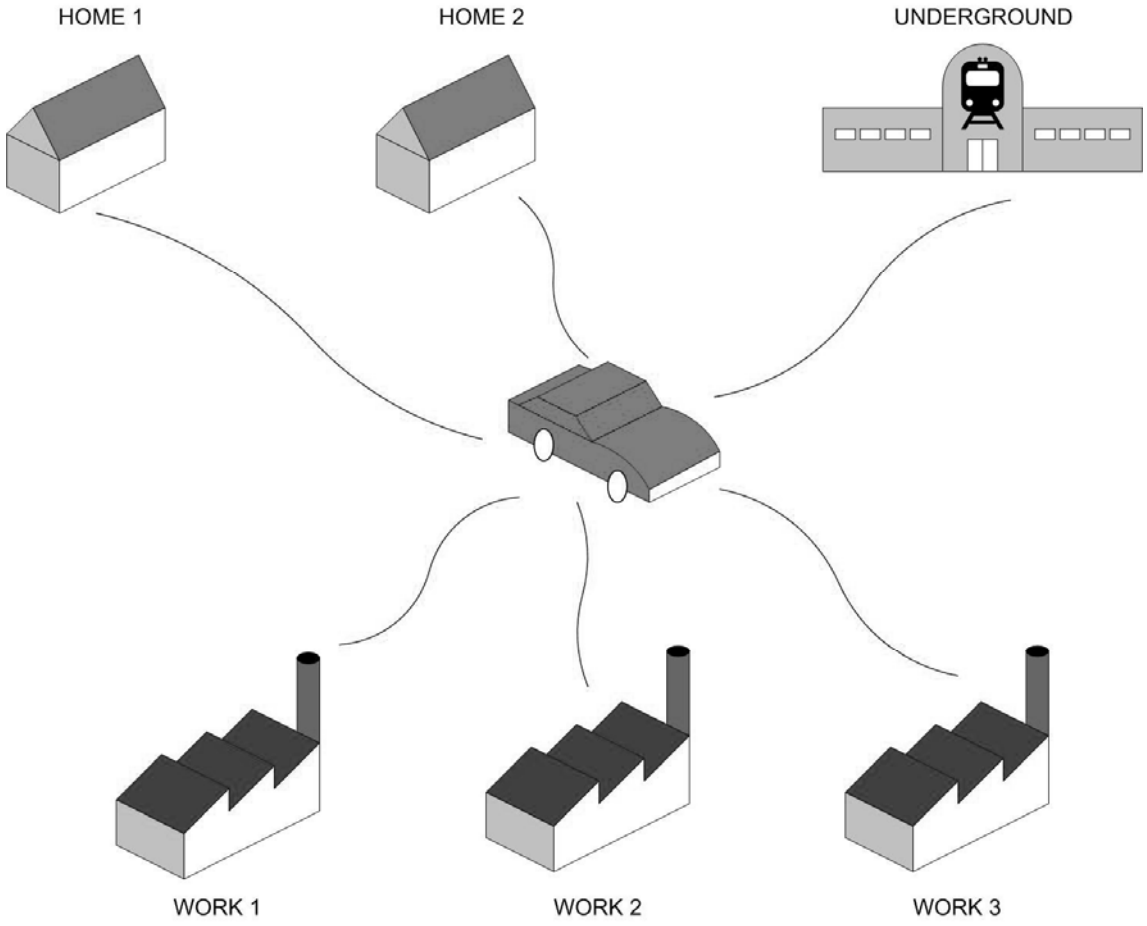

Fig. 2: car pooling flow

Car sharing

Car sharing is a service that permits the use of a car when reserved, picking it up and dropping it in a parking close to home, or work place and paying for the service received. This service is applied within sustainable mobility policies in order to encourage the shift from ownership to consumption. Automobile is no more a good but should be considered a service. Car sharing with environmental friendly cars could be usefull for:

- Professional commutes within firms (dfferent nature errands);
- Employees' work-home-work journeys;

This could be possible with the constitution of new "car sharing" parking spaces near the firms' location and homes.

Possible incentives

- Free CARD for the employees of the firms that have joined the project;
- Free annual fee for the employees of the firms that have joined the project;
- Flexible working hours (entry and exit times) for who participates;
- 20% hourly discount;
- 10% discount in relation to the fee one pays per Km.

Possible flows

A possible flow is here proposed. 1) A car sharing vehicle is used by a firm for professional movements and will be parked at the end of the day at the firm's parking space. Enterprise pays for the time and the kms for the "work-to-work" movements; 2) at the end of the day the employee picks the car up at work and goes home: he/she pays for the time and the Kms "work-home" he/she has used; 3) employee can use the car for leisure purposes during week-ends: he/she pays only the Kms he/she has done; 4) employee picks the car up at home and goes to work: he/she pays for the time and the Kms "home-work" that have been used.

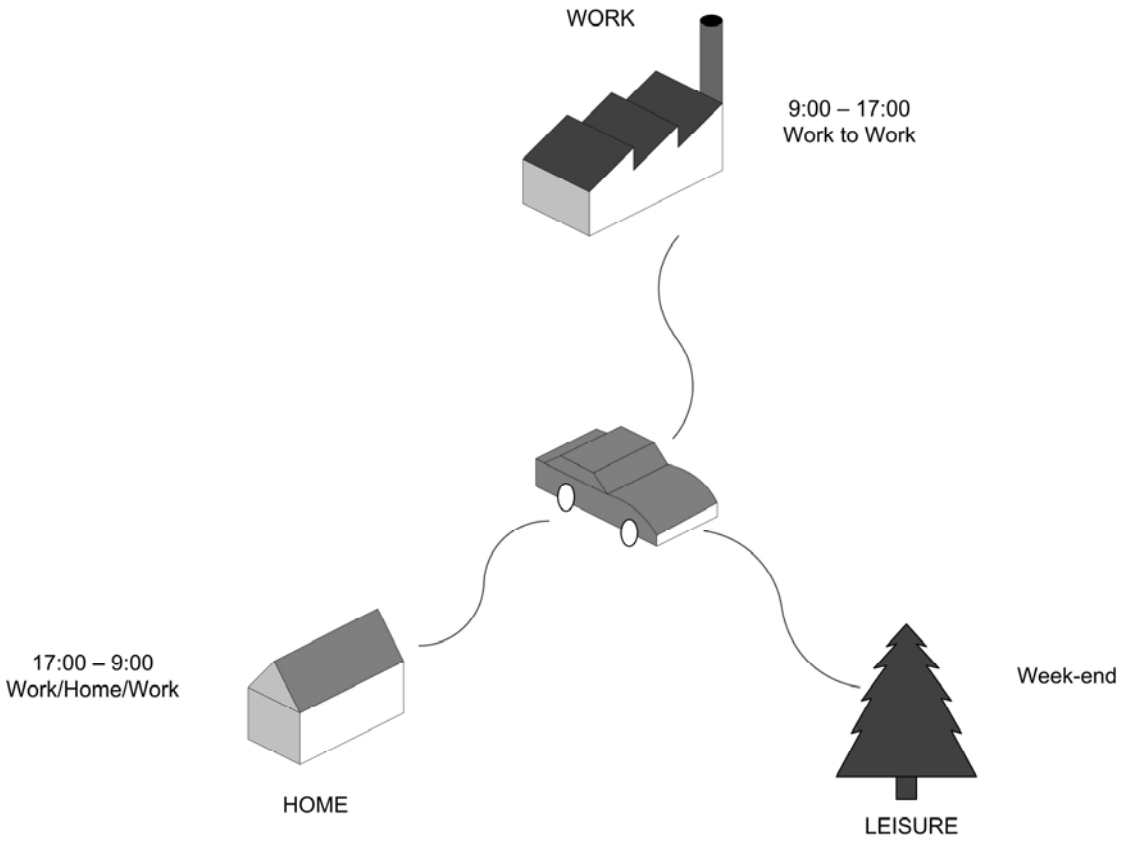

Fig. 3: car sharing flow

4. Needs and attributes of artefacts

It is possible to individuate the most significant attributes the artefacts above described should deliver in order to satisfy a number and level of individuals' needs which have emerged in the study. On one side a basic level of need (*functional-critical need*) emerges and is satisfied when the service is able to guarantee **efficiency** and **reliability** (time saving, cost saving…). On the other side, more abstract and emotional needs are evident: *social needs* that can be satisfied if the service favours a sense of **belonging**, community cohesion, social inclusion. At a *symbolic level* the attributes of the service should give importance to appeal able to create **desire**. The final level, the least tangible, is the one related to *self-fulfilment*, or the possibility to develop a human, very personal side of oneself. It implies an active change in behaviour opposed to the majority's one, endorsing a project that should be perceived as highly **significant**.

4.1 Attitudes and behaviours in transport

From a marketing perspective product-service innovation can follow two different processes: the first defined "technology push" that means that the initial creative process has been

processed within the company (usually r&s department) and then launched or "pushed" towards the market. The second strategy is called "market pull" and it implies that innovation is demanded, generated and defined by consumers (through market and consumer research) (Lambin 2004, 272; Lambin 2008, 12). The system we are proposing stands in the middle of these two processes: it is a "broad" concept of market that is demanding a shift in transport behaviour (stakeholders, public institutions, opinion leaders, green associations…). Strictly speaking demand is not generated by individuals (employees) who are, infact, generally quite satisfied of their private way of commuting. On the other side, potential consumers have been the centre of the system design which will generate its creative process by analyzing and taking into great considerations present consumers' needs, perceptions, values. The company (in this case we are referring to a mixed group of public institutions and private companies) will have to "push" the system because it will not easily be accepted (the main obstacle is defined below). The present approach is defined a societal marketing perspective: according to this concept marketing should be able to deliver superiour value to customers in a way that maintains or improves the consumer's and the society's well being (Kotler, Armstrong 2001, 20).

The major problem the services (enterprise's shuttles, car pool, car sharing), described in the previous paragraphes, could encounter if launched, are strong cultural and psychological barriers which represent a significant obstacle in the adoption and use of the system. And this leads us to attitudes, which can be defined as an enduring organization of motivational, emotional, perceptual, cognitive processes with respect to some aspect of our environment (Petty, Wegener, Fabriger 1997, 609-38). It is learned predisposition to respond in a consistently favorable or unfavorable manner with respect to a given object[3]. In relation to the issue of mobility it is useful to consider attitudes as having three components: cognitive (beliefs), affective (feelings), and behavioural (response tendencies). All three attitudes components tend to be consistent. This means that a change in one attitude component tends to produce related changes in the other components (Ruth 2001, 99-113). Marketing managers are ultimately concerned with influencing behaviour. But it is often difficult to influence behaviour directly. Let's see which appraoches can be applied in the present case.

– **Change the cognitive belief**: four basic strategies are used for altering the cognitive structure of a consumer's attitude a) change belief – shifting beliefs about the performance of the product-service on one or more attributes; b) shift importance – most consumers consider some product attributes to be more important than others. Marketers often try to convince consumers that those attributes on wich their brands are relatively strong are the most important; c) add beliefs – add new beliefs to the consumer's belief structure.

– **Change the affective component**: it is increasingly common for a firm to attempt to influence consumers' liking of its brand without directly influencing either beliefs or behaviour. Marketers use three basic approaches to directly increase affect: a) classical conditioning – a stimulus the audience likes, such as music, is consistently paired with the brand name. Over time some of the positive effects associated to the music will be transferred to the brand; b) affect towards the communication tools – liking the messages increases the tendency to like the product; c) mere exposure – while controversial, there is evidence that affect or product-service preference may also be increased by mere exposure (exposition on a large number of occasions).

– **Change the behavioural component**: behaviour, specifically purchase or use behaviour, may precede the development of cognition and affect. Changing behaviour prior to changing

[3] Attributes serve four key functions for individuals:

1. Knowledge function: some attitudes serve primarily as a means of organizing beliefs about objects or activities.
2. Value-expressive function: other attitudes are formed and serve to express an individual's central values and self-concept.
3. Utilitarian function: it is based on operant conditioning (reward or punishment).
4. Ego-defensive function: people form and use attitudes to defend their egos and self-images against threats and shortcomings (Katz 1960, 163-204). For discussion on a fifth function, social identity, see Grewal, Metha, Kardes 2000, 233-52.

affect or cognition is based primarily on operant conditioning. Thus, the key marketing task is to induce people to purchase or consume a product while ensuring that the purchase or consumption will indeed be rewarding. Coupons, free samples, point-of-purchase displays, price reductions, etc, are common techniqus for inducing trial behaviour. Since behaviour often leads to strong positive attitudes toward the consumer brand, it is possible to believe that this strategy would be effective in changing transport attitudes.

5. Communication strategies

A guideline for a persuasive strategy is outlined in order to provide possible suggestions to overcome the first barrier category (employees' social and cultural rigidity). Throughout the study three attitude categories appear to be the most significant (a number of others have been proposed in the study but they do not appear as so definite). It would be interesting to focus on these in relation to communication processes[4].

– **The status and ostentation attitude**

Automobile still carries a strong symbolic meaning especially for individuals who have a deeply developed need of *status*, ostentation and power. For this category giving up their car (or limiting its use) has a strong social shortcoming. This attitude is caracterized by low involvement to the issue which is not perceived as relevant and has not been recognized as a problem. Behavioural change appears improbable (a possibility can be thought in the long term). It is the most difficult category to capture. Positive cognitive components of communication strategies would probably have limited effect: individuals in this category will probably avoid messages that are counter to their attitude (tendency to discount them). This attitude leads to 1) an emotional and rational low involvement, 2) limited attention, focused on peripheral service-related features and on feelings; 3) low or nonconscious information processing; 4) persuasion operates through classical conditioning; lattitude toward the communication; and nonconscious belief changes lead to a behavioural and attitude change.

It appears that mere exposure to the system could possibly be a way to change attitude in this category. The system's users should however be perceived as a strong aspiration group whose ability to communicate economic and social power has not been undermined by the use of the system (possibly even enhanced). In relation to a communication process, as individuals in this attitude will probably process information in the following way: affective-behavioural-cognitive, it is advisable the use of an attractive and appealing source of communication with a use of affective and symbolic formats.

– **The freedom attitude**

This category is constituted by individuals who associates travelling by private car to *freedom*, opposed to the concepts of bounderies and constraints, typical of public and collective mobility systems. Although reality seems to disconfirm this stereotype (iadvertising and marketing tend to represent automobile in immense and isolated landscapes, but the realities of large cities is certainly different - the experience of traffic jams is quite common).

This attitude leads to 1) an emotional but low involvement, 2) limited attention, focused on peripheral service-related features and on feelings; 3) low or nonconscious information processing; 4) persuasion operates through classical conditioning; attitude toward the communication; and nonconscious belief changes lead to a behavioural and attitude change.

The freedom attitude will process information in the following way: affective-cognitive-behavioural.

The concept of freedom should be transferred to the new system that should emphasize the ability to provide customers with the freedom to do something else instead of driving (reading, chatting with colleagues, relaxing). The main factual feature of the system should be flexibility

[4] The attitudes categories which are proposed can be considered only as a supposition, qualitatevely relevant but without statistical significance.

and it must be communicated with value-expressive appeals (maybe with humour formats or social representation).

Application: design a trial behaviour project with the goal to select the most desirable elements of the services and package a highly rewarding service (operant conditioning) “trial project” of a short length of time before the real implementation. A group of aspiration could be selected at first (charismatic, innovative, creative opinion leaders) and then extend the process to everybody (two step flow communication).

– **The practical-functional attitude**

This category is constituted by individuals who allready perceive transport as a problem: iit is willing to change travel behaviour if presented with an efficient and reliable service (public and collective modes). Behavioural change is highly possible (even in the short term).

This attitude leads to 1) high rational involvement, 2) strong attention focused on central service-related features and factual information; 3) conscious thoughts about service attributes and use outcomes; 4) persuasion generally alters beliefs, which influence attitude, which influences behavioural intentions.

Individuals in this category carry out a cost-benefit analysis comparing alternatives, therefore comparative formats of information should be provided by a credible source of information. The practical-functional attitude will process information in the following way: cognitive-affective-behavioural.

In conclusion it is possible to state that solutions exist and are able to satisfy a number of needs; they need to create attention, awareness and desire to be adopted. A vertical-logical decision process is not enough to change embedded behaviours. Communication strategies should be able to communicate the idea that he/she who uses collective transport is the clever employee, the one who is the first to experiment and be innovative, the opposite to an old-fashioned and conservative person who needs to show off going to work with a new car.

The tools, added services, interfaces, communicational strategies, social network initiatives should be creative and appropriate in order to encourage the “tasting” of the services by employees and therefore stimulate a further and more permanent shift in attitude and therefore in a stable behaviour.

Directions for pursuing further research

This thesis has reflected several initial steps to help with the design of alternative modes of transport for industrial areas. The many directions in which further research can be pursued will be discussed below.

A first, and theoretically attractive, could fosus the person-based accessibility approach, which could also reveal higher accessibility benefits than utility-based measures, derived from conventional trip-based transport demand models. For example, intensive mixed land-use policy strategies increase the density and diversity of activities of the area (at present exclusively industrial and commercial) and may result in more complex accessibility and travel behaviour patterns, since individuals are then better capable of combining trip purposes and making multipurpose trips.

A second could be directed at examining the potential impacts of ICT on accessibility and mobility of an area. The accessibility approaches developed in thisi study focused on physical mobility and information and communication technology are only proposed rekated to the management of the system. To date, there is little information on how people’s use of ICT affect their individual their individual accessibility and quality of life with respect to mobility and activity patterns and accessibility (Geurs 2006, 221): ICT may for example relax spatial and temporal constriants that limit mobility and accessibility (Kwan, Weber, 2003) or maybe it could erase or decrease the need of mobility (teleworking).

A third direction for pursuit could focus on the social impacts of transport changes (ex post evaluation). In general, relatively little work seems to have been done to develop methods, tools, techniques to rigorously estimate probable social-psychological effects of transport changes. To date, social impact assessments typically focus on accessibility impacts, traffic safety, noise and

air quality, visual impacts. The works which could be taken into consideration could be the manuals on assessment methodologies for transport investments that have been recently developed in the UK (DfT, 2000) and in the US (Forcken and Weisbrod, 2001).

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Designing Innovation collecting Wishes

A method to integrate individual users into the product innovation process

Kohei Nishiyama[1], Pier Paolo Peruccio[2]

Abstract

This paper explores certain phenomena of innovation ascribable to the area of process mediators, those who facilitate and promote consumer access to products. Precisely the mediation processes, acknowledged as having strategic importance in the race toward innovation, are undergoing a trend crisis today: a weak phase that in the broad view includes design culture (Celaschi 2007, 34-38)[3].

In particular the aim of the paper is to investigate applications of the DTO (Design to Order) business model to various contexts. More important, it includes a case study of the company Elephant Design and its website *cuusoo.com*.

[1] Elephant Design co. ldt (Japan), nishiyama@cuusoo.com
[2] Politecnico di Torino (Italy), 1 Facoltà di Architettura, DIPRADI, pierpaolo.peruccio@polito.it

[3] "A trend crisis in mediation processes" is the fitting slogan used by Celaschi to indicate the current weak phase. This crisis involves design as well as all the actors who mediate between production and consumption and regards:
- the economic-cultural system (with a shift in the economic barycentre from Western markets, in which society has slowly absorbed the economic model, to Oriental markets which have transitioned from underdevelopment to hyperdevelopment with an exponential growth of consumer processes);
- communication (experiment new communication processes suited to non-mass markets or SMEs that do not reach the traditional media),
- industrial design instruments (instruments and methods that are inadequate when designing immaterialized goods, services, experiences, anything that does not fall within the traditional way of understanding the discipline of design),
- the cultural growth and competencies of consumers, the creation of hyper-commodities;
- the separation of the global production system into two large systems: one that deals with goods and expendable materials and the other with finance, gold, oil, war. These two worlds will not be able to continue pretending they are not related to each other for much longer. (Celaschi 2007,34-36)

1. Introduction

There are essentially three indispensable actors in the design process of a product: the manufacturer, the consumer and – to bridge the two worlds – the so-called mediator of the process, who facilitates and promotes consumer access to products, working at the "mediation processes" (Celaschi 2007, 31). Acknowledged as having strategic importance in the race toward innovation, this kind of process is undergoing a trend crisis today: a weak phase that in the broad view includes design culture.

The mediator is the designer, which sometimes includes the people who work in advertising or distribution. In more general terms the role of mediation also is played by those who provide services to the design process.

This is a necessary premise for introducing Elephant Design[4], a company founded in 1997 by Kohei Nishiyama and Yosuke Masumoto to create an online network (during the dotcom boom) among companies, consumers and designers. Their purpose was clear: to put themselves in a barycentric position between the three main actors of any given design project. The means they chose is almost too obvious: the Internet and their own website cuusoo.com became a platform for these two worlds to communicate.

2. Aims

Elephant Design is Japanese user-community which since 1997 has been forming a community of users-innovators on the Internet. The result is extraordinary human capital capable of triggering sudden accelerations in the innovation processes of project culture and conceiving objects based on the specific desires of people.

Elephant Design uses the system *Design to Order* (DTO), a concept devised that same year by Nishiyama, for which a patent was registered at the end of the 1990s. In short it consists of the design of objects requested by consumers themselves (Peruccio 2008, Ogawa and Piller 2006). The methodology bridges the gap between consumers, designers and enterprises and fits nicely in the context of crowdsourcing

DTO is an innovative business model through which users express their wishes and the approximate product budget they can afford.

This methodology offers users the chance to get their desired products. Users in this case, are not only consumers, but also those who play an active role in getting what they really want. By using DTO, users innovations are self-marketed by users themselves, until an accumulated number of reservations reaches manufactures' break even point. In this way users reduce new product development risks for manufacturers by demonstrating their purchase commitments upfront. By this methodology users make reservations for product ideas while manufactures choose to invest to produce ideas which are identified as having controlled risks.

From its website *cuusoo.com* (a Japanese word that means *ideal*) Elephant Design listens to the wishes of people, which are almost always objects that have never been

[4] Elephant Design is a community formed by 2300 designer members, 530 companies, nearly all Japanese SMEs, and the users amount to over 23,000 potential buyers. The main office is in Tokyo where 14 people work, and nearly all of them are young (average age 32). They follow the system closely and provide assistance to the numerous visitors of the website.

manufactured. If after a few days – sometimes even weeks or months – the orders for that product reach a minimum threshold, production is started.

On this website users can purchase products that are already published in the catalogue. Up to this point there is nothing new. But these products are made according to the descriptions of the desires of other users. In other words they are described, requested and voted. Finally they are designed and built.

If you don't find what you want or something that satisfies you at cuusoo.com, you can go to a section on the website to describe your object in detail. Your description is examined by Elephant Design and, after conducting an economic feasibility study, it is shown with a price next to it depending on the quantities produced. At this point the orders can be made and may lead to the object being produced.

The *cuusoo index* at the website next to the products indicates the probability (by of percentage) that the object requested on the Web and then designed will actually enter production at a company in Japan, in Italy or anywhere.

Any designer can try out his/her design capabilities by entering a consumer description. The companies can also go online to gauge interest in an object and decide whether or not to produce it and in what quantities. Naturally the price may also vary depending on the demand for the product. In fact *cuusoo.com* is a virtual market.

There are many benefits to this system. Whereas in a traditional process the company sustains an investment and the entrepreneur risks capital, here the dynamic is extremely transparent. There are no leftovers in the warehouse because the products are not mass-produced but only in the quantities requested by the consumers. The consumers can choose not only items that are available on the market but request the design and production of their ideas, wishes and dreams.

Elephant Design gathers this information and forecasts the costs. Then the system finds a company interested in making it and the price is determined.

This system offers advantages to designers too. These creatives rarely ever see the materialization of their works because they often just make sketches, computer elaborations or prototypes. So in this system they naturally benefit, and not only in terms of image and glory. If the objects they produce are sold, the royalties are distributed among the partners who participated in the process.

For certain products today you have to wait a long time, sometimes even a year, before the *cuusoo index* gives the go-ahead for production[5]. One reason for this is the language of the website, which today is only in Japanese. The language barrier has prevented the market from expanding and the platform from connecting the three actors.

Elephant Design is not the only virtual design opportunity out there.

Other companies exist that have used the same principle of DTO or similar systems, e.g. “Custom Mass Production” (Elofson and Robinson 1998).

[5] Some of the more successful products are the sofa designed in 2003 by Fumie Shibata and sold by Muji: besides being quite popular with customers, it is also the most widely sold item at the Muji. Among those waiting to enter the production phase is the bear shaped TV remote control (nuigurumi-kun) designed by graphic artist Hibiki Tokiwa. An attempt was made to change the form of a remote control to make it easier to recognize at home. So here we have the proposal of a little teddy bear: if you rotate its head, it turns the TV on or off; by moving the front legs you regulate the volume and change the channel. The time component is another interesting aspect of the system. It is remarkable that The “Muji Lamp”, a wireless lamp designed by Jun Maekawa in 2002, was transformed from an idea into a product in only 18 days. Cigarro (Personal Computer for CEOs) is the computer designed in 2000 by Masamichi Katayama, manufactured and distributed by ABA-House. As soon as it appeared on the webpage, it product promptly drew the number of orders required to start production. At that time consumers were willing to pay even $4000 to have it, about twice the price of similar products on the market.

Deluxe Washing Machine is the name of a washing machine shaped like a doughnut that was first described on the Internet site, then ordered and designed in 1999 by the architecture studio Klein Dytham. It is a home appliance made of a soft plastic semitransparent material which makes it comfortable for sitting on the washing machine in the living room or the bedroom.

There is also the well-known *threadless.com*, a North American fashion company founded in 2000 by Jake Nickell and Jacob De Hart (Ogawa and Piller 2006, 66) whose DTO principle is applied to the youth fashion sector, more specifically T-shirts[6]. We would also like to mention the British company *BuilderSite* which applies the same principle to the construction sector to promote interactions between builders and users who want to renovate their homes. Then there is the company *iStockphoto* for photographs, *Ninesigma* (an immense creativity workshop for problem solving) and ZERI, a community of scientists founded by Gunter Pauli and committed all over the world to transform outputs from one factory into inputs for another factory with the goal of arriving at zero emissions (Pauli 1999, 247-249).

These phenomena can be ascribed to Crowdsourcing (a neologism formed by *crowd* and *outsourcing*) invented and outlined by Jeff Howe in 2006 in the magazine *Wired* (Howe 2006) to describe the phenomenon of externalization, mainly of creativity, by exploiting the aggregating power of the Internet to build a network of creatives, scientists, photographers, interior decorators, designers, etc.

After all, the strength of the network and its connective tissue eliminates the distance between people and companies and enables the "crowd" to become involved in the creative process. It connects an immense heterogeneous bunch of talents by means of e-mail, blogs, communities and chat rooms. This is the real innovation of the 21st century.

It is an extraordinary human resources tank you can draw from for innovation: "How Mass Collaboration Changes Everything" is the Wikinomics heading (Tapscott and Williams 2006), a metaphor for this approach to economics: new trends have demolished, among other things, the traditional concept of marketing (Kotler 1999). The digital revolution has opened the door of the global market to companies (niche companies and SMEs alike), and the Web has given them access to information. This has accelerated some market processes that no longer require huge investments in market surveys or advertising (see the crowdsourcing case).

This process of bringing companies closer to consumers allows the latter to become the producers (or "prosumers", a term coined in the 1980s by Alvin Toffler). This reflects a change in the role and activities of the "model consumer" thanks to the use of information and low-cost services and it is the basis for democratizing the innovation process as pointed out by Von Hippel.

When I say that innovation is being democratized, I mean that users of products and services – both firms and individuals consumers – are increasingly able to innovate for themselves. User-centred innovation processes offer great advantages over the manufacturer-centric innovation development systems that have been the mainstay of commerce for hundreds of years. Users that innovate can develop exactly what they want, rather than relying on manufacturers to act as their (often very imperfect) agents. Moreover, individual users do not have to develop everything they need on their own: they can benefit from innovations developed and freely shared by others. The trend toward democratizing innovation applies to information products, such as software, and physical products (Von Hippel, 2005, p.1).

Central to these processes is the Internet and its evolution (Web 2.0 or Internet 2.0) with particular focus on the content, information and relations among people and various hardware and software platforms.

Some interesting phenomena, such as *citizen journalism* or the creation of an online encyclopaedia like Wikipedia, demonstrate that there are people in the world who are willing to seriously contribute to a shared project using their own experience, know-how, talent and, last but not least, time. In the case of an encyclopaedia, the high quality standards of the product are guaranteed by responsible users (the majority) who regularly correct the information entered by

[6] Anyone can register at the website and propose their design. Once it is online the design is open for seven days to voting and the opinion of a vast community of prosumers. If it gets beyond this stringent selection, the design becomes a T-shirt, enters the production phase and generates immediate revenue for the inventor.

vandals or misinformed users, much like a living organism defeats viruses with the help of antibodies.

Citizen journalism shows that in our epoch, characterized by an excess of information, the role of some process mediators has become almost pleonastic, like that of journalists. Leaving aside the issue of the authoritativeness of newspapers, we are starting to realize the growing importance of being informed about what is happening in the world in real time. If news of a tragic event arrives while a newspaper is being written, the editorial office sends a reporter and a photographer to the scene. These professionals merely "record" what others have seen or heard or they fixate on a given image of the scene much later than the witnesses perceived and/or recorded their own images.

Eyewitness snapshots or video clips and descriptions are much more interesting and realistic. *Citizen journalism* is booming. Every day the Web, newspapers and TV programs dip into the huge well of new crowdsourced news stories.

There is a short transition from *citizen journalist* to the *citizen innovator* of Von Hippel. Who truly knows a certain product thoroughly? Not the manufacturer …and not even the designer. However, the people who use it habitually have all the information needed to improve it. This mother lode of knowledge should be shared free of charge according to the aforementioned Democracy of Innovation model (Von Hippel 2005).

The Internet has been one of the major driving behind the transition from the mass-production paradigm to the mass-customization model with its redefinition of relations between enterprises and the market. With the approach of mass-customization, companies have abandoned the MTS (Make to Stock) model to embrace a more evolved BTO (Build to Order) production model. This model inevitably entails an approach of companies relating more directly to customers. It also enables personalization and adaptation of the product to specific customer needs (Pine 1993). Customers in the system of mass-customization are at the beginning of the value chain. In other words, the enterprise will produce only what consumers actually need or desire, thus delineating the figure of the prosumer who collaborates in the production process and participates in defining what he/she wants to buy. The result is a tailored product.

With the application of the DTO system there is an additional development and mass-customization is surpassed to arrive at a model that involves the following stages: prepurchase, judgments (the voting process) with the participation of a large number of customers (the Network users). This process clearly goes beyond the traditional system of market surveys which collect and interpret customer needs (Market pull) or introduce new technology into products that are already well-established on the market (Technology push). It innovates the process in a way that goes beyond traditional marketing models, thereby generating (see the *cuusoo.com* case and the *zeri.org* case) extraordinary phenomena of innovation which is not expected from the market. Equally important is the freedom from risk for companies because the products designed on platforms such as *cuusoo.com* or *threadless.com* are wanted, designed, voted and reserved. This innovation process is also called "Collective customer commitment" and it totally absorbs the customer while sparing companies the risk of flops (Ogawa and Piller 2006).

This group of users includes all the user-innovators identified by Von Hippel as "Lead Users" (Von Hippel 1986), i.e. consumers who are particularly competent and sophisticated, with a high degree of expertise, who can develop innovative solutions for companies in full autonomy, but also users from additional user communities for group purchasing as well as more "passive" participants such as ROM (Read Only Members).

This creative approach, indebted to the neo-Lamarckian theory (which says evolution is based on environmental factors (Johnson-Laird 1993)) mainly mirrors the characteristics of a living system: all the desired products are submitted to self-selection by the users themselves and the "negative" ideas are automatically removed from the wishes system. Self-selection occurs when we accept the state of disorder implicit in the fragmentation and segmentation of skills within the community. Therefore the members of the community of online prosumers (virtual) – and this is one of the most interesting aspects from the perspective of sociological dynamics –

make a selection from which the best products emerge.

In this methodology users reserve product ideas, while manufactures choose to invest in and produce ideas which are identified as having a controlled risk.

In the DTO model users' innovations are self-marketed by the users themselves until the number of reservations accumulated reaches the manufacturers' breakeven point. In this way, users reduce new product development risks for manufacturers by demonstrating their purchase commitments upfront (Nishiyama and Ogawa 2008).

Returning to ours case of cuusoo.com, innovation comes from the description of a desire: people who work in the world of design generally neglect the consideration of "generic needs" (innate, natural needs, intrinsic to the characteristics of each individual) and focus on derived or acquired needs that emerge from the ongoing dialectics of needs created by the social environment, cultural context and technological evolution. These derived needs already represent particular technological answers given to generic needs (Lambin 2004, 66-68). The automobile is an example of a need derived from a generic need for transportation: "In the marketing vision, derived needs constitute the base from which consumers develop desires and elaborate their own imagery of the product. In other words, consumers do not dream of new forms of individual mobility but want a certain type of automobile" (Deserti 2007, 99).

Thanks to its potentially vast outreach, and non-invasive means, the DTO model intercepts the demand of generic needs (e.g. sustainable mobility projects and process innovation elements) as well as "hidden needs" which are difficult to determine by traditional market analyses. This enables the DTO model to form a real competitive advantage for the company.

While the first innovative aspect for the company is the conception (and then production) of objects that have already become successful with the public, the second innovative aspect is that the goods have been sold a priori. This weighs significantly on the "trade value" of the goods (usually a concern of economists) in addition to the designer's focus on the so-called "utility value", a term which has been enriched with new meanings over the past few years (Celaschi 2007, 25)[7].

The DTO model postulates the presale of goods in which the relations between producers and final users are changed and the figure of the process mediator evolves. These actors alternate – thanks to the flow of information – and the values in play determine a new trade system.

[7] Contemporary goods nearly always have a "function" needed to determine their "utility value" (bicycles serve to get rapidly from point A to point B). Moreover the well-known "trade value" corresponds to the higher price of money that the consumer is willing to pay in exchange for using or having or owning the good. For more on this subject, see Celasci 2007, 25.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Knowledge cartographies

Tools for the social structures of knowledge

Marco Quaggiotto[1]

Abstract

This paper aims to propose a 'cartographic' approach to the representation of knowledge in its present configurations, with the aim to visually represent not so much a disciplinary partitioning, as the interconnection of the its composing entities, the paths that develop, the thematic and transdisciplinary domains that emerge.

A cartography of knowledge spaces that takes advantage of the experience developed by maps in the representation of complex and open spaces, historically able to hold heterogenous, natural and social elements together in the same picture.

The first section of the paper is devoted to the rhetoric of cartography in its traditional meaning. In the second section of the paper a proposal for a 'knowledge atlas' is discussed.

1. Introduction

In recent years, the methods of creation, organization and management of knowledge are changing. The causes for this global transformation of knowledge dynamics are multiple, varied, and complex in nature.

On the one hand, starting from the second post-war period, an *epistemological change* has revolutionized the way science is being done by introducing (or at least by revealing), a social dimension in the processes of knowledge construction. The individualistic models of early xx century epistemology give way to models that describe the creation of new knowledge in terms of social processes. Disciplines such as social epistemology and sociology of scientific knowledge, with some contributions from anthropology, describe a convincing scenario that connects knowledge and society, inextricably linking knowledge to the society that produces it and, conversely, proposing a model of society based on knowledge and skills.

On the other hand, *technological changes* brought by the digital revolution in the ’80s and by icts in the ’90s, have transformed channels, tools and methods for the creation, diffusion and management of knowledge. The democratization of publishing, the immediate distribution of knowledge, the emergence of alternative economies for intangible goods, the proliferation of free information and the transformation of the very concept of *author*, revolutionize the dynamics of knowledge.

Knowledge thus assumes the structure of an heterogeneous space, consisting of physical and digital resources, both textual and human, in permanent evolution. Both in the case of new digital forms (websites, blogs, databases), and in traditional formats of knowledge (libraries, books, files), authors and users interact, albeit indirectly, in the management and creation of new knowledge: they classify, link, comment, amend, edit, supplement.

Both in the contexts of scientific research and in everyday life, science and knowledge are changing shape and behavior.

- Besides centralized information collected in books and universities, a new kind of diffuse information (similar in form to once-forgotten oral knowledge), is emerging in forums, blogs and websites, or in implicit form through persons, groups, companies.
- Besides universal classifications defined aprioristically by experts, imperfect categorizations are appearing, emerging from the aggregation of the personal opinions of thousands of individuals.
- Besides rigid and permanent disciplinary structures, dynamic and fluid structures in permanent evolution, are helping describe the thematic routes cross-cutting disciplines and areas of interest.
- Knowledge is less and less manageable in terms of possession, and increasingly in terms of access to information and skills. Knowing means having access to social networks and technology able to provide necessary information and insight at the time of need.

In research focused on knowledge tools, this new cultural shift transforms needs and purposes of research. Today, the challenge is no longer that of looking for the *perfect classification,* a *permanent structure* able to divide and sort disciplines and skills into cultural sectors. On the contrary, the current urgency is trying to *‘keep together’* different kinds of knowledge resources: to gather social and cultural elements, people, research groups,

texts, designs and concepts in a single *knowledge space*. As a direct result, in the Communication Design field, the urgency concerns the creation of tools enabling the exploration, the description and the design of such spaces.

The Changing the Change Conference's main aim is to present and discuss the design research in a sustainable knowledge society. That is, its capability to generate visions, proposals and tools to re-orient the emerging knowledge society towards more socially and environmentally sustainable directions. contribution to the transition towards more socially and environmentally sustainable directions.

2. Knowledge spaces

The space metaphor, increasingly common in research relating to knowledge tools, is anything but random. Unlike the structures used over the centuries to manage knowledge by subdividing it in discrete areas, *space* is a continuous substrate: it doesn't divide culture in sections, it doesn't create hierarchies or define order in absolute terms, but on the contrary, it defines relations, proximities. Space defines groups, creates clusters, identifies pathways and highlights priorities in a dynamic structure, and likewise it allows to locate, to remember, to order.

The use of space as a metaphorical concept is not a recent invention, as it may be considered an ancestral knowledge strategy exploiting sensorial experience and spatial abilities to tackle abstract problems. Confirmation of this cognitive role of space – as reported by Lakoff and Johnson – is found in the lexicon widely used in referring to abstract domains: *"Orientational metaphors give a concept a spatial orientation; for example, happy is up. The fact that the concept HAPPY is oriented up leads to English expressions like «I'm feeling up today»"* (Lakoff e Johnson 1982, 31). The topics covered by the space metaphor are so many, that it can be said to organize, according to Lakoff and Johnson, most fundamental concepts. Unlike most other metaphors, space constitutes an analog based on direct physical experience, and not culturally mediated (Lakoff e Johnson 1982, 34).

Even when referring to knowledge itself, the analogy keeps strong: theories that differ are said to *depart*, researches can be *large* or *small*, students *follow* study *paths*, scientists are *exploring new territories*, going *beyond the frontiers* of research, sometimes even *going too far*. The metaphor of space was used in ancient and medieval times in order to remember and organize orations and texts, creating imaginary *palaces* and *gardens of memory* in which the speaker arranges columns, arches and statues to represent arguments and sections of the speech. Later, during the oration, he would then retrace his steps through the space of memory choosing the most suitable path, dwelling in depth on a subject or jumping whole shares.[2]

Even though, with the diffusion of the printed book, these mnemotechnics have lost much of their usefulness, the use of abstract spaces inhabited by non-geographical concepts and entities has never declined, and with the arrival of post-modernism their victory over has been announced. At present times, since the development of a post-modern society, abstract spaces are taking the place of geographic territories: we are therefore talking about *multiple* spaces, which arrange cultural actors of a society according to systems of values. The same elements can appear close in a semantic space and further apart in a disciplinary space, two authors may be colleagues (relational space) but interested in different topics (thematic space), etc.

In this context, the need is to find adequate practices and tools for complex and multidimensional spaces. Tools able to describe them, to make them navigable, to allow their exploration.

[2] For a thorough discussion of mnemonic devices and 'memory palaces' cf. (Illich 1994) and (Yates 2001)

3. Tools for knowledge spaces

Like any good metaphor, the spatial-territorial analogy applied to knowledge is not a mere *lexical* transfer from a '*literal domain'* to a '*figurative domain'*, on the contrary it allows to transfer *concepts, procedures* and *tools* from a known area to a still unexplored area.

As far as *knowledge spaces* is concerned, metaphors of this kind are multiple and varied: the popular concept of computer *desktop*, mixing the personal space of the desk with the work space of the office, is still dominant and despite the obvious shortcomings still seems to work pretty well. The metaphor of navigation and the spatial terminology used in the description of activities related to the use of the Internet (*website*, site *map*, IP *address*, *to visit* a site, *to follow* a link), although less imaginative than those used in the '90s (*electronic highway, cyberspace, to surf*) remain on par with more 'bookish' analogies (web *pages*, *index* of the site, *to browse*).

Even the *map*, spatial instrument par excellence, is not a recent metaphor. In addition to the famous image evoked by D'Alembert (D'Alembert 1978) in the 'Preliminary speech' to the Encyclopédie, and its appearance in the founding work of Paul Otlet (1934), one of the fathers of information science, in the last 30 years (in connection with the outburst of issues and potentials related to digital information management), we have witnessed a surge in academic research in the field of information visualization and abstract domain mapping. The approach to representation proposed by disciplines like *information visualization*, however, is mainly technical and computer-oriented, targeted mostly at the design of suitable algorithms for the display of enormous data quantities, with a perceptual-functionalist attitude toward representation. The term *'map'*, used quite often in this field's scientific literature, is therefore often a poor metaphor, applied more on an evocative and linguistic level than on a structural and cultural level.

The aim of this paper, on the contrary, is to extend the cartographic metaphor beyond visual analogy, and to expose it as a narrative model and tool to intervene in complex, heterogeneous, dynamic realities, just like those of human geography. The map, in this context, is not only a passive *representation* of reality but a *tool* for the production of meaning. The analogy, in this case, becomes not so much visual as structural and methodological in nature: it rests upon modalities, languages and tools developed by *cartographic discourse* over thousands of years to represent open spaces in constant evolution, both social and cultural at the same time.

The map is thus analyzed as a *communication device*: a mature representation artefact, aware of its own language and its own rhetoric, equipped with it its own tools, languages, techniques and supports.[3] A model that recovers the narrative abilities of pre-scientific maps and presents itself not as a mere mimetic artefact, but as a poetic and political tool: *"Make maps, not tracings.*—write Deleuze and Guattari in 'A thousand Plateaus'—*The map does not reproduce an unconscious closed on itself; it constructs it. The map is open, connectable in all its dimensions, and capable of being dismantled; it is reversible, and susceptible to constant modification. It can be torn, reversed, adapted to montages of every kind, taken in hand by an individual, a group or a social formation. It can be drawn on a wall, conceived of as a work of art, constructed as a political action or as a mediation. Contrary to a tracing, which always returns to the 'same', a map has multiple entrances."* (Deleuze e Guattari 1987)

The map as narration, is thus the expression of a communicative purpose. Just like a text, the map makes *selections* on reality, distorts events, classifies and clarifies the world in order to better tell a particular aspect of a territory, an event, a space. When used with malice, it can hide, conceal, falsify or diminish a reality through the construction of an ideological discourse, in which the communicative aims are hidden to the user. In this context, the term 'map' is a synonym of

[3] Cfr (Baule 2007b)

visual narration of space: a cultural artefact created by an *author* to describe a *space* according to an *objective*.

The map as a tool appears instead as a means that enables the user to reach an otherwise unattainable goal. It allows not only *to do* things better, more efficiently, but also to *create* new realities. As an instrument, the map expects *a user* using it to achieve an end, and similarly a *designer*, who must ensure that the structure of the instrument is as suited as possible for the achievement of the planned tasks.

In this delicate relationship, the designer's responsibility as creator of a cultural instrument becomes clear: operations of abstraction, scale choice and language work together in the narration of a virtual reality which constitutes the basis for potential action. The designer thus assumes the role of co-author of each subsequent action taking the responsibility to decide what exists, what is important. By drawing the territory, he distinguishes the significant from the secondary, the transitory from the permanent, the visible from the invisible.

In this context, the role of the communication designer is to provide methods and tools for designing images able to combine both *narrative* and *instrumental* dimensions. In a time of ever increasing power of the image (even in scientific contexts), the development of a model for the design of 'visual tools' is already a priority. A narrative for the representation of complex systems enabling not only to depict and explain, but also to act and influence the very reality that's being represented.

Beside the development of a scientific cartography, focused on neutralizing and naturalizing the cartographer's point of view, a need for a narrative approach to the depiction of geographic and abstract spaces is emerging: a *rhetoric*[4] as a technique for building visual discourses, strategic tools that enable to see and act in physical and abstract territories.

4. Cartographic rhetoric

Like any discourse, also cartography has its own *rhetoric*. Despite the negative connotations acquired by this term (often linked to operations of persuasion and concealment through linguistic stratagems), *rhetoric* is, in its original meaning, a technique for the construction of speeches.

Rhetoric, in the meaning used in this text, appears as an art in the classical sense, a linguistic technique used to *select* and *processes* elements of reality in order to transform them in an effective speech. With this in mind, the rhetoric nature of cartography shouldn't appear as a novelty: the authorial and cultural character of maps has always been one of the fundamental themes of cartographic literature and criticism, and it still is one of its major worries. The narrative component of the cartographic speech has often been regarded as a sort of unavoidable flaw, a collateral effect of an essential tool: the map. Point of view and narration manifest themselves through the operations that transform the *territory* in *image*. A rhetoric of this kind, applied both to *traditional territories* and to *knowledge spaces* can provide a meta-language, a technique conceived as *method* for the design on the map.

Just like in classical Aristotelian rhetoric, in this cartographic rhetoric it is possible to distinguish operations concerned with the selection of material (*inventio*), with the structuring and composition of speech (*dispositio*), and with language choice (*elocutio*). Obviously, the correspondence between these categories should be regarded more as a guide to the creation of a speech rather than as a deep correspondence between the operations of spoken language and those of visual discourse. In fact, while an excessive stubbornness in seeking matches at all

[4] When referring to multimodal communication models Anceschi (1993) uses the term 'registica' (direction). Nevertheless, despite the involvement of interaction elements, when speaking about the cartographic expression the term 'rhetoric' has been preferred.

levels between the symbolic-linear language of speech and the iconic-synoptic language of images could be forced and misleading, on the contrary the exploitation of the deep structure of the rhetoric discourse underlying the entire Western literature, may be particularly useful to investigate the workings of complex communicative artefacts (such as maps and diagrams) and thus to suggest a methodology for their design.[5]

4.1 Inventio

In Aristotle's *Rhetoric* the *inventio* is the first of the five operations of the rhetorical *techne*: it consists in the '*invenire quid dicas'* (i.e. *'to find what to say'*), the gathering of arguments, evidence and issues to be exposed. The *inventio* as such is not an *invention*, but rather, as Barthes noted, an operation of discovery and selection of the material.

In cartography, operations of selection, collection, classification and simplification decide what to say. They define, albeit in an abstract way, the materials of the speech to be arranged in the *dispositio* and translated into words (or images) in the *elocutio*. In the depiction of an infinitely complex reality, the cartographic narrative makes selections that decide what is relevant and what is not by creating a simplified copy of the territory, retaining only the *useful* features.

The decision of which aspects of the territory are worth showing, allows to highlight important elements of the territory, hidden correlations, significant distributions, or also deficiencies. At the same time, however, the choice is also political and moral, and it interferes in turn on the represented reality: showing something means recognizing its importance, its relevance, and its *status* as part of the territory. In this context, cartography is exposed as an intrinsically *partial* representation model, which has *incompleteness* as its strong point. It allows a narrative of open and complex spaces through the creation of multiple stories that abandon any presumption of completeness in favour of the creation of local stories, valid for limited objectives.

Within knowledge representation systems, the application of a cartographic approach, partial and selective in nature, provides a substantial change when compared to historical and recent models of knowledge representation. If, on the one hand, both linear and hierarchical representation models of knowledge are built on *a priori* categories, on the other hand cartographic representation is based on the definition of local stories, and on the rejection of a totalizing structure.

In this context, selection represents the operation deciding the extension of the research, and the elements of the story that is going to be told: people, publications, conferences, but also professionals, forums, companies, and abstract concepts can be combined in the narrative of a space as complex as the social space of knowledge, or they may be neglected and relegated to irrelevance. Maps resulting from these choices reflect, in addition to the subject of study, the epistemic context of the cartographer. *Showing*, once again, means *giving dignity* and *authority*. Drawing users, next to books, authors and Dewey codes in a library map, means to recognize the users' role in the definition of a cultural area. Drawing websites, *blogs* and forums in a map of academic research, communicates the awareness of the virtual communities' function in the processes of knowledge creation.

[5] This approach stems in many ways from research that analyzed visual rhetoric both as difference between natural and figurative language (Barthes, Bonsiepe, Group μ), and in the broader meaning previously specified (Anceschi, Arneim).
However, unlike these contributions, in this context the focus will be on the *cartographic language* as a model specific to the narrative of space, developing critical cartography research (Wood, Monmonier, Harley).

4.2 Dispositio

In the rhetoric of spoken discourse as well as in cartographic rhetoric, this first phase of speech construction (*inventio*) comes to a conclusion without any use of actual words or pictures: the materials of the *inventio* are abstract, they are *"pieces of language in a reversible state, that must be arranged in the fatally irreversible order of speech"* (Barthes 1972, author's translation).

The creation of the *'oratio'*, the *speech* (or image in our case), is carried out by two other operations: the construction of the speech (*dispositio*) and its translation into words (*elocutio*). The *dispositio* is the placement of the parts of the speech, the composition. Given a series of data elements, facts, and arguments, the *dispositio* arranges, sorts and orders the arguments in order to convince (or touch) the spectator.

The first concrete issue in the construction of the cartographic discourse lies therefore in the construction of the analogy that enables to associate every point in space with a point on the map. The map, in other words, is useful because it constitutes an *analogue* of the represented object, an *icon* that establishes a geometric or human relation between a virtual and a real space.

In case of large-scale maps the transformation of these spaces is trivial: the *projection*, this *rule* that transforms a space in another, simply 'shrinks' the two-dimensional space of the territory in the two-dimensional space of the map. On the other hand, when the analogy concerns spaces of uneven nature or dimensionality (e.g. the projection of a three-dimensional globe on a two-dimensional map), than the projection can not occur without deformation. Being impossible to avoid deformations, the projection must be carefully chosen by the cartographer on the basis of its characteristics. As in a hypothetical 'uncertainty principle' of cartography, it's impossible to simultaneously maintain a correspondence between angles, areas, distances and directions.

Cartography, once again, becomes an art of compromise and partial solutions. From a narrative point of view, however, projection operations give the designer a chance to highlight specific aspects of the territory at the expense of others. Finally, only the users' needs determine the 'better' projection.

This importance of projection operations is not limited to geographic spaces but extends also in the realm of metaphorical mapping of abstract spaces. *To project* an abstract space (e.g. a knowledge space, a social space) on paper, means to identify a transformation that matches elements of a non-geometric 'space' to elements of a two-dimensional representation. The transformation, in this case, is therefore no longer a geometric projection, but a isomorphism that *"constitutes a biunique match of points in space (and we call space also the* virtual space *of content)."*

"The assumption in this case—writes Eco—*is the acceptance of a metaphorical nature of the concept of abstract space, definable through a convention (based on mental mechanisms that make possible to imagine abstract relations in terms of spatial proximity) which stipulates that certain abstract relations are expressed by certain spatial relations."* (Eco 1975, author's translation)

Once again, the transformation between spaces is not trivial nor unique, but on the contrary it appears as an arbitrary process. The convention referenced by Eco's definition of metaphorical space may consist of an unlimited number of different rules, potentially giving shape to unlimited types of space: semantic spaces where physical proximity indicates similarity of content, relational spaces where closeness is determined by the intensity of relations between the elements, temporal spaces in which temporal closeness is translated in concrete proximity.

As with geometric projections, space-creation operations founded on abstract values imply the choice of a criterion to be used for the transformation of space. As for the rhetoric of the speech, a change in the order of the arguments does not leave the content unchanged,

but on the contrary it affects the narrative. These cartographic operations strongly define the nature of space. They show, like the more traditional projections, some characteristics of the area to the detriment of others: the choice highlights a discourse, creates an order, tells a story.

4.3 Elocutio

Elocutio, the third part of the rhetorical *techne*, deals with finding the *form* of concepts, choosing the right words, picking the right images. In semiotic terms, the *elocutio* works on the expressive functions of signs, their denotations and connotations: the aim is on the one hand to express the content of the sign, and the other hand to define a *tone* of the speech and to work on its (possible) connotations.

This third part of the *ars rhetorica* is therefore a technique concerned with words and figures, but not limited to that as, on the contrary, “it defines a field containing language altogether: it includes our grammar and what is called diction” (Barthes 1972, author's translation). In addition to ornamental functions, *elocutio* therefore appears also as an operation of moulding, of *in-formation* of the speech. The speech’s effect on the public depends both on the careful communication of meaning, and on the connotations conveyed by stylistic choice (the greater the openness of the sign, the more powerful the connotations).

In the contexts of a cartographic rhetoric, the *sign types* that can be placed on the semantic space of the map represent almost any mode of visual meaning. The signification mode of each of these signs can be purely symbolic or it can assume a more or less iconic character, reproducing the look of the depicted element. In turn these signs may refer to the denoted entities in many ways: more or less realistically, more or less abstractly, representing a single specific object (a specific lighthouse) or category of items (lighthouses in general) depending on the degree of classifications established by cartographer.

The choice of these qualities defines the overall appearance of the map, and therefore affects the user’s interpretation: the creation of a strongly ‘realistic’ map, for example, contributes to the reality effect typical of the iconic mode of signification, while a schematic and highly symbolic representation will strengthen the technical connotations.

The symbolization activities therefore act on two main levels. First of all, they determine an *order* of the image, a *value* of the represented entities. In traditional and abstract maps, larger and more visible symbols express weakly codified connotations of importance with respect to less visible signs: they become the map *theme,* expressing the author’s intentions and the representation’s point of view. Size, chromatic contrast, brightness, formal distinctions and, in general, all the visual qualities of the image define the figure’s depth, highlighting distributions, emergencies, and exceptions. In short, they define a *tone* of discourse, they raise their voice on some issues and disregard others, differentiating more or less emphatically the various arguments.

On the other hand, this definition of a *tone* together with the establishment of a cartographic lexicon (defined by the symbolic and iconic repertoire), and together with the choice of a *form* which embodies the entities, defines a *style* of communication. The *style* is therefore the result of symbolization choices, the domain of form and figure, however its function is not limited to a generic search for pleasantness. On the contrary the map *style* defines a system of connotations that carries out a meta-communicative function: it describes the communication itself by providing clues for its interpretation.

In geographical and abstract maps, language and style expose the communicative intentions of the author. However, while with regard to geographical maps, tourist maps, and technical plans, over the centuries there has been a codification of *styles* in *genres* that match form to

content according to relatively stable codes, with regard to the *new maps* this process is still being defined, and attention to the map drawing process is rather lacking.

The current look of abstract maps is in fact often an involuntary tribute to technology, exposing the automated nature of the systems that generated them. Forms and typographical elements hardly commit to a precise stance, human intervention is excluded from connotations, and the image neutrality is ensured by the *perfect naivety* of the machine. Just like in scientific cartography, the rhetoric of selection, spatialization, classification and silence is hidden by the 'neutral reality' of language. Well-camouflaged in the database structure responsible for the collected information, in data selection queries, and in layout algorithms, the *human choice* never appears in the visualization's language.

In this context, research needs to develop suitable languages for the communication of dynamic spaces and define both technical and human codes, in order to recognize the cultural role of images and of design processes.

5. Project: the Knowledge Atlas

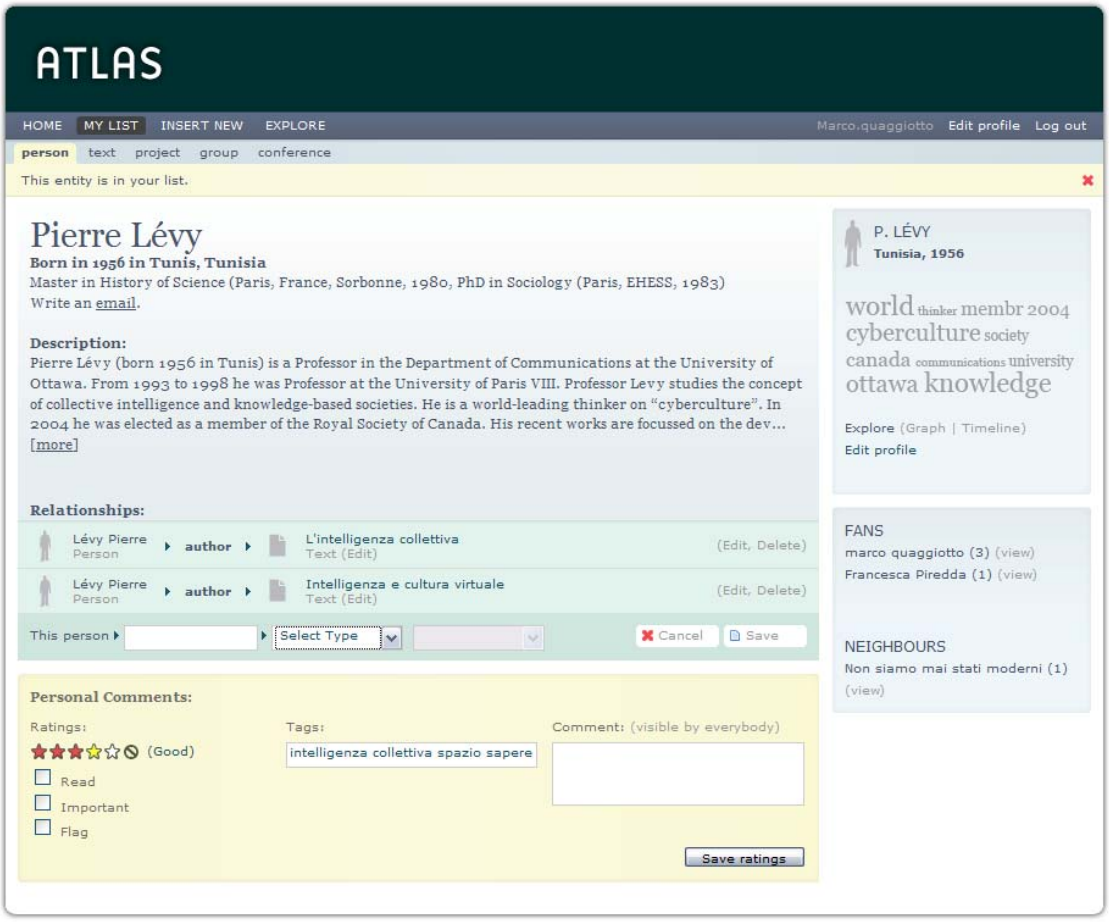
Building on these reflections concerning the use of a cartographic approach in the design of *knowledge interfaces*, during the research a software (*Atlas*) has been developed *to experimentally verify the theoretical assumptions* developed during the research, and *to explore the identified design methodologies* in order to call them into question, and retrospectively improve the theoretical and analytical framework.

From a practical point of view, '*Atlas'* is a software prototype being developed by the *Communication Design Research Unit (d.com)* at the *Politecnico di Milano*, for the management of research systems (i.e. resources, actors and relationships that interact in the creation of new knowledge), designed to support common tasks of research such as survey, mapping and analysis. The software, built on web-based technology, is a social web-application that allows users to build their own bio-bibliographic database by adding five types of resources (authors, texts, projects, conferences and research groups) related to their research. Each resource in the system can than be described *collectively* by the users (as in a wiki) in its essential features (such as date, description, location,…) and *individually,* by each user, through the definition of tags, comments, and through the establishment of relationships between entities (e.g. relating a text to its author, a person to a research group).

The aim of this management structure, expanding beyond classic bibliographic management, is to adapt to contemporary forms of cultural production: to collect non only explicit knowledge, but also implicit knowledge embodied in people, in communities and in objects. Traditional bibliographic models are therefore hybridized with a model for the mapping of social, cultural and scientific contexts.

Using this management structure for the research ecosystem, all the resources inserted in the database are shared at different levels between the users. The entities, in this context, are not limited to their individual use, but instead they represent the nodes of a big network that ties together users, resources, and keywords.

Of course, a naive visualization of *all* the entities stored within the database would be both impossible and useless because of excessive information density. As with traditional cartography, the task of representation doesn't simply lie in the creation of a *replica* of reality, but appears as a cultural process for the narration of the territory. Nevertheless, working on these data through the rhetoric methodology previously explained, it's possible to create an Atlas of knowledge spaces made of maps at various levels of scale, ranging from personal research maps to department-level maps of knowledge, or even collective maps of research areas emerging at university level. In this context, the design of the interface has a fundamental importance: its function is no longer

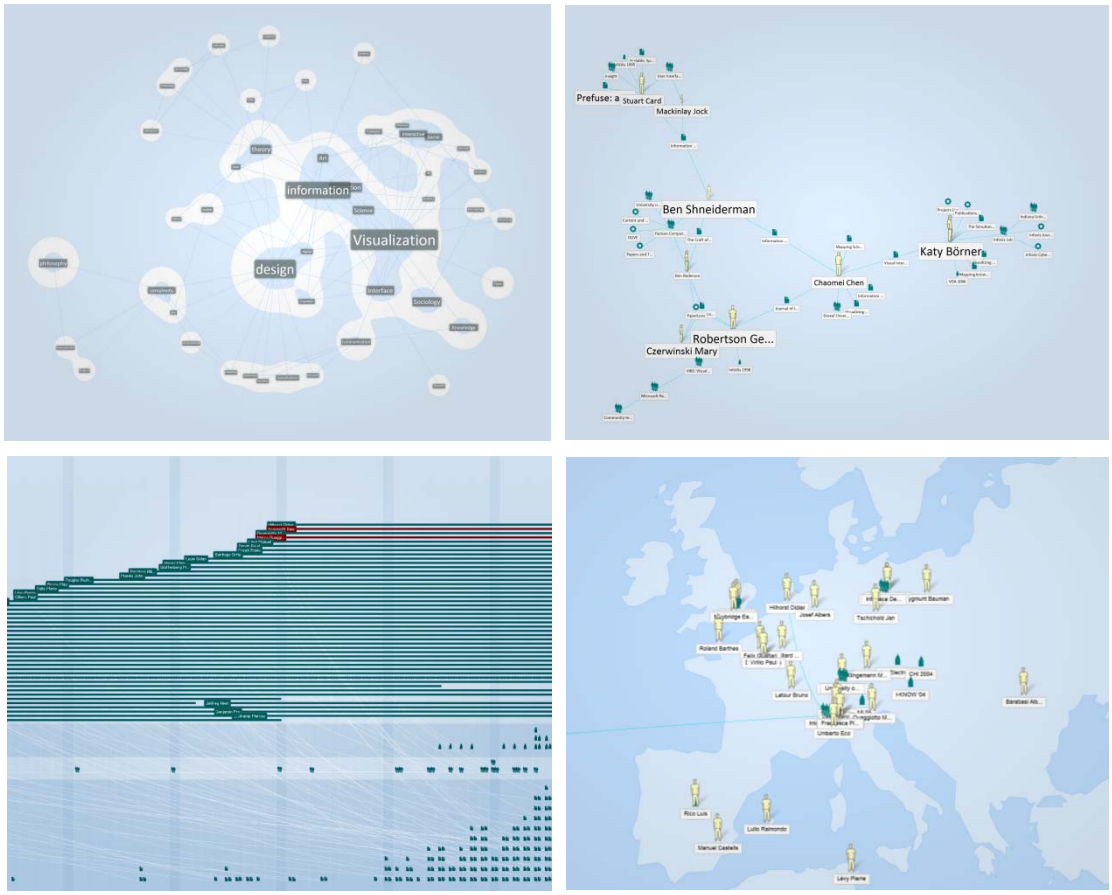


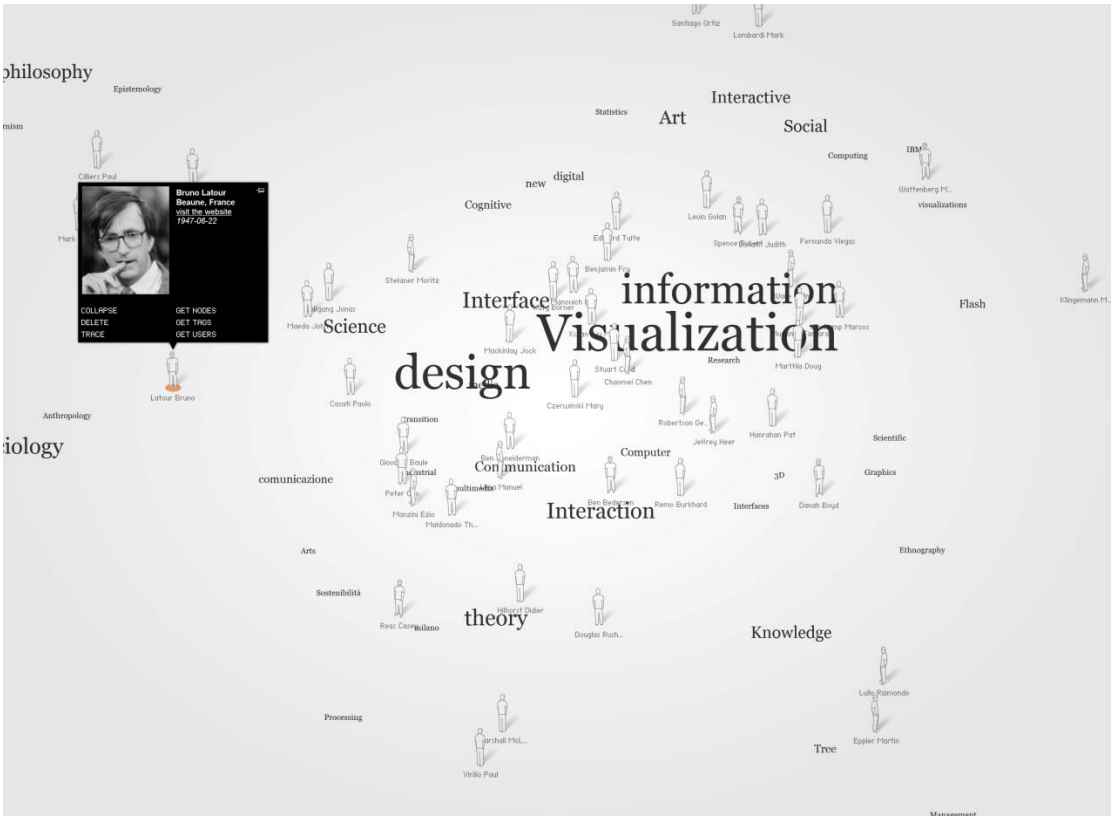
Atlas, resource page: in this page, the user can describe his resources in terms of metadata, ratings, tags, comments and through the definition of relations with other entities.

aimed exclusively at facilitating the recovery of saved entities (as in traditional bibliographic software), but on the contrary it takes on the task of representing knowledge contexts in order to allow their exploration, thus helping in their understanding.

On the basis of a cartographic metaphor, *Atlas* is an attempt at building an atlas of knowledge spaces. The concept of *'atlas'* in this context doesn't depict so much a list of maps, but rather a system for the representation of space, a *communication device* aimed at representing complex contexts through the use of many partial overlapping narrations. A tool combining multiple images with the aim to describe the many aspects creating a space.

Thanks to the design of consultation mechanisms and to the institution of a linguistic coherence, the multiplicity and heterogeneity of the images becomes an explorable system, a story on multiple levels, a mosaic made of many tiles. Just like the map itself, the atlas is a *communication tool* with its own mechanisms, materials and supports, an instrument that enables users to act on space: it allows navigation, exploration, change of scale, comparisons.





Atlas, projection: examples of semantic, relational, temporal and geographical spaces.

5.1 The Atlas

Specifically, in the case of *Atlas*, the 'atlas of knowledge spaces' consists of a series of maps, visualizations and dynamic representations created by the system starting from user-chosen parameters. If compared to the traditional Atlas format (which provides the metaphor underlying the representation system), the number of maps, their type and their arrangement is not directly defined, but they are dynamically generated in accordance to specific needs and directions.

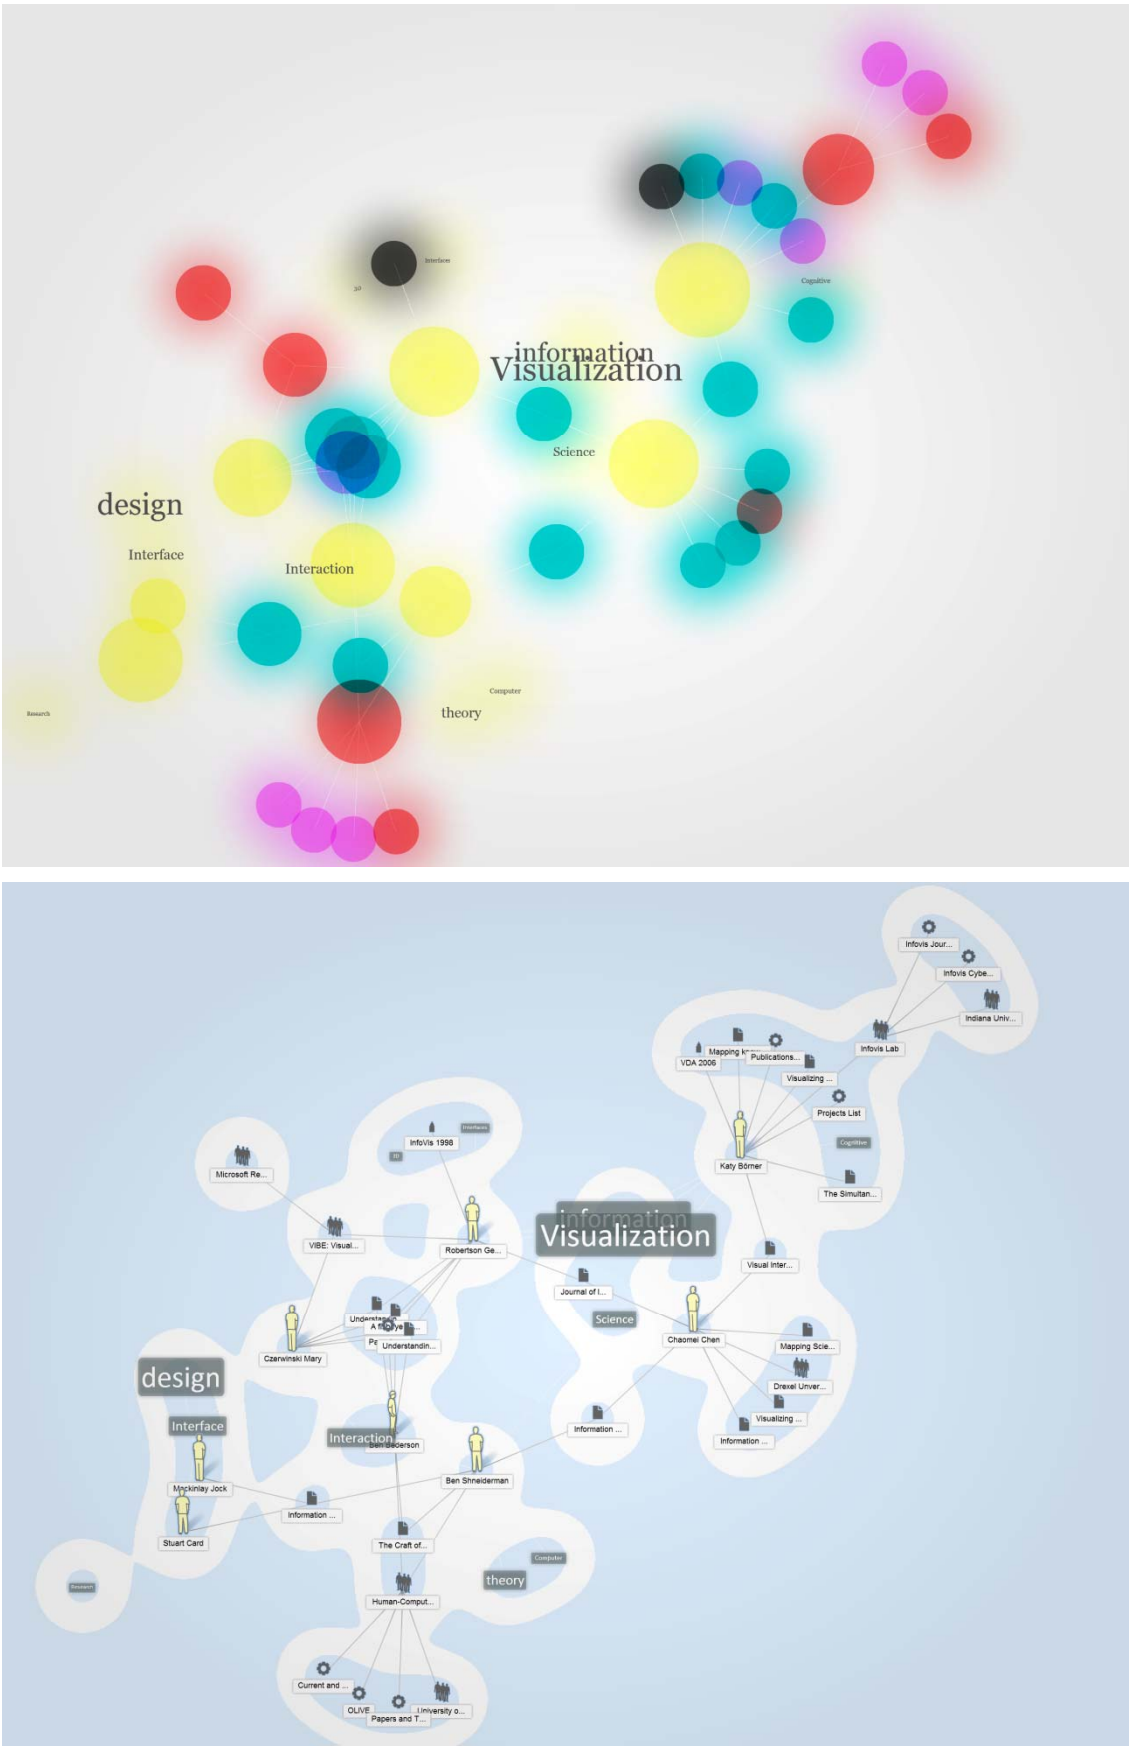
Building on a cartographic rhetoric of knowledge spaces, information and data entered by the users is selected, filtered, prepared, screened and symbolized in order to create *images* of the research. *Selections, projections,* and *symbolizations*, find in *Atlas'* interface model their practical application: the atlas becomes a machine for the production of maps, the embodiment of a theory and methodology in which the elements of a designerly approach are clearly recognizable.

Selection: The selection process distinguishes the elements relevant to the description of space according the map intended use. Depending on the author's choices, *Atlas'* maps can display every kind of resources or only selected types: just books, people, keywords, just items that have been given a certain grade, just texts of a precise historical period. Similarly, links can be shown or hidden depending on the communication strategy. Also the extensive limits of the map are potentially manageable: it is possible to create personal knowledge maps, department-level research maps, or global maps made up of all the users who show affinities between them. As in traditional cartography, the combination of these different selection patterns has great narrative power (for good or evil), enabling the user both to explain clearly and to conceal or falsify data.

Projection: The projection process, just like in traditional cartography, aims at placing the cartographic entities on the map space in order to create the best possible image for a specific activity. In the context of knowledge spaces, the *Atlas* currently provides four main projection modes, allowing the user to create maps based on *semantic*, *socio-relational*, *geographic* and *temporal* substrates.

Symbolization: Finally, the symbolization process on the one hand allows to create a visual hierarchy of resources, highlighting some of them depending on the map's intended function, and on the other hand it lets the author adjust the connotations related to the visual form through the definition of a representation language, a lexicon and a visual style. In *Atlas*, this third kind of operations allows to control aspect and form of each element of the map (including the space). Symbols and icons for the representation of each entity can be chosen, thus deciding graphic abstraction level, degree of generalization, colours, and other visual qualities. Even the space between the entities, the background constituting the *meaningful space* substrate, can be left blank or can be symbolized in order to highlight meaning or relation 'fields' such as clusters emerging in the projection operation.

The design process appears then not so mush as the process of designing an artefact, but rather as a process concerned with the design of a 'graphic machine', a *system* capable of articulating series of individual artefacts as expressions of a previously defined logic and language. This design model, which emphasizes a typical design characteristic, that of designing at a *systemic* level (Baule 2007a), proposes a formal encoding of the concept of *format* or *communication format*: a set of generative rules for the development of communication systems focused on the process rather than on the single artefact.



Atlas, *symbolization* process: Examples of different symbolizations of the same space.

5.2 A new kind of interaction

Unlike the traditional maps and atlases, *Atlas* enables users not only to get involved in the processes of space use (exploration, navigation), but also in the processes of map creation. The static structure of traditional maps is therefore replaced by maps able to change limits and scale level, maps capable of changing their appearance in order to allow deeper explorations. The user can then move in the representation space by dynamically redefining the limits of the map, zooming on areas of particular interest to gather details, or stepping away from the territory in order to obtain a more comprehensive view, heavily focused on the overall aspect of the 'landscape'. Clicking on individual elements, finally, *Atlas* gives a chance to get some details on the selected resource, and to perform operations on it: to have a look at the entity's complete file (as compiled by the community), to add any related resource or keyword to the map, to hide the selected node from the map, etc.

These operations, besides giving some tools to explore one's own research areas, give also the possibility to explore alternative paths as identified by the *Atlas* community. For example, by clicking on an author's icon in one's personal map, the user can interact with the mapping system by asking to see related entities (entered by other users). These elements, even if they haven't been entered by the user, become part of the map and can be further expanded to identify possible research directions. Just like ancient maps, this kind of map which at first is just a guide to known territories, then becomes an instrument of discovery for uncharted territories.

Another kind of interaction, which in the paper atlas is limited to the comparison of maps, in its digital counterpart allows not only to move between visualizations models at any time (allowing comparisons between geographical, semantic, relational and temporal distributions), but it also shares with the user the main operations of mapping rhetoric. The cartographer thus shares his role with the user, who becomes active participant in the creation of his own maps, designing them specifically to communicate the most interesting, or useful aspects of their research. The power of mapping, historically serving power centres (military, political, religious or economic), is then shared, if only partially, with the community.

6. Directions

In the field of interface design and research, this paper aims to make a step towards the definition of an approach for the design of cultural instruments. In this context there is a urgent need for a further exploration of *social interfaces* as means to provide instruments of interaction, exploration and knowledge in the present world. In regard to the interface model exposed in this paper, the aim is to experiment (and refine) its approach in the different spaces of knowledge, such as archives, libraries and research centers.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Towards a Sustainable Design Framework

A Study of Design Methods for Sustainable Innovation

Alex Quinto[1]

Abstract

This paper presents a *sustainable design framework*—a model that embeds sustainability criteria into the design process of material and strategic outcomes. Two criteria for developing such framework are required. First, organizations that document design processes are in a better position to articulate the value of design to stakeholders. Second, the framework calls for the use of assessment tools that measure an organization's social, economic, and environmental impact. The presented framework forms the basis for a future study that will be conducted to determine the barriers and determinants for adopting a sustainable innovation strategy inside organizations. It is informed by three case studies from the Work Worth Doing design consultancy as well as design research literature.

[1] Work Worth Doing (CANADA), Partner, alex@workworthdoing.com

Goals of this study

By doing this study, the founders of Work Worth Doing would like to strengthen the discourse around design for sustainability by proposing a framework that allows designers to accelerate the adoption of common terminology around design for sustainability and promotes the sharing of best-practices in design methodologies. A later study based on this framework will investigate the barriers and determinants iof instilling a framework that allows organizations to embed sustainability criteria into their design processes.

Introduction

Design is beginning to be understood as an activity that can address a variety of issues beyond the design of singular products. Terms such as business innovation, eco-design, social design, interdisciplinary design, among others, have become part of the terminology used by designers, business leaders and social entrepreneurs. The extent to which design methods are developed and used in practice remains to be better documented. A common viewpoint—a *sustainable design framework*—is needed.

A *sustainable design framework* would create a common platform that compares design methods being used in various types of organizations. Such *sustainable design framework* would address the social, environmental and economic dimensions of sustainability during the entire process of a given design challenge. This paper presents the methodology being used to carry a study on the use of design methods that can address sustainability. The *sustainable design framework* presented in this paper is based on the methods and experience of the Work Worth Doing design studio in Toronto, Canada. The methods presented in this paper may directly correlate to those used by other small to medium-sized design studios. It is hoped that this study will serve as a point of reference in similar organizations that are developing their own sustainable innovation strategies. Once the full study is complete, similar frameworks could be developed for other industries and types of organizations.

The research method being used for this paper is based on Dawn Chandler and Bill Torbert's definition of action research, based on first, second and third person positions. Our first person position is based on reflections of the author's experience as a founding partner and designer at Work Worth Doing. The second person position is based on a number of interviews with organizations that are documenting and applying design methods in their practices. The third person position research is based on a review of literature: how various organizations describe the work they do, as well as a review of existing design research literature (Chandler, Torbet, 2003).

This study was born out of the interest of Work Worth Doing, a design studio that applies design to social and environmental challenges, to better understand how the studio can be more effective in using design to address sustainability.

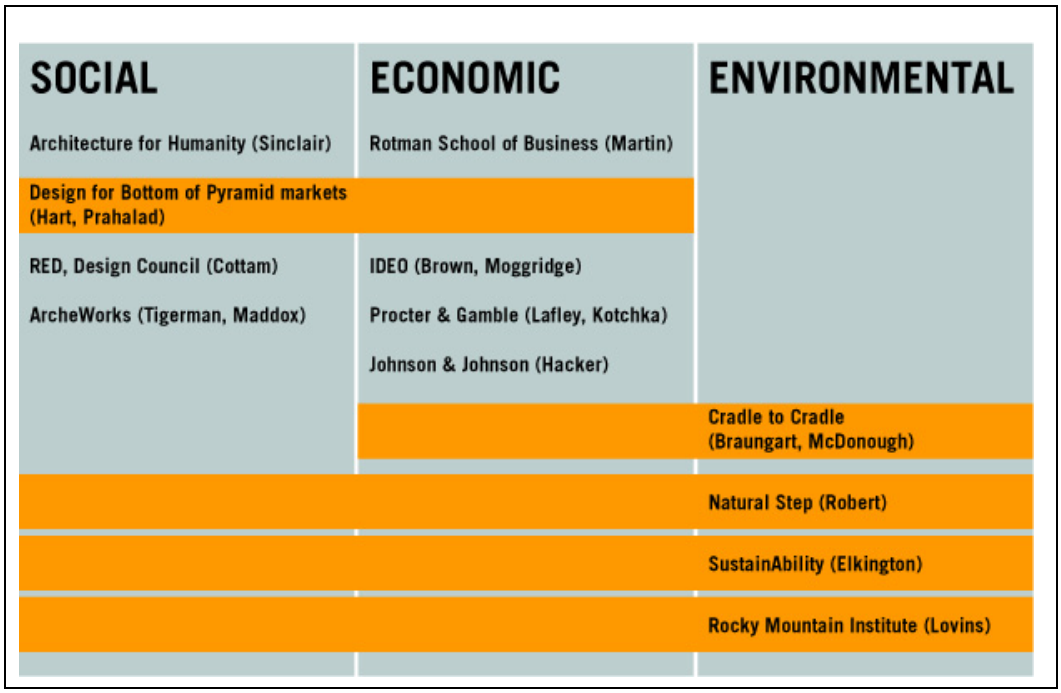
The Sustainability Challenge.

In the last half century or so, the world has gained a broader global conscience in hopes of addressing issues that threaten life on the planet. From futurists, to scientists, numerous experts have raised flags as it is more evident that human activity has detrimental effects on the environment at large. Two early wake-up calls were the books *Design for the Real World*, (Papanek, 1971) and *The Limits to Growth*, (Donella, Meadows, Randers, and Behrens, 1972).

Based on a systems dynamics simulation that factored in future uses of natural resources, the latter authors estimated the world would run out of key natural resources to sustain human life by the end of the 20th century. Although their model was far from accurate, their point about the interdependence between nations was captured in this statement: “no country, no matter how big, can solve its own internal problems before solving the problems threatening the global system.”

By 1992, world leaders started taking notice. Government representatives from 172 countries gathered at the Earth Summit in Rio de Janeiro to define a global partnership that would address the environment and development. Agenda 21, the resulting document, became a global plan for governments to begin practicing sustainable development. This document reinstated the 1987 United Nations Brundtland Commission’s definition of sustainable development as one that “meets present needs without compromising the ability of future generations to meet their own needs.” By 1994, John Elkington and his peers at SustainAbility coined the term “triple bottom line”, refering to the three dimensions of sustainability—social, economic and environmental (Elkington, 2004). This paper proposes the understanding of design for sustainability based on those three areas of sustainability. See Figure 1 for an example of organizations using design along the lines of the triple bottom line.

Fig. 1. Examples of design-driven organizations and their advocates, seen through the triple bottom line perspective.



Anticipatory and interdisciplinary design methods can address sustainability

Studying the process of designing has become the interest of the design research community. While some design processes and tools remain in the domain of trained designers, a basic definition of design, understood as a plan to achieve a desired outcome, is broadly used by many professions. Design methods are used knowingly, or not, by a wide range of professionals. This is confirmed by various authors (Brown, 2005; Buchanan, 1995; Simon, 1996). Design used in this paper is referred to as a *verb*, rather than a *noun*, a process, rather than a tangible outcome (Boland, 2008).

It is now a well-known fact that humanity's current patterns of production and consumption are contributing factors to global warming and climate change. The challenges brought about by climate change are complex and need to be tackled from a systems perspective since environmental conditions such as water shortages, greenhouse gas emissions and energy-intensive industrial process are interrelated. Furthermore, social factors brought about by poverty, government corruption, aging populations and fluctuating migration patterns, require interdisciplinary and anticipatory approaches if design is to make a contribution to these issues. This study focuses on those two aspects of design: the ability of design to synthesize solutions out of an interdisciplinary process and the anticipatory aspects of the design process. Some examples of those skills will be illustrated later through case studies.

The anticipatory qualities of the design process, or the ability of designers to portray more desirable states of being, is an important skill of design thinking that is well-suited to address sustainability dilemmas. Design provides a different type of value from other activities such as science or management. In contrast with science's concerns with understanding how things are, design is concerned with how things could be.

The benefits of such anticipatory thinking could result in the design of material and immaterial outcomes. The design of sustainability strategies, for example, could prove to be better solutions than technical fixes. "A change in worldview, intention and lifestyle, facilitated by dialogue and education, may be a far more effective way of problem-solving than the creation of more artifacts and technical fixes." (Christian Wahl, Baxter, 2008). Similarly, the World Wildlife Fund (WWF) supports the need to re-think existing approaches to socio-technical solutions. In its Climate Solutions: WWF's Vision for 2050 report, the WWF mentions that "it is technically possible to prevent irreparable damage to the world's biosphere, economy and society if significant action is taken today using existing technologies and simply scaling up what we already know how to do." What is needed from designers is new articulations of compelling systems that take advantage of existing technologies.

In order to better address climate change, for example, policy-makers could use the advice from designers to inform their decision-making process. It is commonplace for governments to receive advice from the scientific community on the need to stop greenhouse gas emissions—what not to do. Designers could provide "what to do" advices, complimenting wisdom with vision (Owen, 2005).

Leading design firms are well equipped to address interdisciplinary and anticipatory issues. It is commonplace for design departments in medium-to-large companies to be staffed with professionals from diverse backgrounds such as psychology, anthropology, ergonomics, management and economics. Interdisciplinary design tools such as charrettes, dialogue processes, anthropological studies, ergonomic studies are common practice among designers. Designers are well skilled in anticipatory design tools, such as visualization and prototyping of material and "immaterial" outcomes. The design of products, strategies and experiences in design firms using these types of tools are commonplace. However, an increasing demand for sustainable innovation strategies would require design groups to address sustainability criteria (a practice that is just emerging).

A common viewpoint is needed

Understanding design inside an organization.

One key criteria that is required to better design for sustainability, is the need to document design processes that can be improved upon. Some companies are accustomed to documenting their own design methods.

The British Design Council, in their study of eleven global companies, mention the use of 'methods banks' to improve the performance of design teams inside companies (Design Council, 2007). "The capture and re-use of best practice design methods in 'banks' or programmes are considered to encourage best practice in design, avoid re-work and improve robustness and efficiency of outputs." The report also mentions the value of documenting design methods when assessing the contribution of design in a company's products or services: "Documenting [design methods] in a formal tool shows the designer and the company that their work is valuable, appreciated and has tangible outputs. Design methods help to define the project that will prove a product or service's business potential and bring it through development and implementation phases. Having a resource that advises on this helps process planning and management."

Documenting methods can help an organization identify typologies of design processes. Such typologies could indicate which methods are successful in reaching specific goals, whether they are financial, social, or environmental. Documentation can also pinpoint methods that need to be re-designed, or invented.

Articulating a shared framework in an organization.

Between 2003 and 2006, the Centre for Sustainable Design at the Surrey Institute of Art & Design hosted a number of conferences under the theme 'Sustainable Innovation'. The conferences reached a number of conclusions, including the need to:

- Articulate a common design framework that deals with sustainability. Although "there are a range of eco-design and Sustainable Product Design & Development (SPDD) tools and methodologies starting to emerge, there is no common viewpoint."

- Promote more systems-based thinking skills. “SPDD is different from eco-design, in that it takes account of social and ethical considerations alongside more traditional environmental and financial aspects.”
- Define a framework that recognizes the designer within a broader team of participants, and recognize the issues beyond the control of a team working in sustainable innovation.
- Understand the limits of a designers’ skills/contributions and acknowledge what others might bring to the table.
- “Make better connections between stakeholders in the development of Sustainable Innovation Systems (SIS), e.g. investors, inventors, entrepreneurs, academia, etc.”

The *Sustainable Design Framework* presented in this paper is based on Martin Charter’s definition of sustainable innovation understood as “a process where sustainability considerations (environmental, social, financial) are integrated into company systems from idea generation through to research and development (R&D) and commercialization. This applies to products, services and technologies, as well as new business and organization models” (Charter, Clark, 2007).

The proposed framework

The *Sustainable Design Framework* is a model that embeds sustainability criteria into the design processes of an organization. The framework calls for establishing a common vocabulary among designers and other professionals on the implications and potential benefits of having design capabilities within an organization, as they can contribute to an organization’s sustainable innovation strategy. It is based on systems thinking in the context of designing social, economic and environmental outcomes. Having a *sustainable design framework* in place can educate stakeholders in an organization on the required steps needed to address sustainability. It is informed by J.P. Guilford’s models on creativity (Guilford, 1967) and other design processes used by other organizations.

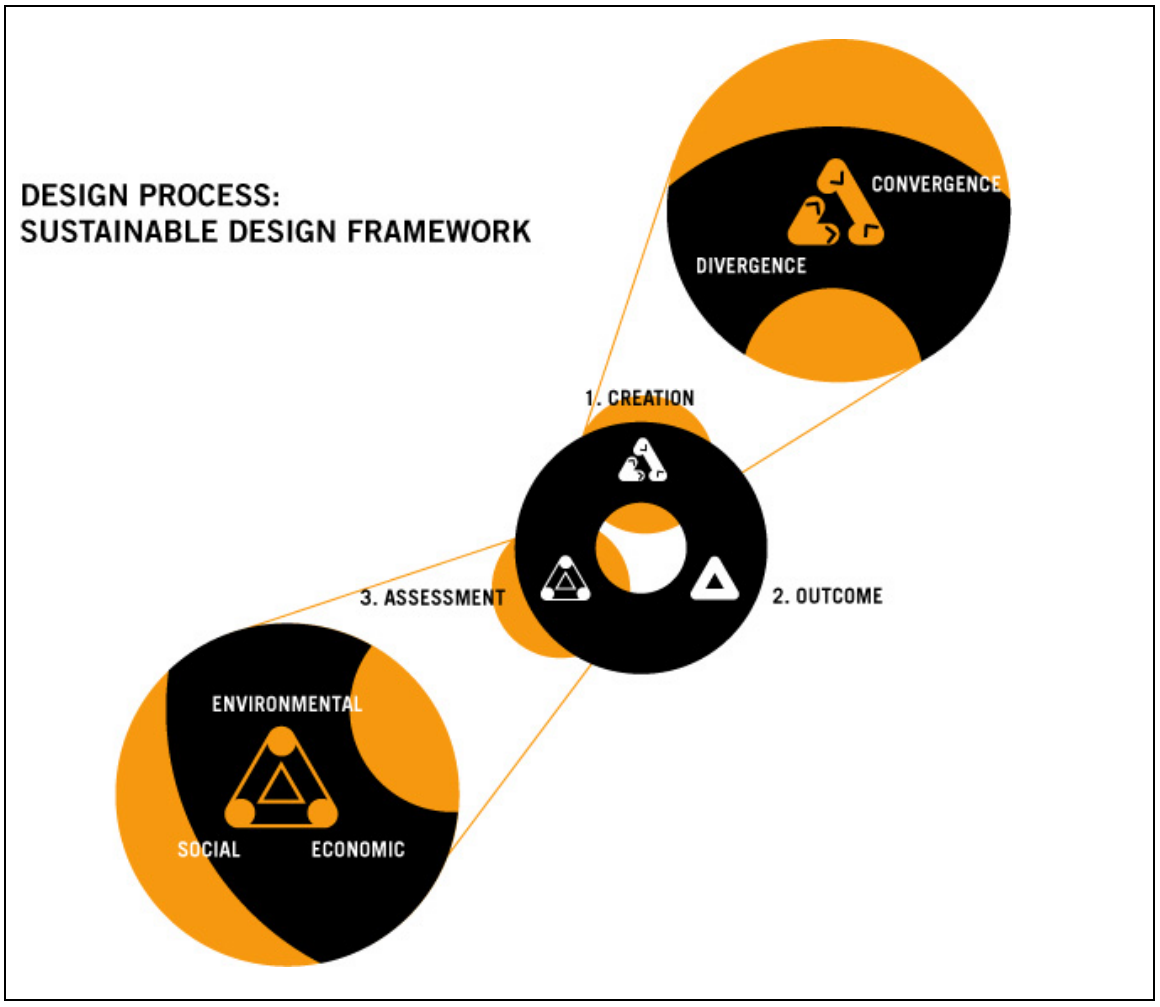
Similar frameworks exist that address sustainability during the entire life-cycle of development, such as Cradle to Cradle and the Natural Step. Cradle to Cradle embeds the Hannover principles of waste reduction, longevity, natural energy flows, among others, which perform particularly well on the environmental and economic dimensions of sustainability. On the other hand, the Natural Step can be applied to social, economic and environmental dimensions of design processes. It is based on scientifically-proven methods that can move communities, companies and organizations towards a sustainable path. A more diverse pool of similar frameworks informed by the experiences of organizations are needed to enrich discourse around design for sustainability.

The *Sustainable Design Framework* presented in this paper promotes:

- a documentation of design processes that advocates for:
    - a shared language and understanding among stakeholders inside an organization as all participants move towards sustainability.
    - an understanding of design's contributions to an organization's sustainable innovation strategy
- the use of assessment tools that:
    - assess an organization's social, economic and environmental impact
    - benchmark an organization's progress on developing sustainable practices.

The *sustainable design framework* is composed of a creation phase and an assessment phase (see figure 2).

Fig. 2. Design process of the *Sustainable Design Framework*.



Creation.

The creation phase is composed of two sub-phases: an exploration period (divergence), followed by a period of decision-making (convergence) that generates outcomes in the form of material and strategic solutions.

In the divergence period, designers often use tools and methods that allow them to ideate possibilities, prototype solutions and gather insights. Some examples of tools used in the divergence sub-phase are listed in figure 3. Although many of the tools and methods mentioned are generic, some specialized tools are becoming more widely used. Social interaction methods such as Open Space, World Café, Appreciative Inquiry and Engagement Continuum, are examples of specialized methods used when designing for social groups.

Fig. 3. Design Tools and Methods used in the creation phase.

Ideation processes - brainstorming - hypothesis-forming - theory-forming - scenario planning
Prototyping - model building - storyboarding - sketching - mapping - visualization
Insights gathering - anthropological studies - ethnographic studies - ergonomic studies - surveys/interviews on stakeholders - research - data analysis - testing - trend forecasting
Social interaction - dialogue processes - workshops/charrettes - strategic conversations

Designers usually play an important role in the divergence period, while managers are more likely to play the convergent role. Richard J. Boland, quoting Herbert Simon, mentions the three factors in decision-making processes: design, intelligence and choice. Boland highlights the different management styles that result in different combinations of these factors. The framework presented in this paper is similar to the management style that Boland describes as a process that begins with Design, applies

Intelligence and ends in Choice. Design shapes things and is followed by a sensemaking process. Boland explains that “during sensemaking, intelligence is applied to order [elements] in ways that make the situation meaningful, aesthetically pleasing, and morally acceptable. This intelligence is followed by a choice of which meanings and sensemaking structures to carry forward into future enactments” (Boland, 2004). This decision-making process is referred to as a convergence period in the *sustainable design framework*.

Many companies that emphasize design have iterative design processes in place that promote creative thinking, while companies that emphasize management over design, may be driven by previously-tested strategies for reducing costs and lowering risks. In the creation phase of the *sustainable design framework*, design and management teams could create a shared vocabulary, as suggested by Boland, that promotes a mutual understanding of design and management processes and articulates a shared process of creative exploration and decision-making. When faced with the need to implement an environmental strategy, managers managers might turn to the ISO 14000 protocol to gradually reduce waste and energy use in a company, therefore reducing costs and increasing productivity. Designers, on the other hand, would take a different approach. Rather than gradually lessening the environmental harm, they might prototype new services that have no impact on the environment.

Documenting design methods can educate designers and managers on the need for a shared design and management process. This documentation can provide supporting evidence that an organization’s process is in need of disruptive innovation, a need that designers could meet. It can also highlight processes that only need linear improvements. Numerous classes of processes used in an organization could emerge as a result of such documentation. The methods bank inside an organization could catalog methods that could range from the repeatable to the disruptive. When addressing sustainability, companies are challenged to develop new areas of expertise. Having an on-going documentation process helps organizations understand the role of design in unfamiliar territories. When designing for communities, for example, designers might play the role of ‘facilitators’, co-designing with a diverse group of stakeholders (Manzini, 2004), an atypical role for designers who are used to being the sole authors of their designs.

Assessment.

The triple bottom line can serve as the basis for assessing the impact of design on sustainability issues. Measuring the impact of organizations on the social fabric of communities, their economic development and natural habitats, are crucial tactics that designers are just beginning to understand. The role of assessment tools, metrics, and certifications are particularly important in informing the design of sustainable solutions.

Many assessment tools, metrics, and certifications are already in place (see figure 4). Having assessment metrics informs the design process in the creation phase of the *sustainable design framework*. Metrics provide evidence of the state of an organization’s sustainable innovation strategy, signaling the need for design thinking when progress is not being made.

Fig. 4. Examples of existing assessment tools and certifications.

Social	Economic	Environmental
Social Footprint Index, Global Compact, The Natural Step, Corporate Social Responsibility (CSR) policy, Universal Design principles.	Global Compact, The Natural Step, Integrative Thinking Process, Six Sigma, TRIZ, cost-benefit analysis, ISO 9000.	Cradle to Cradle, ISO14000, Life-cycle assessments/ eco-indicators, LEED, BREAM, Green Globe certification, The Natural Step, Environmental Management Systems (EMS).

A later phase of this study will necessarily have to learn what impact assessment methods have on an organization's design processes. It will also be necessary to better understand the positive feedback loops that take place in the triple bottom line. A company that has an Environmental Management System in place, for example, reduces operating costs, thus increasing productivity and profit inside a company—an example of how the environmental bottom line has a positive effect on the economic bottom line. Similarly, companies provide social services simply by employing personnel, thus keeping unemployment and inflation rates down in the local community where they operate—a positive social effect resulting from the economic bottom line.

The Work Worth Doing experience

Work Worth Doing (WWD) is an interdisciplinary design studio employing anywhere between two and five designers at any given time. It was created in 2004 for the purpose of applying design to social and environmental challenges. WWD believes there is a business case for creating projects that benefit the environment, communities, and organizations. Because the studio's mission is to create positive social and environmental change, it has a need to measure the impact of its projects.

The studio takes on client-based projects and also generates its own projects. Initiating its own projects allows the studio the flexibility to experiment with various methods, development processes, interventions, timelines, and potential solutions.

Client-based projects tend to be more outcome-driven, and the end-results are determined by clients from the beginning of a project. Examples of these client requirements are: research and innovation documents, exhibitions, and publications.

The studio's approach to design and sustainability.

Based on a review of WWD's previous projects, the author identified two themes that capture the studio's approach to sustainability: Knowledge and Action. Knowledge projects create or promote knowledge about sustainability, while Action projects implement sustainability practices through measurable results. Initial projects that the studio embarked on dealt with educational products, tools, and experiences. Two case studies of Knowledge projects are included in this paper (see Case Studies I and II). This paper is also an example of an Action project, as it promotes ideas, and knowledge around sustainability issues.

Case Studies I and II
Knowledge: Tools to Think With

Case Study I
Greenland: Too Perfect. What if Greenland was Africa's Water Fountain?
This exhibition project was developed in collaboration with Bruce Mau Design and commissioned by the Danish Architecture Center to demonstrate how designers could operate in 'new areas'. Through design thinking, a system was developed that promotes capturing glacial meltwater in order to prevent the disruption of ocean currents in the Atlantic. Taking advantage of the captured melt-water, the proposed design includes a water-shipping system composed of massive ocean-going water bags that transport Greenland's pure melt-water to water-stressed regions of Western Africa. To finance such a system, the design includes a program for bottling Greenland's iceberg water and exporting it to affluent markets, thus diversifying Greenland's economy. The project also identifies a variety of partnerships between Greenland's government, African communities, and water companies. This project is an example of how designers could articulate disruptive innovations, in this instance, for Greenland's government.

Case Study II
Hyperborder: The Contemporary U.S.-Mexico Border and Its Future.
This publication project was developed in collaboration with Fernando Romero and his LAR architecture studio in Mexico City. This research-based book project had two parts. The first part contextualizes the current challenges found in the U.S.-Mexico border region with other examples of collaboration and conflict found in other international boundaries. It is complimented by an extensive mapping, and visual analysis of Mexican and U.S. political systems and economies as well as infrastructures. The second part of the book presents future scenarios—both positive and negative—that both countries are likely to face in coming decades. The scenarios are designed from the perspective of complex issues such as security, narcotraffic and corruption, economic development, health, aging and migration, among others. Such comprehensive presentation is a useful tool for decision-makers in both countries as well as educating broad audiences in both countries on the need for a systems approach to designing binational solutions.

The projects presented in Case Studies I and II can also be considered as “tools to think with”. They engage broad audiences and clients around issues related to global warming and water shortages as in the case of Greenland: Too Perfect, or around complex social, political and environmental issues between Mexico and the U.S. as in the case of the Hyperborder project. They both make use of anticipatory skills since they present potential solutions or future paths of action, rather than technical fixes to solutions. They were also developed using interdisciplinary approaches. A team of young professionals with backgrounds in sociology, anthropology and international relations was assembled to develop the Hyperborder project. Similarly, the Greenland project was informed by a diverse pool of experts. Both case studies were presented to decision-makers in government (Greenland, and Mexico) for consideration. The use of design for political decision-making processes is an area that the studio would like to continue exploring.

Since the studio’s founding, WWD has been developing a project called Now House which the studio considers its first Action project, since it embeds sustainability criteria into the project’s social and environmental outputs (See Case Study III). It also makes use of anticipatory and interdisciplinary design approaches.

Case Study III

Now House™: One Small House, One Million Opportunities.

Now house will turn a 60-year-old WWII house into a near zero energy house—one that produces almost as much energy as it uses. Now House is one of twelve winning teams from across Canada in a competition organized by the Canadian Mortgage and Housing Corporation (CMHC) that called for housing designs that are healthy, affordable, sustainable and energy-efficient. The Now House retrofit design will reduce greenhouse gas emissions by 5.4 tonnes annually. Solar photovoltaic and solar thermal panels will reduce the homeowner’s energy bills to zero on an annual basis. The demonstration house, located in Toronto, will be open for tours once it is completed in the summer of 2008. WWD has also started a community project inspired by the Now House project. Work Worth Doing is working with a community of 200 wartime house owners on a community-driven project that promotes energy-saving campaigns in the community with the goal of reducing energy use by 25% against a benchmark. With one million similar wartime houses across Canada, the team is starting with one house, then a community of wartime houses, then a million houses across the country.

The Case Study III project, unlike the Knowledge projects, introduced the use of metrics to measure the project’s impact on the environment. The studio is currently applying the knowledge acquired from retrofiting a house to near-zero energy into a community project. The studio wants to use similar metrics to measure its environmental, as well as social impacts in this community as the studio shares its knowledge and experiences with that community. A key factor that required the studio to begin using metrics around sustainability was a requirement by the competition organizer (CMHC) to ensure the Now House project met the competition entry criteria. Competition parameters required the team to conduct an integrated design charrette and use energy modelling tools to predict measurable results.

The charrette was attended by engineers, architects, product manufacturers, students, urban planners, graphic designers, and economists. They had to work together to design the retrofit in such a way that it would reach net-zero energy on an annual basis. Through a modeling exercise, the team was able to simulate the amount of annual energy reductions, meaured in Joules, and greenhouse gas emissions reductions (measured in CO_2 emissions) that would be achieved with the proposed house retrofit design.

The studio's Knowledge projects (case studies I and II) are similar to the work of universities and non-profit organizations that promote knowledge and new ideas. An Action project, like the Now House, is comparable to the work done by private-sector companies and non-profit groups. This evolution in the studio's practice from Knowledge into Action is consistent with a review of how other organizations use design for sustainability, by talking about sustainability, and implementing sustainable practices.

The fact that the studio has Knowledge and Action projects, which are comparable to the work done by universities, companies, and non-profit organizations is in line with the vision of the founders of the studio. In 2004, the founders stated that WWD would be a mix of an innovative enterprise, a philanthropic NGO, a research lab, a cultural institution, a think-tank, a production house, and an entertainment company. The studio is in itself an evolving organizational design that is learning how to best use design to create positive social and environmental change. Figure 5 contextualizes the studio's methods in the creation and assessment phases of the *sustainable design framework.* This framework will inform how the studio approaches future projects.

Fig. 5. A *Sustainable Design Framework* applied to WWD projects.

Project	Methods used in the Creation Process	Design Outcome	Results Assessment
Greenland: Too Perfect	Prototyping, Mapping, Visualization, Interviews with stakeholders, Research, Data analysis, scenario planning, hypothesis-forming	Exhibition	Social and environmental criteria were used when designing, but no measurable criteria can be assessed.
Hyperborder	Prototyping, Mapping, Visualization, Workshops, Interviews with stakeholders, Research, Data analysis, scenario planning, Trend forecasting	Publication	Social and environmental criteria were used when designing, but no measurable criteria can be assessed.
Now House	Dialogue processes, Workshops, Charrettes, Model building, Theory-forming, Scenario planning, Surveys and interviews with stakeholders, Data analysis	Housing retrofit, Community project, Business model	Environmental metrics: Greenhouse gas emissions, Energy use reduction and energy production measured in Joules. Social metrics (qualitative and quantitative): Number of new community social networks will be counted; Interviews in the community will measure positive impact as a result of the intervention.

Going forward

The *sustainable design framework* mentioned in this paper forms the basis of a methodology to be followed in a later part of this study. WWD will conduct interviews in organizations that have design policies in place and that are in the process of developing a sustainable innovation strategy. This second phase will study study the barriers and determinants in adopting a *sustainable design framework* inside organizations.

Numerous challenges in attempting to implement a *sustainable design framework* in an organization can be identified already, including some of the following:

- Allowing time for design groups to catalogue their design processes is not a common practice and is often considered as non-essential to the financial goals of companies. Companies that use repeatable design methods for 'repeat' client work often have implicit methods that are developed through experience and are not formally articulated.
- Establishing a common vocabulary that describes the methods used both for creation and assessment phases of development is a challenge, as management and design groups are trained using different terminologies. There is a need to promote generalist and specialist approaches of design. The need for interdisciplinary and anticipatory approaches in design can be traced back to Buckminster Fuller, who in 1964 called upon designers to be comprehensive and adaptive professionals (Fuller, 1964). However, many companies and organizations only hire specialist designers. Staffing organizations with designers with knowledge of management, and managers with knowledge in design should be promoted.
- The study of design methods used in different industries will require the acknowledgement of specialized terminology. Some methods used in one industry may not apply to other industries. Specialized *sustainable design frameworks* that acknowledge an industry's terminology might be necessary.
- Encouraging private-sector design groups to share their design methods with the design community at large remains a challenge, since it can compromise the competitiveness of some companies. Cradle to Cradle and The Natural Step serve as points of reference to instigate this question. The former has both for-profit and non-profit organizational models (McDonough Braungart Design Chemistry, LLC and GreenBlue), while the latter is solely a non-profit organization.
- Establishing a shared understanding of the design processes among diverse stakeholders in different sectors, such as government, communities, and organizations would require increased promotion of design's value. Design organizations might play a valuable role in this regard.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design for all

A co-design experience in rural India for healthy indoor cooking

Simona Rocchi[1] and Yasushi Kusume[2]

Abstract

For many women in rural India spending several hours a day cooking over an indoor open stove is the norm. What these women fail to realize is that there is a dangerous killer in their kitchen: burning biomass fuels causes almost 500,000 deaths every year in India alone.

What can creative design do to help these women continue with their traditional culture, while empowering them to select a way of cooking that does not endanger their lives?

This paper illustrates an initiative built up within Philips' global design community, where employees used their capabilities to face important current social and environmental issues and, in the paradigm of open-innovation, to provide a concrete context-specific humanitarian answer to one such issue.

1. Background

We are currently living in an increasingly complex, inter-connected and fragile world characterized by population growth, globalization, political instability, social and economic inequality, and environmental degradation. These trends are transforming our society and our economy: sustainable development is no longer an option, it is imperative. Companies with long-term economic ambitions must find new ways to continue being competitive in the saturated markets of advanced economies, but they also need to learn how to flourish in emerging and developing markets that represent a growth opportunity for the coming years (Prahalad 2005: 3-21).

In order to address the 'un-met' needs of low-income people in emerging and developing economies, creative thinking, system views and open innovation seem essential nowadays. Standard process and product related eco-efficient practices cannot, on their own, provide competitive and valuable answers (Hart 2005, 85-104). The challenge is to create accessible and affordable solutions that match local infrastructural and economic conditions and socio-cultural preferences, without expanding the current use of environmental resources. To face this challenge, new and appropriate business and design practices are necessary to define effective and sustainable growth trajectories.

Within this search, a promising path is emerging: a mutual value creation process between companies and local stakeholders who have a deep understanding of specific contexts, issues, and opportunities; an 'intensive listening' to the 'voice' of potential target communities, families, and individuals (Simanis, Hart, Enk, et al. 2005, 5-13). Pioneering activities of this type are initiated in various ways. Companies that aim to become truly sustainable, and develop propositions for 'underserved' people, often use social investment budgets while on their journey of learning.

The tendency is to replace traditional cash donations - to organizations that deliver a variety of social and environmental benefits - with activities connected to internal competencies and with specific actions carried out by employees. The conviction is that humanitarian projects, conducted with a business-like approach, can generate both value to society and competitive assets (Porter and Kramer 2002, 1-14). They can support socio-economic and environmental causes, but they can also serve as laboratories to develop new, sustainable solutions, new insights into resolving societal problems, and new ways of working.

2. Introduction

It is against this background that this paper intends to illustrate how to leverage design and research capabilities to create a common vision of sustainable development, and to translate this vision into context-specific humanitarian solutions. To do so, it draws on the experience built up within Philips Design[3], one in which employees worked together in a large-scale design workshop, and on a local follow-up activity.

Using this experience, the paper aims to:

[3] Philips Design is the design service unit of Royal Philips Electronics. It covers 11 locations around the world, with a total of 550 professionals from more than 30 nationalities. Its creative force embraces disciplines as diverse as product, interaction and web design, sociology, anthropology and socio-cultural trends research.

- provide an overview of the design process and tools used to inform, inspire and engage the creative 'sustainability' thinking of 275 designers and researchers challenged to confront global sustainable development issues, and a variety of 'quality of life' topics affecting people on very low incomes;

- describe the open innovation approach adopted for the implementation - in rural and semi-urban India - of one of the design concepts generated during the creative phase: the 'Chulha', a stove for healthy indoor cooking co-developed with various local stakeholders and end-users. The stove is designed to combat sickness and death due to indoor air pollution from cooking with biomass fuels, but also to stimulate the formation of local groups of entrepreneurs to produce and distribute it.

The paper starts with a summary of the initial design workshop, defined in terms of scope, structure, participants and type of research input. It continues with a description of the methods used to gather information, generate users' insights, and consolidate knowledge. It then illustrates the design tools and criteria used to generate ideas.

Along the way, it moves from concept-design to concept-development and piloting by describing: the approach used and the stakeholders involved in carrying out the project in India; the current project status; achievements/obstacles; next steps, including scaling-up activities.

It concludes with a few reflections on the learning from the project, and on a few thoughts regarding the specific contribution of design towards sustainable development.

3. Raising awareness, stimulating creative thinking

In September 2005, the Philips Design global community came together in Eindhoven for a one-and-a-half day workshop entitled 'A Sustainable Design Vision - Design for Sense & Simplicity', in an attempt to rethink charitable donations beyond financial sponsorship. The workshop, which followed the Philips' themes of social investments (Philips 2005) – access to healthcare, wellness and education – aimed to explore directions and opportunities for innovative humanitarian propositions that would express our company's mission[4], and would consider:

- internal competencies, technology and know-how, combined with external, complementary expertise;

- people's needs and aspirations manifested in various regions of the world, and more specifically, in their contexts-of-life.

The aim was to come up with products and services able to support Non-Governmental Organizations (NGOs) in relieving the suffering of people in emergencies (resulting from natural disasters), or enhancing individual empowerment and the socio-economic development of local communities at very low income level.

In preparation for the workshop, a core project team, comprising design innovation, environmental science, user's research and socio-cultural trends capabilities from headquarters and a few regional branches, was assembled to conduct six months of extensive research and organizational activities. To create enthusiasm within the Philips Design community for the coming event, three packages of material designed to promote communication were distributed several months in advance. The material introduced the setting, aim and ambitions of the event and provided examples of innovative companies' humanitarian actions to tackle environmental and social challenges. Such challenges were brought to life at the opening of the workshop

[4] Philips' mission states: "*Improve the quality of people's lives through the timely introduction of meaningful innovations* ".

through speeches given by representatives of three international Non-Governmental Organizations (NGOs): Médecins Sans Frontières, Save the Children and Light Up the World[5]. They described the problems encountered in their work, using touching, real life stories.

During the event, the 'Design Times' internal newsletters, which offer additional informative and inspirational input, were used to guide the creative process towards the specific challenges to be faced. The users targeted in the creative brainstorming sessions were representing the most fragile categories of our societies, including children and women living in remote rural areas, elderly people living alone in urban spaces and low-income workers in suburban areas of highly populated cities: all affected by specific diseases / mental wellness issues, or with learning and educational access problems. Such issues were identified by desk and field research, and by the NGOs that participated in the workshop. Gaining the insights of real people was the primary task in preparing for the event. It was our belief that only through a deep understanding of people's real needs and aspirations in their physical and socio-cultural environments would it been possible to create a solid opportunity for meaningful and sustainable design interventions.

4. Gathering people insights for a human-focused design

Qualitative and quantitative data gathering focused mainly on emerging and developing socio-economic contexts in which Philips operates: Latin America; Eastern Europe; Russia; India; China. Issues that came under the spotlight included, for example, malnutrition, pneumonia, malaria, sanitation, water purification, air pollution and environmental degradation, energy consumption, lighting, and illiteracy. The selection of issues to be tackled was defined by their urgency, as indicated by the quantitative data collected from various sources. Methods used for data and knowledge gathering included:

- desk research into the databases and reports from international aid organizations, scientific environmental institutes, and sustainable development trend-watchers (UNESCO 2005; UNICEF 2005; WHO 2005; WRI 2005, etc.) to gather global figures;
- interviews with NGOs working in the field[6] to understand both their daily challenges and how they deal with such challenges;
- field visits conducted by our user researchers and designers to observe and/or interview people in their communities and homes, and so gain direct insights into people's life experiences and true stories from specific environments.

More precisely, the information from the NGOs covered questions concerning their work-related problems, as well as their experience of people's living conditions, any infrastructural and technological constraints, solutions currently used and their limitations. Research into individuals was also addressed via face-to-face interviews, observations and focus groups, where possible to leverage the informal regional networks made available by our designers and researchers in the various branches. Knowledge and data collected in the regions were then conveyed to the Philips Design headquarter where they were consolidated into common 'digestible', informative and inspirational formats.

Consolidating informative and inspirational input: 'personas' in local contexts

[5] Workshop speakers were: Derryck Klarkowsky of Médecins Sans Frontières (MSF), an international humanitarian aid organization that provides emergency medical assistance to populations in danger worldwide; Meredith McWade of Save the Children, an organization that provides opportunities for the world's children to live safely and healthily; Dave Irvine-Halliday of the Light Up The World, a foundation that provides white LED lighting solutions powered by renewable energy to the world's poor in remote rural areas.
[6] In addition to the three main NGOs previously quoted, UNICEF should also be mentioned as an initial useful source of information.

Qualitative and quantitative information was matched and compiled into 'personas'[7]: flexible design instruments used to provide insights into 'a-day-in-the-life' of the targeted individual or community. In total, 19 'personas' were created to be used as specific design briefs for the creative session. These 'personas' were delivered in A3 format newsletters: 'The Design Times'. Their aim was to summarize relevant statistics on key issues, together with related informative and inspirational knowledge such as case studies on context-specific technological challenges and emerging opportunities, testimonials, individual or collective stories reflecting people's needs and aspirations, interactions with products and services, and their socio-cultural habits.

In the workshop, 'personas' were key tools in thinking of people-focused solutions. They helped participants to experience the main issues faced by their protagonists in certain geographical and socio-cultural conditions, and they stimulated the imagination of designers when it came to forming possible answers to such issues. In total, 33 healthcare/wellness and education related issues were addressed in compelling stories used as design briefs.

5. Ideation: design process and tools

The workshop participants, representing more than 30 different nationalities, were divided into 46 teams comprising designers and researchers with different backgrounds and capabilities. The teams, made up of five members each, received a specific 'persona' brief to work on, under the guidance of a facilitator[8] assigned to steer the discussion and the design activities. The overall process consisted of four main phases. In the 'opening' phase, employees got to know each other and familiarized themselves with the key global social and environmental challenges. In the 'analytical' phase, they learned about and analyzed the specific issue/s and contexts to be dealt with. In the 'thinking and creative' phase, they explored design ideas and they dealt with their conceptualization and visualization. In the 'promotional' phase, they were asked to market the value of the concept(s) generated to the Philips Design community.

Guideline design tools and templates were made available, but they respected the necessary freedom of thinking and creativity of the teams at all times. Two tools in particular – the 'chain reaction' exercise and the 'design-for-sustainability' design orientation criteria – were used to increase the prospects of envisaging environmentally and socially effective product and service ideas.

'Chain reaction' exercise

With this tool, the teams were invited not just to solve the problem(s) raised by their assignment, but also to understand them by examining related people's socio-cultural values and behaviors, as well as the consequences of these. The teams therefore analyzed every issue through a mental framework linking values/behaviors > problem > consequences, to understand how to break this vicious circle and introduce solutions able to stimulate a new, positive chain to improve quality of life. For example, to understand the problem of indoor air pollution in rural India, the teams connected with:

- its causes - the use of wood and inappropriate stoves, the enjoyment of tasting food cooked on wood, the lack of knowledge regarding possible health-related effects, etc.

[7] 'Personas' are defined here as fictional characters that encapsulate global issues in regional contexts. More precisely, they are representations of certain categories of individuals and groups of people dealing with various issues and quality of life concerns in specific geographical and socio-cultural contexts.

[8] The facilitators were trained beforehand to use a series of supporting design tools and exercises (included in a facilitation notes booklet) specifically developed for this workshop.

- its consequences - respiratory and eye-related diseases, children's healthcare costs, children's time spent in collecting wood, women's time spent cleaning the kitchen, etc.

Then, to overcome the problem, the teams tried to come up with actions that would deliver direct healthcare benefits, together with positive parallel environmental and socio-economic advantages, both at the individual and the community level. For instance, by introducing a smart cooking device, it was hoped that children would have more time to study because they had to spend less time collecting wood, CO_2 emissions and wood consumption would decrease and healthcare awareness in the family would increase, all of which might result in healthcare cost savings and more efficient work activities.

'Design-for-sustainability' orientation criteria

This tool was designed to take into account both environmental and social criteria 'up-stream' in the concept creation phase, and to stimulate a 'system thinking' approach, one that moves beyond technical product changes towards a more holistic concept of innovation. Its aim was to prompt designers with principles and criteria that could support innovative design strategies to influence patterns of production, distribution, marketing and use. Indeed, only by contextualizing technological opportunities, and considering regional and local community requirements is it possible to aim to deliver truly sustainable solutions (Manzini and Jegou 2003, 36-68).

The 'design-for-sustainability' tool made use of five main clusters, and further specific design orientation criteria:

- Design for longevity: aesthetic and functional up-grading; modularity and scalability; durability; recovery in its various forms; etc.
- Design for dematerialization: miniaturization; integration and multi-functionality; virtualization; biodegradability; etc.
- Design for efficient and clean energy: solar / wind power; human power; hydrogen power; hybrid systems; etc.
- Design for cultural diversity: local resources; technologies appropriate to the context of application; traditional smart practices; individual and community empowerment, etc.
- Design for sharing: common use of space, assets, time, knowledge, etc.

A few of these criteria were selected by the designers so that they could set up their own design strategy and specify the potential of their concepts in terms of environmental and social performance.

6. Value co-creation: a 'chulha' for healthy indoor cooking

The intensive burst of focused creativity generated approximately 80 design ideas for products and product-service-systems. Following the workshop, these ideas were filtered by criteria such as their fit with the Philips strategy and social investment policy, their technological feasibility, and their fit with the Millennium Development Goals[9]. The screening, carried out with

[9] In September 2000, all 191 United Nations Members States pledged to meet eight socio-economic and environmental goals by the year 2015. The goals, stated in the Millennium Declaration, include: 1. Eradicate extreme poverty and hunger; 2. Achieve universal primary education; 3. Promote gender equality and empower women; 4. Reduce child mortality; 5. Improve maternal health; 6. Combat HIV/AIDS, malaria and other diseases; 7. Ensure environmental sustainability; 8. Develop a global partnership for development (UN 2000).

various stakeholders, narrowed the number of potential solutions to 20, re-grouped into seven promising clusters considered to be opportunities for intervention. From the various opportunities available, a couple of design ideas were chosen for implementation. The first one to come to life was a low-tech stove that would tackle the respiratory problems affecting the health of millions of people (especially women and children) in the developing world who still cook indoors using biomass fuels[10]. The aim was to design, develop and test an appropriate solution for local cooking habits in rural and semi-urban areas of India. The goal was to provide a wood-burning solution that was:

- easy to access (easy to distribute/install/use/maintain)
- locally produced
- able to reduce indoor pollution
- low cost for replication and scalability.

Within eight months, a three-person design team from Philips Design Pune evolved an initial design idea into a concrete solution tested in the field. In a collaborative effort with local social stakeholders, entrepreneurs, and a few families, they produced two versions of the 'Chulha' stove in an attempt to satisfy people's cooking needs more healthily and, at the same time, stimulate socio-economic activities for local business development (Fig. 1).

Input from various local social stakeholders included a solid contribution from SEDT (Socio Economic Development Trust) NGO for rural development programs and people mobilization in the field, Dhanalaxmi Bachat Gat and Mahalaxmi Bachat Gat, two SHGs (Self-Help Groups) that empower local women to become entrepreneurs.

Particularly instrumental in this humanitarian design project was the cooperation of ARTI[11] (Appropriate Rural Technology Institute), an NGO with considerable expertise in the smokeless cooking domain. ARTI helped the team to scan available technologies and benchmark current smokeless and non-smokeless solutions; identify specific challenges and opportunities for design interventions and scalability; and carry out technology development and field tests.

7. Field research in rural and semi-urban areas

The research previously carried out (for the 'Sustainable Design Vision – Design for Sense and Simplicity' workshop) on indoor air pollution in India was sufficient to provide a basic understanding of the issue and its context, and to feed the initial creative process. However, at this stage, additional knowledge was necessary to develop a truly effective solution: knowledge of people's purchasing power; specific culinary habits; cooking behavior and user interaction with available devices; information on local production and distribution channels, etc.

The design team - with the support of Green Earth, a local sustainable development agency dealing with grass root behaviors and social studies – gathered deeper, more specific insights into people by carrying out research in the villages of Kerwadi, Phaltan, Maltan and Karad, all in the state of Maharashtra. The research consisted of an initial 3-day visit and introductory meetings with people from the villages, followed by one week of observations and in-depth

[10] Total world deaths from indoor air pollution due to burning solid fuels are estimated at 1,619,000 each year. India alone accounts for 25% of such deaths. Almost 500,000 of the victims are women and children (WHO 2000).
[11] ARTI develops and promotes the diffusion of innovative rural technologies to improve the quality of life and standard of living of India's rural inhabitants. It operates in various areas and acts through its training centre located at Phaltan, 120 km north of Pune.

interviews targeting four rural and two semi-urban families[12]. The interviews, conducted in the local language (Marathi), were kept quite informal. All the family members were observed, with particular attention paid to the women who were carrying out cooking activities. The findings were then synthesized and consolidated in 'contexts-of-life cards' describing the women's profile and related cooking activities, the families' way of life, and their environment.

Infrastructural conditions, production facilities and distribution channels for stoves currently in use were investigated using the ARTI network. A needs analysis of stakeholders already active in the business of smokeless and non-smokeless stoves was performed by organizing various focus groups involving local entrepreneurs and self-help groups, in order to understand the major issues they face with regard to current solutions and the replication and scalability of their activities. Focus areas regarding logistical transportation constraints and maintenance were extracted and consolidated in the same format used to summarize the findings from users.

It soon became clear from the results of the research that the key local design requirements called for a cooking solution able to fulfill the following physical and socio-cultural conditions:

- adaptability to different biomass fuels (from wood to cow dung), available in different seasons and locations
- adaptability to people's needs when cooking 'chappati' (bread), steaming rice, boiling water
- adaptability to the use of different, non-standard cooking vessels
- adaptability to various vehicles and distribution channels.

8. Concept development and testing

In both the concept development and the concept prototyping and testing phases, there was a collaborative effort to provide a meaningful response to the product requirements identified. Users' insights, and the findings relating to stakeholders' needs were used in a local workshop involving the various players engaged in the design process (ARTI, SEDT, SHGs, two local entrepreneurs and two users). The workshop, intended to define the key product features desired, involved 16 participants who were invited to share their viewpoints and concerns in informal dialogues. The dialogues were then followed by a session to conceptualize ideal stoves and their expected performance within the contexts under investigation. During this phase, several pages of insights (context-of-life cards) offering a stakeholder's needs analysis - including end-users' needs - were circulated among 'experts' in the production, distribution and use of wood-burning stoves, for their feedback and refinement.

At the end of the workshop, key design features were pinpointed and prioritized as 'easy-to-use and maintain', 'context-specific', 'flexible', 'able-to-radiate-value', and 'accommodating'. These features were visualized into design sketches. In the next step, a fine-tuning process conducted by the design team proposed the following major design innovations:

- modularity to facilitate distribution, installation and reparability of both the stove and the chimney

[12] The rural families had an average of four adults and three children, with a monthly income of between 73 and 184 Euros. The semi-urban families on the other hand had an average of two/four adults and two children, with a monthly income of between 92 and 184 Euros.

- mechanisms to ensure the chimney could be cleaned safely (currently, where chimneys are available, they are monolithic blocks which can be cleaned only from the roof)

- improvement to construction (the weak bridge in current stoves is a common problem)

- flexibility of use for roasting and steaming, additional functional features and appealing design format.

These innovations were incorporated in two versions of our 'Chulha': 'Sampoorna' and 'Saral'. In collaboration with ARTI, both versions have been translated into real applications. The 'Saral' is a double oven with a hotbox which costs between 9 to 10 Euros. The 'Sampoorna' offers a more sophisticated solution, including a steamer, at a cost of around 14 Euros. The stoves and their chimneys are mainly made of concrete modular components, covered with clay. Their modularity facilitates the replacement of broken parts over time as well as transportation (Fig. 2). The stoves can be packed in recycled woven polypropylene bags, which are by-products of waste from agricultural storage, etc. The moulds are made of FRP - fiber reinforced plastic - at a cost of 183 Euros, with the capacity to turn out more than 3,000 pieces.

Prototyping at the ARTI training centre in Phaltan, and testing in rural and semi-urban homes, involved SHG representatives and stove users. Feedback regarding improvements suggested a few modifications to the initial versions of the stove. Design interventions included technical changes related to the manufacturing process to optimize gas flow within the stoves and improve their thermal efficiency, an easier way of assembling components such as self-locking pieces for do-it-yourself assembly, the introduction of a soot collector, and a solution for fixing chimneys to the wall. Modified versions were then installed in 12 homes for further trial and to evaluate their technical performance.

9. Achievements and obstacles

The value co-creation process undertaken during this journey of understanding and learning has resulted in a stove that makes indoor cooking healthier when compared with traditional indoor open cooking fires - a stove that also claims to be simple to use, easy to maintain, produced and distributed locally, relatively cheap, and suitable for different culinary habits. It also helped to go one step further. According to Dr. P. Karve of ARTI, the overall research and design contribution has helped in proposing a "*Chulha that has a better chance of succeeding than other concrete smokeless stoves because it is more attractive, and has improved functional features*" (Karve 2007). It has helped to shape a stove that is easy to handle, from manufacturing to installation and maintenance. "*The 'Chulha' and its chimney are easy to transport thanks to their modular design. They are quick to assemble and broken parts can be easily replaced over time*" (Karve 2007).

The route to reaching these results was not without obstacles, however. Initially, we faced a communication barrier that slowed down interaction with the key stakeholders and end-users, and therefore the entire design and development process. We had to learn to speak a 'language' able to:

- create convergence of different (political, social and economic) interests;

- give 'voice' to 'vulnerable' end-users, bringing their viewpoints into the dialogue with multiple stakeholders with precise, and often consolidated, opinions.

Such a 'language' could be developed only through a long and patient process of 'intensive listening' and engagement. An effort that, in the end, paid off.

Indeed, it should be noted that, among the various cooking solutions already available for low-income people, the 'Sampoorna' and 'Saral' seem to be competitive: their original objectives - adaptation to local culinary habits, use of available resources and infrastructural conditions; value chain optimization; economic affordability[13]; reduction of indoor air pollution – have been reached through careful improvements. With regard to environmental aspects in particular, it has been estimated that, in theory, the 'Sampoorna' and 'Saral' stoves could reduce indoor air pollution from smoke by up to 90% in comparison with indoor open cooking fires. What's more, technical evaluations conducted by ARTI shows that exhaust gases and carbon monoxide emissions were reduced in comparison with other concrete-based indoor smokeless stoves. Specifically, a deeper evaluation of our stoves' technical performance, made by the College of Engineering in Pune, reveals:

- better heat distribution, fuel and thermal efficiency (time and fuel required for boiling 1 liter of water is 11.5 min. and 255 gm for Saral and 14 min. and 315 gm for Sampoorna, in comparison with 22 min. and 415 gm required by traditional stoves)
- higher retention of soot (100 mg for Saral and 80 mg for Sampoorna, in comparison to 20 mg for traditional stoves).

However, no official quality standards of reference are currently available to judge the technical performance of concrete stoves. Various NGOs use different criteria to evaluate performance and different values for acceptable emissions. As a consequence, it becomes difficult to scientifically prove the added value of the 'Sampoorna' and the 'Saral'. At the moment, our intention is to go beyond evaluating the technical performance of our stoves, to fully assess their economic and social performance over the long-term, in order to verify all the benefits they claim to deliver. Current plans include an impact study that will run from October 2008 to July 2009 to monitor a few cases where final versions of the stoves are in use (Fig. 3).

10. Replication and scalability

So far, to facilitate replication and diffusion of the 'Sampoorna' and 'Saral' stoves, design innovations have been recorded in sketches and technical drawings. A comprehensive package of communication and training materials, including posters and videos, has also been created to explain how to produce, distribute, install and maintain the stoves. With the support of local NGOs, the intention is to allow Self-Help Groups and citizens to use this knowledge for free. The hope is that this will create not only better living conditions for the end-users - women and children - but also stimulate local entrepreneurial activities centered on the production and distribution of safe and healthy stoves.

ARTI will continue to play an essential role in all of this. It has included our solutions in its portfolio of stoves ('gas-fired', double wood-burning stove, simple concrete stove) for rural and semi-urban communities, and it trains local stakeholders to produce and distribute the most appropriate solution for the selected target audience, according to income level and infrastructural conditions. The current production and distribution model proposed for the 'Sampoorna' and 'Saral' stoves can easily be adapted as a decentralized model, in which a trained entrepreneur invests in a mould that is able to cover the demand of a couple of villages, with 50-60 households each. However, the aim is to shift to a semi-decentralized model where localization takes place at district level: with this model of scalability, the new entrepreneur will be able to serve up to 30-40 villages, with 200-250 households each.

Besides the activities carried out by Arti, another NGO, already approached us with the intention of stimulating the broad diffusion of the 'Sampoorna' and 'Saral' stoves in the rural areas

[13] Cooking solutions currently available in rural areas cost 2-3 Euros for an open non-smokeless stove made by local craftsmen, and 8 –12 Euros for basic indoor smokeless solutions made by NGOs and local entrepreneurs.

of Karnataka state (Southern India). Knowledge transfer from our side is currently running and scaling up activities from the NGO[14] will start in July-August 2008. Our ambition is to answer requests from NGOs spread throughout India, but also in countries such as Pakistan, Bangladesh, etc., where these stoves can provide appropriate solutions to very similar people's needs and culinary habits.

11. Conclusions

How have design and creativity contributed to sustainable development in this overall humanitarian experience? What are the major lessons learned? Although it is difficult to provide a complete evaluation of an experiment still in progress, when we look back at our original workshop and at the project in India, it is possible to outline certain considerations about the approach used and the results achieved to date.

From the very start of the experience, adopting a process in which designers and researchers operate in a multidisciplinary team, in open dialogue with NGOs bringing knowledge from the field, was essential in ensuring that people's real needs and true aspirations (life stories and user insights) were integrated into the initial creative 'thinking'. This was done not only to raise the level of understanding about sustainable development challenges and quality of life issues, but also to set up ideation sessions related to specific locations and infrastructures, ways of living and socio-cultural habits, to help our work force to envision effective human-centered solutions.

By using design skills and competencies to face crucial social / environmental problems affecting the most fragile categories of our society, employees felt motivated and empowered to make a difference through their own work. The 'momentum' created with this event has resulted in a practical and effective way of pushing forward our organization's social commitment. Since that time, a few employees have started to make use of their free time and training time to do some more work on ideas that came out of the creative workshop. The management has established the 'Philanthropy by Design Initiative' in order to continue the collaboration with some of the NGOs[15] involved at the beginning of this experience.

Along the journey, design capabilities have demonstrated their full range of potential when it comes to contributing to the creation of sustainable value: from the power of creativity in generating a common vision outlining directions for specific humanitarian opportunities, to the importance of design skills in articulating this vision, and even to translating this vision into concrete humanitarian answers. By utilizing a tangible design application, we were able to bring our Philips brand to life and, consequently, establish conditions for a return on brand equity: either by putting an appropriate solution to the problem in place directly, or by enabling local players to replicate and diffuse such a solution autonomously. We have, as a matter of fact, used our design knowledge to go beyond traditional tasks of technical product design. Our designers, often used to working in different domains and across various businesses, have demonstrated that it is possible to assume a steering role in organizing a proper network of competencies, connecting multiple players with complementary expertise, and facilitating a value co-creation process right up to its implementation.

All this has resulted in what M. Porter defines, in one of his articles, as capacity building, organizational learning and input for long term business strategy (Porter and Kramer 2006, 1-15). More specifically, we believe it has generated innovative ways of working that can stimulate

[14] The NGO is setting up a plan with the ambition to reach 250,000 families in five years time.

[15] Beside the 'Chulha' project, we are currently working on a concept to support Médecins Sans Frontières in their task of diagnosing infectious diseases in remote areas, and in training local healthcare workers. It is a solution able to better capture microscope images of the malaria parasite and facilitate quality control of diagnosis in front line health stations and medical camps. The solution can also be used to support educational activities for malaria parasite identification.

social innovation on the one hand, while supporting business innovation on the other. Indeed, this humanitarian project offered us the opportunity to discover new insights when it comes to resolving societal problems within non-familiar realities, triggering the identification of innovation spaces for business growth.

Operating in contexts of developing and emerging economies, we have certainly learned some basic ground rules that should be considered in future projects, especially when addressing 'underserved' people.

First of all, we have realized that an understanding of the local physical infrastructural, economic and socio-cultural conditions is imperative before making any technological choices. The challenge in coming up with an accessible, affordable and sustainable solution for local needs is to evaluate the best technological solution at a given moment in time, rather than opt for the best available technology (which is typical of a technology push approach). With our 'Chulha' for instance, insights from the targeted users and local stakeholders helped us to understand current barriers to cultural acceptance, as well as constraints on replication and scalability. It is on the basis of these insights that we were able to decide on the most feasible and appropriate technological answer to achieve our objectives.

Another thing we learnt is that the design phase should be treated as a continuous and iterative process, which goes backwards and forwards in relation to the feedback received when the solution is tested in the field. Any change and adjustment made to the initial proposition needs to be evaluated in the field, not only in terms of technical performance, but also in terms of possibly wider-reaching effects. For instance, feedback from evaluation of the 'Chulha' gave us information to inspire improvements beyond product and usage performance, to include instructions for easy and cost-effective installation, distribution and production - aspects that have stimulated new design interventions which could result in the optimization of the entire value network.

Last but not least, it should be noted that the co-design approach resulted not only in a way of delivering a solution that better fit the context of application, but also enhanced the potential benefits of the stakeholders involved, democratizing the value creation process, and therefore increasing the chance of implementing valuable solutions for all. Indeed, with this approach, users and stakeholders worked together in a participatory process where they all put their own interests on the table. Key, in this regard, was to go beyond the 'intensive listening' principle described by S. Hart in 'Strategic Initiatives at the Base of the Pyramid. A Protocol for Mutual Value Creation' paper (Simanis, Hart, Enk et al. 2005), to include a 'true engagement', where users were even empowered in the decision making process.

The question facing us now is this: how do we capitalize on what we have learned? Our hope is that we can continue make use of our imagination. It is our belief that imagination, creativity and 'holistic thinking' from design communities - if they are underpinned by solid research to help understand people and their socio-cultural and natural environments - can become important assets to break down boundaries and help move sustainable development forward. After all, at the end of the day, sustainability is, and remains, a collective creative process of change.

Acknowledgements

We are grateful to our CEO, Stefano Marzano, and to all 275 Philips Design employees who made the 'A sustainable Design Vision' workshop a success; to Bas Griffioen for managing the initiative; to the core research team working at the headquarters (in particular, Lira Nikolovska and Andreas Fruchtl); and to the regional branches. Special thanks go to Unmesh Kulkarni for directing and executing the 'Chulha' project in India, and to Praveen Mareguddi and Karma Lendup. Last, but not least, we would like to thank the NGO representatives who worked with us and made both their time and energy available.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

P-KIT, picture listening for community planning

A simple and effective design research tool for facilitators and habitants in participated urban processes.

Liat Rogel[1]

Abstract

This paper suggests a new possible role for designers in participated urban processes: the creation of tools designed for the facilitation and improvement of communication between stakeholders in urban participated development.

P-KIT is a new and effective toolkit used in six different phases ranging from expressing problems to creating future scenarios. With this kit, problems are discussed using photos made by the inhabitants. It is designed specifically to ensure effective communication in urban areas with a high concentration of immigrants.

[1] DIS (Design and Innovation for Sustainability), Politecnico di Milano, Italy liat.rogel@gmail.com

1. Introduction

The idea for this paper and project came about during community planning workshops in the city of Pioltello in the province of Milan. The research unit DIS, design and innovation for sustainability in 'Politecnico di Milano' have been collaborating with Pioltello on social networks for several years. One particular district in Pioltello has a large concentration of immigrants. It is a very interesting and multicultural area with, however, many economical and social problems. The municipality has decided to deal with these problems by using a participatory process that involves the inhabitants. The inclusive processes described below have a lot of advantages, but are hard to perform. "Participation, like democracy, has meant many things to many people. The opportunities for participation are there to be grasped but only if all those involved have a common understanding and share a common language". (Batson 1994,1) When many people are involved, new ways of communication are needed that will allow and stimulate the collaboration between experts and laypersons. In situations where there are language and cultural gaps, circumstances prove to be especially challenging. Understanding and communication between all stakeholders is extremely important.

Facilitators are people that work especially for that aim. They are professionals, usually psychologists, social workers or educators that have a large experience working with people. Interviews with several facilitators, as well as the opportunity to also work as a facilitator, have shown that there are certain communication difficulties that arise during the process. These are solved with the application of certain methods and tools. Research about existing methods for urban participation was thus necessary as the first step of this study. This research has revealed that there are many established theoretical methods created especially for this purpose or taken and readapted from other disciplines. These methods are very helpful, but most of them are also complex. To make them more visual and simple, the facilitators tend to invent tangible tools, for example: questionnaires, opinion-boards, video boxes etc. Most of the facilitators however, have no professional background in visualisation or tool creation and often have no time or resources to develop such skills. These findings have lead to the central question of this project:

How can designers significantly enable the communication between inhabitants and facilitators in order to obtain the best project results?

This question has led to a new toolkit for participation called the P-KIT. The motivations to create it as well as a detailed explanation on how it works are the focal point of this paper. Hopefully, this toolkit could be an inspiration for a whole range of new opportunities for designers.

2. Short background

To better understand the reasons for this paper it is worthy to note some details about urban participation.

In social scientific theory, participation is an umbrella term that includes different means for the public to directly participate in political, economic, managerial or other social decisions. Ideally, each actor has a voice in decisions directly proportional to decisions that affect him or herself personally. Participatory decision making infers a level of proportionate decision-making power and can take place at any level of human social activity, including economic, political, cultural etc.

It is hard to say exactly when citizen participation in urban development began. Many consider two important initial experiences in England and the United States. In the eighteenth and the nineteenth centuries in England, there were major developments in urban studies, caused by the industrial revolution. Very innovative views and actions can be found in the works of Patrick Geddes (1854 - 1932) and Peter Alexeyevich Kropotkin (1842 -1921). Unfortunately their ideas could not overcome the negative effects of industrialisation at the time. In the United States,

participation has had a long history, from the early beginnings of nation's formation. Thomas Jefferson's model of self-help, the early community barn raising and others, clearly prognosticated the 'Community Design Centres' of the XIX century. (Lorenzo 1998,39-45) With protest movements of 1968 in Europe, the 1970s began as a fertile period for participation. Many architects embraced citizen participation in different ways. Renzo Piano's work in Ottranto and Carlo de Carli's in Terni are good examples for understanding the character of that moment in Italy.

A crucial step took part in the 1990s. Participation was integrated in urban development programs as part of the agenda 21 and contributed to the diffusion of this practice. In certain countries, participation has become obligatory on some levels. Different urban development programs like CdQ (contratti di quartiere) in Italy, or URBACT on a European level include citizen participation as their main concern. That means that the ideas of citizen involvement are not left to the idealism of a few but are becoming an integral part of urban decision-making procedures.

3. Participation - circumstances and difficulties

To participate means to take part, share decisions and influence processes towards achieving solutions. This is a non-innate capacity, but one that must be gained through study and practice, or in other words, through an educational process. Consequently, the choice to work with inclusive processes is a significant decision wherein one must consider the difficulties and benefits. According to Rymond Lorenzo (Lorenzo 1998,72) the most important characteristics of a participatory process include:

- Sharing the nature and aim of the process with all stakeholders from the beginning;
- Adapting customs, tools and timing to the personal and professional characteristics of the involved subjects and to the context in which the process takes place;
- Evaluation of competences and locally available resources;
- Systematic and continuous involvement of all participants in analysing and evaluating the process itself and its final results.

The participatory process involves dealing with a relatively large number of people, the heterogeneity of the group and the integration of non-specialists. The most common difficulties that arise in this situation are:

- Different views of problems
- Communication difficulties
- More conflicts

A participation strategy should be decided on from the beginning. Various occasions must be created with ad-hoc tools that facilitate the practice in the best possible way, with consideration of context, age, attention capacity, willingness and responsibility (contratti di quartiere II). To achieve this kind of strategy, it is extremely important to provide a comprehensive education for social operators, facilitators, technicians, politicians etc. The effort of using an inclusive process has many advantages in the short and long-term:

- Creating relationships and networks between all stakeholders - individuals that can become part of an independent teamwork in the future;

- Achieving sustainable results and therefore avoiding NIMBY[2].
- Creating a strong emotional involvement within the community and the neigborhood;
- Building a collective awareness of joint responsibility

Of all the stakeholders, those who work most of the time “on site” are the facilitators and habitants. Facilitators find themselves in various situations, dealing with many different kinds of communities. In order to build a participation strategy, they use certain methods and tools. Luigi Bobbio (Bobbio 2004, 55-56) divides the methods in 3 major categories:

- Methods for listening: techniques that help in understanding the problems and needs of the stakeholders. This can be used in the preliminary phase of participation to understand the most important issues and identify the most important actors.
- Methods for constructive interaction: techniques that assist the participants to communicate and produce interesting conclusions. These are used during the whole process.
- Methods for conflict solving: techniques that are made to confront controversial positions, and are applied when conflicts arise.

To make these methods easier to use, facilitators tend to invent tangible tools. Tools can also be divided depending on the function they fulfil, the principal functions are:

- Expressing opinions: about the situation or about participation
- Expressing problems: talk specifically about existing problems
- Expressing needs: what is missing, needed, or desired.
- Making Decisions: choosing which problems to approach
- Giving priority: making a strategic plan out of the choices
- Planning: the actual planning of solutions. It is a very vast role that can be divided between many participants.

With the exception of ‘planning for real’[3] the other tools are not ready-to-use toolkits. Descriptions of these tools exist, but one should address them individually. Furthermore, only ‘planning for real’ covers a large range of activities. One can work through the whole process, using only ‘planning for real’. Facilitators could benefit from more “ready to use” toolkits. The creation of such toolkits belongs to the repertoire of abilities of a (good) designer.

4. Design and participation

Participation is not new to design. In usability and human centred design disciplines, for example, final consumers are often involved in all phases of the (commercial) design process. Designers have some special abilities that are beneficial for participation processes. On the one hand, there is a general consideration of many factors and actors before approaching solutions. On the other hand, designers have an ability to invent new ways of communication and visualization. In urban participation, where everyone is called upon to design, designers cannot be

[2] NIMBY is an acronym for “Not In My Back Yard.” The term is used to describe opposition to a new project by residents, even if they themselves will benefit from the construction. Often, the new project being opposed is generally considered a benefit for many, but residents nearby the immediate location consider it undesirable and would generally prefer the building to be "elsewhere".

[3] "Planning for Real®" is a whole process of community consultation. It begins with contacting the local community networks and reaches a conclusion with the formation of an Action Plan for taking forward the decisions made during the process. It was created and distributed by NIF - The Neighborhood Initiatives Foundation.

seen as the ultimate solution-inventors. They can however answer the need for new tools to sustain the communication between non-specialists. Those tools could be placed in the hand of inhabitants and facilitators, providing them with some of the designer's capacities to work with and towards the best project results. What follows is a personal experience that has led to the invention of such a tool.

5. Project brief

Fig. 1: moodboard, Cimarosa 1

In February 2006, a community-planning workshop took place in Cimarosa street number one in Pioltello (province of Milano). Cimarosa one consists of five residence buildings that perform as one. 800 people, from 30 different countries live at Cimarosa 1. Most of these people have, for different reasons, severe collective debts. The idea of the workshop was to create some services that could help them overcome their economic problems. To achieve this goal it was necessary to involve as many people as possible and to get their opinions and ideas. It was a difficult task because of the heterogeneity of the group and the fact that most of them didn't speak Italian. People with linguistic difficulties have many worries when it comes to participation. On the one hand they feel that they are not able to understand enough. On the other hand they cannot sufficiently express themselves. Some of them, therefore, will decide not participate at all. Embarrassment and feelings of inequity are frequent problems of foreigners in participatory settings. From the beginning, there was a clear need for new communication strategies. A new tool-idea was invented to facilitate the listening phase, and cover a wide range of roles.

The first phase in participation is listening. It is very important, not only for the determination of aims and actors, but also for building a trust-relationship between the habitants and the facilitators. This is a very difficult phase for foreigners since most of the used techniques are based on verbal language. The new tool was conceived for facilitating the process and alleviating stress during interviews and discussions. This tool covers the roles from expressing an opinion to building a small strategic plan. These roles are particularly related to the listening phase. It was important to cover a large number of roles and create a progression by using the same tool.

The apparent linguistic problem in Cimarosa 1 led to the choice of a particular visual language - photography.

6. Photography and participation

Several reasons had led to the choice of photography:

- Facilitated expression: Photography is used for tangible/visible problems. It is extremely easy to show a problem and not to have to describe or explain it. Sometimes one picture can lead to a constructive conversation about other similar problems.
- A testimony of existing problems: Photography is considered by most of the people as an objective way of expression. This detail is useful for dealing with diffidence problems, often found in a situation like Cimarosa 1.
- An international language: in contrast to other visual languages, photography can virtually overcome cultural differences. “Photography is the only language understood in all parts of the world and bridging all nations and cultures, it links the family of man...” (Gernsheim quoted in Sontag, 1973,192).
- There is a strong relationship between the photographer and what he/she photographs. The person that chooses to photograph a problem immediately begins to resolve it. From the moment one photographs, one immediately becomes a part of his/her surroundings. Feeling a part and a sense of belonging, are essential for long-term results. “To photograph is to appropriate the thing photographed. It means putting oneself into a certain relation to the world that feels like knowledge --and, therefore, like power ” (Sontag 1973, 4)
- In the new participation tool, photographs have different meanings. First they provide evidence of the problems in the eyes of the inhabitants. In the second phase they act as conversation stimulators or discussion initiators. In the last phase, every participant has the opportunity to imagine something different for the future. The pictures represent something in the present the must be changed for the future.

7. P-KIT

With the above brief in mind, a first version of the toolkit was created. The first version of the P-kit was created with a priority board and photo cards. The cards represented major problems in Cimarosa 1 and were made with photographs taken by the facilitators[4]. On the board there were six numbered spaces for positioning the cards. During an interview, the facilitator would take out the kit in order to stimulate the conversation and concentrate on concrete problems. After that, the person interviewed was asked to choose six pictures and position them on the board. At the end of the interview, the facilitator photographed the board and kept the results for further work.

Several advantages and problems were identified. Using the kit did help break the ice between the facilitator and the occupants of Cimarosa 1. It helped the habitant express him/herself better and focus on concrete problems. The kit looked professional and thus inspired trust.

Nevertheless this was not enough. Some doubts arose about the different activities and who must accomplish them. Below, the activities and their distribution in the first p-kit:

[4] The pictures were taken after an information exchange between the facilitators and people from the municipality who were associated with Cimarosa 1 for a long time.

Activity	Facilitator	Habitant
Take pictures	X	
Choose pictures for the kit	X	
Conversation	X	X
Choose 6 main problems		X
Give priority		X

The first two activities, taking photos and making cards, were initially carried out by the facilitators alone. Using the kit showed that the early involvement of the inhabitants in those activities could be very helpful. Taking photographs, as mentioned above, cannot be seen as an objective activity and therefore should not be left to people from the outside. Another critique that arose was the identification of a missing activity. The first kit ended by making a small strategic plan but neglected to give the people an opportunity to talk about their desires. It is very important to discuss problems, but this inevitably concentrates on the negative side of the situation. A positive point of view was crucial in order to open the way for a successful planning project.

In the end it was important to involve as many people as possible, and so another board was added to the kit - the collective priority board. The final version of p-kit had the following activities:

Activity	Facilitator	Habitant
Take pictures		X
Choose pictures for the kit	X	X
Conversation	X	X
Choose 6 main problems		X
Give priority		X
Imagine a future scenario	X	X
Catalogue and exhibition	X	X

To achieve the final requirements, the definitive kit is made up of the following elements:

1. Facilitator's handbook
2. Photo cards
3. Individual priority board
4. Collective priority board
5. Future scenario card

Fig. 2: The components of the p-kit

Each element of the kit is explained below, followed by a step-by-step explanation of the whole process.

Facilitator handbook: Instructions for use and explanations of method**.** This is the only part solely dedicated to the facilitator. In this small handbook there are instructions for use, detailed descriptions of every part of the kit and explanations about the methods that are used during all phases. This last part is particularly important, as it opens a wide range of new ideas for facilitators. There are references and reading suggestions about the methods. The six phases of the p-kit, together with the methods that go along with them, act as guidelines for participation. Depending on their personal experience in the field, facilitators may choose to integrate other methods, to follow some or all of the steps offered in the p-kit.

Photo cards: Photo cards are made of rigid paper, on which one can position a picture and cover it with a transparent sticker. The choice to not simply use printed pictures can be argued in two ways. On the one hand, a technical or official look inspires trust. This aspect has been considered for the whole kit. On the other hand, the act of making the cards (see step 2) is important for the overall process. The cards are made to contain standard 10x15 pictures.

Individual priority board for one-on-one interviews: The individual priority board is similar to a game-board. On this board there are 4 numbered positions in the size of the photo cards. There is also a designated space for the person's name and a general title.

Collective priority board/poster for a public meeting: This collective board is made in order to involve multiple individuals in prioritizing their problems. It is a big poster that is divided in 4 columns. Above each column there is a space for a picture card. Only the public can decide which one of the four is more important and mark it with a sticker.

Future scenario card: The importance of this card is the passage from real to desirable. In the upper part there is a space for the chosen picture and bellow it a space for a future scenario. Participants can use any method they want to describe the future scenario. They can write, draw, make a collage etc. When competed, this card becomes a desired “before and after” picture.

8. Using the kit step by step

The kit is made to guide the participants in a few important steps. Following these steps helps to achieve important solutions, but it is also helpful for the facilitator-habitant relationship. The path these two actors walk together will deepen their relation and subsequently their trust in one another. This will be very helpful to the process that follows the phase of listening.

1° step: The first thing to do is a neighbourhood walk[5]. In this walk, the facilitator has the occasion to learn from the inhabitants, directly on site, and to find out what their main problems are. The facilitator learns new things about the area and the inhabitant experiences the first feeling of empowerment. He/she can teach someone about his/her neighbourhood. He/she is the expert (Sclavi, 2003). The active participation of the local residents in this phase is crucial for the rest of the process. During this walk, the inhabitants will take pictures of what they recognize as problems. There are no choosing criteria in this phase. Each participant is free to decide what he wants to photograph.

2° step: During a Focus group[6], the inhabitants are asked to choose no more than 20 pictures to transform into photo cards. The most important thing in a focus group is the interaction between participants. It is important in this phase to involve other stakeholders like politicians or businessmen and women in order to stimulate a discussion about all kinds of problems from different points of view. The first choice of pictures is significant. It is also possible that during the discussion, a lack of some pictures may be perceived. In this case they should be prepared for the next phase. There shouldn’t be a real conflict in this phase because of the great number of pictures.

3° step: This step is built from a series of personal interviews. The facilitators dedicate around 40 minutes to each participant. During this time, the participant may express his/her needs and problems and finally chooses four precise problems and gives each one a priority number. In these interviews there is a unique opportunity to get to know the inhabitants in depth. One has enough time to talk, and by not having anyone around, he/she doesn’t refrain from expressing everything he/she thinks. It is an excellent chance to collect stories and thoughts. Furthermore, the inhabitant is now directly involved in making a strategic plan for the solution of his/her own problems. The power to choose is directly in his/her hands. Even though he/her is not the only one to decide, in that moment someone is interested in his/her personal opinion. The facilitator has the freedom to decide when to pull out the individual priority board and ask the participant to give a priority. Using the board will help break the ice, concentrate on particular problems and remind the inhabitant of others. When the interview is over, the facilitator will take a picture of the complete board in order to conserve the results.

4° step: ‘Collective priority giving’ establishes an important channel between individuals and the group. After the facilitators have carried out the personal interviews, they are in a position to choose 4 pictures and ask the public to choose the most urgent one. It is important to create this occasion in a public place, for example in the neighbourhood community centre or the local market. The collective priority board will be positioned there and a facilitator or an active citizen will give each participant a sticker in order to express the most urgent problem. In this way there is a good chance that new people will get involved. A central location is also important in order to stimulate discussion. The best results of this step are the discussions the board may impart. Indifference is one of the behaviours that participation tries to avoid. At the end of this step there

[5] This is a method in which the stakeholders go to explore the area on foot. All participants are equal in this walk and are there to learn and teach about important elements of the neighborhood.

[6] A focus group is a form of qualitative research in which a group of people is asked about their attitudes towards a product, service, concept, advertisement, idea, or packaging. Questions are asked in an interactive group setting where participants are free to talk with other group members.

will be one or two problems with which to continue on to the next step.

5° step: The fifth step is called ‘from reality to a desired situation.’ In this phase, one finally has the opportunity to express his desires regarding the future of actual situations. This step will be handled as a brainstorming[7]. Many people are encouraged to participate in small groups. Every group will discuss a future scenario for the one or two pictures previously chosen. As a result, the future scenario card will be complete with a description of the group ideas. The group can write, draw or use any technique to explain their idea. They can also make several cards. As with any brainstorming, the basic rules are: focus on quantity, avoid criticism, welcome unusual ideas, and combine and improve ideas. The solutions should not be thought through all their details. These are just first ideas and wishes. Even if they seem to be too imaginary or unrealistic, they might lead to real solutions. This step remains optimistic and positive and people should be ready to express their dreams about where they would like to live. When every group has completed one or more cards, everyone can share the ideas with the other groups. The facilitators will act as moderators for each group and will take care that every card is completed and clear enough to be presented in a small exhibition.

6° step: The ‘before and after’ cards are presented in an exhibition in a central location. The exhibition should include other materials such as pictures documenting the whole process, videos or other items that explain how the process was carried out and who was involved. The exhibition is important in order to valorise the work of all the people that have taken part. It is also an occasion for convincing other people to participate. The exhibition itself is a result of the p-kit process but is only part of a greater participation process towards reaching valuable solutions. One can use the exhibition for collecting further opinions from the visitors. Encounters with various stakeholders can be held during the exhibition too.

9. Results and Conclusions

Using the kit in its final version has had successful results. In addition to the advantages of the first version, the local citizens were involved from the very beginning, while each step encouraged more people to participate. The pictures that the inhabitants took, expressed some problems that the facilitators would not have identified on their own. Problems were discussed in a serious and responsible way during the focus groups and interviews. There were many discussions about the most urgent problems to choose from. These discussions were eventually positive, as they created an opportunity to discuss different issues and showed that there can be many different approaches towards finding solutions. It was also clear that the choice of only one or two problems did not mean that the others would not be approached. The most important results were the relationships created between the participants. Even those that spoke accusingly about particular neighbours in the beginning were able to establish partnerships with those same neighbours. Some independent initiatives took place right after the p-kit process. For example, two “enemy neighbours” decided spontaneity to collaborate and paint the entrance to their building.

The main deficit the kit has is the representation of non-tangible problems. Most of the problems in ‘Cimarosa 1’ were easy to show. But what can be photographed when the problem is not visual, like people’s behaviour or organisation difficulties. This problem was initially solved with written words, but a different solution could be developed as an additional step for improving the kit. Other elements that could complete the kit are small exhibition and catalogue tips. Moreover, it would be very useful to try and use this kit in different contexts.

In a situation in which everyone is called upon to design their own solution, new definitions and discussions about the designer’s role are important. In participation processes, the creator of the solution is not usually the designer. P-KIT represents an effective design research tool that

[7] Brainstorming is a group creativity technique designed to generate a large number of ideas for the solution to a problem. Alex Faickney Osborn, an advertising executive and one of the founders of BBDO, in a book called Applied Imagination, first popularized the method in the late 1930s. Osborn proposed that groups could double their creative output by using the method of brainstorming.

can be placed in the hands of inhabitants and facilitators, providing them with some of the designer's capacities to work with and towards best project results.

A Study on the Framework Development for Context Analysis in Smart Home Environment

With emphasis on user's intention and behaviour

Sumin Ryu[1], Yuri Kim[2] and Jiwon Song[3]

Abstract

Designing smart home means designing system, object, and services for the future homes to improve user's life. To design a smart home to support user's domestic life, understanding the context of the life is crucial.

The purpose of this study is to analyze domestic context and develop a visualized framework of it so that a designer can apply the analytical framework for future smart home research and design. The analysis and the framework in this study are particularly focused on user's intention and behaviour. We belive that this understanding on user centric-context could provide fundamental clues in designing smart home fit to user's reqirements.The framework is visualized to provide clear understanding on complex domestic context which has dynamic feature. We expect that the visualized analytical framework would help the future domestic design by assisting in selection of appropriate service for certain context.

1. Introduction

1.1. Background and Aims

Computers are everywhere, all around us in modern society, and becoming part of a ubiquitous networked environment. This change as it impacts upon the environment of a smart home is part of an active study currently underway. The smart home environment exists in a surrounding environment, using information from a wide range of consumer information and present user behavior patterns. Designing a smart home means designing for the future systems, objects, and services intended to improve the user's life. In order to design a smart home that supports its user's domestic life, understanding the context of that life is crucial.

To begin, the needs of smart home users and the life patterns of those users at home should be recognized in order to advance smart home study. The behavior of users can be analyzed as part of the method. Behaviors, as expressed on the outside, can be divided by many kinds of intentions. These intentions are affected by context. Context, at the same time, can be changed by intentions. That is, there are close connections among behaviors, intentions, and contexts, so it is important to determine contexts focusing on users and then to find needed information according to that determination, strategically, in order to design a smart home. Nevertheless, the study is centered on the user context where there is a lack of related research, with most of the focus on the technology sector.

The purpose of this study is to analyze the domestic context and develop a visualized analytical framework of it that a designer can apply to future smart home research and design. The analysis and the framework in this study are particularly focused on user intentions and behaviors. The framework is visualized to provide a clear understanding of complex domestic and dynamic contexts. We expect the visualized analytical framework will aid future domestic design by assisting in the selection of appropriate services for certain contexts.

1.2. Methods and Scope

This study was conducted as follows:

First, we redefined the context of the smart home and reselected the basic elements of the context based upon references in the context and the smart home research area. Our definition and basic element selection was affected by the work of Dey et al. and Jang et al. and the researcher's 5W1H (Who, What, Where, When, Why, How) elements. Then we classified the elements into physical context, user context, and interaction. The user context includes that of family members, and the user's intentions and behaviors. Object, home space, and time are included in the physical context. Interaction is associated with physical and user contexts.

Second, we analyzed user behaviors and contextual elements by observing the real domestic environments in three Korean homes. We patterned them after classifying the elements of context that cause such intentions and behaviors to arise.

Third, we developed a user context-centered framework on the basis of elements taken in concrete form and visualized. In the visualized framework, user intentions that generate related behaviors are centered. The main elements of the context are given access to intentions. After approaching the intentions of the user, we were able to understand user needs quickly from an overall view. We visualized various domestic intentions. In this study we introduce four visualized events based on the framework. These are inviting guests, getting ready to go out, holding family councils, and caring for a baby.

2. Theoretical Background for Conceptual Definition

2.1. Concept of a Smart Home

A smart home is one 'of life environment', and so supports quality of life, environmental friendliness, the realization of a ubiquitous computer environment by which equipment, wherever, whenever in the home uses home networking and the Internet on the basis of wired and wireless communication and digital information.

Smart home means that everything exists and reacts with users as the central figure, social, technological, physical space mutually giving feedback such as Fig.1 to understand it on the basis of these definitions. The living space (Fig. 1) includes three structural components: the social space, the physical space and the technological space. The social space consists of the members of the household, the activities performed by them in the home, the time spent on those activities, and the interactions between the members of the family. The physical space refers to the physical layout of the home and its constituent parts (kitchen, bedrooms, bathrooms etc.) The technological space consists of the household technologies that are embedded in the physical space and used by the members of the family as part of the social space. The structural concept of the home does not exist in a vacuum. It is related to the organic aspects of the home.[4]

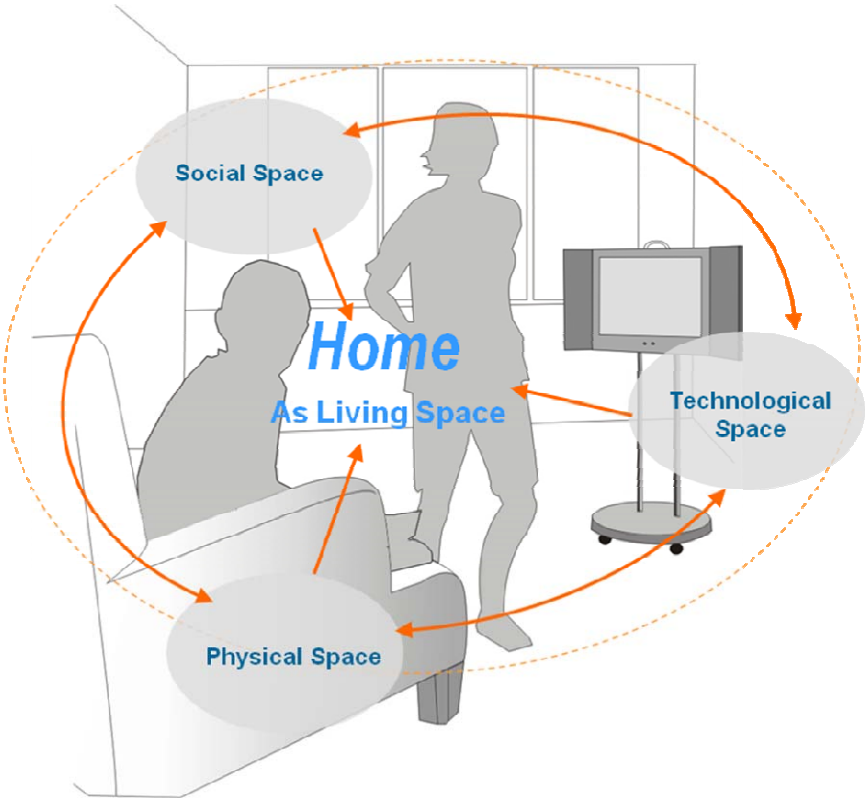

Fig. 1: Concept of Smart Home

[4] Venkatesh, A. Kruse, E. and Shih, E. 2003. *The Networked Home: An Analysis of Current Developments and Future Trends,* Cognition, Technology & Work, 5, 1, 23-32

2.2. Concept of the Context

Context is often translated as ‘line of thought’, ’relationship of sequence’, ‘the state of things’, and ’background’, and the dictionary definition is ‘a state or situation mutually related in the case that something exists or happens’. However, the concept of context used in the ubiquitous environment has no single definition.

Context is defined, for instance, as “location and the identity of nearby people and objects” (Schilit & Theimer, 1994, quoted in Dourish, 2004), or “location, identity, environment and time” (Ryan et al., 1997 Ryan, N., Pascoe, J., & Morse, D. (1997). Enhanced reality fieldwork: the context-aware archeological assistant. In V. Gaffney, M. van Leusen, & S. Exxon(Eds.), Computer applications in archeology. British Archaelogical Reports, Oxford, UK.Ryan, Pascoe, & Morse, 1997, quoted in Dourish, 2004). So location is part of context, but context is far more than location (Schmidt, Beigl, & Gellersen, 1999).

Dey et al.(2001)[5] defined context as “any information that can be used to characterize the situation of an entity,” where “an entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves.”

Jang et al.’s(2005)[6] “User-centric context” refers to information that decides which services and what kind of actions will be automatically triggered according to user’s requirements. Of course, various contexts such as environmental, computational and user’s information can be exploited by context-aware services. However, he believe that user-centric context can be fundamental clues to be aware of user’s implicit expression to trigger services with assumption that a goal of ubiquitous computing is to provide user-required services in any where at any time. As a first step to represent context for services, he focus on user-centric context. In addition, to simply represent user-centric context, he classify the context into 5W1H which is independent of the specific purpose of any service. 5W1H is a popular way to describe a fact with “Who, What, Where, When, How and Why”. 5W1H that is applied to unify user-centric context depicting “a certain user (Who) is”, “in a certain location (Where)”, “in a certain time (When)”, “paying attention to a certain object/service (What)”, “representing a certain expression with physical signs (How)”, or “because of a certain intention or emotion (Why)”. User-centric context, in terms of 5W1H, can provide applications with basic but enough information to trigger appropriate actions.

The elements of context in this study refer to those in smart homes. The smart home is defined as an intellectualized life space for the pursuit of an intellectualizing life environment, an environmentally friendly life and an innovating quality of life. The domestic environment is made up of complex contextual elements in which family members and objects exist together. Therefore, it is important to understand the relationships among the complex contextual elements in order to comprehend them.

These are defined as centering around technical service. They needed to be reinterpreted as focusing on users. Therefore, in this study, we selected the concept of Dey et al. stressing the interaction and the concept of Jang et al.’s 5W1H emphasizing the context centering around users. We used the combination of selected concepts as the concept of this study. Complex knowledge is needed to realize a smart home. It is a means by which to attain all possible knowledge in analyzing and collecting context. Jang et al.’s 5W1H is one of the most suitable methods by which to explain some situations. It was selected as a main concept because it inclusively and exactly explains the situational information of users.

2.3. Contextual Elements in the Smart Home

It is essential to know such elements of context as users, time, space, actions, etc., in the study of a smart home. Using concept as defined by Dey et al. and Jang et al. among other past researchers, we classified those elements suitable for the environment of a smart home (table 1).

Table 1: Context element in the Smart Home

Conceptual elements	Conceptual definition	Smart Home environment
Who	User	Home Members
What	Object	Object
Where	Home Space	Home Space
When	Time	Time
How	User Behavior	Behavior
Why	Intention	Intention
W-W	Interaction	Interaction

Looking at the above table, ‘W-W’ expressing interactive concepts is added to the conceptual elements 5W1H defined above. ‘W-W’ is named by the researchers of this study and it means Who-Who, Who-What, Who-Where, etc. In other words, it means interaction with various contextual elements. The reason for adding ‘W-W’ to the element of context is to more closely approach understanding the intentions of the users. It is also important to look at only each element. However, the intentions of the users are collected recognizing how interaction occurs between the users and other physical elements. This is connected with the viewpoint centering around the interaction of Dey et al. It is defined as each user, object, home space, time, user behavior, intention, and interaction. Based on this, we express the elements in the smart home environment as home members, objects, home space, time, intentions, behaviors, and interaction.

These factors can be categorized as either user context or physical context. User context includes home members, intentions, and behaviors. Physical context includes objects, home space, time, and other family members/others. Interaction is a component connecting user context to physical context. The physical context affects the user context, two contexts very closely connected to each other.

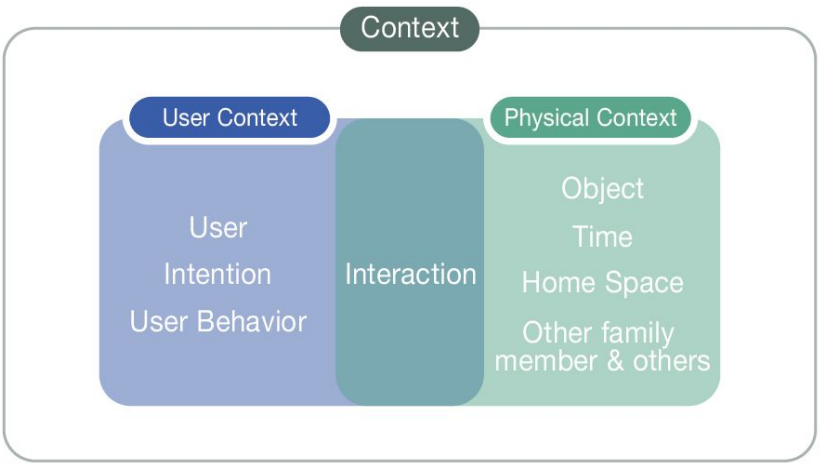

Fig. 2: Category of context element

3. User Observational Research on Domestic Behavior

3.1. Overview of Observation

Observational research was conducted in order to understand how each element in the domestic context is related. The detailed purposes are as follows:

- to determine the patterns of behavior actually undertaken at home
- to understand the intentions or purposes in carrying out the behaviors
- to understand the physical context that affects behavior and intention

Three homes were selected as the objects of the study and we observed them, given these purposes. Home A is a family comprised of four people in 66.12 m². There are two children, 2 and 4 years old. Compared with the other two families, this family is young and has younger children. Home B is a family comprised of five people in 99.17 m². There are three children, 19, 25 and 27 years old. Home C is a family comprised of four people in 66.12 m². There are two children, 25 and 27 years old. Homes B and C are distinguished by house size and the number of children, even though of similar ages. Detailed profiles of each family are tabulated as table 2.

Table 2: Participant Profile

	Home members	**Age**	**Occupation**
Home A	Father	33 years	Office worker
	Mother	33 years	Housewife
	Older son	4 years	Kindergarten
	Younger son	2 years	-
Home B	Father	55 years	Office worker
	Mother	51 years	Nurse
	Older daughter	27 years	Graduate student
	Younger daughter	25 years	Office worker
	Son	19 years	High school student
Home C	Father	58 years	Office worker
	Mother	50 years	Cook
	Daughter	27 years	Office worker
	Son	25 years	Office worker

3.2. Methods of Observation

We stayed in each home for a day and took notes while observing the behavior of each family member. Note-taking involved the use of observation sheets based on the contextual elements of table 1 such as actions, time, home members, home space, etc. We came to understand reasons, intentions, frequency, etc., through supplimentary interview.

4. Analysis of Domestic Behavior Patterns and Intentions

4.1. Methods of Analysis

We analyzed the collected data from three homes through the affinity diagram method. First, we materialized behaviors grouped through post-it grouping (see table 3). Second, we came to know intentions by centering on patterns of behavior (see table 4). Third, the behaviors were rearranged by centering them around intentions again (see table 5). The rearranged table was used as a basic material when visualizing later.

The intentions of each behavior were gathered through user interview during the observation period. We analyzed what intentions are affected by what kinds of context after understanding various of these. The procedure for analysis is the same as in fig. 3.

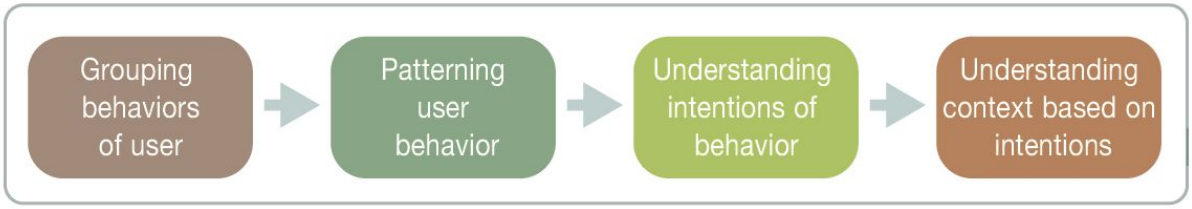

Fig. 3: Progress

4.2. Analysis of User Behavior Patterns

The behaviors of the users were divided according to their common features. As a result, the behaviors of the users could be divided into eight types: entertainment/hobbies/education, toilet hygiene, communications, security/safety, cleanliness/hygiene, food, breaks, management. Representative behaviors for each type are listed in table 3. It was patterned by centering around general behaviors, although there were many details other than the behaviors included in the eight types.

Table 3: User behavior pattern

Type	Representative behavior
Hobbies/Education /Entertainment	Doing computer, Watching TV, Reading books, Listening to music and radio, Exercising, Studying, Other hobbies
Toilet hygiene	Urine and feces
Communications	Calling, Conversation, Health/Greeting, Care
Security/Safety	Safety checks, Locking a door
Cleanliness/Hygiene	Bath/Shower, put on and take off, Dressing up, Personal hygiene(gargle, Face washing etc.), Arrangement, Cleaning, Washing the dishes, Separate collection, Ironing, Laundry
Food	Preparing a meal, Taking a meal
Break	Sleeping, Rest
Management	Energy management, Financial planning, Health care

4.3. Analysis of User Intentions

In this research, we came to know intentions by focusing on the representative behaviors as categorized above. We analyzed the context regarded as important in centering on these intentions. For example, a behavior like 'preparing a meal' was arranged by order of behavior – intention – and the important context such as preparing breakfast – time; preparing a meal for an invited guest – user/time; preparing a meal for self-satisfaction – user/object; preparing a meal for health care – user/space of home.

The intentions were analyzed via the interviews conducted during the observational research. The researchers carried out discussion to learn of more intentions. Two external researchers are included in this discussion to verify the connections between intentions and behaviors. Intentions by behaviors and physical contexts are listed in table 4. Then table 4 was rearranged by centering around intentions again (table 5). Rearranging table 5 made it easy to develop a framework. The contexts were readjusted by each intention and more concrete intentions were added when rearranging them.

Table 4: Behavior- Intention- Physical contexts

Representative Behavior	**Intention**	**Physical contexts**
Computing	Acquiring information, Entertainment, Business	object, space
Watching TV	Entertainment, Break	object, space
Reading books	Leisure, Acquiring information	object, space
Listening to music and radio	Leisure, Break	object, space
Exercising	Health maintenance, Diet, Fitness Management	object, others, time
Studying	Self-contentment, Prepareing for an examination	space, time
Toilet hygiene	Physiological phenomenon	object, space
Calling	Health, Communications, Passing information	object, others
Communications	Communications, Friendship, Entertainment, Business	space, others, time
Health/Greeting	Friendship, Ceremony, Courtesy	object, others, time
Care	Hobbies, Duty, Love	others, object, time
Safety checks	Security, Protect of families,	object, space,
/Locking a door	Psychological stability, Going out	others, time
Bath/Shower	Cleanliness, Self-contentment, Break	space, object
Dressing	Cleanliness	object
Dressing up	Self-contentment, Entertaining guests, Going out	object, time
Personal hygiene	Cleanliness, Going out	space, object
Arrangement	Self-contentment, Cleanliness, Entertaining guests	space, object
Cleaning	Cleanliness, Entertaining guests	space, object
Washing the dishes	Cleanliness, Entertaining guests	space, object
Separate collection	Cleanliness, Protection of environment	space, object, time
Ironing	Neat, Going out, Self-contentment	object
Laundry	Cleanliness, Self-contentment	object, time
Preparing a meal	Entertaining guests, Self-contentment, Health care	others, object, time
Taking a meal	Basic needs, Self-contentment	others, time
Sleeping	Break, Basic needs	space, time
Resting	Break	space, time
Energy management	Economy	object, time
Financial planning	Economy, Housekeeping	object
Health care	Health maintenance	others, object

*others(including other family members)

Table 5: Intention- Behavior- Physical contexts

Intention	Representative Behavior	Physical contexts
Acquiring information	Computing, Reading books	space, object, others
Entertainment	Computing, Watching TV, Communications	space, object, time, others
Business	Computing, Communications	space, object, time
Break	Watching TV, Listening to music and radio, Bath/Shower, Sleeping, Resting	space, object, time
Leisure	Reading books, Listening to music and radio	object, time
Health	Exercising, Calling, Preparing a meal, Health care	space, object, others
Diet	Exercising	space, object, time
Fitness Management	Exercising	space, object, time
Self-contentment	Studying, Bath/Shower, Dressing up, Arrangement, Ironing, Laundry, Preparing a meal, Taking a meal	space, object, time
Prepare for an examination	Studying	space, object, time
Physiological phenomenon	Toilet hygiene	space, object
Communications	Calling, Communications	space, time, others
Passing information	Calling	object, others
Friendship	Communications, Greeting	space, others
Ceremony	Greeting	space, time, others
Courtesy	Greeting	space, time, others
Hobbies	Care	space, object, time
Duty	Care	space, object, time, others
Love	Care	space, object, time, others
Security	Safety checks, Locking a door	space, object, time
Protect of families	Safety checks, Locking a door	space, object, others
Psychological stability	Safety checks, Locking a door	space, object, time, others
Going out	Safety checks, Locking a door, Dressing up, Personal hygiene, Ironing	space, object, time, others
Cleanliness	Bath/Shower, Dressing, Personal hygiene, Arrangement, Cleaning, Washing the dishes, Separate collection, Laundry,	space, object, others
Entertaining guests	Dressing up, Arrangement, Cleaning, Washing the dishes, Preparing a meal	space, object, time
Protection of environment	Separate collection	space, object
Neat	Ironing	object
Basic needs	Taking a meal, Sleep	space, object, time
Economy	Energy management, Financial planning	space, object
Housekeeping	Financial planning	space, object

We determined not only the relationships between contexts and behaviors but also the following through an analysis of intentions:

First, there were many actions caused by the same intention through other behaviors. For example, the intention of ‘inviting guests’ is connected with various behaviors including cleaning and preparing a meal.

Second, there are some differences in physical context affected according to the intentions of a kind of behavior. A meal with a guest, for instance, is most affected by space and person.

Third, there are common characteristics found in looking at those intentions and actions depending upon the physical context. There are many behaviors in which a person usually uses those instruments much affected by the object. There are many behaviors impossible in the space. There are many behaviors connected with the external environment, like freshness, humidity, or the visit of another person, in those affected by time.

Finally, there are many behaviors connected with family in those greatly affected by others. This shows that users interacting among themselves is more important than any other elements, because it is connected with most behaviors.

5. Development of the Framework

5.1. Conceptual Definition of the Framework

The term 'framework' has been used in various fields. Thus, this study had a need to be sure of the meaning of its framework. It is this: visualized pieces showing dynamic movement. This can approach the fundamental user intentions from a wide point of view, not merely focusing on partial needs. The reason for developing a framework in this study is its capacity for deducing needs faster and more precisely (fig. 4).

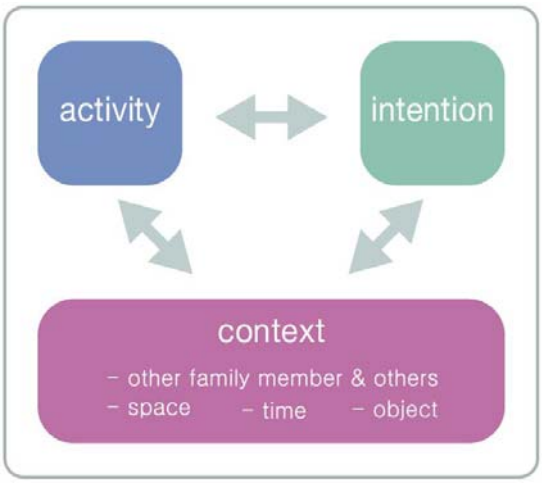

Fig. 4: Conceptual definition of framework

5.2. Visualization of the Framework

In the study, we visualize the framework according to main intentions. In the visualized context web, each in context, intention, and activity are correlated and they can be explained focusing on the following (fig. 5):

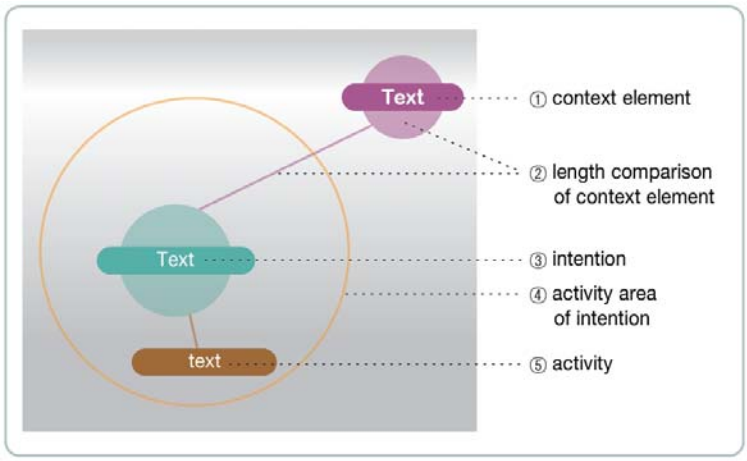

Fig. 5: Unit of Context Framework

①There are four elements of physical context, including family members and others, space, time, and object. The context is located out of the activity area of intention. ②The circle surrounding the elements of context expresses a relative range. The length of the contextual elements shows their relationship with intention. The shorter the length, the more it affects the intention. ③There are four events in this study observed by intention. ④The user context is located in the center as the activity area by intention. ⑤The context is located in the circle with a yellow line as activity by intention.

Among the various intentions, we have created four: inviting guests, holding family councils, getting ready to go out, and caring for a baby.

The representative behaviors of inviting guests are cleaning, preparing a meal, dressing up, greeting guests, partaking of the meal, conversation, entertainment and so on. In accordance with these behaviors, there is interaction between family members and the others they have invited. That is, there would be interations between ‘Who-Who’, and users and time could be understood as physical contexts. As we have to consider that all behaviors should be completed according to time and what kind of guests will visit and how they will act, we place less weight on space and time. This is displayed in fig. 6.

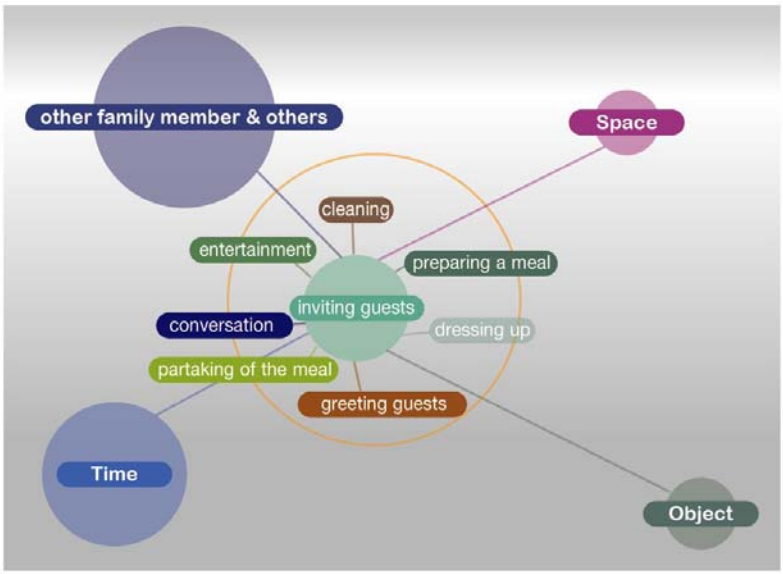

Fig. 6: Context web of inviting guests

There are cleaning, dressing up, checking, and security as typical behaviors of getting ready to go out. The preparations for going out in this situation are conducted by one person. This behavior results from interaction between 'Who-What' and time and object appear as key contexts. This is because such behaviors as inspecting the gas valve and securing the door are generated according to time before dressing up for going out and going out itself. This makes for relatively reduced proportions occupied by users and space. Its result is shown in fig. 7.

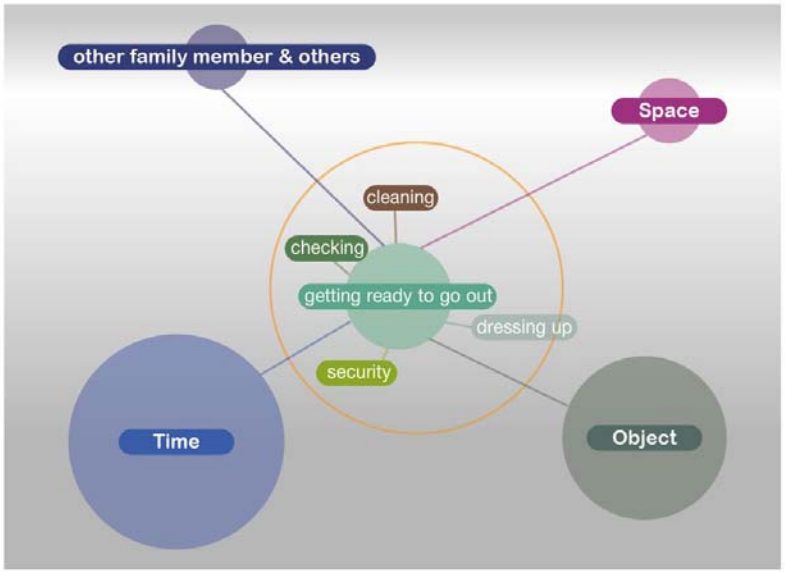

Fig. 7: Context web of getting ready to go out

As typical behaviors of holding a family council, there would be calling, preparing a meal, partaking of the meal, conversation, entertainment, and financial planning. This action makes family members and individuals interact with one another and one can see users and space as physical contexts. Because there would be more actions carried out in a shared space such as a living room rather than in individual rooms, we place more weight on users and space. This is seen in fig. 8.

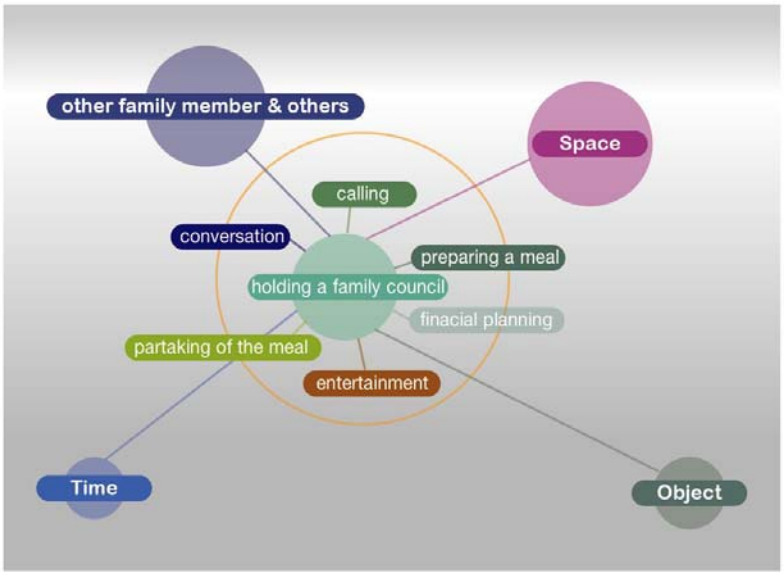

Fig. 8: Context web of holding a family council

The most behaviors of take care of baby are cleanlig, health, education, food, toilet hygiene and these behaviors are happened by interactions between individual and individual(Who-Who), between individual and object(Who-What). Physical contexts are user, object and time. Every behavior are closely related to babies just not individual from serving babies with food, keeping them health to giving them an education by looking after babies This appears like Fig 9.

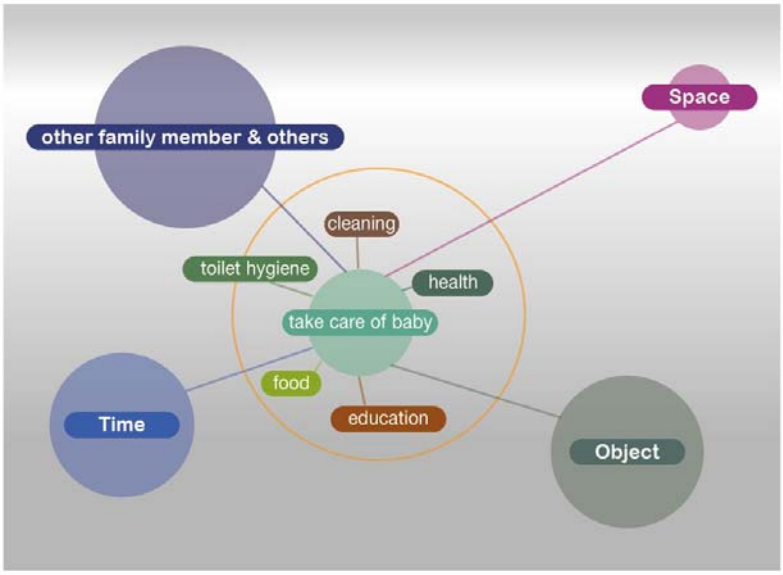

Fig. 9: Context web of take care of baby

From the context web, we find that the picture of the context is different depending upon the user's intention and the relationship between the elements of the context. The visualized context analysis of this study suggests it can be applied to design a smart home system in the future that reveals the dynamic and occasional relationships between user intentions, behaviors, and other contextual elements.

6. Conclusion and Future Study

6.1. Conclusion

A smart home is a life space guaranteed safe and convenient for family members providing the various functions users need without restriction of place and time. In this study, a visualized framework was developed after analyzing the context by making the centerpoint the intentions and behaviors of the users.

The framework developed from this study could be evaluated as follows:

A framework centering around user context was developed from materialized elements and visualized. This makes it easy to understand the relationships between elements by showing complex interactions between users and application services through simple visualization. It renders the visualized materials different from those of other studies by realizing the Internet as another aspect for the context of classifying behavior patterns. It will be often used because it is observed through a new point of view, understanding the context through analyzing and appreciating the intentions and behaviors of users.

6.2. Future Study

Studies for smart home design are advancing in all aspects; however, at present studies of users are relatively lacking. Therefore, this study holds the behavior patterns of users and context in accordance with user intentions, developed through a visualized framework. Therefore such studies as the following should be conducted based upon this study:

First, the study should be made more concrete by a more regulated framework because the framework developed herein was visualized as one that uses a relative rate.

Second, determination and analysis of the various intentions of users, except analysis of the four kinds of intentions listed herein, should be undertaken.

Third, an experiment method for verifying the framework should be put into place.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Everyday Imagination, Practices, Systems

Designing with people for systemic change

Daniela Sangiorgi[1], Hemment Drew[2], Monika Büscher[3]

Abstract

In this paper we bring together three different perspectives on collaborative innovation: service design, ethnographically informed innovation, and participatory art practice. All three afford important insights into the opportunities and challenges of 'changing the change' for a more sustainable future. We focus on the dynamic and complex, 'systemic' nature of change and – against the backdrop of our individual practical experiences – explore how we might design on such shifting ground. In this process, we all seek to harness everyday creativity and DIY solutions to design *with* as well as *for* people. Folding this ongoing concern from our individual work into a recently begun collaboration has leveraged powerful synergies for collaborative innovation for more sustainable living and we discuss a planned project.

1. Introduction

Designing for a sustainable future poses many challenges. There is, on the one hand, a need to be bold; to imagine and 'design' new systems that enable more sustainable lifestyles. On the other, sustainability depends on unpredictable changes in people's daily life practices as well as on how they adapt to, and adopt, new system possibilities (Halpern *et al.* 2004).

Control may seem possible through education, incentives, coercion, (social) engineering and design, but historical studies of systemic change (e.g. Mosley 2001 on air pollution, Worpole 2000 on architecture) show that while these approaches may play a valuable part, if education, engineering, policy or design are 'done *to* people, not *with* them' (Worpole 2000, 68), they fail.

Yet endeavours to design with people face a catch 22. The emergence of new practices happens as part of doing things differently. To enable and study the everyday imagination that underpins this emergence and to fold it into design requires realistic appropriation of (prototype versions of) the system that is being 'designed' (Büscher 2005). A critical mass of technologies, policies, services, infrastructures, etc. must be implemented, not just as scenarios but in some way 'for real', e.g. through experimental implementation of prototypes. This makes for a costly iterative design process that has to fight to resist the momentum of investment in particular ideas. The challenge is to remain able to radically revise ideas – intellectually, creatively, and practically.

In our recently begun collaboration we bring together methodologies from service design, ethnographically informed participatory socio-technical innovation and participatory art practice. We argue that our methodologies can be fruitfully combined to draw people into 'designing' systems and 'change the change'. We aim to leverage the fact that people are already inventing DIY sustainable solutions (Meroni 2007; Willis *et al.* 2007), and to study, encourage and design for emergent future practices.

In this paper we describe how the synergy between these different methods can overcome individual limitations and amplify the benefits of each, while improving the ability to design for sustainable futures. We present and compare experiences that applied the singular methodologies, as well as a planned collaborative research project that brings them together in an experimental way.

2. Post-disciplinary collaborations

When Buchanan (1994) talks about 'third order' and 'fourth order' design, he refers to the recent need for design to move where strategic decisions are made in order to be in a position to influence future directions. This means moving from designing single objects (products and graphics) to design action/processes (like services) and systems; moving from end of chain contributions toward upward positions and roles within society.

The complexity of contemporary challenges (climate change, poverty, rising and ageing populations, chronic disease, epidemics, security crises etc.) need a wider perspective and the introduction of aware design decisions and approaches at levels where there is real possibility to influence choices; as Thackara says "many of the troubling situations in our world are the result of design decisions" and "if we can design our way into difficulty, we can design our way out" (2005, 1). This requires a shift from narrowly conceived development to 'design mindfulness' for dynamic complexity: "design responsibility means that designers should be conscious of the fact that, each time they engage themselves in a design project, they somehow recreate the world" (Findeli 2001, 14).

While *scaling up* design is also *reaching out*, meaning that when both the complexity of challenges and the objects of design become bigger, design needs to collaborate with a wider

number of stakeholders and professions. This requires designers to *bring in* design resources and tools to enable 'strategic conversations' among key stakeholders, experts, and creative visionaries (Manzini *et al.* 2004) to co-design future solutions, but at the same time they must also *bring out and develop* creative everyday imagination resources and skills in those who are part of co-designed solutions, so that they can 'change the change' from within and work and live differently.

The role and practice of Design is therefore changing in response to, and in anticipation of, complex demands of contemporary life. In this paper we suggest that there is a need to explore and support this development and to make it more effective in "changing the change".

Instead of a designer centred approach, we are moving toward a 'creativity' and 'design thinking' oriented one that focuses on how can we leverage and align both professional and everyday creative resources and skills to move toward more sustainable forms of life and economic exchange. This trend has begun to foster 'multi-disciplinarity' in research, education and business as a way forward (Cox 2005): multidisciplinary courses of education are recommended as a way to ensure that specialists will have a broader understanding of creativity and of other specialisms and will be able to better collaborate in the future.

With regard to everyday imagination, creativity is increasingly understood as a basic skill inherent in all human activities and people already use this resource in their daily life to improve their life conditions (Meroni 2007). Designers are therefore moving toward working with people to leverage these existing resources and connect them to wider systems and strategies (Thackara 2007; Manzini *et al.* 2003; Burns *et al.* 2006).

In this paper we would like to develop these considerations, because we believe that in order to expand designers' role and influence into contemporary society multidisciplinarity and an appreciation of everyday imagination are not enough. Disciplines carve up the world and, by studying different areas (the economy, society, ecology, etc.) from different perspectives, they separate what needs to be understood as a whole. Multi-disciplinarity, at best allows a mutually informing overlap of perspectives. At worst, it gives rise to competing accounts of reality, undermining rather than enabling collaboration. While multi-disciplinarity can facilitate important insights into the dynamic complexities of systems, it does not enable an understanding of systems' lived autopoesis. We believe that what is required is a post-disciplinary approach. Post-disciplinarity (Sayer 2001) fosters study and intervention as a holistic endeavour. Post-disciplinarity supports groups of people (with a range of expertise and skills) to address complex problems and opportunities. It enables analysis and design to follow connections all the way through and to forge viable new connections, because they are more mindful of the multitude of dependencies. It does not need to lead into eclecticism or, even worse, dilettantism. Post-disciplinary research and design crucially requires collaboration between diverse actors: we do not expect that individuals could or should be able to understand and 'design' systems as individuals. It is important that individuals have grounding in disciplinary and practical everyday skills and knowledge, and that they are able to open up and become mindful to previously unkown or unnoticed phenomena. Post-disciplinary researchers and designers must step outside their box and become mindful of other disciplines' knowledge and skills to a very high degree, enabling them to work closely with experts from that discipline, or experts from particular walks of everyday life. This requires listening, learning, visualizing, arguing, experimenting. Working like this goes beyond collaboration with clearly demarcated responsibilities and knowledges. It allows for sophisticated interferences and synergies that allow groups of people to grasp complex problems more firmly, at multiple points simultaneously, and in ways that are mindful of connections and interdependencies than they could otherwise. What makes this post-disciplinary is that while people maintain their roots in their own discipline, they acquire the skills to 'seriously' work *with* others, not just alongside others.

In this paper we discuss the potential of this convergence for the design of sustainable futures. We will do this by exploring the combination of three experiences and approaches to post-disciplinary design _ service design, ethnographically informed socio-technical innovation

and participatory art practice _ to explore future sustainable scenarios in collaboration with people and potential users.

3. Service solutions, future laboratories and strange connectors

In this section we describe our individual experiences in design. These are not mainly in designing for sustainability, which makes it clear that other challenges/opportunities are also multi-dimensional and dynamic and that good design as well as effective appropriation are fostered by post-disciplinary approaches. In this section, we explore how our experience can be transposed into design for sustainability and to 'change the change'.

We argue that our methodologies (see fig. 1) can be fruitfully combined to draw people in and 'change the change'. We aim to leverage the fact people are already inventing DIY sustainable solutions (Meroni 2007; Willis *et al.* 2007), and to study, encourage and design for such (and further) emergent future practices, by combining three different experiences and approaches.

3.1 Service design

Service designers observe, analyse and interpret markets, current social and technological trends and users' behaviours to identify areas of opportunities for the development of new service solutions for the future. Areas of opportunity are elaborated into overall scenarios that delimit and visualise possible futures. Single service solutions are therefore designed starting from these wider scenarios, as possible manifestations of these platforms. Service solutions are designed in terms of their offering (what the user will be able to do), experiences (how the user will experience the service) and system (who is the supplier and how it is organised). Visualisations like storyboards, videos, maps and moodboards are developed to communicate the service scenarios and ideas back to users and suppliers during an iterative design process.

An example of Service Design applied to developing future sustainable solutions has been the research project[4] developed for the multinational Qfree, the European leading supplier of Electronic Tolling Collection systems. The aim of the research project was to conceive new multimodal mobility services for the Italian market where charging and traceability systems could be profitably used to improve urban and social well-being.

The Electronic Toll Collection (ETC) technology, currently used to collect tolls from the urban mobilities, is based on Onboard Units endowed with a Smart Card. The Smart Card can communicate via microwaves with specific points of transit and is currently adopted for motorway and urban user charging, where vehicles are tolled without the need to pass through specific toll plazas, or reduce their speed. The research project aimed to move from this simple tolling logic, detached from the mobility system and not providing alternatives to users, to a service oriented logic; to use ETC technology as a platform to improve the efficiency of and to integrate the mobility and service system, on one hand, and on the other hand to enable more sustainable behaviours.

The research team has worked on three main interrelated levels - context, technology and users - and have moved backward and forward from analysis to design within real contexts to the visualisation and design of abstract scenarios.

[4] The project "Intelligent Mobility System Sector Scenarios" was developed from January to May 2007 by a research team from INDACO Department of Politecnico di Milano.

As the Smart Card can be used also as personal card to access various services (public transportation, private cars and services), ETC technology can allow the management of *mobility credits*, where the user can buy, spend and gain credits according to his/her behaviour, in the light of a multimodal mobility scenario. The adoption of such a perspective (practically encouraging and rewarding positive behaviours instead of only punishing the wrong ones) allowed the team to shed a new light on the mobility services that invoke the positive psychology approach (Csikszentmihalyi 1991; Seligman 2002).

Based on this overall scenario the research project has developed 6 *service solutions* for 6 *metacontexts*, that is to say, typologies of emblematic Italian urban or extra-urban settlements with recurring mobility features:

1) the metropolis, Milan: Providing multimodal possibilities to integrate public and private transportation;
2) the hinterland with a trade fair pole, Rho-Fiera: Access to organized mobility and fair services for exhibitors;
3) the historic/productive town, Como: Multi modal mobility system based on the use of green vehicles to access an historic city downtown;
4) the skiing area, Alta Badia: Skiing services integration through the ETC system and built-in additional technologies;
5) the inhabited natural park, Parco Nazionale delle 5 terre transformed into an harbour scenario, where the system is adopted in the marine sector;
6) the Motorway system: Introduction of the ETC system in the motorway adopting a mobility credits model.

3.2 *Ethnographically informed socio-technical co-realization*

Amongst many other methods, a design orientation towards ethnographically informed 'co-realization' (Hartswood *et al.* 2002) comprises two experimental approaches to achieving far future oriented change: 'future laboratories' and 'bricolage'. Future laboratories either bring the real world into the laboratory or take the laboratory into the field. Placing an emphasis on realism, collaboration and experimentation, future laboratories assemble components of the future (e.g. functional prototypes of technologies) and enable people to colonize new socio-technical futures. This encourages people to bring everyday imagination into the process and to explore and shape new practices not only discursively, but also through embodied appropriation and real time habitation in (partial) futures. 'Bricolage' goes further, seeking to fold future technologies productively into real world work (Büscher et al. 2007 and 2008).

As an example, we have designed and experimentally implemented pervasive technologies (embedded, ambient, and mobile computing technologies) to support improvisation and collaboration amongst emergency response personnel, using 'future laboratories' in the emergency training ground at the Aarhus Brandskolen, and through 'bricolaging' prototype technologies into real world work at the Tall Ships' Races in Aarhus in July 2007, where prototypes were used as part of the event management in the command centre. This concrete practical experience enabled the application of everyday creativity – connecting design of technologies with the 'design' of future practices. It makes it possible for designers and users to 'colonize' rather than just visualize the future.

Pervasive technologies have the potential to support professionals in their effort to collaboratively produce and update their assessment of the situation. This was the premise of our participatory design collaboration. Between 2003 and 2007 we have developed prototype technologies to support professionals, especially police, fire brigade, pre-hospital, and ambulance personnel. This culminated in a prototype of a fully functional 'assembly' of technologies during Tall Ships' Races 2007 implemented in and around the command station at Aarhus harbour.

3.3 *Art: Strange connectors*

Art offers a set of resources for envisioning social and technological change in a way that is inherently participatory, and for opening up disruptive spaces of play. It escapes the bounds of realism, not through flights of fancy, but through critical imagination and rupture. Such creative practice 'hacks' into different social, professional, technological and institutional situations, often acting as an intermediary or 'strange connector,' linking things in unexpected ways, or linking things one would not expect to be linked. The method involves a process of creative exploratory work involving artists within an interdisciplinary group, with the researcher often in the role of curator, working to 'create context' and to originate new artistic work with the artists that addresses the research questions. Integral to this method is the active involvement of audiences through the public presentation or iterative development of artworks. This method involves working abreast of practices that are contemporary, new and continually evolving, and drawing from them a process or a new way of looking at things.

'Social Networking Unplugged' is an example that focuses on social networking or 'Web 2.0' technologies (flickr, twitter, myspace, etc.). It was a curatorial project on social networking that involved people across Manchester in large-scale art installations and events. It was the first major art exhibition to present a comprehensive and creative look at social networking featuring twenty artworks, each one taking a sideways glance at online social networking and virtual worlds. Here artists have been invited to create offline equivalents of social networking websites such as FaceBook and MySpace so that comparison can be made with the way people socially interact in different scenarios when online and offline. The artworks 'unplugged' these new social spaces in order to take them apart, see how they work, and put them together in new ways. The experiment aimed to advance understanding of online relationship building and social networks, and also to explore how the requirements for social networking tools vary when sat behind a desk at a computer and when roaming through the city. Many of these projects are provocative and challenging. One example was the Rubbing Shoulders project which created an offline equivalent of the 'digital handshake' involving physical touch. This was already transgressive and involved risk. This was increased when a UK Government report highlighting the dangers of social networking to children was published shortly before the exhibition, resulting in front page news stories equating social networking to paedophilia. This provided an opportunity to address challenging issues and the project was adjusted and a version delivered at a local school to explore an ancillary range of research questions, while also serving to intervene into public discussions on the subject.

4. Designing with people for systemic change

These three projects represent different ways of working towards or 'designing' possible futures, to explore opportunities and new technologies with users and companies.

We argue that the synergy between these different methods overcomes individual limitations and amplifies the benefits of each. For example, co-realization depends on realism and is, therefore, costly. It can suffer from path-dependency, where investments made into one solution influence the allocation of future design efforts. Moreover, while these approaches score high on 'designing *with* people', it can be difficult to shape bold visions when immersed in the detail of everyday practice. These limitations can be overcome by introducing methods from service design and art. Design of service scenarios, for example, provides 'systemic' visions of future solutions based on existing needs and trends. It, in turn, benefits from combination with more experimental methods through being able to ground visions more clearly in emergent practices. Art transcends the confines of future visions through critical reflection on the tensions between the kinds of futures we actually want and those we may be creating, and enabling people to colonize these futures experimentally, playfully, critically. At the same time Art is often based on a one off event that provokes critical reflection and engages the public, but lacks in

terms of capacity to collect, interpret and develop a critical mass of ideas, experiences and motivations into solutions that can contribute to ‘changing the change’.

As part of our current collaboration we are exploring how to converge these practices in the design of a new project that will take place in the Futuresonic festival in May 2009 as part of an exhibition titled *Through Cracks In The Pavement*. Accepting the hypothesis that human actions are affecting climate change, the proposal is to create precedents for social change through creative, participatory interventions involving artists and experts in the environment, technology, and society. The focus is on urban environments - one type of environment where problems stem from, and where change needs to take place.

A new methodology will be experimentally employed on a range of projects exploring how to harness everyday creativity to enhance environmental sustainability in urban contexts. The objective is to *develop an art event into a platform for participatory service co-realization projects* that are transformational and involve people in making a meaningful difference to the sustainability of their lives.

It will present newly commissioned artworks and future scenarios that through *combined arts and design approaches* will seek to inspire social change and to enhance environmental sustainability. Featured artworks will be participatory, sited in public space, and in an urban context to experiment with technologies and possible future scenarios in an engaging and playful way, enabling ideas, changes and proposals to emerge and be visually recorded.

Ethnographic studies will document the events, reporting the detailed interactions of people with the artworks and scenarios feeding back the design of technologies and services; participatory and service design will provide the context and tools to enable people to experimentally intervene and change the proposed scenarios and express their perspectives through interaction and participation; as well as elaborate results into solutions and possible concrete interventions.

Urban Climate Camp, a workshop involving artists, communities, technologists and environmental experts, will use these experiments as material for discussion and further development of the emerged ideas.

Within the wider art event on climate change, an example of potential participatory service co-realisation projects, will be ‘A-mobs: Alternative mobilities for sustainability’. The purpose of this project is to ‘design’ alternative mobility systems, that is, to co-realize technologies, infrastructures, objects, and practices needed for more sustainable movement within and around Manchester as a typical post-industrial major city. This project will combine exploratory art installations that will work as both creative and participatory interventions (see social technologies unplugged example) and ‘service prototypes’; this to generate ‘strange connections’ that help questioning current mobility patterns and their effects on the environment as well as engaging users to experiment, evaluate and modify proposed service scenarios through ethnographically informed co-realisation processes and tools. The documentation and output of these projects will be elaborated into detailed service scenarios to inform Private and Public sector organisations, that will participate, with the public, as partners, users and co-creators of the alternative mobility system.

This sketched approach draws a direction to improve the effectiveness of designing futures that need to be experimented in field, to evaluate synergies while converging the single methodologies.

5. Changing design for Change

As Alain Findeli reminds (2001) Design have been alternatively associated with Arts, Technology and Science as main sources for education curricula. Design has traditionally been part of ‘applied arts’ tradition, moving then, with the emergence of the new industrial paradigm, to

a more scientific driven approach (applied science) as promoted by the Hochschule für Gestaltung at Ulm.

The radical changes in the context where Design operates today as well as the inadequacy of the mechanistic model of the traditional design process (from problem identification to solution), ask for a new convergence and a new sensitivity (and maybe for a new vocabulary as well).

In this paper we have explored the potential benefits of converging Design, Arts and Ethnography to improve the way to understand and act within complex systems in order to orient them toward more sustainable futures. We do this acknowledging how Design, Arts and Ethnography are actually already converging in their recent evolutions, moving toward more interventionist and participatory approaches.

Art practice is changing, with many contemporary artists (including those working outside an academic context) adopting participatory and process-based ways of working which are convergent with developments in social-science and other academic research methodologies. The methodology outlined above draws on socially and politically engaged art practices within Media Art, notably 'tactical media,' a critical art practice which departs from Modernist understandings of artistic autonomy and seeks to intervene within specific social and technological processes. And fields such as locative art involve artists in experimentation, which is social and technological as well as aesthetic (Hemment 2006).

Social observation, too, has changed. The most relevant innovations relevant to design have been a move away from ‘scientistic’, quantitative research and theoretical abstractions towards more philosophical, ethnographic, ‘grammatical’ investigations (Garfinkel 1967; Suchman 2007). Human behaviour is increasingly recognized not as governed by rules and social and material structures, but as performative. People create social and material orders as they live their lives, interact with others, and with their environments. They simultaneously create and orient to social and material rules and structures. Based on more than two decades of collaboration between designers, practitioners and social scientists who study the performance of everyday order, post-disciplinary assemblages of expertise and skill have emerged in socio-technical innovation, computer-supported collaborative work, and participatory design. As design is ‘no longer the exclusive province of professional practitioners’ and design practitioners recognise the complex dynamics of shaping and re-making whole systems, social science can not only help think through the possibilities of redrawing complex connections but also help to co-realize them (Suchman 2007). Moreover, social science can accompany design with studies of emergent future practices (Büscher 2005). Future Laboratories and bricolage techniques are examples of methods that create possible futures to explore *what might be* and evaluate how the design visions are interpreted and inhabited by users in realistic contexts.

These already existing convergences can be therefore amplified to strengthen the potential of each to use creative and participatory methods and tools to imagine, explore, questioning and experimenting with people possible futures.

This paper is a first platform for us to evaluate and explore these synergies; the coming projects will enable us to implement and evaluate this research direction toward post-disciplinarity as a way to contribute to the “changing the change’ movement.

Embedding sustainability on do-it-yourself products aiming at low-income families

A Case Study on Shelves Used to Divide Living Spaces

Santos, Aguinaldo dos[1], Lepre, Priscilla Ramalho[2], Rollof, Dörte[3]

Abstract

Around 85% of the products present on low-income houses in Brazil, including the house itself, have a direct involvement of the user him/herself or the surrounding community on the assembling or maintenance process. However, there are little examples of products in the country that were actually designed for this reality. In this way, this study has investigated the use of a Do-It-Yourself (DIY) approach as a means to introduce sustainable principles, with a focus on both the environmental and social dimension. DIY products are those in which users they can be involved on designing, producing, maintaining and even recycling a given product. The reduced amount of bibliography about this theme reflects the broader neglect of the research community on this field of activity, despite its scale as a social phenomenon. On this research project we have developed a case study with the aim of designing shelves that could also be used to divide living spaces.

1 Introduction

Do-It-Yourself (DIY) products are those in which users themselves can be involved on designing, producing, maintaining and even recycling a given product. Campbell (2005) proposes the use of the term “craft consumer” as a more precise definition for DIY. Craft consumption explicitly entails production of a product made and designed by consumer him/herself, involving the application of competences and passion in order to creatively transform raw material and components into an actual product (CAMPBELL, 2005; WATSON & SHOVE, 2007). To Watson & Shove (2007) and Mintel (2005) DIY can simultaneously figure as leisure and work, and as consumption (of materials and tools) and production (of changes to the home). Edwards (2006) argues that nowadays DIY is handwork but not craft and is done in leisure time but is often not a hobby.

A more restricted variation of the DIY concept is the Ready-to-Assemble (RTA) product where the focus is solely on the final assembly. RTA furniture, for instance, include products such as entertainment centers, electronic and computer furniture, storage units, cabinets, desks, and dressers. RTA furniture has flexible designs that allow multiple pieces to be made from basic configurations. A simple bookcase can be transformed into a chest of drawers, a closed cabinet and an entertainment center by adding the appropriate drawers, doors, shelves, and hardware (VLOSKY, POKU & WILLE, 2007). .

In developed countries the market of do-it-yourself (DIY) products is already well structured and consolidated. One of the reasons pointed for such situation is the high cost of manual labour and also cultural issues. In countries like the US, England and Germany, there is an widespread habit of people engaging on renovating their own places or assembling sub-systems.

In Brazil this engagement by users in assembling sub-systems and products is also disseminated, however for quite different reasons. There are even government programs that focus on the involvement of the low income family on the actual construction of their houses. As a matter of fact, building in Brazil, is majorly ‘build-it-yourself’, which means that the own resident is engaged in building the home or managing the construction process. Cuperus & Napolitano (2005) argues that such activities could also be considered as “decide-it-yourself” activities. Here, according to this authors, work has been removed from the traditional manufacturer/builder towards consumer driven trades.

However this ‘do-it-yourself’ practice in Brazil happens without components and sub-system being designed for such approach, resulting in hazardous situations, high environmental damage and poor results on the habitat. It oftens ignored issues such as product ergonomics, information design, sustainability, modular design, maintenance, upgradability and other key-aspects in product design. The situation is critical since competence on DIY is distributed both between the human DIYer and the tools and materials themselves with which he/she engage to undertake DIY production. Painting a panel door, using the example provided by Watson & Shove (2007), used to require that the painter knew the appropriate order in which to paint it and how to apply the paint without drags or drips. Meanwhile a fast drying non drip water based paints ‘know’ how to go on to a door with an acceptable finish, not requiring any special skills from a painter.

DIY can clearly contribute to provide better quality of life to low income families in Third World countries such as Brazil. The reduction of resources used in production by the manufacturer is the most obvious source of cost reduction but other areas such as distribution can also achieve better cost performance. However, little is known regarding the requirements of a DIY for a Third World environment. In this context the present paper reports a research project that investigated the requirements for do-it-yourself furniture within low-income houses in Brazil, with a focus on furniture that can be used to divide living spaces.

During previous studies the research team has identified that in most low-income houses in Curitiba the family often uses a wardrobe to provide a visual separation between living room and

the main bedroom. Such situation often resulted on poor living conditions both from the aesthetic and functional point of view as well from the point of view of thermal and acoustic insulation. The research team intended to contribute to solve the problem under the economical constraints of these families and, at the same time, to adopt the main guidelines proposed by Manzini & Vezzoli (2002) regarding the sustainability of the product. Also, in order to enable full flexibility to the user regarding the position of the "furniture/partition wall" the product had to be able to be assembled by the user him/herself.

2 Historical Context

DIY could be traced back to the pre-history of mankind since it was the only way to obtain a desired product. Edwards (2006) argues that prehistory provided an opportunity to investigate the reasons why people want to "do-it-themselves" (EDWARDS, 2006). Edwards (2006) analyses this issue on the more recent history of mankind through the continuities between modern DIY and the crafts pursued by women in the eighteenth and nineteenth centuries. Eighteenth century creative work was about self-expression through craft work. Gebler's (1997) has identified such craft motivation on his historical analysis that pointed the arts and crafts movement of the late 19th century as one of the main influences on redefining DIY. At that time aspects of DIY such as ingenuity, enterprise and self-reliance, were common among female homemakers using their own craft and design skills.

Women's domestic arts and crafts reflected a process of design democratization through self-expression. By the end of the nineteenth century women were still defined by their ability to create crafts for the Home. The change in the roles and status of, and attitudes towards women from the early to the mid-twentieth century has allowed a shift on the gender paradigm. However, there are still many who still distinguish between soft (decorative) DIY and hard (structural) DIY with its gendered stereotypes (EDWARDS, 2006). Similarly Gebler (1997) has identified a the relation of DIY and the masculine domesticity in the US through early to mid 20th century. He highlights the role of DIY as a an increasing cultural requirement for men to play an active role in the home from the end of the 19th century.

Elements of personal "handicraft" often are mentioned alongside the concept of DIY. Edwards (2006) cited that in an early DIY text from the 1950s this proximity of craft with DIY was expressly stated: "Do-It-Yourself is an expression of the ingenuity, enterprise and self reliance of the individual, and in an age of automation it is good that fundamental arts and crafts are not being lost '.

Nowadays Watson & Shove (2007) argues that DIY moved from a largely unwanted responsibility of householders to a desirable pass-time for a man/woman, enabling release from alienated paid work through being a part-time craft activity. Nowadays modern DIY appears to reflect aspects of self-expression together with the turning of alienated products into artefacts with personal associations; of leisure pursuits and the desire to be creative, and the need for economy (EDWARDS, 2007).

The reduced amount of bibliography about this theme reflects the broader neglect of the research community on this field of activity, despite its scale as a social phenomenon. The result, according to Watson & Shove (2007) is an under-theorization of the complex phenomenon through which objects shape and are shaped by everyday life.

3 Motivations and Challenges for DIY

There are a number of challenges that DIY products face in order to have success from a sustainability point view, particularly on the Third World:

- short learning curve leading to potential quality problems: competence and confidence is developed among DIYers by pushing back boundaries based on active synthesis of existing experience and knowledge through practical engagement with the DIY activity (WATSON & SHOVE, 2007). However, repeating the same assembling procedure within

a manufacturing environment presents benefits that cannot be replicated on a normal DIY setting. Thus, DIY can result on products with poor quality and on an unsafe assembling process. There is a need of staff at stores that are able to help consumer to understand the DIY product and its associated process. Information boards and free “how to” leaflets with are also useful practices to enable customer learning on DIY. However, most DIY products have multiple ways to assemble and use, thus making impractical to display all possibilities both graphically and physically;

- Resistance from conventional trades: DIY can be seen simply as a process of deskilling and, thus, it can receive strong resistance by professionals and companies that continue to provide products on conventional ways. Watson & Shove (2007) argues that rather than facing DIY simply as deskilling it should be understood as a “redistribution of competences” enabling a wider range of people to take on the task of painting a door;
- Supply-chain constraints: Vloski, Poku and Wille (2007) have investigated the challenges for ready-to-assemble furniture manufactures and their findings included getting consistent raw materials, volatile pricing in the marketplace, overseas competition and local competition. Despite these barriers it is important to notice that in sector such as furniture recent advances in production machinery have enabled more intricate cuts which then have provided more freedom to designers of DIY products (VLOSKY, POKU & WILLE, 2007);
- Lack of proper tools with DIYers: whilst on developed countries there can be few households that do not have a set of basic tools such as hammers and screwdrivers, in developing countries that itself can be a barrier for DIY. Watson & Shove (2007) call attention to the fact that it is ultimately in the practice of DIY that lay the importance of usefulness or absence of a given tool;
- Perception of DIY as an inferior product: poor design and deficient DIY assembling process as resulted on an image of product with inferior quality. DIY/RTA furniture, for instance, once viewed as an inferior alternative to solid wood furniture today are quality products while still being offered at lower price. In order to be more competitive with pre-assembled furniture DIY/RTA furniture is adding real wood surfaces and other authentic looking finishes such as veneer, improved laminates, coatings, and other finishes to enhance quality and protect the surface against scratches (VLOSKY, POKU & WILLE, 2007).

Despite these barriers “lower cost” is clearly the main driver for people choosing DIY products and processes. However, it could also be pointed the ethics of self-sufficiency; the desire to demonstrate to him/herself capability; the pleasure that comes from solving practical problems; the recreational properties of physical labour; the satisfaction of competently use the right tool for the job, or a skill mastered, or a job done (WATSON & SHOVE, 2007). Current quality, easy assembly and increased options and styles are also important explanations for the phenomenon of DIY globally (VLOSKY, POKU & WILLE, 2007).

Pollakowski (1988) founded a strong correlation between household DIY and age and that renovations are most likely to be undertaken by a recent mover. Bogdon (1996) finds household composition a major determinant of the likelihood of a household taking on DIY, with multiple adult households most likely to undertake it, single parent families the least likely. Baker and Kaul (2002) and Clarke (2001) highlight the significant relationship of changes to household composition and financial situation with the likelihood of home remodeling. There is also the “no one can do a better job than me” syndrome among DIYers which also motivated by the wish to minimise engagement with tradespeople (WATSON & SHOVE, 2007).

Motivations for DIY can also be linked to postmodern consumption where the consumer is also a manipulator of symbolic resources afforded by commodities, under which DIY can be a means to realising effects which convey individuality and self-identity (WOODWARD, 2003). That might even include media inspired aspirations.

4 Learning from the “Build-it-Yourself” practice

In Brazil there is a great lack of research regarding design and implementation of DIY products. Most of the research in this area deals with the strategies to obtain user engagement in the architectonic project or with the construction process with the support of construction experts (ABIKO, 1995). The participation of owners when designing their houses or even building it, is of great importance, because it makes them more commited with their house and their neighborhood, making them feel part of the community. Hence, a do-it-yourself product has a social impact since it can provide satisfaction and pride to the prospective resident of a low-income house, since the producdt is the result of his/her own labour (VIEIRA; MARCHETTI; DA SILVA, 1993)3.

Several writers have noticed that joint or group building and build-it-yourself bring out many technical and constructive aspect issues in the houses, many times not even reaching a standard quality level, which means a very rough living condition (LIMA, 1979; ROMERO,CRUZ e ORNSTEIN, 1995; TARSCHNER, 1998). Having that in mind, DIY products give opportunity to anticipate possible mistakes in assemblage through the use of poka-yoke systems (error proof devices), increasing chances to achieve the desired quality level.

One way users can engage in building their own house is called joint or group building. Joint-building is also known as mutual help building according to ABIKO (1995). This joint-building strategy is defined as a mutual effort driven by a community in order to build their own homes, being financially and technically supported by the government. Although they use low-tech assets and simple projects this all results in bonding between users and the product of their work, inducing a proper use and maintenance of their own houses (ABIKO,1995). There are two types of joint or group building according to ABIKO and CARDOSO (1993):

- Institutional management: a public agent manages the whole enterprise. That means making all projects, supplying the work with the technical team that will manage all financial and non-financial assets;
- Co-managing: the government supplies all assets to the community. The community then hires independent offices of technicians to assist them on how to manage those assets. These offices are also responsible for technical issues as technical managers and making projects;

According to ABIKO (1995), in the case of people building their own house the main strategies are:

- Supply of standard or personalized building plans: the Government or union may supply design as an incentive to improve building done by build-it-yourself, and also facilitating their control. A personalized design makes one choose the best way to implement it, taking into account land topography, insolation and ventilation at their home;
- Design and distribution of handbooks for building: these handbooks feature easy to understand language, step-by-step on how to build a home concerning design; best choice of material and equipment; details for an assisted building; gear and required tools, etc;
- Supply of technical advisors to an entire project: technical advising is formed by architects, technologists, designers and engineers who provide guidance through all steps of the assembling process. It allows users to build a personalized house filling their needs and expectations with the right project;
- Technical assistance on part of the building process: building assistance is provided by engineers, technologists and architects at different stages and at many housing projects throughout a city.

The wide presence of build-it-yourself in Brazil raises the idea that developing products following this concept should have no or almost no rejection among working class families.

Santos (2002) suggests that having these products packed as “kits” would make easier for the government and industry to get to an agreement regarding benefits for this kind of social asset lowering taxes for buildings erected using them.

5 Research Method

The data collection for this research project was carried out within a low income community on the suburbs of Curitiba and it focused on the furniture used to divide living spaces within the houses. The initial phase involved a literature review on the issue of DIY and, subsequently, it was carried out a mini-survey within ten houses with low-income community, followed by a case study on furniture design. Curitiba´s City Council Housing Agency (COHAB-CT) has provided the researchers with access to the community.

It is important to mention that this study was developed in partnership with Masisa, a corporation that has as one of its strategic goals developing pilot “socially inclusive business” projects with low-income segments of the market. The company established the goal that 12% of total sales in 2010 would come from the base of the pyramid and socially inclusive businesses. To this end, Masisa has created partnerships with more than 300 of its retail outlets (PlacasCentro) licensed in Latin America so as to train carpenters in producing improved furniture that meets the needs of the poor. Also, in order to create a new sales force for these products it is contracting and training women from low-income segments of society. It is also helping carpenters, with the collaboration of other civil society organizations, to become micro-entrepreneurs and thus participate in the formal economy.

The aim of this particular project was the development of furniture that works as a partition wall. Most low-income houses in Brazil already use furniture to divide spaces but there is no product in the market that has been actually designed to this purpose. In order to achieve this goal the project involved UFPR (Paraná Federal University), the client (through COHAB – Curitiba´s City Council Housing Developer), the material manufacturer (MASISA), the furniture maker (PlacasCentro), a Furniture Retail Company (M&M Móveis) and Aliança Empreendedora (an NGO that provides support for cooperatives of craftsman). Next section presents the partial results of this phase and discusses some implications and opportunities of DIY solutions for the low income market in Brazil.

6 Results & Analysis

All ten houses investigated on this research project have already experienced the use of a DIY solution and most of this experience related to furniture. Also, every house on this community has adopted the practice of using furniture as the strategy to create artificial walls within the house. This practice was particularly frequent between kitchen and the living room (see illustration below). One important aspect to take into consideration here is the fact that what we call “living room” could be used as a bedroom in the night or a workshop during the day. This variations on the type of activities were absent on the design of all furniture solutions observed during this study. On the case of furniture that was used to divide living spaces this problem was worsened since it allow little flexibility in terms of position.

Based on these premises the research team at the Sustainable Design Research Center (UFPR) have generated around four hundred ideas after a period of one month of applying creativity techniques (from 635 and analogy to brainstorming). The range of solutions went from multi-functional shelves to inflatable furniture.

A key aspect for this first case study was its short term viability with regards to the manufacturing capability of the research project partners and, also, the requisite of simplicity on the assembling process. The product had to be compactable during transport and allow high flexibility to the user decide where exactly he/whe want to the division between the living room and the bedroom. Also, very important was the need to achieve acoustic insulation performance similar to a drywall or brickwall.

The chosen solution which was developed and tested by the research team is the “zig-zag” concept, illustrated on the next Figure. On this concept the furniture can be used on both sides and it is composed of a set of rectangular modular components, that allows a variety of layout solutions.

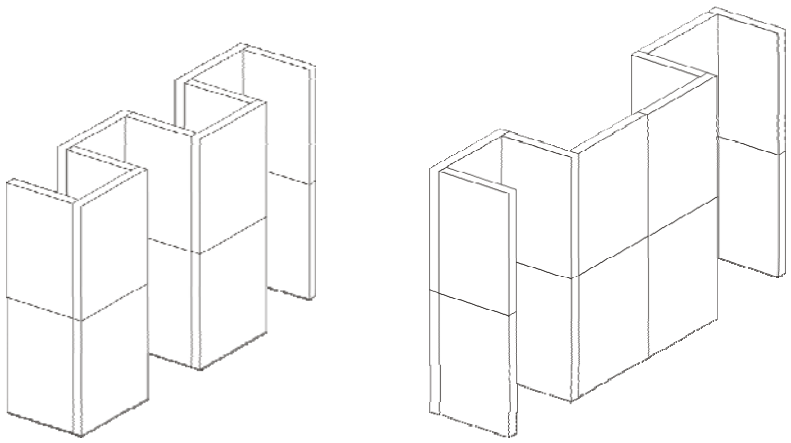

Figure 1 – Shelf to Divide Living Spaces within Low-Income Houses Using a Ziz-Zag Concept

Based on the barriers for DIY identified in the literature review and the observation carried out on the Sambaqui Community the research team have identified a set of important issues that should be considered on the development of this product:

- short learning curve leading to potential quality problems: none of families have experience on assembling furniture and the damages observed on the furniture were mostly caused by the lack of skill or knowledge on assembling, storage or transporting;
    - Lesson: the Ziz-zag Shelf has to integrate information design solutions into the product that go beyond written information; also it should consider the possibility of integrating mistake-proof solutions (poka-yoke);
- Resistance from conventional trades: this is the only barrier pointed in the literature that was not validated on this study. These families, as the majority of low income families in Brazil, were out of the conventional trade market. In fact there was even an urge to integrate more work into the community in order to generate employment;
    - Lesson: it will be quite valuable to integrate part of the manufacturing process of the Ziz-zag Shelf close to the community, which require the use of materials and process technologies available on the region;
- Supply-chain constraints: spare parts or technical assistance were not available at a reasonable distance and, quite often, the families have no economical condition to buy new parts/components anyway. Most of the furniture they have were second hand or it was inherited from their parents/relations;
    - Lesson: the Ziz-zag Shelf need to consider not only the need of using parts that are effectively available to the community but, also, the need for developing local manufacturers hence allowing its maintenance or upgrade on the long term;
- Lack of proper tools: none of the families have a toolbox;
    - Lesson: the Ziz-zag have to consider solutions that do not require tools and/or the use of very simples tools, including kitchen knives;
- Perception of DIY as an inferior product: that was indeed a widespread perception among all families. They pointed out that such perception occurs mostly because the type of material used on DIY products, leading to short life span. Also, they call attention to the perceived poor quality of finishing both in aesthetical terms as well as on durability terms;

- Lesson: increase the commitment of the user with the life cycle of a given DIY furniture requires solutions that result ona perception of it as a durable and more sophisticated product;

A first prototype has been produced (see next image) and the project now has entered on the stage of external validation of its concept. The image on the left shows some examples of alternative shapes and textures that has been developed for the structure of this shelf. The image on the right shows the final stage of the assembling process, during the trials of the first prototype.

Figure 2 – Visualization of the Final Product

With the idea of enabling small businesses within the low-income communities to have an active involvement on the production of this product or its components, the design team also conceived a number of accessories such as the ones presented on the next figure. These acessories provide further functions to the shelf and, at the same time, respect their economical constraints.

Figure 3 – Examples of accessories developed for the Ziz Zag Shelf

After tests carried out within a house build within the university, the project is now being applied on seven houses at COHAB-CT. This field study will enable a validation of the project and, also, enable the identification of further improvements on the design of this product. DIY has so far presented as viable alternative for providing furniture for low income families in a sustainable way:

- Environmental dimension: renewable materials, and use of scrap material, etc;
- Social-ethic dimension: focus on the well being of all individuals and means for them to practice their capabilities;

- Economic dimension: having as focus an increase in employment opportunities by enabling the engagement of workers with low or non technical skills.

Indeed, on the environmental dimension, for instance, a number of sustainable principles habe been applied, such as:

- To reduce the usage of materials and energy sources (MANZINI & VEZZOLI, 2002): with the substitution of a brickwall+shelves for a wooden shelf there is far less material involved; the product has been designed to reduce the need of packaging;
- To select materials that have lower impact on the environment (MANZINI & VEZZOLI, 2002; KRONKA, 2001): the wood used on this panel is FSC certified;
- To choose products and materials which are durable and which life cycle is compatible with their shelf life (MANZINI & VEZZOLI, 2002), preventing maintenance and high energy consumption (FUAD-LUKE, 2002): inevitable expansion of low-income houses face little problem with this solution since it can be disassembled and assembled elsewhere;
- To select materials which are found locally, reducing costs with transportation (MANZINI & VEZZOLI, 2002): all products are produced locally;
- To use materials that are easily recycled (MANZINI & VEZZOLI, 2002); advancing its shelf life and preventing dumping and use of raw materials to produce new materials: it was reduced the insertion of non wood material, enabling an easy recycling of the product at the end of its life cycle; besides, damaged parts can be easily assembled into smaller furniture;
- To use materials which have a scrap that can be recycled (FUAD-LUKE, 2002): the waste from the manufacturing process can be either burned to generate energy or generate wooed moulded products;
- To design products with components that are easier to set apart (MANZINI & VEZZOLI, 2002): the product do not require any special tool besides a screw driver.

DIY in the case of the Brazilian context offers a great opportunity to introduce sustainable principles within the homes of low-income families because it is already a reality in this populaton, weather the products have being designed to be DIY or not. This case study has shown that environmental constraints do not conflict with the need of producing products with lower cost and higher value. Decisions taken by designers, architects and engineers play a significant role in getting sustainability concepts applied to the construction of a built environment and fully integrating all dimensions in such a way to benefit the environment, mankind, and technological and economic development.

7 Conclusion

Current furniture market in Brazil provides a reduced amount of solutions aligned to the fact that around 85% of the houses in the country are constructed by the low-income families themselves, without any technical support. Hence, an important motivation to promote the development of DIY solutions on the context of a Third World country like Brazil is the possibility of closing the gap between the embodied knowledge (in embodied human subject) and the embedded knowledge (in the subjects and materials with and on which the subject acts), such as proposed by Dant (2005) apud Watson & Shove (2007).

By embedding products with solutions that consider the involvement of the user on the assembling process and by considering the existing embodied knowledge within low-income families, DIY seems to be a feasible strategy to provide higher living standards for these families.

8 Acknowledgements

The authors would like to thank the financial aid of FINEP (Brazilian Innovation Agency), CNPq (National Counsel of Technological and Scientific Development) and Masisa (MDF/OSB

manufacturer), the partnership of COHAB (Curitiba City Council Housing Company) and the Sambaqui Community for their readiness to welcome to the research team.

DESIGN VISIONS PROPOSALS AND TOOLS

Integration through communication tools

How design can facilitate social system integration processes

Gaia Scagnetti[1]

Abstract

Combining the opportunity offered by the findings of the Complexity Science, that has provided a theoretical framework to understand and study Complex Systems, with the empirical and theoretical knowledge about integration processes, this research investigates where Communication Design artefacts can intervene to facilitate in designing integration processes. This paper presents the result of an on-field research in Emergency hospital in Cambodia. The on-field investigation has used a qualitative research methodology (Grounded-Theory) and has led to design a model of sustainable integration. This paper results from a design oriented qualitative study aiming to define social integration in the context of the Complexity science findings, construct a conceptual model and develop an empirically derived theory that explains how to facilitate sustainable integration.

[1] Politecnico di Milano (ITALY) - INDACO department. PhD candidate, gaia.scagnetti@polimi.it

1. Introduction

In contemporary discussion the notion of integration has many different meanings and is used in many different contexts so much as to be defined as an *umbrella concept* which encompasses a large number of ways this idea can be understood and will be understood in the future (Hornemann Møller 2002).
In defining the word integration the dictionaries note its relation to *integrare* and then to *integer*. Integer means whole or undivided, in the sense of being untouched or unhurt, and the Latin verb *integrare,* related to the participle *integratus* means renewed or restored (Ritter 1922).
Generally speaking, the word integration means combining parts so that they work together or form a whole and it is a fundamental concept in functionalist theory. It describes a mode of relation of the units of a system by virtue of which, on the one hand, they act so as collectively to avoid disrupting the system and making it impossible to maintain its stability, and, on the other hand, to *co-operate*, to promote its functioning as a unity (Parsons 1954).
It has been stated that the social science needs a variety of integration concepts to reflect the real complexity of society. The many different conceptions of integration and the many different connotations in which the concept is used should not be seen as some error to be avoided; nor should the goal be a single unitary conception of integration in society. **Society simply needs many different conceptions of integration at the same time** (Hornemann Møller 2002).
The British sociologist David Lockwood (1964) had distinguished between *social* integration and *system* integration. The first refers to the way individuals are related to one another in a society, while the second refers to the relationships between parts of a society or social system. In his essay, he criticised the two main approaches of sociologists: some theorists emphasize the relations between actors, while others downplay the role of actors and seek to emphasize the relationships between the institutions of society. For Lockwood neither of these two approaches is satisfying because the task of sociological theory is to overcome this dualism[2] examining both of those crucial features.

According to Lockwood idea that system integration is strictly related to social integration, in this paper a process of social system **integration is intended as the practise of structure a new configuration out of two social systems related one to the other or, in other words to form an interrelated whole by adding single actors or clusters to an existing system and maintaining and improve relationship within it**. In this framework social system integration can be seen both as a *state* of stable, cooperative relations within a social system, and as a *process* of introducing new actors and groups into a system and its institutions, and strengthening relationships within it.

The subject of social integration has long been a crucial concern of social sciences; it is a complex idea that means different things to different people and that do not have a unique denotation. The term can be made more concrete by specifying the elements, the resulting structures and their particular properties and they are applicable to any area of study. The interest in integration processes is actually increasing in different disciplines not only because of its wide applications - from the implementation of new infrastructure to the isolation in inner city communities - but also for its role in preventing situations of chronic conflict that can arise from an unsuccessful or bad designed integration process. Since the 1995 World Summit for Social Development, social integration has been considered a key point to forge agreement on social challenges and responses to them. The Social Summit, which was the largest gathering ever of world leaders at that time, reached a new consensus on the need to put people at the centre of

[2] The debate surrounding the influence of structure and agency on human thought and behaviour is one of the central issues in sociology and other social sciences. "Agency" refers to the autonomy of an individual from both internal and external inclination. In short, it refers to purposeful action of the individual. This term implies that individuals are free to create, change, or influence events. "Structure," or patterns of organization and institutions of society which constrain and direct behavior, remain outside the authority of agency. Organizational and institutional activities are characterized as structural behaviors (Hassan and Kundu 2005).

development. It identified social integration as one of the three overriding objectives of development, together with poverty eradication and employment creation. In commitment 4 the UN Member States committed themselves to promote social integration by fostering societies that are stable, safe and just and that are based on the promotion and protection of all human rights, as well as on non-discrimination, tolerance, respect for diversity, equality of opportunity, solidarity, security, and participation of all people, including disadvantaged and vulnerable groups and persons (Hemmati 2007).

2. Sustainable integration

It has been observed that contemporary world present a peculiar combination of integration and disintegration circumstances; on one hand, technological innovations have connected people and cultures, groups and individuals and have reduced cultural and physical distances. International and local economies are now highly connected in complex networks and faraway social systems are intertwined with each other's. The almost instantaneous information flow among individuals and groups has become powerful forces for cultural integration, promoting common interests, values and aspirations among them.
Obviously, expanding the boundaries of exchange and cultural contact creates both opportunity and risk.Rapid elimination of cultural and economic barriers among nations and peoples has proceeded for the past 20 years within a context of stubborn and recurrent recession, as well as increasing indebtedness, over a considerable part of the developed and the developing world. Within such settings, **the question of how to promote just and equitable patterns of social integration takes on special meaning**; and knowledge of local society, combined with a willingness to engage in wide-ranging dialogue is essential (de Alcántara 1995).

It has been argued that in industrial society a specific agency for integration is not necessary any longer, because integration would come about of its own, by means of something like Adam Smith's hidden hand (Spencer 1862). Even if undoubtedly time by itself could eventually end up in a state of integration, a deeper knowledge about how to facilitate the process will lead to a more sustainable intervention model. Sustainability is here intended to reduce the probability of fatal error that could produce conflicts and controversies difficult to be handled. Increasing integration imply that the complexity of social relations increase and people are more linked and intertwined. Disintegration, in contrast, signifies the undo of existing relations. The relevant question for those who look at social integration in these terms is not how to increase integration *per se*, but **how to promote a kind of integration which can be define *sustainable integration***.

In defining the concept of sustainable integration, some of the different elements that partake of the process and that can lead to critical situations – **fatal erorr, inertia, cost** - must be taken into account. Designing a sustainable process of integration means mainly to minimize the chances that the process will incur in fatal error. The notion of system inertia can be of help in understanding what fatal error means in the framework of integration processes. When working on such a project as the integration of a new infrastructure – where the design is a relatively short term action, the impact on the environment is highly predictable and more generally the project has been planned and carefully evaluated – the system has a low level of inertia: conflicts could quickly arise and lead to the complete halt of the activity. The fatal error is related to the project failure and is therefore easily recognizable. Differently, when intervening in such a case as the migration of a group in a different nation – where the process has long term evolution, strongly unpredictable consequences and above all a bottom up features – the system inertia is very high: conflicts won't be able to stop the process but will affect the amount of time needed to reach a situation of integration; in this case the fatal error is function of time.

Given that self-organization and adaptability is one aspect of how complex behaviour arises, it would seem unnecessary to strive for designing integration processes. Here the emphasis should not be put on integration but should be given on the concept of sustainable integration and

its relation with the notion of cost. An integration process that will last for a long time in a situation of stagnation or micro-conflicts entails very high costs in term of instability and stress that reverberate on both the systems.

Furthermore if the sustainability discourse is about how to make human systems last longer and have less impact on ecological systems and the sustainable development is the one that meets the needs of the present without compromising the ability of future generations to meet their own needs (Brundtland 1987), than talking about sustainable integration means paying attention to comprehensive outcomes of events and actions insofar as they can be anticipated at present. Despite the general use of the word integration there is no assumption that the relationships so described are harmonious. The terms social integration and system integration can embrace both order and conflict. Giving value to **an investment in terms of awareness and knowledge of the integration processes phases can play a key role in impeding that conflicts, inevitably involved in the process, become chronic**. Furthermore to reduce the level of stress in the system, facilitating dialogue and consensus cut the cost in terms of human and economic resources and make the integration process sustainable.

Design emerges as the discipline that can play a more constructive role in the definition of such a model of intervention in order to produce a positive re-orientation in the practice of merging two systems.

Combining the opportunity offered by the findings of the Complexity Science, that has provided a theoretical framework to understand and study Complex Systems, with the empirical and theoretical knowledge about integration processes, this research investigates where Communication Design tools and artefacts can intervene to help and facilitate the designer in designing sustainable integration processes.

3. Complexity and human social system

Complexity theory was developed in the physic field of theory in the second half of the XX century. It was built around an interpretative paradigm based on the notion that in a system with a large quantity of agents a high number of interaction process are able to form more complex behaviours and to change the structural condition of the system itself. Internal to a Complex systems are agents; depending on the scale of analysis, an agent may represent an individual, a project team, a division, or an entire organization. With roots in numerous disciplines, modern theories and models of Complex Systems, or more specifically, Complex Adaptive Systems focus on the interplay between a system and its environment and the co-evolution of both. Complex Adaptive Systems models extend traditional systems theory by explicitly representing the dimension of time and its related concepts (Scagnetti et al. 2007).

The above theories can be summarised as five main areas of research on (a) complex adaptive systems at Santa Fe Institute and Europe; (b) dissipative structures by Ilya Prigogine and his co-authors; (c) autopoiesis based on the work of Maturana in biology and its application to social systems by Luhman; (d) chaos theory; and (e) increasing returns and path dependence by Brian Arthur and other economists (Mitleton-Kelly 2003).
Professor Eve Mitleton-Kelly and the Complexity Research group have make a step forward on developing a theory of complex *social* systems and an explanatory framework that helps us understand the behaviour of a complex social (human) system.

Certainly human social systems are, by their very nature, complex systems, but particular attention must be paid in applying the complexity framework to the human domain as humans are far more complex in their behaviours as actors of a system than any others non human agents. As Nicolis and Prigogine (1989) has stated “It is more natural, or at least less ambiguous, to speak of complex behaviour rather than Complex systems. The study of such behaviour will reveal certain common characteristics among different classes of systems and will allow us to arrive at a proper understanding of complexity.”

4. Emergency and the research methodology

This paper presents the result of an on-field research experience in *Emergency* war hospital in Cambodia. Emergency is an NGO operating in war and post-war zones implementing high-quality rehabilitative care hospitals, designed to be handled back to local authorities when completely integrated in the territory. **The on-field investigation has used a qualitative research methodology (Grounded Theory)** [3] and has led to design a model of sustainable integration process. The two complex systems considered for this research has been the Emergency war hospital and the Cambodian social environment in which it was built.

This organization features suited the research interests. The structure of Emergency has two parallel realities: the organisation headquarter with its two offices in Milan and Rome that coordinate about 172 volunteers groups spread in all Italy and a network of cooperation projects in 13 countries around the world. This research focuses on how Emergency designs and implements its projects. Emergency interventions have specific characteristics:

- New project often originate in consequence of a **bottom-up process**. An emblematic case is the Emergency Sri Lanka project that was born in consequence of a significant private funding specifically addressed to the tsunami victims; the intervention resulted from a decision to use the many contributions on a project rather than give it back to the donors as the Emergency policy of intervention address only war and post war territories. This created a new knowhow in the organization of interventions in natural disaster areas

- Each project has specific characteristics due to the fact that the intervention conditions are always peculiar and different even if the intervention is carried out on a territory already known. Each intervention can be considered a ***wicked problem*** (Rittel and Webber 1973), always unique and novel in continuous evolution and with more than one resolution. This requires the system to be highly adaptive and reactive to the environment in which it operates.

- The result of each intervention is a self-sufficient and totally integrated structure designed to be given to local health authorities. This implies that each project has to foresee a **very subtle handover and withdrawal process**.

- A war territory is a highly complex environment, many agents are active and their **relationships are often hidden, unpredictable and non-linear**.

- The aim is the **integration** of the structure within the territory from the very first design phase.

The bottom up process, the wicked problem, the handover and withdrawal process, the complexity of a war territory and the value of integration have been one of the main reason to choose Emergency as a case study for this research.

The used methodology springs from the social research techniques framework and combines its methods in the so-called qualitative triangulation. In social research, at least four different meanings of the term triangulation based on a different reading of topographical metaphor coexist. The one this research refers to is the third reflective triangulation of the epistemological field of Hammersley e Atkinson (1995). In this framework the use of different techniques help the research to determine which conclusions can be derived by the empirical documentation delivered by each technique. Triangulation helps to identified and overcome the specific limits of each survey techniques. The use of joint methods allows to approach in a more efficient manner

[3] It is a research method that operates almost in a reverse fashion to traditional research. Rather than beginning by researching & developing a hypothesis, a variety of data collection methods are the first step. From the data collected from this first step, the key points are marked with a series of codes. The codes are grouped into similar concepts, in order to make them more workable. From these concepts categories are formed, which are the basis for the creation of a theory, or a reverse engineered hypothesis. This contradicts the traditional model of research, where the researcher chooses a theoretical framework, and only then applies this model to the studied phenomenon. (Wikipedia)

the two parallel reality of Emergency. From on hand both free and structured interviews has been carried out so as to set a research relationship with the Italian headquarter operators, from the other Grounded Theorymethods has been used in an on field research period in the *Ilaria Alpi* Hospital in Battambang, Cambodia[4].

There is a striking incongruence between on one hand patterns of social integration which bind people around the world more closely together than ever before and on the other the frailty of existing mechanisms for promoting joint action. But if different attempt to tracing the evolution of sociological theories about integration and community has been made, and very much attention has been paid on the process of integration between individual and society (Bosswick and Heckmann 2006, de Alcántara 1995, Hornemann Møller 2002, Delhey 2004), it seems there is a lack of studies providing tools for designing interventions in social integration processes between systems.

5. A model for sustainable integration

This paper results from a design oriented, qualitative study that aimed to define social integration in the context of the Complexity science findings, **construct a conceptual model depicting social integration processes**, and develop an empirically derived theory that explains how social integration can be facilitate suggesting which communication design artefacts can be use to facilitate the success of the step.

In this chapter, the model of sustainable integration developed in the research will be explain and described more in detail. Each phase is provided with a box that links the Emergency practical experience with the theoretical assumptions. Three keywords are also supplied to better orientate the reader in the understanding what happen in each phase.

An integration process between two systems can be synthesized in four phases: structural, cultural, interactive and identification integration. If we follow what happened to communication these four steps can also be defined as information, communication, dialog and knowledge phases.

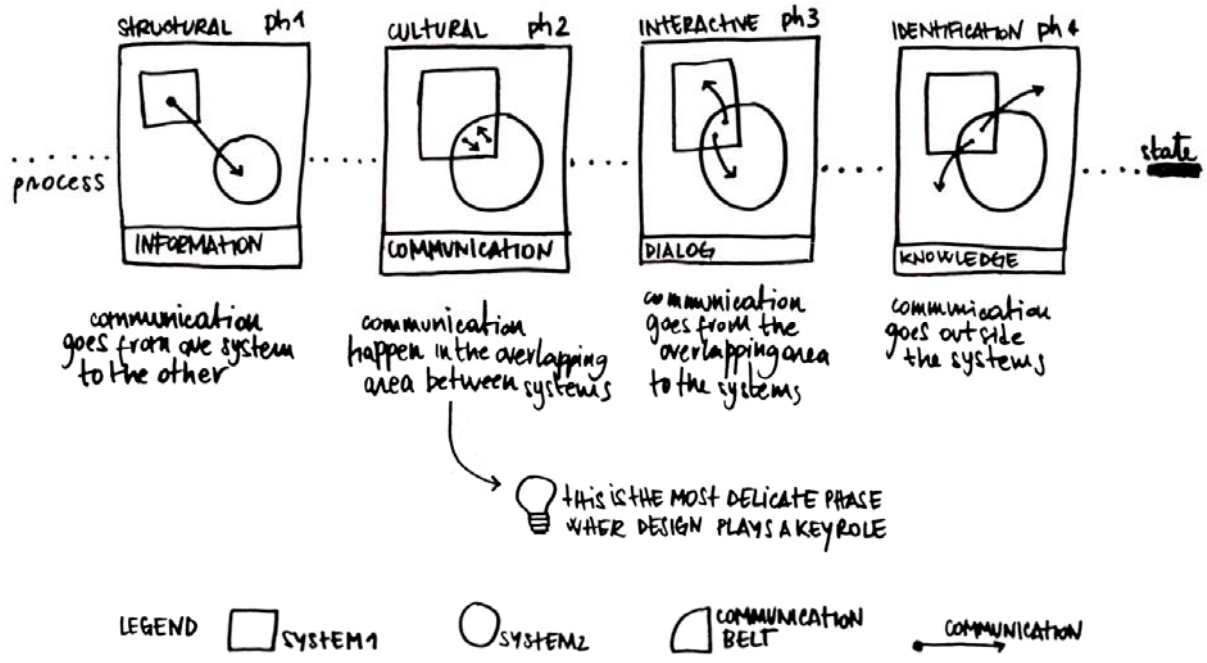

Fig. 1: Model of integration process

[4] The on-field research was carried out in winter 2007. The research on Emergency started in 2006.

5.1 Information

ACCESS SPACE POSITION

The *structural integration* is the phase in which System1 approaches System2 creating relationships among their elements. In this phase, the information flow has a stated direction and communication moves mainly from System1 in order to introduce new actors into System2. This is the process by which an actor acquires cultural standards and competence needed to interact successfully in the other system. **Social integration works on the base of identity**. The partners do not have to identify with each other, but they must accept each other's right to mean what they mean (Hornemann Møller 2002).

The peculiar characteristics of the two systems should be made evident as the intentions of change and integration. The most of information about the approaching system should be provided in order to facilitate the first connection with the approached systems. Fear and rejection is very often rooted in lack of knowledge: the unknown generates anxiety and denial of other culture, nation or religions. This means it is very important to represent and convey the systems identity which its rule and values. Transparency of vision and intentions play a fundamental role in this phase and ensure recognisability of the identity of both systems. Identity comes in many different shapes and forms, but always carries with it the double function of signifying differentiation, as well as relationship. Regardless of language or semantic nuance, the former indicates singular character, is about the state of being oneself (and not another), and remaining distinctive under different conditions; the latter centers on kinship, oneness, and likeness. Identification, then, is the act or instance of - identifying both to differentiate and to relate (Peters 2005). Visual communication is the first alphabet for creating a sense of identity and participation and to understand that pictures, colours and signs create a code which is used to get together, to share objects and spaces (Brunelli 2005). In these phase all those artefact that communicate identity and share vision and values should be considered as strategic device able to start dialog between the two systems.

Emergency has a very strong identity and since the early stage of intervention has tried to make evident the rule at the basis of its philosophy in developing its projects. These rule work on the concept of space as a medium for integration. More in detail: the host nation must provide a plot of **green land** where Emergency can build a **free high qualitative care hospital** in which it will be guaranteed safety and **neutrality** by the unconditional personal **disarm** of each person entering the hospital. These features define the emergency projects plot and establish a set of rules that are shared and made evident at the beginning of every project.
At the same time, Emergency shows great **flexibility** in the project management and a great ability in **adapting** to the need of the host country and in embracing its rules. The success of this approach is due to the Emergency ability in communicate its core values.

5.2 Communication

COLLABORATION COOPERATION EXCHANGE

The *cultural integration* is the phase where the two systems overlap. In this phase, some part of the two systems intersects and occupies a shared area where communication between the two systems primarily happens. This area identifies a space - dense of interactions, connections and dialogues - and can be defined **C*ommunication belt***. This is the area where the communication design tools can play a key role in facilitate the integration process. In the communication belt the system peculiar characteristics, its languages and features become evident: different cultures, opinions, beliefs and viewpoints face each other's. In the cultural integration phase **the two systems start a dialogical process**, pillar of this phase is collaboration and cooperation. To collaborate means that both parties commit the required resources and time to provide support to

viewpoints, follow up on key actions, and jointly perform due diligence. For parties to collaborate, they must have adequate information so that data can be assimilated, processed, and combined to evaluate and react to the negotiation environment (Harris 2007). In the Communication belt the two systems work together to solve problems. Every actor defines the problem in reference to its own knowledge, resources, objectives, etc. Actors can differ in their standards as well as in their perceptions of the situation, and consequently in their problem definition. Therefore, the outcomes of the problem definition by different actors can be different and, in some cases, even conflicting (Dente et al. 1998). **To minimize the conflicts impact a common language is needed.** As a matter of fact every design intervention is a fundamentally social activity and is therefore based on dialogical process, integration happens through a dialogic process between the system and its environment. Habermas (1987) has shown that to start a dialogue, discourse is necessary. Discourse refers to a context whereby individuals begin to communicate with certain mutual understandings and normative expectations. To facilitate a process of integration the designer should give very much attention **to create a common language that match or near the systems features**. Commonality of language is the most powerful form of interaction that enhances cooperation. Shared symbols, meanings, and communication rules facilitate both economic exchanges and social cooperation (Kuran e Sandholm 2008). If this is not possible and the two systems identities are inevitably hostile, the approach should be a combination of interest-based negotiation and consensus building. Conflicts can develop in any situation where people interact, in every situation where two or more persons, or groups of people, perceive that their interests are opposing, and that these interests cannot be met to the satisfaction of all the parties involved. Because conflicts are an integral part of human interaction, one must learn to manage them, to deal with them in a way that will prevent escalation and destruction, and come up with innovative and creative ideas to resolve them (Shamir 2003). The challenge could lay in the use of the visual language abilities, utilized for the definition of the common objectives, to create pivots so as to work in a resourceful manner even in a multi-organizational or multi-lateral context. All those artefacts able to shape understanding and clarifying meaning that have the ability to communicate narrations and to enable a process of storytelling and sense-making are here fundamental. This kind of communication artefacts takes many forms and appears in many media. Some familiar forms include mood-boards, maps, storyboards and scenarios. They are interfaces between knowledge and experience. They are a picture of impressions and points of view, rather than descriptions. They can be studied and used to generate new metadata, in order to discover new chances of change and development of the system we operate in (Scagnetti e Ricci 2007).

The first stage of the on field research in Cambodia has lead to the definition of the peculiar characteristic of this territory. If we compare them with the Emergency identity and behaviours, we can find an interesting correspondence. Emergency actions, choices and values often respond to the needs and distinctiveness of Cambodian society. This correlation has been made more evident by moving on to a higher level of abstraction in categorising these emerging properties (following Grounded theory methodology). For example, Cambodian people are used to call dust the *Cambodian snow* and they hate it very much. In categorising this behaviour abstractly, it can be interpreted as a need of protection and defence. Emergency responds to this need providing in its hospital a green and very cared environment and putting strong effort in taking care of it – Emergency maintenances paint the hospital wall face in white every season in a very hard job against dust and rain!
Another example, Cambodia is a country of contrasts, between the wet and the dry season, between the jungle and the wetland, between a land that feeds people with its products but often kills them with landmines. Contrast is a sensible[5] concept that portrays Cambodian identity. Emergency identity, with its red on white logos, with its name that seems to indicate very quick and necessary interventions but then its patience in taking care of long-term patients[6] include in itself the concept of contrast.

[5] In Grounded theory methodology they are called *sensitizing concept*.
[6] Traumas are very long time recovery injuries

5.3 Dialog

DEPENDENCE COEVOLUTION

In the *interactive integration* phase the two systems interaction results in a completely inclusive dialog and communication flow goes from the Communication Belt to both systems. **The generated knowhow reverberates within the systems themselves producing dependence and co-evolution**.The notion of co-evolution means empowerment, as it suggests that all actions and decisions affect the social environment. No individual or organisation is powerless—as each entity's actions reverberate through the intricate web of inter-relationships and affects the social ecosystem. But co-evolution also invites notions of responsibility, as once the ecosystem is influenced and affected it will in turn affect the entities (individuals, organisations, and institutions) within it (Mitleton-Kelly 2003).

Interactive integration means the acceptance and inclusion in the social networks of system2. Communicative competencies of the cultural integration phase are preconditions for the interactive integration stage. Complex systems have a history. Not only do they evolve through time, but also their past is co responsible for their present behaviour. In a complex system is very different to design for short term or for long term. That is because interactions are non-linear. A non-linear change is a change that is not based on a simple proportional relationship between cause and effect. Therefore, such changes are often abrupt, unexpected, and difficult to predict. A small change in the value of a driver could produce a disproportionate change in the outcome. When an organisation as a system is thus disturbed (e.g. after restructuring or a merger), it may reach a critical point and either degrade into disorder (loss of morale, loss of productivity, etc.) or create some new order and organisation—i.e. find new ways of working and relating—and thus create a new coherence (Mitleton-Kelly 2003). **To facilitate the creation of some new order and organisation designer should concentrate on the dynamic interaction among the elements**. The interaction does not have to be physical it can also be thought as a transference of information (Cilliers 1998). The process can begin by understanding the relationship that the system1 seeks to establish, then diagramming the relationships in which this strategic target is embedded, using a series of symbols comparable to a flow chart or organizational diagram. Once the diagram is complete, it is used to understand which relationship each tactic is expected to affect, and how. In the process of rearrange information it could be useful to look for driving forces converging and merging elements into meaningful clusters and relating the clusters to each other. Forming and studying these clusters helps to detect the driving forces of the system. Kees van der Heijden (1999) defines a driving force as a variable which has a relatively high level of explanatory power in relation to the data displayed in the cluster. By observing this rearranged diagram the systems criticality could be spotted, highlighting where the designer is required. This is an action of pinpointing able to suggest new directions for the design intervention. Visualizations clarify the relationships between the parties in a given situation. As an *abstract machine* a diagram goes beyond it own substance and representation to become an effective conceptual device. It is at the same time a tool for comprehension and design able to create significant relations between reality and its interpretation. This happens because the relations between forces, or power relations, are merely virtual, potential, unstable, vanishing and molecular, and define only possibilities of interaction, so long as they do not enter into a macroscopic whole capable of giving form to their fluid matter and their diffuse function (Deleuze 1981). Indeed diagrams effectiveness lays in the ability to act as go-between with explicative functions of the different correlated quantities, as a sort of graphic shortcut for the representation of complex phenomena. They can be used to identify which key relationships need to be affected to move your strategy forward, what tactics are currently being used or potentially available, how these tactics might affect key institutions, relationships, social groups and contexts that you want to target, which key groups, relationships or contexts are not affected by current tactics, what tactics might be brought into play to engage targets that are not currently affected, who are your potential allies for building a more comprehensive and effective strategy (Emerson 2008).

At one point when the hospital was fully implemented the Emergency staff noticed that the patient's relatives were feeling useless and uncomfortable in not giving anything in exchange for the free treatment the hospital was giving. This situation was engaging a feeling of distance between the hospital social system and the Cambodian people for whom the value of exchange and trade is central. This distance could have hindered the integration process and make the people feeling the hospital as something outside their territory social system. Emergency staff made the double choice of firstly ask the relatives to help in taking care of the patients - giving them free clean clothes and food and offering the possibility of take active part of the hospital system - and on the other hand donate blood for the hospital - even if the blood donation was something far from the Cambodian culture. Now in Battambang, Emergency has a blood bank that supply others hospital and NGOs. The interactive integration has successfully led to the we-feeling of the identification phase.

5.4 Knowledge

COSTANCY FUSION ENRICHMENT

In the *identification phase* the two systems form a new structure and produce knowledge that can be communicated outside. In this phase the two systems can be considered successfully integrated. The systems actors identify themselves with the new formed social system: they see themselves as part of a collective body. Identification has both cognitive and emotional aspects as Deutsch has argued: the populations of different territories might easily profess verbal attachment to the same set of values without having a sense of community that leads to integration. The kind of sense of community that is relevant for integration turned out to be rather a matter of mutual sympathy and loyalties; **of we-feeling, trust, and mutual consideration**; of identification in terms of self-images and interests; of mutually successful predictions of behaviour, and of co-operative action in accordance with it (Deutsch 1966). Inclusion in a new society on the subjective level – identification integration – is indicated by feelings of belonging to, and identification with, groups, particularly in ethnic, regional, local and/or national identification (Bosswick e Heckmann 2006). Social, moral, and emotional competencies are required to sustain interpersonal connectedness. Social competencies refer here to effective communication. Moral competencies are the basis of trust—for example, accountability, reliability, credibility, and honesty. Empathy and a capacity for commitment are examples of emotional competencies for connectedness. Connectedness also means identifying with a larger group. Connectedness in this sense is subjective—the feeling of being part of a whole. Identification is based on the perception of *having things in common with* others and leads to the sense that one has a stake in (is personally affected by) what happens in and to the group (Ware et al. 2007). The social integration at this stage **has to be maintained as it is potentially reversible even if successfully achieved**. The communication artefacts that help in maintaining and strengthening the mutual agreement between the two systems are very important for this phase. They are highly contingent on the context for which are designed, they convey the knowhow outside the systems and aim to share experiences, skills and knowledge. Report and article, publication and conferences are the typical example of these kinds of communication artefacts. This group also include those behaviours and performances able to narrate and make visible the systems knowledge resulting from the process of fusion: **knowledge itself is vehicle for communication of an enrich identity**.

Cambodian poor people in the countryside around Battambang were interviewed on their knowledge about Emergency. The results of the research were very interesting: even if Emergency did not communicate itself on the territory with the artefacts typically used in this phase as publications or ADV campaigns, the knowledge about the hospital had spread around the country. What people knew about Emergency was not that it is a free and international hospital, neither that it is an NGO project for land mines victims, but what they did clearly know was that if someone is victim of a trauma should go to Emergency facilities. At this point of the

integration process the kind of knowledge people have about the Emergency hospital had resulted be strictly related to their performance and their practical acting and partaking of the Cambodian society.

6. Limits and future work

The integration model described in this paper do not has to be considered exaustive, it rather provide a theoretical framework that incorporates many communication artefacts suggesting a use of them with a special attention to improve the designer consciousness about what is happening within the system he is designing for. The Communication belt is a operational concept that help in gaving a stated direction for facilitating integration processes, it is a *space* in which the two systems tell a story about themselves. It can be identified both as that phisical space surrounding the hospital both as a space of communication and dialog that evolve throught the different phases of the process.

The next step of this on going research would be to prove the practical utility of this model especially from the early phases of integration processes. The output of this research focussing on the Communication Design abilities is now to be development in a project: a practical tools based on this sustainable integration model that could help practitioners in using communication artefacts to facilitate the process of social integration between Complex Systems.
Given the need of integration, taking experiences from the local level into account might help to transcend the difficulties that result from ignoring the hidden dynamics between two systems that are approaching each other's and the complexity of these systems, thus making an important contribution towards a sustainable framework for designing integration.

7. Acknowledgment

The presented results have been achieved with the indispensable supervision and advice of Professor Giovanni Baule.

My sincere thank goes to the people from the Emergency Hospital in Battambang for their helpfulness in my on-field research and expecially to Merja Heitto, Tobias Berger, Khun Bunlee, Madam Hourt and all the people that are doing such a great job in Cambodia and to Gianfranco Sonia, Pietro and Fabrizio from the Milan headquarter.

I'm very much indebited to Dr Donato Ricci for his support in developing this research and his priceless collaboration in the Cambodian experience.

I also want to thank the Density Design Lab, Professor Paolo Ciuccarelli and Professor Ezio Manzini for being such a precious thinktank.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

WHEN HORNS BECOME METHOD

Celso Scaletsky[1]

Abstract

This article addresses the possible and desirable relationship between applied and academic research. The project set up for Indústria Sander in southern Brazil and the study about the blue sky survey concept developed in it seek to provide fresh knowledge on the project processes contained in the design activity.

[1] Unisinos (BRAZIL) – Mestrado em Design Estratégico – Escola de Design Unisinos, celsocs@unisinos.br

1. Introduction

Sander Company counts with over 80 years of existence and is specialized in the transformation of horns and bones into combs, buttons, handles for pocketknives, covering ceramics, among other products. From the serial production of objects to handcrafted objects and from the simple bone that becomes a dog toy to the sophisticated buckle of women's shoes, Sander products are high quality. However, the company was undergoing financial difficulty because its products value is the lowest in the value chain. This, plus the Brazilian exchange crisis in 2007, created an unbearable situation for the company. Great amounts of commodities are produced by Sander daily and exported to countries such as the US, France, Germany, and Australia. It was amidst this threatening situation that Sander sought the Design Center of the School of Design at Unisinos for the development of a new product.

The School of Design at Unisinos sprung up from the cooperation between Universidade do Vale do Rio dos Sinos and POLI.Design – Consorzio del Politecnico di Milano. The objective was to create a center of excellence in design in the south of Brazil. All actions of the School of Design are based on the concepts of strategic design and product-system. In 2007, at a lecture for the Specialization Course on Strategic Design, Venanzio Arquilla from POLI.Design defined in a nutshell these two concepts as "the whole of products, services and communication (the product-system) with which a company places itself in the market and in society and shapes its strategy and its offer". This position demands designers to see beyond the classic action of design (pode deixar assim…) – focused in the product that is being developed – and articulates services, communication, and experiences that may be associated to it within a previously idealized strategy.

The present paper presents in brief how the Sander Project was developed and how it inserts itself in the theoretical reflection that seeks to understand processes and methods used by designers at the early moments of conception. More specifically, this paper deals with some project strategies that aim at the creation of concept maps and blue sky research. These concepts will be defined and detailed herein. This investigation created possible and necessary relationships between applied and academic research.

2. Project Development

Definition of the brief

Design and project are two very close words, and this topic has already been quite developed. The two words may be used to describe both a creation process of something that does not exist in time (the act of projecting something forward) and to describe the result of this process (the project). Moreover, design is used to describe a relatively new professional activity whose frontiers are not well-defined. In professional courses based on the project's culture, the creation process is many times associated with a complex problem-solving process. Such problems have two characteristics: first, not being well structured; second, being open. They are not well-structured because they are usually vague and full of contradictions in the beginning. They are said to be open because a single problem allows for several solutions, which many times are all valid. For Herbert Simon, the problem-solving process could be translated as an investigation in the interior of a huge maze of possibilities, a maze that describes an environment (Simon, 1991). Donald Schön goes further in the fields of knowledge related to the culture of design and says that "in applied sciences it all depends on the understanding established when one decides on the objectives to be achieved. If the latter are steady and precise, the decision to act may present itself as an instrumental problem. However, it they are confusing and conflicting, one cannot even talk in terms of a 'problem' to be solved. A conflict over objectives cannot be

solved by using (classic) applied research techniques. On the contrary, it is through the structuring of the problematic situation that one may organize and clarify the goals to be achieved and the possible means to reach them; it is not a technical process" (Schön, 1994). For Flaviano Celaschi and Alessandro Deserti (Celaschi, 2007), this process is closer to being characterized as problem finding, that is, the search for directions towards which innovations may be guided, or even problem setting, the characterization of the problem to be solved taking into consideration the complexities of contemporary life. The construction of what design calls design brief is an essential creative preliminary activity that will conduct the process towards the stage of problem solving.

In the case of Sander Company, this process was no difference. The first articulations helped understand the context of risk the company was undergoing. The brief was characterized by the need of imagining a new product to be developed, one of greater added value that would work as a pilot that could affect all the rest of the company.

Carrying out of the studies

Three researches were conducted for the Sander project. The two first tackle the definition of the profile of the company and its productive materials/processes. These two are briefly commented herein because they are not the object of discussion of the present paper. Prof. Felipe Campelo characterized the company as "being bought" by costumers but has difficulties in "offering itself" to the market. Nevertheless, Sander's success in international fairs showed the potential of its supply. On its turn, the research conducted by Prof. André Marques identified the two main productive processes related to bones and horns. The great waste of noble raw materials called attention and decisively influenced this work.

Blue sky was the third study conducted by Prof. Celso Scaletsky and jewel designer Moema Debiagi. This study is discussed in detail in item 3, which demonstrates the relationships between applied research and theoretical investigation. The study pointed to some behavioral trends that were tackled at the workshop to develop project concepts.

Rebrief

The studies conducted and the close contact with Sander led to what is usually called rebrief. We observed that the creation of one, two or three new products would not be enough. Within the concept of product-system we decided to guide the workshop towards the realization of a system of components with its own identity, one that could be adapted to different contexts of use, for example, something similar to one of the connection images made by Azerra Company, present in the blue sky study. Combined these pieces or components generate completely different products that are adapted to particular realities. Similarly, the new guidance indicated that this system of components should preferably be manufactured either with daily production residues or by means a more rational use of basic raw materials. The transformation of "waste" or low added value products into precious objects became the conceptual image of the project.

Workshop

The workshop lasted for 3 days; around 10 professionals and students were divided in two groups; each group generated a "competing" concept for the project.

- Concept 1 – *Links*
  From the definitions presented by the studies and the formulation of the rebrief, group 1 based its work on the idea that company materials established a link between past and modernity and that the formulation of the new system of products should reaffirm this aspect. In the end, this relationship was conceptually called *link*. The group developed a system of links that could create varied products through the combination of metallic bolts and other accessories. This system will be traded as mounting kits. Thus, the product-system was characterized in the idea of the kit (product), in the way to trade it, and this lead to a fun experience of mounting and combining pieces (experience), creating a strong and easily recognizable identity in the image of links

(communication);

- Concept 2 – *Sander Homeskin*
  Having the same basis as group 1, Group 2 sought to mark Sander with a new and strong identity (communication). The proposition sprung from the realization that the company already developed surfaces manufactured from bones or horns (checked ceramics of approximately 2.5 x 2.5 cm). However, Sander was not recognized as a company that develops these products. The developed concept proposes that Sander presented itself to the market as a company that makes surfaces and generates trends. Annually, Sander could launch a new surface line that, contrary to what happens nowadays, would have a name and a brand. Thus, the company would advance one step in the productive chain. To exemplify this concept, 6 new surfaces that could be characterized as the 2008/2009 surface line were imagined.

The two generated concepts were reworked on after the workshop was over. Details were added to each of the products, and the result became a publication. This was the moment of valorization of workshop results. The work printed with the two concepts was given to the company and is to become a project development for its production. Besides the concepts, the most important result of the work was to show the company the need of a new market position and to indicate ways to reach do it.

3. The blue sky study

Theoretical basis

Up to this point, the development of the project carried out for Sander Industry was presented. However, the main objective of the present paper is to demonstrate the possible and expected relationship between an applied and academic research. More specifically, this paper approaches strategies to construct design concepts through concept maps and a blue sky research; finally, it shows how these concepts were applied in practice to the Sander project. The present paper is a continuation of previous studies focused on the definition of mechanisms that can stimulate and favor the generation of design ideas.

The design process may be artificially divided in stages. For example, for Jean-Pierre Chupin there would be long stages called sleeping phases or quiet phases of visual exploration. These phases are characterized by navigation as a dream and free interpretation of the project context and are interchanged by short phases called awakening phases or intensive phases of fast model figuration (Chupin, 1998).

Another possible representation for the creation process in Design divides projects in two major stages: one called *metadesign* and another called *projectual*. In this representation of process, the *metadesign* stage takes place as a “knowledge platform that supports and guides project activity” (Moraes, 2006). According to Dijon de Moraes, this stage does not aim to formulate ideas or precious and concrete outputs. According to Moraes, the idea of the metaproject is inserted in a highly dynamic, constantly mutating space that is characterized both by the complexity of the act of projecting and the complexity of contemporary society. All these models of representation of the projectual act are evidently characterized by nonlinearity, redundancy, as well as by its elliptical cycles. Every model of the complex process of creation will be imprecise, for in the origin of the process there will always be an open and not well-structured problem.

This study focuses the first moments of the project in which concept designers aim to identify opportunities for their projectual action. Here we are close to the moments that Chupin called “navigation or dream” or that Dijon called metaproject. Our intention is to propose mechanisms that reconcile the intuition of the project designer (hardly programmable) with elements that are defined by many authors as “facilitators of thought” (Gosselin, 1998).

Often such mechanisms are based on less direct looks, which seek references in other domains that are not directly articulated with the design problem. This type of research is many times associated to the idea of lateral view or a blue sky research. In general terms, a blue sky research seeks examples and stimuli (in the most varied forms) in order to, by means of transferences through analogical thinking, obtain indicatives of possible scenarios for the construction of answers to a design problem. Scenarios are spaces or possible worlds; they are not necessarily materials, where designers may "act" in search of answers to the brief.

We have presented (Scaletsky, 2007) how according to our investigation the two forms of above-mentioned studies may be organized and represented through concept maps. According to Joseph D. Novak, concept maps are graphical tools used to organize and represent concepts and their links or relationships. For Novak, this way of observing and organizing exiting knowledge makes space for the creation of new knowledge (Novak, 2006). In the context of the present investigation, the new knowledge will be the possible scenarios where a designer may create. Thus, concept maps may work as a support not only to represent studied elements in the first stages of the project but also to work as leverage for the generation of ideas. Experienced designers usually draw simple maps and graphs and after that group them by topics or affinities. Little by little, project scenarios are constructed. The present investigation aims to create or test some graphic and computerized tools to facilitate this work. Concept maps represent a support tool for analogy thinking, which consists of important factors to solve design problems. According to Hernan Casakin (Casakin, 2004), analogy thinking is a process of identification, mapping and transference of knowledge between a problem (target element) and familiar and known paradigmatic situations (source elements). As it is proposed here, the construction of concept maps as an articulation between concepts (represented in the maps by us) and its propositions may work both as a tool to represent analogies and as a tool to provoke new analogical thinking.

The Sander Case

The first contextual researches sought to identify the current Sander costumers, products supplied, and equipment used in production. A first approximation led us to identify some key words that could work as concepts. Figure 1 shows how these concepts were represented in a concept map constructed by means of Cmap software[2]. At that moment, the project idea consisted in the construction of a system of components that could be combined in many ways and applied to several areas, such as fashion, home, or free gifts. Later, workshop participants opted for focusing on home products.

During the construction of this map, many difficulties in the representation of images were observed. Analogical visual thinking is an important aspect for the type of proposition made by us, and in the continuation of this investigation a solution for this problem should be sought. On the other hand, the easy handling of Cmap software makes concept organization a simple and efficient task. The diffusion of this resource via web is another factor of interest since it favors the communication between the professionals who work in the development of this product line. In the initial moments of conception, computerized support tools for the project must possess this quality.

[2] Cmap software can be obtained on the following site:
http://Cmap.ihmc.us/Publications/ResearchPapers/TheoryCmaps/TheoryUnderlyingConceptMaps.htm

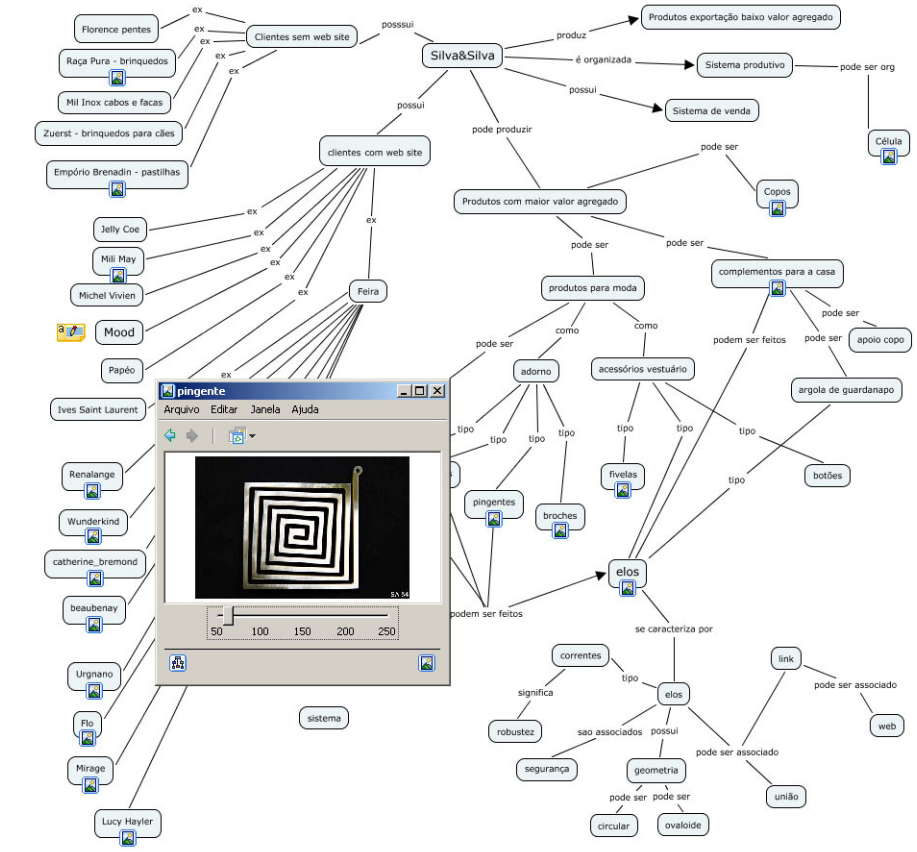

Fig. 1: Example of a map constructed with Cmap software. Source: Celso Scaletsky

The concept map partially helped the organization of the main work in this stage of the project that represented the construction of the blue sky research. From the concept map, it became more evident that the new product to be developed by Sander should have characteristics that would differentiate it from artificial. The image of plastic products, cheaper and many times more efficient, was always present in our thoughts. The opposition between artificial/plastic and organic/horn was the way to find the support to shelter the reference images that would be sought during the blue sky research.

Most of blue sky researches that serve as reference to the present investigation are characterized by the quality and consistency of their information. These studies were sought at presentations made by professors of the Polytechnic of Milan who often visit the School of Design Unisinos, where the present investigation was developed. The difficulty of investigations that focus this moment of the design process has been a lack of academic papers that seek to better understand how blue sky research are constructed. How much method there is and how the method is related to project designers' intuition are questions that arise. In this sense, the Sander case served as a real case of reflexive observation. From the first approximation made with the concept map and through our innumerable internal discussions, we reached the fundamental nucleus of the blue sky research: artificial X organic. This nucleus soon focused on the dimension that interested us most, that is, the "organic" dimension. Blue sky research favor the transference of visual, textual, sound or other types of knowledge or information. This transference is only possible from the existence of elements in common between strong analogy elements. Despite the broad look towards other reference sources not necessarily connected to the project problem, the blue sky research needs a support to justify it. The difficulty is defining these points in common that bridge the universal whole to the specific project problem.

The procedure adopted was to generate a series of key words that could work as “drawers” where reference images would be stored[3]. These key words underwent several filtering processes. Many images were found and stored, and these images served as a test to the adequacy (or not) of one key word or another. Finally, 12 key words were inserted in the organic circle. The 12 key words were related by means of 6 opposing axes (Figure 2). Each axis had a name that established the field of relationship between each pair of key words. For example, the key words “slow life” and “fast-food” are related by an axis called “life style”. To a certain extent, a blue sky study thus organized resembles the concept of concept maps as knots (slow life and fast-food) connected by propositions (life style). From this definition the way was opened to the systematization of the blue sky research.

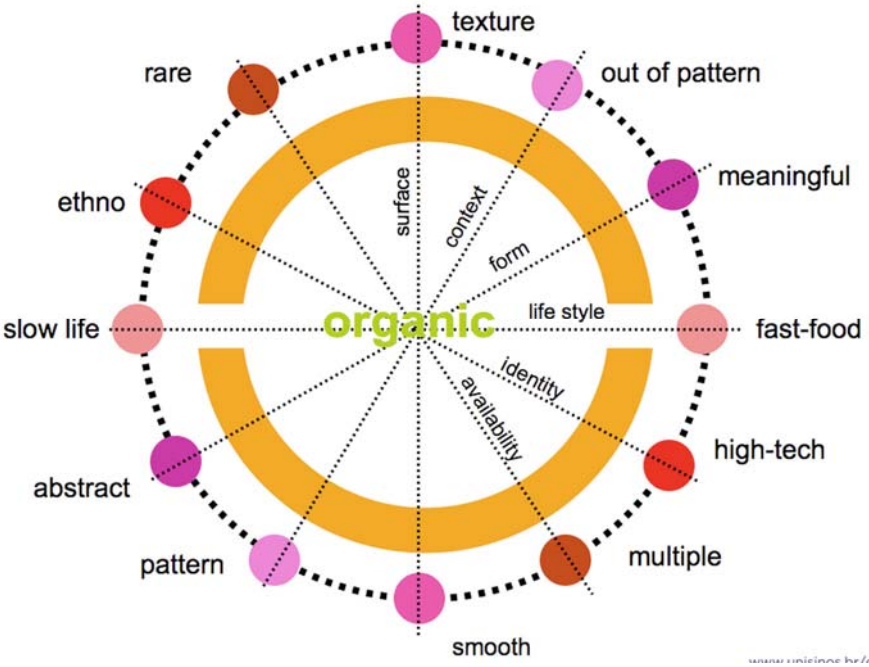

Fig. 2: 12 key words and their opposing axis. Source: Celso Scaletsky

[3] References may be sounds, smells, texts, or static or moving images. For a designer, image, even static, is an important source of knowledge as long as it is interpreted and not passively absorbed by designers. Consequently, our investigations have always favored images as main sources of project reference.

Fig. 3: Examples of reference images of the blue sky research. Source: Celso Scaletsky

3. Conclusions

The organization and strategy for the construction of the blue sky research for Sander had a clear intention of associating the left column (slow, ethno, rare, texture, out of pattern and meaningful) with elements closer to those called organic. At first, slow, ethno, etc. would be closer to the basic raw materials of this industry. However, during the workshop some images similar to what could be called an artificial world came (unconsciously or not) to designers, in other words, some of the main ideas that later would become design concepts. The image of the metallic couplings and Lego itself clearly represent the concept of component system that may be combined and applied to several situations, such as proposed by group 1 in the workshop. On the other hand, images referring to textures seem to be closer to the second concept generated. It is quite hard to affirm with certainty the influence of one reference image or another. However, it may be affirmed that many times what seems distant to our design context ("artificiality") may be the key element to a project idea.

The blue sky research was equally important in the characterization and decision on the inherent characteristics of products made from horns or bovine bones mainly as to their formal diversity and irregularity. The position assumed was that no matter the product generated in this project these characteristics would be considered positive factors that precisely set a significant difference to, for instance, plastic.

The operational question as to the software programs used is yet to be further defined. The study developed herein was guided mostly by the formulation of methods related to the research called blue sky, not to the use of concept maps. There are overlapping points between the creation of graphs translated into maps and the organization of blue sky research, and perhaps these points in common are the key to the continuation of this investigation. The great challenge is to identify methods and strategies at a moment of the project characterized by intuition.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

A proposal for communicating systemic design

A "systemic tour" showing systems design applications in the region

Lidia Signori[1]

Abstract

The systemic design approach can activate a new economic model based on the design of industrial open cycles. This methodology invites the industry to apply natural dynamic: in fact, productive activities can reflect the way Nature is organized, where, for example, surpluses get metabolized and integrated by the system itself.

The Ecodesign 2nd degree of *Politecnico di Torino* has been launching projects focused on different application fields of the systemic design in the Piedmont Region. Those examples allow to structure a tour to understand the systemic approach directly on the ground, presenting solutions and real data about the systemic development applied on industry.
In a future optic, the systemic tour will be a useful instrument for didactics, research and industrial development.

[1] Politecnico di Torino (ITALY) - DIPRADI department. Ph.D Student, lidia.signori@polito.it

1. Systems design approach

Today's society has a linear approach towards economic innovation, progress and development. By analysing social, economic and political phenomena searching "cause-effect" dynamics, we will not get to have a global vision of the events, we will hace a limited study of the technical and specific solutions that do not take into consideration the connections among the different factors. In the design world the linear approach comes from the attention given to the project, but only regarding the production of products and services responding to market needs created upstream of the possible needs in a punctual way. This approach does not let us take into consideration the system of social, cultural and ethic values which represents the real essence of the product or the service and give dignity back to design.

The systems design approach allows to extend the reference borders, not limitedly to the product but extending the focus of the project to the series of connections produced and the individuation of the flows of energy and matter that constitute input and output of the productive, communicative and social system.

The basis of the systemic approach are to be found in Nature and in its operating dynamics. Man is effectively part of nature, he does not have the capacity of completely managing it, but can observe it and imitate it, and today more than never we have to learn from Nature as far as efficiency of materials, processes, complexity and need of relationships are concerned. From electrons to cells, from living species to social communities and ecosystems, each of them is a complex system which exists thanks to the connection among its components, it lives on the base of the connections with other systems and establishes reciprocity relationships, always according to non-linear dynamics and evolution processes that various scholars, among which F. Capra, M. Castells, L. Von Bertalanffy, N. Luhmann[2], have been theorizing.

Starting from these assumption it should be easy to develop sustainable scenarios of social evolution, but nowadays the dominant culture shows communities that have completely changed their *perception* regarding their own constituent principles.

Today Man does not consider himself as part of an ecosystem, but lives as an individual in a society that tends to favour individualism. That loss of perception exists even in knowledge, which develops vertically, according to areas and sectors without inner communication, in spite of the strong impulse to multidisciplinarity that has recently been collecting approvals in the academic world but which is finding it hard to get real applications.
We are witnessing how learning is becoming more and more fragmented at all levels, from scholastic to scientific, in a process which is fostering high specialization in the different single areas of reference but is also having as a result the loss of the global and interrelated view of all phenomena. This fragmentation causes a loss of information, energy and matter, impeding the creation of connections among those flows.

[2] The systemic thinking deals with the context and the network of relationships inside of a system: in the front line the network and the connections among the elements and the whole, in case of an ecosystem as well as in case of a community or a natural organization system.
"In the systemic approach, the properties of the parts can only be understood by studying the organization of the whole. Consequently, the systemic thinking does not focus on single elementary bricks, but on basic principles of organization [...] Analysing means to disassemble something in order to understand it: systemic thought means to put the object in the context of a larger complex" (Capra, F.)

2. Communicating the systems design

The original meaning of the term "communication" is to pool, to share information as well as behaviours, cultures, "meanings" and everything that contributes to create social networks in the human societies which our community consists of. Communities, in fact, create communication networks and produce "autopoietic knowledge" in a dynamic, not linear, continuous evolutionary process.

If it is true that the evolution of our communities and the development of the communication networks follows the principles of the systemic thinking, way seems to be that difficult to communicate the systems design? We probably lost the cultural premises that let us understand what is complexity, what are the interconnections among events and relationships established among living systems; probably we are no longer able to observe Nature. Didactics and university research can contribute in training people able to observe phenomena from a different point of view. Besides, they create stimulus in new generations together with a broader vision of the same phenomena.

Scientific research, with its theory of complexity and studies of non-linear mathematics, faced the issue at a theoretical level: but the fact of understanding what complexity means, does not ensure you to find a solution, it simply describes an approach used to face problems. In fact, if physics and linear mathematics describe reproducible models and formulas that brings to a unique result, the results of the approach to complexity will be structures, trends and cycles, where numerical values cannot be measured because they depend on non-measurable factors. Nevertheless, the communication of systems design starting from these theoretical premises makes it understandable only by technicians and experts of the sector.

A less abstract example of systemic design application is the creation of school gardens: this way we understand how the study of natural phenomena allows a wide knowledge of different learning and not only.
At primary schools (children from 6 to 10 years old) there is a common practice of cultivating a garden inside of the school and this make the children observe a real natural cycle: birth, growth, decline and death, getting them aware of the natural life cycles that all the living creatures have in common. Besides, by observing the natural growth of plants and vegetables, we put the basis for the knowledge of the chemical and biological principles. Finally, the study of the natural “forms” offers interesting cues for non-linear mathematic sciences like the study of fractals or logarithmic growth. So those are no longer simple vegetables, but a multidisciplinary instrument in service of didactics.

These two examples let us understand how difficult it is to communicate the systems design: on one side complex scientific theories, on the other examples of elementary systemic development. In both case we do not use a language ideal for presentations or dialogues with economists and entrepreneurs. For this reason the Ecodesign 2nd degree of *Politecnico di Torino* has been actively working for 7 years with local productive realities in order to expand an ecological culture and develop systems design projects.
The research projects started with the students do not take into consideration single productive realities as linear closed processes, trying to observe them on the base of the internal and external relationships which characterize those productions.
Power use, emission monitoring, supplying and matter transformation, process output managing at territorial level undergo a planning redefinition that give back to the territory a wide production system, which is branch and complex, and tightly linked to the local administration of goods and services.

So we do not assist to a purely “green” project, but to the definition of a real economic model based on bioeconomics principles (or ecological economics): Nicholas Georgescu-Roegen, economist and founder of this economic theory observed as almost all economic process that produces material commodities decreases the power and commodities availability in the future. Matter decays and this decreases the possibility of its future use, this is way we need to radically

rethink economic science, making it similar to the complex systems that regulate matter and power flows.

3. Systemic tour: proposal for a communicative instrument

Thanks to the researches carried out by the Ecodesign 2nd Degree, by the II Level Master in Systems Design and by some other PhD researches[3], a lot of systems design projects have been actuated: some of them only as theoretical feasibility studies while others have seen an interesting practical development with local economic realities like SlowFood, NN Euroball and Agrindustria.
During the last years different issues have been faced, from hand-made food to industrial production, from the integrated development of a territory to the solutions to optimize the use of resources

- Frejus Tunnel: re-use of the specific mineral *(smarino)* proceeding from the extractions for the realization of the service gallery (in collaboration with Sitaf S.p.A.)
- Multilayer: proposals of collection aimed at re-using raw materials of multilayer materials to be used in productive and valuable applications (in collaboration with Amiat S.p.A.)
- Waste water treatment: analysis and proposal for the integration of domestic waste water cycles and others coming from local industrial productions, among which meat slaughtering (in collaboration with the District of Turin – Water Resources Department)
- Olive oil production: proposal for the integration of the olive oil production with the cosmetic and pharmaceutical industry
- Communicate the product cascading: case of coffee production in Colombia and communication of a systemic production path (in collaboration with ZERI)
- Micro-breweries production in Piedmont: possible use of the beer production outputs in the local context and development of the accommodating facilities – proposal for systemic menu

[3] www.systemsdesign.polito.it

All the research issues are analyzed following the same methodology: firstly the introduction of the reality in its own territorial and productive context of reference; secondly comes the analysis of the matter and power flows, that is to say of the system outputs and inputs in the light of the raw materials and chemical-physical and energetic properties.
After a deep analysis of the production flow it's time to look for the possible connections with other local productive realities (even very different ones) which should integrate with the analyzed production. Generally this process leads to an exponential growth of the productive capacity of a territory of producing new material goods, offering services to citizens and consequently increasing productivity and jobs.
The most frequent critic to this methodological approach puts in question the fact that often we do not really need new productions, nevertheless the analysis of the context shows how the request actually exists but it is covered by imports or external resources.
Exploiting the territoriality of resources we increase a development that tends to benefit local realities, allowing the creation of auto-sufficient situations, under the energetic, productive and supplying point of view.

The Piedmontese territory offers many examples of application of the systemic thinking to design, nevertheless we do not have the connections and relationships to join the different experiences in a collective communicative project that could underline the peculiarities of each single project and offering a solid qualitative and quantitative base for the following studies and researches. In this area we propose a systemic tour able to create relationships among the different projects already started or in experimentation presents on the territory, so to have a real structure showing the systemic growth of communication, society and culture.

The tour is an instrument that gives the opportunity to totally merge in what one wants to visit and communicate, and what you visit can change the normal approach to didactics and industrial production. Thanks to the examples of systemic design applied to the territory and to the direct experience, you can notice rules and flows generating an open productive system and what kind of environmental and economic benefits you can obtain.
Obviously this kind of communication cannot be unilateral and only directed towards a single destination, but should address different levels of study. For this reason, it is important to create specific channels of information and learning.

First of all, it is very important to address the school system and young students (from primary to high school) who are accustomed to head-on didactic models and very rarely have the opportunity of training or getting direct on-site experiences. It is fundamental for young people to be stimulated and given the chance to compare different realties so as to develop new ways of communication and relate between the different components of a productive, ecological, communicative and social system.
Is well known that school age is the period when thoughts are more sensible to external influences: through the main phases of children's development they pass from the sensitive perception to the shaping of their personalities that will characterize them all life long. Thanks to their comprehension skills, even in abstract terms, and to their thinking elasticity, young students result to be the best interlocutors with whom to treat innovation issues, intended as generation of new ideas. This way we get to establish foundations for their ecoliteracy that should be a challenge for the future.
Being ecologically literate, or ecoliterate, means understanding the basic principles of ecology and being able to embody them in the daily life of human communities: the principles of ecology should be the guiding principles for creating sustainable learning communities

The tools used and the learning methodologies need to be restructured according to the needs but the mentioned examples of school gardens offers good didactic ideas. The possibility of visiting industrial productive realities integrated in the territory thanks to a systemic re-design of the flows of production offers other tools for an ecological didactics.

The world of university research has different learning criteria, but multidisiplinarity is the base of the systemic approach and today is the only real way research can develop.
Sustainable development, ecological education and systemic thinking are all feasible approaches

only if we all consider ourselves as part of a network where relationships have greater importance than single parts. Passing these concepts to research, If specializing in a determined field is fundamental, it is equally important to be able to comprehend the various relationships that exist among different fields of study, which also imply a universal grounding: only from the hidden connections among these different fields can originate new research areas and innovation gets to be possible, if we intend it not as technological obstinacy but as different perspective from where to observe problems, in order to find non-conventional solutions.
The possibility of observing real examples of systemic integration on the ground, starting new scientific, economic, sociologic and politic research partnerships with the other actors from the territory, implies an high innovative territorial development, oriented to progress.
The same tour is an example of multidisciplinary research because in order to communicate on different levels it has to dialogue with multiple disciplines and create topic path suitable to different interlocutors.

In the last analysis it is necessary to involve the entrepreneurial and industrial worlds. Systems design opens up the possibility of innovative and virtuous business models in which the waste, that is today a burden, tomorrow can become a resource for new industrial systems offering numerous opportunities of development in the region, in productive areas and in connected services.
For all the cases analysed in Piedmont it has been produced a document about its economic feasibility. Those studies underline the need of short term investments aimed at improving the infrastructures and the actual production, anyway the huge quantity of new productive flows produced and the best quality of the offered products, generates a lot of benefits. In this case also, an information network should be created among entrepreneurs to extend the possibilities that a systemic project can offer.

It is important not to make the mistake of considering a systemic productive reality as a cluster. In that case the stress would be on the territoriality of the enterprises, while they have in common only the location and the type of production. Those are quite different concepts compared to the integration with the territory in the larger sense of resources supplying and innovative development. In Italy, in fact, there are a lot of clusters that have been developing around a specific production (jewels, shoes, furniture...) but unfortunately none of them has an internal systemic management.

Any enterprise wishing to be competitive, sustainable and looking at the future in the optic of meeting the needs of the society and the current market requests, must relate with needs like innovation capacity, introduction of new technologies and action in always evolving areas right as the systemic approach proposes. Thus it is essential to develop multiple and simultaneous actions, able to consider both profitability and sustainability: from this point on it is necessary to create new learning models, a new professional role for designers, and it is also useful to deeply analyze the entrepreneurial activity of people that believed in the development of this model.

4. Conclusions

The systemic tour is not a simple visit to enterprises that have been developing a system design project on their territory, but it is intended to be a wide exploitation instrument. Depending on the target of reference, it is possible to create customized paths thinking about didactic infrastructures specially created to be introduced in the productive reality (the enterprise or a group of them), and, for some of the project, it is possible to develop a systemic tour simultaneously with the enogastronomic events on the territory. Quite often, in fact, a systemic design project develops strong relationships with the production and the consumption of local food.

Parallel to the ludic aspect of the tour, in the spirit of the integration of the scientific research regarding the different subjects, the firms interested in the project could represent real independent research centres aimed at developing new projects and increasing the existing ones, giving to universities the possibility of creating a real knowledge network.

DESIGN VISIONS PROPOSALS AND TOOLS

DESIGN METHODOLOGY AND SUSTAINABILITY:
Between craftwork production and industrial production

Virginia Cavalcanti, Ana Maria de Andrade, Germannya Silva and Vinícius Botelho[1]

Abstract

The article presents the methodological approaches used by the ***Imaginário*** Laboratory in the craftwork and industrial environment, and points out the relationship between design and sustainability.

The *Imaginário* is a research and extra-mural laboratory of UFPE, comprising teachers, professionals and students from several areas of knowledge and is active throughout the State of Pernambuco.

The strategies set out are exemplified using case studies of design; in the industrial environment, the CIV and in the craft environment, the Pottery Workers of Cabo.

Historical methods and comparative procedure are used in this research. The results point to contemporary possibilities of working on the diversity of insertion of the designer, using methodologies the flexibility of which are adapted to contemporary complex scenarios.

1. Introduction

Artifacts reveal habits, values, knowledge, concepts and needs which, when analyzed together, permit the process of mankind's evolution to be understood. As silent witnesses of our civilization, artifacts represent our culture, not only the material one, but also aspects of immaterial culture, such as modes of doing, the forms of organization and management of what we produce.

One should not find it odd that the form of production of artifacts has marked the distinction between design and craftwork for such a long time. Currently, discussions take on other perspectives, and are committed to issues of sustainability. Therefore, the different forms of craftwork production, some aiming at uniquely authored pieces, others being the result of the production of utilitarian pieces produced collectively, illustrate the various possibilities for interface between craftwork and design.

In dealing with sustainability, and especially in developing countries, like, for example, Brazil, craftwork gains importance because it contains the possibility of generating income and including communities socially in urban and rural environments.

Craftwork, as a sustainable activity needs specific pieces of knowledge the broad range of which meets social, environmental and economic aspects. It is precisely where these pieces of knowledge meet that there is the great interface with design, for without losing the focus on the craftwork, it balances the dialog between social, cultural and economic questions.

It is not by chance that what can be observed is the growth in giving value to the participation of design in formulating development policies and, principally, those that target social inclusion and sustainability. In this case, the fomenting of craftwork and design in Brazil can be exemplified by means of governmental programs and support companies like the Support Service to Small and Micro Companies | SEBRAE.

The interlocution between craftwork and industrial production is, undoubtedly, facilitated by the use of design methodologies. The form of approaching the problem and the logic of procedures allow issues relating to use, form and meaning to be dealt with also in the sphere of craftwork. As a consequence, the relations established between consumers, users, productive systems and the market, using this point of view, make viable and prompt the formulation of public policies directed towards the social and economic development of producer groups of craftwork.

On the other hand, if we consider the investment policies for development, especially in peripheral countries, it is important to find alternatives which may permit the balance between fomenting development and strengthening small productive groups.

In order to transit securely in the universes of craftwork and industry, design needs, among other attributes, methodological tools which safeguard the path to be taken. This is the argument to be developed in this article, by means of comparative analysis between the comparative approaches used by the *Imaginário* Laboratory, based on reflection and the results of the actions implemented and products developed in producer communities of craftwork (Cabo de Santo Agostinho) and industries of the State of Pernambuco (Companhia Industrial de Vidros – CIV).

2. The *Imaginário* – path followed in research and extension

The *Imaginário* is a research and extra-mural laboratory of the Federal University of Pernambuco comprising teachers, specialists and students from various areas of knowledge. However, there is a predominance of designers in the composition of its team. Its mission is to

offer design solutions based on research and which are committed to sustainable development. It is active in the states of the regions of the south, center-west and northeast such as, for example, in the states of Pernambuco, Rio Grande do Sul and Mato Grosso.

The application of the knowledge produced with regard to craftwork production has contributed to the strengthening of the productive groups. In this sense, the activities undertaken together with the craftwork communities has nurtured the generation of jobs and income, the consolidation and the emergence of local community leaders and, principally, given value to local culture. The multi-disciplinary approach is oriented towards improving the quality of products and of production processes, taking into consideration respect for human, cultural and environmental issues.

In the industrial environment, applied research has prompted reflection on the design process and liaison with other areas of knowledge. The improvement in the quaity of products and productive processes, the satisfaction of the user/consumer and the market positioning of local Companies are results of actions of the Laboratory. As an example, the Companhia Industrial de Vidros de Pernambuco| CIV (the Industrial Glassware Company of Pernambuco), a partner since 2003, which has developed and launched 15 products, is recognized as one of the most innovative companies in the national market for tableware utilities in its category.

The *Imaginário* – craftwork environment

In the craftwork environment, the *Imagináro* laboratory started its activities in 2001 still under the name of *Projeto Imaginário Pernambucano* (Pernambuco Imaginary Project) and with the mission of *firming up craftwork activity in Pernambuco as a sustainable means of living, through interventions which respect the cultural values of the communities producing craftwork.*

Historically, the first actions were undertaken, 550 kilometers away from the central office at the University, in Conceição das Crioulas, a former runaway-slave community (*quilombo* in Portuguese) located in the municipality of Salgueiro, in the Pernambuco semi-arid region known as the *sertão*. The result of the actions led the community to winning the 1st World Bank Award for Citizenship, in recognition of the project giving value to *quilombo* craftwork developed by the Pernambuco *Imaginário.* Building on the success obtained in Conceição das Crioulas, and from 2002, the *Imaginário* began to work with other communities producing craftwork and widened its partnership with Sebrae-PE and other government and non-governmental bodies.

Since 2001, more than 500 craftworkers, distributed in 15 communities from the Zona da Mata to the Sertão have been guided by the *Imaginário*, amongst which are: Alto do Moura, Cabo de Santo Agostinho, Caroalina, Conceição das Crioulas, Goiana, Kambiwá, Lagoa do Carro and Tracunhaém.

The *Imáginário* believes, that by guaranteeing access by popular artists and craftworkers to the consumer market by means of coordinated and sustainable actions, it will be promoting giving value to culture and to organized forms of these and other communities, thus ensuring the modernization of craftwork production and strengthening other local structures which will sustain regional development.

The *Imaginário* – industrial environment

It was at the start of 2003 that the Companhia Industrial de Vidros – CIV proposed the partnership to the Department of Design of the Federal University of Pernambuco. At that moment, the company, a traditional producer of packaging for the foodstuffs and pharmaceutical sectors, was undergoing a moment of internal re-structuring and widening its *mix* of products to include utilities in glass. The challenge thrown down to the design team consisted of making the company's commercial interests and technological features compatible with the physical, social and cultural needs of the consumer from classes C and D[2].

Out of this partnership emerged the industrial environment approach of the *Imaginário* – established in the relationship between Design x company x consumer and with the focus *on improving the quality of the products and productive processes, satisfying the user consumer and market repositioning of local and national Companies.*

From that year until today, 15 (fifteen) projects for products have been drawn up, the successful results of which can be verified in the consolidation of the partnership of the company with the laboratory and, on the receptivity of the products developed on national and international consumer markets. This experimentation, undergone in the praxis of the activity and based on theory through research, allowed the main elements of the design process and the reflection on project methods to be identified and value to be given to them.

3. Methodology

Generally speaking, methodological approaches practiced by the *Imaginário* use the relationship between design and sustainability, such as Manzini argues for, in macro dimensions: the economic and productive dimension and the social and cultural dimension (Manzini 2006, 50 e 55)[3]. Although indissociable, and bearing in mind that the environmental theme permeates such questions, the classification of these dimensions will allow analysis of the conduct of the methodological strategies directed towards the craftwork environment and the industrial environment.

Methodological approach – craftwork environment

The methodological approach of the *Imaginário's* ways of acting in the craftwork environment has shown itself to be effective in generating strategies which are capable of promoting the social inclusion of communities in situations of vulnerability. It prioritizes strategic actions aimed at giving value to the cultural identity of the communities; it optimizes craftwork production through technological assistance; it widens publicizing and commercializing the craftwork produced; it contributes to promoting social inclusion of the craftworkers and fosters sustainable development.

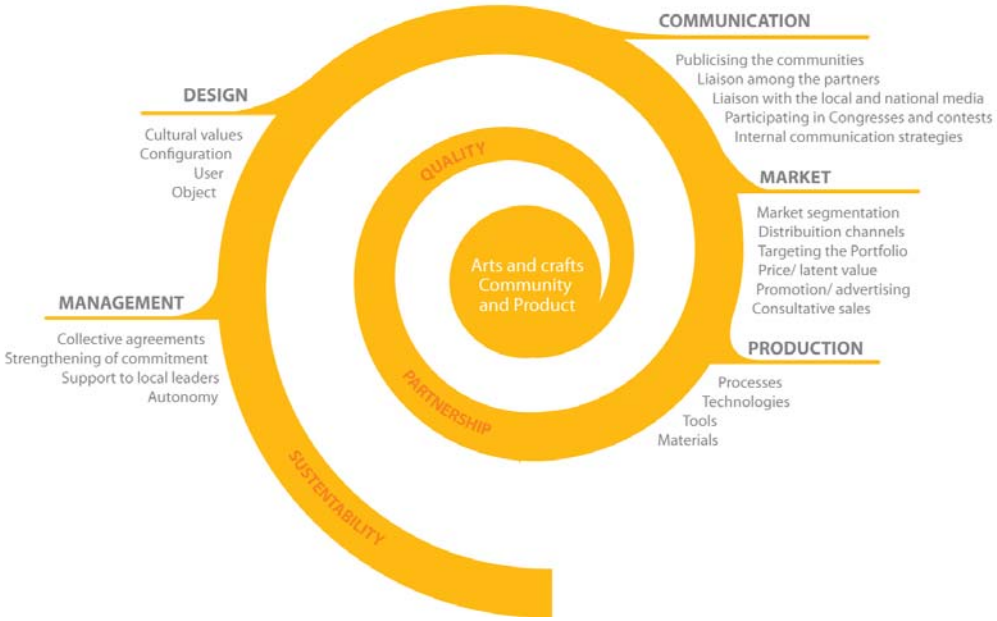
---

[2] The consumers of the classes C and D, according to studies conducted by A C Nielsen (2001), have a monthly income of up to R$ 1.800,00 per household and represent about 50% of the economically active population. These consumers are characterized by buying in cash (83.5%). For them, price is the decisive factor (61,5%) and so they are not loyal to brands. (http://www.acnielsen.com.br)

[3] Manzini presents, in the book *O desenvolvimento de produtos sustentáveis* (*The development of sustainable products),* the environmental requisites of the industrial products, the dimensions necessary for the scenario of a sustainable society: the economic and productive dimension, and the social and cultural dimension ; while the IDIS – Institute for the Development of Social Investment – Glossary classifies the dimensions into economic, social and environmental, but on introducing the concept of sustainable development another two dimensions are incorporated: the political and the cultural.

The *Imaginário* puts forward a format of intervention directed towards autonomous management, by nurturing the self-esteem of the participants, and, at the same time, investing in the growth of co-responsibility for undertaking collective projects. Integrated action, associated with a multi-disciplinary methodology, complement the directing and see to it that it serves, in a sustainable way, communities which traditionally and non-traditionally produce craftwork.

Ever since it was formatted, the craftwork-environment methodological approach has undergone adjustments by means of feedback from the actions implemented, always grounded on five axes which generate strategies capable of mobilizing (human and financial) resources and of promoting social inclusion.



Graphical 1: Representation of the methodological approach of the Imaginário | craftwork environment

Management

This fosters coordinating, forming and strengthening groups, by encouraging the construction of collective agreements and the search for autonomy.

Production

Based on the modes of production and respect for the communities' rhythm of life, the I*maginário* seeks to optimize the productive processes, improve working conditions and the sustainable use of the natural resources. The insertion of new technologies and tools guarantees the quality of craftwork activity and adds value to the product.

Design

Each piece is developed by setting out from giving value to popular knowledge, from acknowledging traditions, skills and the use of materials. Designer and craftworker create lines of products in which shapes, textures and colors reflect the cultural and social values of the communities. The excellence of the product and its compatibility with the demands of the market make the sustainability of the activity possible.

Communication

In order to generate information capable of raising the awareness of public opinion and mobilizing it towards the value of craftwork and the rights of its creators, pieces are created as are folders, labels, etc. A visual identity is constructed for each community which reaffirms the history, culture and feeling of belonging to a group, by printing a seal of origin and quality onto that which is produced by the community.

Market

This directs. The production of the partner communities is steered to specific segments of the market, which are able to recognize the value added to the product, thus guaranteeing a fair remuneration and in this way stimulating the continuity of craftwork activity.

The actions of the *Imaginário* are supported under a methodological approach which is participative, by setting out from the understanding that the men and women craftworkers are subjects of their practices; collective, by means of the incentive of constructing collective agreements and the recognition of local leaders; individualized, through recognizing the abilities and competences of those involved; critical, to the extent that it leads men and women craftworkers to make a reading of their own artistic activities; and contextualizing, since the intervention is anchored on the needs, wants and respect for the identity values of each craftwork community.

Monitoring and evaluating all the activities are undertaken conducted by means of regular follow-up encounters and meetings involving the technical team and the men and women craftworkers. The idea is to ensure the results are reviewed, to give visibility to the work done, and to re-define, if necessary, the strategies of acting by each community.

Access to the market by the communities producing craftwork is based on the preservation of the identity values and principles which guide fair trade. Therefore it is right for there to be publicity among consumers of the importance of products commercialized in a responsible way, which makes it possible for there to be fair remuneration and favorable working conditions, including the sustainable use of natural resources.

Sustainability evokes, in a wider sense, the idea of something that is long-lasting, it being a conceptual relation, and, therefore it does not make sense as an isolated idea. This steering towards a sustainable society is put forward as a conciliator of economic, social and environmental needs.

In such a scenario, according to Manzini, the social actors who act rationally in economic terms should also act positively in ecological[4] terms. This new economic paradigm can be seen in the experience of the Pernambuco *Imaginário* working with the group of pottery workers of Cabo de Santo Agostinho.

The case – Community of Pottery Workers of Cabo de Santo Agostinho.

The municipality of Cabo is endowed with natural resources which have been transformed into tourist attractions and economic potentialities which have repercussions in the development of the State as a whole, as in the example of the Port Complex of Suape.

Although the history of the utilitarian production in pottery in Cabo de Santo Agostinho stretches back to the times of the 16th century colonization by the Portuguese, from the 1990s, the demand for the production began to decrease. Having once been a source that generated

[4] Manzini stresses the importance of the social actors such as mediators of actions capable of promoting a sustainable society.

jobs and incomes for hundreds of families, many potteries closed their gates thus threatening the continuity of the craftwork tradition.

In view of this situation, the challenge fell to the *Imaginário,* together with the craftworkers and other partners, to define a strategy of approach which might strengthen the craftwork production of utilitarian pottery in Cabo de Santo Agostinho.

A full diagnostic study was drawn up, based on the observations of the specialists and craft workers involved. In order to enhance the process and economic sustainability, the *Instituto de Tecnologia de Pernambuco* (Institute of Technology of Pernambuco) – ITEP, a partner of the Laboratory, undertook trials and tests with samples of products produced by the community and evaluated the physico-chemical characteristics of the raw material.

Using these results, the Laboratory proposed a new format of finishing, being implemented in 2008 through the partnership with the Banco do Nordeste do Brasil – BNB by the acquisition of machinery to optimize the productive process.

New products were developed, thus diminishing the use of natural resources, and broadening the portfolio of products supplied to different segments of the market.

Fig. 1: In the Espaço Mauriti, craftsmen at work and the firewood kiln and products developed in partnership with the community

With regard to the development of new products and the reduction of the use of natural resources, the strategy was to maintain the technique and direct it to a market, the added value of which is perceived. Illustrated with the development of a ceramic totem in comparison with a water filter, this action widens the gains under various aspects.

	 **Totem tube**	 **Filter**
Volume de production	Small scale	Large scale
Sale	Directed at market segments	Quantitative
Profit	Widened Value added, brand, history, packaging and quality.	Reduced Yield in quantitative sale
Steps of production	Reduction and optimization of the steps of production	High quantity of steps of production
Remuneration of the craftworker	Far remuneration for the time worked by the craftworker	Low remuneration for the time worked
Production costs	Reduction of production costs and losses with an improvement of the flow ofthe productive environment	High cost of production and losses because of an environment that has been damaged
Purchase suggestions	Suggestion to the buyer of purchase of 3 modules	Single product

Table 1: Comparative table and descriptors of the benefits of the totem in relation to the water filter

At the request of the community which was eager to use new types of surface finishing on its products and, at the same time, the market demand for vitrified utilitarian pieces, a Project was drawn up for a kiln fired by natural gas. This is currently being set up and tests are being carried out. Setting up the gas-fired kiln required the planning of a physical space the location of which would be favored by the passage of a natural gas grid. The new space, built in partnership with the local Town Hall aims to be a training centre as well.

The proposal for using natural gas is to reduce the environmental impact caused by the extraction and burning of wood, and at the same time to make it possible to increase and control the combustion temperature, both of which are indispensable in order to obtain pieces with homogeneous finishes. The use of this technology will guarantee Cabo's line of utilitarian craftwork table crockery meets the technical standards required by the national and international market.

Fig. 2: Façade of Craftwork and Internal Area of the Architect Wilson Campos Júnior Craftwork Center

The use of new technologies associated with the availability of the new spaces for production and sale of products opened perspectives, which included other actors from the community. Young people were incorporated into the group in order to complement skills not found among the craftworkers, such as the use of computing science technologies both to publicize the products and to mange the sale and stock of products.

The multi-disciplinary approach and the dynamics of the process of interaction between the community and its surroundings brought about new challenges. With this outlook, new partnerships were established, involving local industries in order to share solutions for the destination of residues with the craftwork community. The *Indústria Cerâmica Porto Rico*, based in Cabo, made the residue of its production, dumped on neighboring lands, available. Experiments conducted on mixing this with original argile clay produced a paste with characteristics of plasticity compatible with the needs of the craftworkers. This initiative reduced the withdrawal of natural argile clay and, at the same time, reduced the production costs because of the proximity of the company to the craftworkers' spaces of production.

The management of production and commercialization was another challenge taken on by the group of craftworkers. The management of the Arts and Crafts Centre Arquiteto Wilson de Queiroz Campos Júnior required the making of agreements, widening partnerships and incorporating new skills. By considering the profiles and skills found and creating spaces for discussions, the *Imaginário* acted as intermediary for the construction of a working management model which integrates institutional partnerships, craftworkers and representatives of the community.

Methodological approach – industrial environment

For the industrial environment, the methodological approach sets out from *research*, reflects on and consolidates information with *analysis*, makes the product materially concrete by means of *synthesis* and implements the solutions by means of *ongoing monitoring.* These phases are polarized upon two large main concepts: utility and meaning, which transcend old dogmatic statements bounded in the attribute of function and established during the history of design.

The “utility” is related to making something adequate for use, this means that the form interferes in how the objects function and to what degree it meets its natural objectives. In other words, utility has to do with effectiveness, derived from technological and material factors. The “meaning” explains how the forms take on a meaning in accordance with the mode in which they are used. The meaning has to do with expression and feeling, and is subject to values which can vary between different cultures, and excites several interpretations for one and the same object. [5]

The graphical representation shows the main steps of the process of developing the product and its relationship with the company’s departments, especially the marketing department and the engineering department. The consumer is the fundamental element and participates in all stages of the process, which are cyclical and flexible in accordance with the specificity of the project. Nevertheless, it is in the product that there is the focus of actions of the multi-disciplinary team made up of university teachers, students and specialists with complementary knowledge and which permits various ways of looking at one and the same project problem to be established.

Graphical. 2: representation of the Imaginário | industrial environment

The feedback from the phases passes through the stages of incubation, creation and project proposed by the methodological process of the Design.

The case – CIV | Companhia Industrial de Vidros (Industrial Glassware Company

The Companhia Industrial de Vidros has been active in the market of glass products since 1958. It is part of the enterprises of the ICAL/ Cornélio Brennand group and is one of the three

[5] Gillo Dorfles in *O Design Industrial e sua Estética* considers the importance of the symbolical element found in the large majority of objects, a type of symbolism which he defines as “functional”. This is because, the object is led, from the project phase on, to “signifiy its function” in a perfectly evident way through the semantization of a plastic element capable of putting into relief the genre of figurativity which from time to time serves to indicate the specific function of the object to us.

largest glass packaging industries in Brazil. Its installed capacity is 1,000 tonnes of glass per day, the equivalent of 1.5 billion units per year. Its mix of products possesses quality at an international standard and positioning at competitive prices. These comprise **packaging,** which supplies various clients from the foodstuffs, drinks and pharmaceutical sectors and are already consolidated on the market with highly competitive prices; and the line of **utilities** which consist of cups and glasses, jars, bowls, and pots.

It has four factory units located respectively in Fortaleza (CE), Vitória (PE), Recife (PE) and Salvador (BA), which serve the world market from advantageous geographical locations, for all the units are close to the main ports and international routes.

The technology used by the company is called IS - Individual Section, a type of pneumatic machinery commanded mechanically or electronically. This type of equipment is manufactured specifically for producing glass packaging under the blow-blow and press-blow processes [1]. However, CIV and its competitors, on this market niche, make use of this technology to produce tableware.

Blow-Blow Process

The blow-blow process begins with loading a gob of glass, at a temperature around 1200ºC, into a pre-mold which receives an injection of compressed air and forms the neck. After the first blow, the *parison*[6] held by the neck is transferred from the pre-mold to the final packaging mold. During a second phase, compressed air is injected within the *parison* forcing it to take the final format of the piece.

Press-Blow Process

The press-blow process offers greater flexibility in conforming the *shapes* of the product, thus making it possible to have a greater variety of pieces in glass. The gob of glass within a pre-mold is now on a pin which will press the glass against the bottom of the pre-mold. The extraction of the piece is similar to the blow-blow process.

The great challenge for CIV was to insert itself into segment of utilities for the home, using the same industrial production process available for the production of the packaging segment. To do so, the company decided to become active in the consumer market aimed at the public characterized as C| D. CIV's utilities in glass section is, currently, accountable for 20% of the company's business, the turnover of which was R$ 200 million in 2003.

The Consumer

Data from the Jornal Valor of 2006 illustrate the growth of this segment in Brazil in recent years, with the argument being presented that this is due to an increase in consumption by classes CDE in Brazil since 1999 [3].

years/ government	Division of the social classes		
	AB	C	DE
1990/1994 Collor/Itamar	14	26	60
1995/2002 FHC	24	31	45

[6] Parison is the pre-format of the packaging, confectioned in the first step of the press-blow process.

2001/2006 Lula	24	37	39

*Class DE – Family income up to 4 Minimum Salaries

Table 2: The consumer in the Lula era. Source: Latin Panel – Jornal Valor 23.11.2006 p. A4.

Other social occurrences contributed to this reflection in consumption by the least favored social classes: the increase in the minimum salary during the period of the first mandate of the Lula government; agricultural prices at a low level and revaluation of the real in relation to the US dollar, all of which function as anchors for the inflation of commercializable products and raise the income available for consumption by reducing e cost of living; the importance of the informal market in Brazil; the growth of the participation of women in the jobs market; more credit available with an increase in the number of repayment installments. [3].

Faced with these numbers, one of CIV's competitive strategies to ensure the success of the business in the long term and, at the same time, to contribute to economic, social and environmental development of the community, was to invest in research and development in the area of design.

Innovation in the design of products, with the understanding of the needs, behaviors and life-style of the CD public, has been adding value to the products manufactured in glass by paying due attention to the aesthetic language and the quality standard offered to this class of consumers.

It is in this scenario, as a business strategy, that design translates the company's needs and objectives, by linking up areas such as Marketing, Production and Sales, uniting aspects of sustainable development (economy, society and market), to the real and symbolic needs of the individual and social consumer.

Fig. 3: Products developed by the Imaginário for the Companhia Industrial de Vidros

The methodological approach based on research and development required changes in CIV's organizational structure which incorporated research into the development of its products. This meant including gathering information and sharing data referring to aesthetic and symbolic aspects, which are fundamental in the definition of project parties.

Currently, the company has a nucleus for developing products, comprising professionals from various departments of the company such as marketing, production, engineering and quality, which is responsible for finding solutions to possible problems which may arise during the course of the projects for products. Today, the team has, on its permanent staff complement, one professional and one design scholarship holder. However, external design consultants are called

upon to be responsible for the projects, such as the way to seek shared solutions for the development of products.

In the case of the Companhia Industrial de Vidros de Pernambuco, this strategy was opportune because it made it possible to position the company ahead of its competitors. A result which boosted movement in the segment manufacturing glass utilities using IS technology (Individual Section) press-blow technology, and incorporated the research and development model, as a differential factor to improve performance in the process of innovation on account of design.

4. Results – comparing the craftwork and industrial approaches

This article has presented the methodological approaches used by the ***Imaginário*** Laboratory both in the craftwork environment and in the industrial one, underlining the relationship between design and sustainability based on its specificities. The strategies outlined for each productive environment and the way these unfolded have been exemplified using design case studies. While in the craftwork environment, the methodology is rooted in improving the quality of human life, in the industrial environment the focus is the product and the process. The table set out below gives the comparison between the main factors of convergence or dissonance of the methodological approaches.

Factors	Craftwork Environment	Industrial Environment
Focus of the action	Design at the service of improving the quality of life.	Design at the service of improving the quality of the products and productive processes, the satisfaction of the user/ consumer and the market repositioning of the Companies.
Methodological structure	Simultaneous actions anchored in on the axes: management, production, design, market and communication.	Cyclical steps: survey, analysis, synthesis and ongoing monitoring
Interface with other areas of knowledge	Action coordinated among the axes of management, market, production, communication and design based on the needs and planned actions.	Network of partnerships constructed based on the demand of the project, including company departments, the University departments and other companies.
Activities developed	Diagnostic and drawing up the collective project; Conducting capacity-building; Holding workshops; Bibliographical and field surveys; Tests in laboratory; Market survey; Generation of alternatives with community-designers in conjunction Evaluation in the market	Bibliographical surveys Market surveys Survey with users Techniques of analyzing data Generation and selection of alternatives Development and confection of models On-going monitoring of production
Forms of interaction of the team	Weekly meetings with the community Weekly meetings with the laboratory team. Occasional meetings with town halls and or partners	Discussion groups with users Meetings with departments of the company Marketing and production Meetings with other partners
Partnerships	Public institutions, town halls, and non-governmental organizations.	University departments and companies

Authorship of the project for products	The authorship is of the community	The authorship of the project is of the project is of the laboratory

Table 3: Comparison of the methodological approaches of The *Imaginário*

The example of Cabo de Santo Agostinho confirms the possibilities of sustainability coming from the partnerships between the public and the private sectors, as in the example of the partnership entered into with SEBRAE - PE, BNB and COPERGÁS. Allied to this is the capacity of the Pernambuco craftworkers to resist while seeking, in this activity, means to revive their culture and preserve their values. All this effort reflects the concept of sustainable local development, that is, a process of sustainable growth of the social, political, cultural, economic educational and environmental conditions of social groups, based on the raising of individual awareness and taking collective responsibility for undertaking productive local initiatives or not doing so.

In the case of CIV, reducing environmental impacts means contributing to changing users' and consumers' life-styles and therefore, designers can play a great part, although there are few companies, which, in fact integrate design into the definitions of their strategies for their business. This contribution can still be effective when there is a company/client strategy targeting the concepts of eco-efficiency and durability, which, by means of an evaluation of the life cycle of a product (from obtaining the raw material until disposal), balances the environmental implications with the economic factors by means of creative solutions.

The experiences undergone by the *Imaginário* Laboratory team signal the need to use design methodologies, even if they are steered towards solving problems of different natures, as in the examples presented. At the same time, it is important to note that making the methodology suitable for solving the problem is fundamental for the success of the result.

Therefore, understanding the problem by considering the socio-cultural, economic, environmental and productive dimensions is a condition for the good performance of the project and the construction of sustainable models. In this sense, the relationship between academic life and society can contribute significantly to training future professionals, to developing research and to university extension studies which, by means of exchanging experiences, enriches the possibility of finding solutions for the very diverse problems of today's world.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Service Design to foster premium prize and sustainable mobility in urban contexts*

Anna Meroni[1], Daniela Sangiorgi[2], Giulia Simeone[3], Beatrice Villari[4]

Abstract

Some of the problems facing present-day urban mobility could be solved by the so called Intelligent Transport System Sector. Thanks to the Electronic Toll Collection (ETC) technology currently used to collect tolls from urban traffic, which is based on Onboard Units endowed with a Smart Card that can communicate with Antennas placed at specific points of transit, it is now possible to introduce a new approach to urban mobility management and imagine a new generation of services.

In this paper we will explain how ETC technology platforms can bring about sustainable scenarios where new positive social behaviours are enabled by service innovation. Presenting the main results of two research-projects on the Italian mobility system, we will describe a vision of future mobility, based on the development of ETC platforms and the adoption of a series of key service elements.

1. Problematic background

New services adopting Intelligent Transport System (ITS) technologies could contribute to solve some of the problems of present-day urban mobility (Urry 2004; Dennis and Urry, 2007; Urry, 2007). This paper presents the results of two Service Design projects working on a new generation of mobility services that seek to answer the needs of contemporary urban mobility by stimulating more sustainable social behaviours.

In recent decades people mobility has increased and become less standardised; traditional collective transport services are unable to meet new requirements and individual car-based mobility is no longer sustainable. There is therefore a need for integrated, flexible and hybrid mobility services able to give a wider choice to users while orienting toward more sustainable behaviours. The challenge is to move away from toll-based policies and solutions which are detached from the mobility system and do not provide users with alternatives, to service oriented ones; this paper describes a vision of future mobility that uses Electronic Toll Collection (ETC) technology to make the mobility service system more efficient and enable more aware behaviours. Electronic Toll Collection (ETC) technology is currently used to collect tolls from urban traffic thanks to Onboard Units endowed with Smart Cards that communicate with Antennas placed at specific points of transit. This technology can:

1. help integrate services, promote multimodality and make mobility systems more user accessible;

2. enable a series of mobility-related services providing context aware information and a seamless mobility experience that makes travelling more pleasant and personalised to the needs, expectations and characteristics of the traveller.

This new logic presupposes significant changes in user habits: in order to succeed in a sustainable perspective such innovation in technology must stimulate some kind of social innovation, meaning innovation in the way people act to obtain results. For this to occur, social innovation, which is typically a bottom-up process (Meroni, 2007), needs to be recognised by users as more advantageous than their usual habits. So, the service design challenge is to use ETC technology to facilitate “open” (Cottam and Leadbeater, 2004) mobility services, where the user can actively “arrange” his own solutions and strategies and, in doing so, orient the system.

The two Service Design research projects therefore combined technological and social innovation perspective. On one hand the research projects developed ETC technology as a platform for the implementation of different service elements able to generate integrated, flexible and hybrid mobility solutions (modular architecture); on the other they developed these solutions adopting a “positive psychology” approach that recognises and rewards sustainable behaviours.

2. ETC platform

The current challenge in orienting mobility-related behaviour towards a more sustainable pattern is to create an integrated, flexible and hybrid mobility system able to give users a wider choice, therefore reducing the use of private transport (AA.VV. 1999). Recent innovative technologies, like the ETC systems and electric or light vehicles, combined with an innovative vision of the service, could facilitate the development of such a new system.

ETC technology, currently used to collect tolls from urban traffic, is based on Onboard Units endowed with a Smart Card. This is able to communicate via microwaves with specific points of transit and is currently adopted both for motorway and urban traffic, enabling vehicles to be tolled without having to pass through specific toll plazas or reduce their speed. This benefits the

environment, because it eliminates queues and deters the use of private cars in urban areas if the system is installed in towns (road pricing).

Since it is able to recognise and track the user, ETC technology could be further developed into win-win solutions that encourage and reward sustainable behaviour, such as using public instead of private transport, sharing cars instead of owning them or using green vehicles instead of polluting ones. This is because the technological system is made up of three main components that track the mobility of a person or vehicle: (1) antennas placed at specific points of transit; (2) Onboard Units placed in the vehicles; (3) Smart Cards, generally inserted in the Onboard Unit, that can also be used separately as personal cards to access various public transport, personal and public services. It is therefore possible to profile users and encourage them to adopt virtuous behaviour by providing access to different mobility modes and services, rather than through punishments and constraints, while communicating the impact of each choice and rewarding sustainable ones.

Electric vehicles offer further opportunities for sustainable mobility. Considering the use of electric vehicles in new mobility service ideas was the starting point for the Archimede-Ecomobility research: these kinds of vehicles (cars, microcars, bikes) can be integrated into public and private mobility systems.

3. Key service concepts

This vision considers mobility services as nodes of an integrated and flexible system where people are stimulated to adopt certain behaviours by ease of access to the system, its effectiveness and by premium-prize logic.

In order to do this urban mobility has been rethought in the light of a series of key-service-concepts that, when combined together, complement each other and offer the city-user a brand new range of mobility solutions.

The two main mobility concepts in this vision are:

1_ *mobility credits* using ITS technologies to manage each individual mobility pattern through *fees and rewards*;

2_ *intermodality* through connected inter-change nodes all around the city.

1_ Mobility Credits

Thanks to the ETC technology, it is possible to implement the concept of mobility credits, where the user can buy, spend and gain credits according to his/her behaviour, in the light of a multimodal mobility scenario. A credit is a unit which can be used to access operations inside a given system: ETC technology enables credits to be collected and stored automatically in the Smart Card, which becomes the main means of activating the services. Since the same Smart Card can also be used in the main public transport electronic ticketing devices and, in several cases, even be used to manage car-sharing services, it enables a set of interlinked and sequential actions. The principle of mobility credits is currently being explored in several places and conditions in order to determine the feasibility of such a radical shift in urban mobility behaviour (Fondazione Italiana Accenture, 2006; Kalmaje, Kockelman, 2004).

Adopting a credit system allows us to see mobility services in terms of Positive Psychology (Seligman, 2002; Inghilleri, 2003). That's to say, instead of frustrating the user with prohibitions, services can be designed to reward positive behaviour (with credits) and to provide a clear picture of the available mobility choices. These to overcome the difficulty users have in today multimodal mobility system to understand the alternatives and choose the best solution for his/her needs. A credit-collection based system (exploiting ETC technology) should and could systematically overcome this problem by: 1) providing both an analogical and digital map of the

system (info-mobility and advanced navigation systems); 2) effectively fluidizing transition between the different means of transportation and giving access in real time to real alternatives; 3) rewarding sustainable behaviour and choices (i.e. the adoption of public instead of private transport).

The aim of the two research projects was therefore to turn a series of mobility prohibitions, restrictions and constraints into new opportunities, where limited freedom of use for private vehicles is overcome by a set of real and feasible alternatives. This means adopting a positive approach (Csikszentmihalyi 1991) to restrictions using ITS and green technologies as significant drivers of change.

2_ Intermodality

Both the projects adopted a user-profile oriented approach. An analysis of current lifestyles and ways of moving around in the city suggested the need to shift from the current, apparently more convenient, one-vehicle trip model, to a more expedient multi-vehicle trip model. In the latter scenario, users are asked to exchange apparent convenience for tangible benefits in terms of real time-saving, money-saving and rewards for good practice. The aim of the projects was to create real opportunities for an *intermodality* attitude to kick in as a winning strategy in everyday mobility solutions (Jegou, Manzini, 2003).

The user profile approach resulted in a series of *travel demand models* (Kalmaje, Kockelman, 2004), where destinations, needs and time choices of different *personae* were used to stimulate the design of services with a modular architecture, that's to say, made of "service elements" differently combinable by the user according to the specific situation.

Moving on from these two main concepts, and from real to abstract scenarios, some crossing and transferable key concepts have been explored as promising directions for the mobility sector:

- *mobility credits*: units that can be used for operations inside a given system, which the user can buy, spend and gain according to his/her behaviour;
- *user profile personalisation:* thanks to the use of the smart card, every user can decide how to spend his/her gained mobility credits, choosing the most convenient, personalized service and routes;
- *multimodality in inter-change nodes:* inter-change nodes offer the user the possibility to choose among different mobility services depending on his/her needs and the city mobility conditions;
- *privileged access:* users can benefit from signing up to the system e.g. in gaining access to reserved lanes and specific services and privileges;
- *green shared mobility access:* users can access green vehicles located around the city, using the smart card to activate them;
- *mobility info-points:* mobility info-points can communicate with the OBU, on the car or other means of transport, to provide local mobility information such as real time traffic conditions and the availability of parking spaces;
- *all-inclusive personalization or pay per use:* users can choose between paying a flat rate for all services, or just paying for those actually used per unit of time, according to his/her involvement in the system and willingness to take advantage of the benefits available;
- *integrated mobility in a bounded space:* in a closed environment, like a fair, it is possible to integrate mobility services and access to different facilities to enable a seamless experience and increase efficiency;
- *integrated private and public transport:* technology enables private cars to be used in combination with public transport to form an integrated mobility system. A user can

leave his/her car in an inter-change node and catch a bus or a train to get to his/her final destination. This implies a change in mobility model that integrates and facilitates access to different means of transport;

- *advanced technology integration:* in some contexts it is necessary to integrate some advanced technology such as GPS and GPRS (satelite technologies used to map objects in a wide area) to trace or to map a user's movements in an extensive, open space, such as an alpine environment, where traditional ETC radio frequency is not enough to localise a person;
- *road pricing:* road pricing, traditionally used for motorways, is now becoming a common way to combat the increasing pollution in cities. If considered in a service-oriented perspective, road pricing could be a concrete answer to air pollution problems in contemporary urban environments.

4. Case studies

This vision of future mobility has been developed in two applied research projects by a team of design and engineer researchers from the Poli.design consortium:

- a scenario building exercise for the Norwegian company Q-Free, dealing with ETC technology, aiming to explore new service ideas for the Italian context;
- a product-service-system development for the Italian company Archimede Energia, aiming to provide green mobility services, using electric vehicles plus solar energy provision, for the city of Milan and its hinterland.

The common purpose of these projects was to reduce material and psychological dependency on private vehicles and foster the adoption of multi-modal and inter-modal commuting.

Both projects were interested in developing the concept of *road pricing* (recently introduced in different European cities, among which Milano). Nowadays, road pricing is a way of charging for the use of given roads at certain times and conditions: such a solution lacks flexibility as it charges the same amount of money for different mobility profiles (differentiating tariffs only in relation to the kind of vehicle) and is therefore missing the opportunity of developing into a new generation of urban mobility services.

Combined with ETC technology and with a fleet of green powered vehicles (from cars to bikes) for public use, the road pricing strategy could really foster a new generation of urban mobility services. The service design issue, in such a framework, is how to conceive interconnections between different transport options and make them fluid and accessible for the user, so to provide a positive experience in moving around in town.

In addition, extra mobility benefits and services have been added and integrated within the credit system, so as to make it possible for users to benefit from supporting offers connected to his/her needs and preferences.

4.1 Q-Free: mobility scenarios for the Italian market

Italy was selected as the research context because of the peculiarities of its geo-social conditions: historical cities, small metropoli, areas of natural beauty attracting tourism, mountains and sea.

Firstly, six *metacontexts*, that's to say typologies of emblematic urban or extra-urban settlements with recurring features, were identified as characterising the Italian peninsula from a mobility perspective. Each of them was analysed moving from a real case study:

- the metropolis, Milan;
- its hinterland with trade fair centre , Rho;
- the historic/productive town, Como; the motorway system;
- the skiing area, Alta Val Badia;
- the inhabited natural park, Parco Nazionale delle 5 Terre;
- the motorway system.

While exploring the context, the technological state-of-the-art of the main mobility related functions (paying, access, tracing and tracking) were also examined in order to define the corresponding metafunctions (recurring activities that constitute functional typologies).

With these metacontexts and their related metafunctions in mind, the scenario building activity moved from an awareness of the complexity of contemporary mobility behaviour and from the necessity to work on motivations, rewards and values, to seek ways of stimulating relevant changes in lifestyles. Service design is in fact more and more about designing behaviour and may use technological platforms as significant drivers of change.

As a result of the research work, six scenarios of possible solutions were built:

1) Milan: Providing multimodal possibilities to integrate public and private transportation;
2) Rho-Fiera: Access to organized mobility and fair services for exhibitors;
3) Como: Multimodal mobility system based on the use of green vehicles to access a historic city centre;
4) Alta Badia: Skiing services integration through the ETC system and built-in additional technologies;
5) Parco Nazionale delle 5 Terre transformed into a harbour scenario, where the ETC system is adopted in the marine sector;
6) Motorways: Introduction of the ETC system on the motorway adopting a mobility credits model.

Every scenario used mobility credits to foster a premium prize mobility and stimulate potential users to join the system, changing their behaviour as regards the way of moving around. In some cases the mobility credits gained were used to pay for public transport or shared green vehicles, in others to obtain discounts or benefits from services which have special agreements with the system, and which the user had chosen at the moment of adhesion.

Thanks to mobility credit it is now possible to change attitudes towards more sustainable mobility, not only through deprivation of comfort and materials as commonly perceived, but also by enhancing a system where virtuous users are stimulated to act more sustainably because they have something to gain from good practice. Users are really free to choose between paying and being restricted, or joining the system and being awarded for their positive actions.

In the Qfree Project scenarios, the user can always decide which is the best way for him/her to move. Contrary to the mindset where one is really only free to move when using private cars, thanks to ETC technology, a user can decide to maximise freedom of movement, using all the means available, from private cars, to green shared vehicles and the public transport system, with the maximum of flexibility and reliability. The smart card permits intermodality because it can be separated from the OBU, so the user can keep it with him/herself on all means of transport belonging to the service.

4.2 EcoMobility – Archimede Energia

Ecomobility is a research project focusing on sustainable mobility services for the Milan city context developed in 2007. Three design service scenarios were built, based on the Archimede Energia company and its electric vehicle products. The scenarios focused on the integration of different existing urban mobility services (electric vehicles, car sharing, car renting and so on). In accordance with the Archimede Energia strategies, the Ecomobility research scenarios considered the use of renewable energy for the vehicles (green Km concept) produced by photovoltaic panels.

Starting from the Milano city area, the design scenarios aimed to promote a strategic development of the Archimede enterprise towards a sustainable way of living the city of Milan.

The solutions were structured in service ideas mainly based on offering maps, service scenarios and design concepts for the infrastructures to be adopted.

The research approach was based on the integration of context of use (places, mobility user profiles, actors involved) and innovative services ideas based on ITS technologies.

Some design scenarios were created after a preliminary analysis of existing mobility services and infrastructures situated in the city of Milan. Some ideas were described in depth, merging Archimede enterprise strategies with innovative levels of mobility services, and visualizing the main characteristics as described in the following three scenarios:

1. *Greensharing*. A mobility service integrated with a car-sharing company. It considers the use of electric vehicles with GPS technology. The scenario includes the possibility of:

- programming the route on a website before using the cars;
- using the mobility credit cards and the OBU for the TLZ;
- using special parking areas equipped to recharge the vehicles.

The final solution is a car-sharing service performed by electric microcars (also fuelled by photovoltaic energy) that integrates different technological solutions:

- The *Electronic Toll Collection technology*. The microcar can be 'traced' in order to use Urban Road Charging "mobility credits". The microcar includes an On Board Unit able to identify the user when the Smart Card is inserted;
- *Personal Smart Card.* This activates the vehicles and integrates with public transport and car park services..It also enables the use of Mobility Credits;
- *GPS*. This enables access to internet booking services and route programs. The route programs can also be recorded on the personal GPS;
- *Web Site*. This is the interface for the entire service.

The microcar can be recharged in special car parks provided with charging points, often situated in supermarkets. The service also gives the user access to the city center or special car parks. Thanks to the ETC system, the user can manage his mobility credits and use different mobility services offered in the city of Milan.

The idea is to promote an integrated sustainable mobility system using public transport where users gain credits to spend in future when using the Greensharing service.

2. *Micromobility for Milan neighborhoods*. This is a mobility service offered by local supermarkets. It supports individual users in their daily or weekly shopping at the local markets. The service is part of a widening supermarket offer dedicated to user members. For example, people can rent an electric bike with special baskets for a whole day using also the Supermarket card points.

The service includes electric microcars or bikes available in supermarkets or local shops. The service is supposed to facilitate shopping activities on the one hand and on the other it facilitates short trips around the city. For example the users can rent an electrical bike in the

supermarket park area using their personal card. The vehicles can be charged in the supermarket parking area using the charge points.

3. *Company Fleet*. A mobility service that provides electrical vehicles for small enterprises. The service includes green-energy supply and vehicle maintenance.

This mobility service offer includes:

- electrical vehicles customized for different enterprise activities using the ETC technology and the GPS navigators;
- sustainable energy supply (produced by photovoltaic cells);
- photovoltaic infrastructures;
- smart cards to manage access to the service and other integrated services connected to the city;
- vehicle maintenance and charge points;
- mobility management (access, routes, etc.).

This service could be used to deliver goods or as a home delivery service.

By integrating Electronic Toll Collection the vehicles can also be traced for direct payment of urban road charges.

5. Conclusions and replicability

This vision can contribute to foster sustainable moblity as it is potentially transferable and replicable in different urban contexts, with minor or major adjustments.

Conceived as modular architecture, the key-concepts work as guidelines to develop a set of interlinked service-elements that will constitute the final mobility system. To transfer and implement this vision into different contexts, service designers need to match the set of concepts with the different mobility needs and local habits.
