As mobility issues are strictly dependent on contextual needs, but at the same time connected to wider and complex systems and dynamics, design can contribute to *changing the change* by building overall visions and concepts that can orient the development of the overall technological platform and of single situated solutions. Working on the overall technological infrastructure and modular service elements, designers can therefore link the vision with local requirements and mobility profiles, combining technological and social innovation.

This means working both with technology stakeholders potentially able to build the infrastructure, and at the same time with local communities and city councils (Landry, 2000) to translate the vision into effective and useful solutions that motivate changes in mobility habits.

Such a system could, also, foster the development of so-called “local currencies”, represented here by the mobility credits. Local currency enables a community to use its existing resources more fully, which has a catalytic effect on the rest of the local economy. It also enables people to join a system where economic transaction and payment are not a punishment, but a way to use the resources in the best possible way, because of the attribution of a value that is defined within the community itself.

From a designer point of view, these kinds of projects require careful attention to accessibility and usability issues, because of the complexity and flexibility of the system, and a clear communication strategy (transparency) able to effectively show the possible mobility choices as well as the benefits/rewards associated with the use of certain kinds of services. Service design is, in fact, more and more about designing behaviours and can use technological platforms as significant drivers of change (Sangiorgi and Villari, 2006; EMUDE, 2007). The point, is creating solutions that not only satisfy a function or solve a problem, but that are also desirable,

aspirational, compelling and delightful (Burns, Cottam, Vanstone and Winhall, 2006): the way to reach this objective has been the adoption, for both projects of a user-centered approach, where technology has been rethought in the light of the user experience and viewpoint.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

ARK-INC

An alternative view of what 'designing for sustainability' might mean

Benedict Singleton[1], Jon Ardern[2]

Abstract

This paper concerns ARK-INC, an ongoing critical service design project that was initiated at the Royal College of Art in 2006. The project explores radical responses to the unsustainability of current infrastructure, economic paradigms, and modes of everyday life through ARK-INC, an organisation that acts to prepare its fee-paying clients for extreme, yet highly plausible, near-future scenarios in which natural resources are diminished, violent weather part of the everyday, and social unrest widespread. The paper suggests new concepts, such as *guerilla infrastructure*, adaptable and resilient means of moving around and bringing together people, things and information; and *dormant technology*, discarded media that might be re-evaluated in light of new, sustainability-based criteria.

1. Introduction

This paper introduces ARK-INC, an ongoing design and research programme that began life in the Design Interactions department of the Royal College of Art in 2006. The project arose from a sense of frustration: the mounting body of scientific evidence concerning the dangers inherent in continuing with our current lifestyle was (and arguably still is) being ignored or denied for fear of impeding the current economic paradigm. The systems on which familiar ways of life (at least to those in most of the Global North) are contingent are vulnerable to a wide range of stressors, of which *climatic change* and a societal *energy descent* caused by depletion of oil resources are two of the most clearly foreseeable. ARK-INC is a response to this situation, an experiment in envisioning 'sustainability' beyond minimising human behaviour's current detrimental impact on natural systems, to address extreme, yet entirely plausible, near-future scenarios.

Positioning itself as *a radically alternative investment company*, ARK-INC encourages the investment of its fee-paying members' time and money not in ventures projected to yield a fiscal profit, but in developing the skills, contacts, knowledge and equipment appropriate to a near future where natural resources are diminished, violent weather part of the everyday, and social unrest widespread. ARK-INC cultivates and manages a secretive grass-roots network of 'alternative investors' - the 'ARK Movement' - comprised of many semi-autonomous 'Collectives'. The Collectives are groups who have chosen to put aside differences in their political and theological beliefs to take a common stand in developing new, sustainable and (importantly) *resilient* ways of living. ARK-INC supports and shapes the Collectives' endeavours through the products, services and systems it provides. It is also the public face of the Movement, actively recruiting new members and forming partnerships strategic and tactical with other organisations.

ARK-INC's development is a programme of *design research*, practiced from the perspective of artist-designers (Gaver & Dunne, 1997). This approach places less emphasis on strict adherence to a given methodological approach, or on factors such as the 'usability' of designs; instead, it concentrates on opening new spaces for design, exploring how values differing from the mainstream might be embodied in products, services and systems (e.g. Gaver, Dunne & Pacenti, 1999; Dunne & Raby, 2001; Mazé & Redström, 2007). We have been inspired in our approach to this project by recent work such as *SlaveCity*, by Rotterdam-based art and design collective Atelier van Lieshout, and *Edge Town* by British designers Ben Hooker and Shona Kitchen. These very different projects explore the dangers in assuming 'sustainability' to be an *a priori* good (*SlaveCity*), and the role designers might play in creating desirable ways of life in adverse surroundings (*Edge Town*). ARK-INC is, however, predominantly informed by 'real world' material, from scientific writing on global ecologies natural and man-made, to contemporary experiments in alternative living arrangements.

Formally, the ARK project is a *superfiction*, a form of creative practice that blends fiction and real-world structures, presenting organisations, business structures, and the lives of invented individuals as though they were real (Hill, 1997). Superficially this resembles the conceptual design of products and services prevalent in much contemporary design practice. But rather than, for example, being produced as the first stage in the linear process of developing a real-world service, superfictions occupy a more complex and ambiguous position between the fictional and the real. In the case of ARK, the project's superfictional status has allowed it to act as a 'conceptual container' for an ongoing, open-ended series of sub-projects spanning art, interaction design, and academic and other forms of research. The project presents designs for fictional products and services alongside 'real-world' initiatives (for example the ARK-INC website, in whose forums people can discuss the issues ARK-INC is one response to, and ongoing work with the *Phoenix Project* group, a residential experiment in 'post-Crash' living in Northern Scotland) as part of a programmatic whole. To date, this work has entered the public domain in a number of

ways: through installations in galleries and at scientific conferences (e.g. MoMA, 2008; The Tipping Point, 2006), through performance (V&A, 2006), and through written material (e.g. www.ark-inc.info and this paper).

Within ARK-INC, our process has focussed on pragmatic, implementable designs. These designs also serve a critical function, based as they are on a carefully-reasoned departure from mainstream views of 'designing for sustainability'. A second critical dimension is also present in the project, in that we acknowledge - but choose to leave unresolved - the question of whose interests would ultimately be served by the operation of ARK-INC or a similar organisation.

Below, we outline the ARK project, detail some of the products and services ARK-INC provides, and elaborate on more general ideas that have arisen through the research. This paper is not an exhaustive description of the projects which comprise the ARK research programme, nor is its focus on the provision of detailed accounts of the process(es) involved. It is better understood as a piece to encourage reflection and debate, the same end we have sought when presenting ARK-INC through other channels.

2. Sustainability: a perspective

It is surprisingly common, now, to find people asserting that our way of life is unsustainable and must be changed. Yet at the same time, it is striking how many designed responses to this assertion focus on merely *amending* the current paradigm - making familiar practices 'more sustainable', rather than looking for alternatives. An increasingly service-based economy, local sourcing of food and other goods, and extended use of ICT are examples (they have also all been shown to not necessarily decrease adverse impacts on the environment; see Carleston, 2007; Thackara, 2005, respectively).

But: the diminishment of natural resources (especially oil and clean water) and rising levels of pollution; the prospects of resource wars, increasing urban insurgency and unrest, and massive population displacements; stock market instabilities and the sensitivity of agriculture and key infrastructure systems to unanticipated climatic events: all these phenomena threaten the contemporary economic paradigm and familiar modes of everyday life. What is more, they cannot be treated singly, on a case-by-case basis; the test of how 'sustainable' our society actually is would be the interaction of such phenomena in a *convergent catastrophe* (Kunstler, 2005).

To explain: a single network placed under stress becomes, in turn, a source of stress to others with which it intersects; while this has always and everywhere been the case (Delanda, 1997), we live in an era in which our way of life is based on historically new levels of cross-network co-ordination, principally a function of ICT (Homer-Dixon, 2000; Mitchell, 2003). This close interrelation of the systems on which our way of life is based increases the possibility that a single 'shock to the system' creates other shocks in turn. The world's stock markets, from day to day leveraged by faith in economic expansion over terms both short and long, are an exemplar of the mechanisms that serve to distribute shocks across networks.

A convergent catastrophe would be a situation in which multiple simultaneous or closely-spaced events overwhelmed our ability to deal with them. Of these threats, two seem inescapable. Firstly, a key stressor to global systems is climatic change. We must be cautious here about our assertions: a scientific understanding of many of the factors underlying climate change is still relatively rudimentary - the role of stratospheric dynamics and ocean mixing systems, for example, are as-yet poorly understood (Wujdhausen, 2007). But estimations of the rate and severity of global climate change have, of late, routinely exceeded the most pessimistic scientific projections (IPCC, 2007), and the scale, unpredictability, and rapid onset of extreme weather events - especially in hitherto "safe" locales - already confounds our attempts to deal with them. Secondly, although predictions vary as to when and how quickly it will occur, we will at some point enter a state of *energy descent*, caused by the increasing scarcity of easily-extracted oil. Despite gains in the efficiency of alternate energy sources, their status as a viable global

alternative to carbon-based energy systems is yet to be achieved, and expansion of nuclear programmes is costly (and incredibly energy intensive in itself) and creates its own risks (e.g. see Kunstler, 2005).

Two main factors tend to inhibit our ability to apprehend the likelihood of a convergent-crash scenario (which from this point on, in the interests of brevity, will be called *the Crash*). Both are socio-psychological.

First: the seductive appeal of apocalyptic predictions themselves. When possible Crash scenarios are presented through a mixture of cinematic and quasi-religious imagery as awesome spectacles of destruction, we are denied - or better, *absolved of* - responsibility for engaging with them. We dismiss such events as implausible (particularly easy given their religious or science-fictional overtones), fear them, even find them secretly thrilling - perhaps all at the same time (Institute for Public Policy Research, 2006, 2007). But we do not feel the need to prepare for them. Presenting them as both awesome and inevitable generally leaves people, at best, with "...the attitude that if it rains, it rains, if the world ends, the world ends" (Thackara, 1995).

Second: as philosopher Ivan Illich has argued, established institutions tend to frame social issues as best solved by further investment in what they already do (e.g. Illich, 1973). So amongst the proposed responses to climate change, for example, we find 'technologists' suggesting huge interventions like lacing the atmosphere with certain aerosols to cool the planet through 'global dimming' (e.g. Brahic, 2007); many in the business press advocate a laissez-faire approach, trusting that the invisible hand of the market will craft our solutions for us; and so forth (IPPR, 2006).

ARK-INC acknowledges the immediate necessity of *actively* exploring responses to a potential Crash situation. The organisation takes a pragmatic approach to what it sees as a fundamentally unstable, unsustainable current state of affairs - it reasons that *a disaster is not an event, but the effect that event has*. As Thomas Homer-Dixon has observed, "[k]eeping breakdown from becoming catastrophic means making our technologies, economies and communities more resilient... being ready means preparing today for breakdown tomorrow" (Homer-Dixon, 2006: 3). This could be described as a change in the dominant metaphor used when considering 'sustainability' away from that of *David and Goliath* - i.e. that we might prevail through faith, luck or as-yet unknown resources against overwhelming odds - to that of *Noah*, a more pragmatic perspective: let's consider the odds to have already been decided, and not in our favour. ARK-INC's remit is to develop a social organisation, furnished with appropriate technology and systems, which practices a way of life that *will not change as the world does*.

.

3. ARK-INC

Fig. 1: ARK-INC logotype

Our inability to predict the specifics of a Crash scenario requires us to take a broad approach to this process of preparation (Taleb, 2007). ARK-INC positions itself as a radically different form of *investment company*. Clearly, 'investment' refers to the practice of saving assets or otherwise deferring them for later consumption. In conventional practice, this means investing money in ventures which are projected to grow, in the interest of gaining future (financial) returns. But given the potential disruptions to the contemporary socio-economic paradigm, we must appreciate that what is valuable now may not be valuable at all in the future. Technically, this relates to an understanding of the *extrinsic value* of investments. Simply described, the extrinsic value of an object or action is its value determined *in relation to its surroundings* (Lewis, 1983). A banknote's value is almost purely extrinsic: if its value is not *agreed upon* by a social group, it is no more or less valuable than a piece of paper of the same size, printed with any design (its *intrinsic* value - its value as a material thing, independent of the social situation in which it is embedded).

ARK-INC's approach to 'investment', then, sees no value in investing in objects and actions that have a high extrinsic value now (money, cars) that they cannot be expected to retain in a 'post-Crash' world. ARK-INC's alternative strategy is to direct 'investment' into the development of knowledge and equipment that are predicted to have a high extrinsic value in future. This subverted analogy to current investment practices makes clear the relationship between ARK-INC and its fee-paying members: through ARK-INC, the latter develop a *portfolio* of investments that will hold, even gain, value as the systems on which the current paradigm is based creak and begin to crumble.

Structurally, ARK-INC is comprised of a number of anonymous members, a mixture of invited representatives from amongst the Collectives, strategists, advisors and key funders. The organisation's principle functions are:

01 to consolidate the *ARK Movement* - the sum of ARK-INC's members - making key decisions regarding the Movement's structure, goals, strategy and operations

02 to integrate, and act as intermediaries between grass-roots organisations committed to changing their way of life away from the current paradigm: *the Collectives*;

03 to act as an interface between the Movement and the public;

04 to provide products and services that aid ARK members' transition to a post-Crash scenario;

The Movement, the Collectives, and ARK-INC's involvement with them, are explained in detail below.

4. The ARK Movement and the ARK Collectives

There already exists a 'proto-movement' of groups who acknowledge the likelihood of massive global disruption in the near future, from online communities like *www.gaia.com* to fringe political groups and survivalist cadres; in a quieter way, many small, globally dispersed initiatives are underway that seek alternatives to 'the current way of doing things', experiments in more sustainable ways of life with little in the way of rhetoric or expansive ambition (Meroni, 2008). The virtues of sharing knowledge between such groups is clear; but there are ideological gulfs between them, and their most effective actions are often not global in import but reactive to local physical and social conditions. This is an issue of *scaleability*, a recognition that the potentially compatible aims of these groups, achievement of which may be aided by co-operation, co-exist with tensions concerning the self-determined meaning of their operations.

ARK-INC approaches this problem by consolidating groups into a coherent yet heterogenous *meshwork* (Delanda, 1997, 2006), the Movement, of semi-autonomous Collectives. Historically, this model has proven effective at linking groups who may otherwise exist in a state of tension, and at producing action reflexively shaped by local conditions. Organisations that have effectively adopted such a model have proven their resilience and effectiveness in many areas: from the Freemasons and similar societies, to the devotees of non-mainstream religious, sexual and recreational practices; criminal cartels; and cells of political dissidents committed to insurgency both peaceful and violent ('terrorists'/'freedom fighters') in nature. As philosopher John Gray has observed, social structures of this kind (distributed, largely autonomous, inconspicuous, etc.) is not only well suited to direct, locally reflexive, and pragmatic action, but fits well with a contemporary mindset shaped by global migration, communications technology, and the co-existence of differing belief systems both within the overarching organisation, and between the organisation and the wider community within which it operates (Gray, 2003).

Modelled on historical and contemporary examples of social networks of this kind, the Collectives have the following features:

Diverse: Specific beliefs and motivations for participating in the ARK Movement vary

across the Collectives, and even within them: alliances within and between Collectives may be imbued with cameraderie, but as a general rule are pragmatic. Some Collectives are small and loosely, if at all, hierarchised; others are much larger and more formally structured.

Distributed: Each Collective is located in a particular geographic area, affording face-to-face interaction and co-operation (transfer of skills and resources, collaboration on projects, etc.). However the day-to-day proximity of members of a Collective, and the frequency and nature of their meetings, vary widely between Collectives.

Semi-autonomous: The nature, style and motivations for inter-Collective communications and meetings depend on the circumstances and inclinations of the Collectives concerned.

Inconspicuous: The Collectives are inconspicuous, existing out of the public eye: they do not discuss their activities widely. They meet and pursue their agendas covertly, avoiding the pressure brought by the public eye. This preserves their actions from interference, something especially important given the disparity between the Movement's ideals and the values held by the mainstream culture in which they are embedded. All new members are signed up to ARK under a non-disclosure agreement, legalising this inconspicuousness.

Effective: their localised, largely autonomous nature and inconspicuousness allows the Collectives the flexibility to develop responses to local circumstances. Of course, the ideas and practices a Collective develops may be of use to other Collectives, and ARK-INC encourages the dissemination of commentary on both the success and failure of these initiatives more widely in the Movement.

Resilient: This inconspicuousness gives the Collectives resilience, and secrecy consolidates commitment. As resistance movements around the world have shown, inconspicuousness is the key to surviving adverse social upheaval. In less difficult times, the freedom of each Collective to pursue its own goals by the means it selects makes the Movement as a whole resilient, reducing friction within it.

ARK-INC recruits both groups and individuals on the behalf of the Movement. Individual recruits are aided by ARK-INC in the process of integration into an appropriate existing Collective. If this is not possible, the organisation supports individuals founding a new Collective. ARK-INC both responds to interest displayed by other parties - i.e. those who seek out the organisation with the pre-formed intention of joining it - and also actively approaches existing 'groups of interest' with the aim of incorporating them within the Movement (or, should this be inappropriate, to create strategic and tactical alliances with them). In both cases, ARK-INC carefully screens applicants to ensure the Movement is not infiltrated by actively disruptive elements. Membership fees are charged monthly; most forms of payment are accepted.

5. ARK-INC Products and Services

Aside from maintaining the tools that constitute the ARK Movement's 'public face' (for example, its website), ARK-INC's products and services are developed for exclusive use by its members. Some of the most important of these are discussed below, together with a commentary on ARK-INC's approach to the development of products and systems that meet its standards of sustainability.

Guerilla infrastructure

The principle form of *system* that ARK-INC is interested in developing is *guerilla infrastructure*: adaptable and resilient means of moving around and bringing together people, things and information. These systems require little capital investment to create or maintain - generally, they are brought into being through 'unoffical' processes of invention and implementation, by small groups of like-minded people acting outside the explicit sanction of civic or corporate authority. They also tend to be based in the appropriation of existing structures, and thus be minimally detrimental to the environment, often a consequence of their prudent use of resources rather than through deliberate choice (Meroni, 2008).

A good example is *Feral Trade* (www.feraltrade.org), a real-world service that globally moves small quantities of goods by harnessing social networks. Email and text messages are used to co-ordinate the delivery of goods by volunteer participants (*feral trade couriers*) from producers to receivers through existing but underused channels, such as excess space in hand luggage, personally-owned cars already driving long distances for other reasons, and other 'excess capacity' in existing transport. The *Feral Trade* website automatically generates appropriate shipping documents. This network has little environmental impact on its own, although it might be argued that the transport infrastructure to which feral trade parasitically attaches are themselves unsustainable. But feral trade, and other examples of guerilla infrastructure (for example the unofficial credit transfer service *sente*; Chipchase, 2006) share qualities of pragmatism, resourcefulness and resilience that ARK-INC embraces; their 'unofficial' nature also fits well with ARK-INC's emphasis on the low profile of the Collectives and their actions.

ARKNET

During the early phases of the Movement's growth, the provision of a *guerilla infrastructure communications network*, both secure and sustainable, has been of paramount importance. ARKNET is an encrypted global communications network based on a *packet radio* protocol. Packet radio uses the SW radio frequency to transmit binary data; it is so called because it applies packet switching to route messages across the network, in a similar way to the Internet. In fact, packet radio predates the Internet, but its comparatively slow transmission speeds (up to around 7.5 kb/s) mean it is typically used today for low-volume communications, for example transmitting ships' positions (Tucson Amateur Packet Radio Society, 2007). Despite its slow connection speed, and the sensitivity of SW transmissions to the interaction between climate conditions and geographical features, when used as a transmission medium for binary data, the SW spectrum becomes the transmissions medium for *a global free WiFi network*.

ARKNET is accessed through two ARK-INC products. The first is a high-capacity portable USB 2.0 Flash drive. This, the ARK DRIVE, contains plentiful room for data storage alongside an integrated software suite, the ARK OS, an operating system based on the open-source Linux protocol. Plugged into any computer with a USB 2.0 port, ARK OS runs without the installation of software (this use of a limited-function 'external operating system' is made possible by the high data transfer rates available through the USB 2.0 protocol), a parasite that leaves minimal traces on the host system. Users of the ARK OS must enter their ARK ID and 16-digit alphanumeric password, as well as answer three questions from a list of personal information (mother's maiden name, etc.) given to ARK-INC on joining the Movement. As an additional security measure, members must run ARK OS at least once per week, or an automatic secure delete system locks data held on the ARK DRIVE and the member must apply for a new ID through the ARK-INC website.

To access ARKNET, the ARK OS must be used with the ARK RADIO, a shortwave radio transceiver. A cursory examination suggests the RADIO to be a moderately high-end consumer product, one that would not appear out of place in a typical domestic setting, and its does indeed function as a conventional radio. But the ARK RADIO has an additional, latent set of capabilities accessible to the ARK member who owns it. These functions are unlocked by insertion of one of a number of keys into slots along its side; one key, for example, switches the RADIO to receive the PARADIGM INDEX broadcast (described below). But its principle function to ARK members, on insertion of another key, is to switch to SW transceiver mode and wirelessly link to a nearby ARK DRIVE; streaming data to and from the RADIO transceiver, the ARK member is able to create an uplink with ARKNET.

Fig. 2: using ARK RADIO: film still.

ARKNET supports two types of transmission, both accessed through the ARK OS. Firstly, it allows live ASCII messaging (similar to Internet Rely Chat systems) between members of the ARK Movement, with a further ability to leave messages on the system until the target recipient logs onto the network (like a limited form of email). This supports intra- and inter-Collective communication.

Secondly, when an ARKNET link is activated, a more-or-less continuous stream of data is passed between the host computer and other live ARKNET users (as in P2P software systems). This data comprises a body of *useful knowledge* submitted to the system by ARK members via ARK OS, collated and edited by ARK-INC for appropriateness of subject matter, readability, etc. Information deemed 'useful' ranges from reports of events and general conditions in areas where Collectives are based, to how-to manuals dealing with a wide range of situations - from the results of experiments in the creation of local guerilla infrastructure to established knowledge concerning, for example, water purification and emergency dentistry. This is an updated form of community-generated knowledge-building with a long historical pedigree, from the *Whole Earth Catalogue* (Brand, 1968) and the texts collected at www.textfiles.com/survival to 'field manuals' such as the *SAS Survival Handbook* (Wiseman, 1986) and the volumes produced and distributed by anarchist 'ex-worker's collective' CrimethInc (e.g. CrimethInc, 2004). This data is stored on the

individual member's ARK DRIVE, and can be accessed using ARK OS without being on ARKNET.

It is also possible to listen to the robot-like crackle and beep of ARKNET transmissions as audio through the ARK RADIO. Some members find comfort in this; while it would sound to a non-member like barely-structured noise, ARK members understand it as an abstraction of their community's voice as it talks to itself.

ARK-INC, dormant technology and latent functionality

The products that act together to make access to ARKNET possible also illustrate the application of ARK-INC's alternative view of 'investment' to the design of objects. Packet radio is generally regarded as an obsolete communications medium, largely kept alive by committed enthusiasts operating at the fringe of the amateur radio scene. It is an example of what novelist and design commentator Bruce Sterling has called *dead media*, technological systems that failed to be widely adopted, due to an initial overestimation of their virtues, or out-competition by rival systems (see www.deadmedia.org).

ARK-INC prefers to see some of these technologies as *dormant* rather than 'dead'. Within the late capitalist system, technologies such as packet radio were supplanted by newer, faster, more capable and - generally speaking - more energy-intensive, less sustainable alternatives (i.e. packet radio was 'out-competed' by the Internet). These technologies need to be re-evaluated in light of future scenarios, their potential re-discovered - a function of ARK-INC's general programme of critiquing current-versus-projected-future extrinsic value. Of course, the same holds true of current and emerging technologies; ARK-INC does not propose a historical reversal, but a consistent *system of evaluating value* in respect to a projected future scenario, with the general consequence that the products and services it provides are based on a wide range of media.

This idea of 'dormancy' in relation to ARK's development of technological systems has another dimension, one better described, perhaps, as *latent functionality*. They are tools based in a new paradigm of everyday life, and in preparation for it. But ARK-INC does not overlook their existence within the *current* paradigm, where they also must 'fit in'. The ARK RADIO illustrates this design principle well: it appears to be, and can act as, a conventional radio, blending with the contemporary background of consumer products, while at the same time concealing a *latent function* - its role as a gateway to the ARKNET network. This dual status accords to ARK's emphasis on the inconspicuousness of its members' and Collectives' involvement in the Movement; it also gives the product a kind of *cross-paradigm value*, having worth both now and in the future paradigm ARK members are preparing for. This point is explored in more depth in the penultimate section of this paper, *ARK Aesthetics*, but before discussing this in more detail, we will describe some of the services and products developed by ARK-INC that are more focussed on supporting *reflection* by its members than their attainment of pragmatic goals.

Reflective tools and pre-adjustment services

Fig. 3: Near-future London: conceptual advertisement for DISASTER TOURISM

Individuals' adoption of sustainable practices is made more desirable to them by critical reflection on the world around them, something that ARK-INC recognises and helps to guide. The most direct way it does so is through its insistence that new members conduct a PERSONAL INVENTORY of their current lifestyle, and plan how they need to change it. This is an extended and private process of reflection, supported by critical prompts and props developed and provided by ARK-INC, contained in the ARKBOX: a locked container given the new members containing tools that allow access to ARK-INC's core services, including the ARK RADIO and ARK DRIVE whose functions are discussed above.

More 'ongoing' reflection by members on the urgency of changing their way of life is supported by the PARADIGM INDEX (P-Index). The P-Index uses automated algorithms to search for and collect relevant data on 'how well the world is doing'; oil prices, global population, mean pollutant levels, prevalence of communicable diseases, and important events (accidents, civil unrest) collected and distributed at frequent intervals, producing graphed data within ARK OS, and broadcast in verbal form by a computer-generated voice hourly on ARK RADIO. This system's ancestors include Poodwaddle.com's *World* and *Earth Clocks* (www.poodwaddle.com/clocks2.htm) and the *Global Disaster Alert and Co-ordination System* (www.gdacs.org). The P-Index provides a consistent reminder to ARK members that their commitment to changing their way of life is a necessity, not an option; by starkly portraying the global situation, it also reinforces members' sense of achievement at rising to meet this challenge.

ARK-INC also provides *pre-adjustment services*, more structured means of support and training for individual ARK members and Collectives. For example, in order to adjust to landscapes that may unfortunately become much more familiar to us all, the DISASTER TOURISM service organises holidays in apocalyptic locations - areas ravaged by disaster natural and man-made.

An example is the Zone of Alienation around the ex-city of Chernobyl in the Northern Ukraine, evacuated after the nuclear disaster of 1986, but now largely safe to visit, at least for short periods. Already, companies offer tours of the Zone that promise to 'intellectually equip,

practically train and psychologically empower you to successfully survive contemporary contamination incidents' (Pripyat.com, 2008). As ARK-INC's focus is not on survival alone, we are exploring how such an idea might be extended, particularly so that disaster tourists might learn from the current residents of the Zone. These *samosely* ("self-settlers"), often drawn from more comfortable surroundings by adverse personal circumstances (desertion from the armed forces, escape from prison, religious persecution) are beginning to forge a living in the abandoned urban areas. Excursions into these kinds of environments make tangible otherwise difficult to imagine living conditions; and through gaining competence in doing so, ARK members can be both reassured of their capabilities and be better prepared for extreme near-future scenarios.

Closer to home, ARK-INC draws on information provided by ARKNET users to develop and publish *field manuals*, short programmes of self-training in 'survival/prosperity' methods produced in rugged pocket-size book form. These manuals deal with physical and psychological preparation for Crash-style events, and contain exercises that can be carried out in relatively common urban and countryside areas. These include bartering, using one's sexuality as a 'means of persuasion', hunting and trapping and exploring the disparity between the current and potential future value of common household items.

6. ARK aesthetics

Key to ARK-INC's short and long term success is an awareness of its *appeal* to current and prospective members, an acute awareness of its own position within wider social trends - of which the increasing valorisation of 'sustainable' practices is only one dimension. Space does not here permit an extensive discussion of ARK's situation with respect to the potential function(s) of design within, for example, a risk society (Beck, 1992), an anxiety-ridden 'therapeutic culture' (Füredi, 2005), or a popular contemporary desire to engage in voluntary risk-taking, the practice Stephen Lyng (1990, 2004) calls 'edgework'. But ARK-INC's (self-)development is based in large part in acknowledgment and manipulation of what, to borrow a phrase from Philip Tabor (1995), might be called its *less reasoned appeal* - the kinds of qualities readily understood by advertisers, marketers, and politicians.

Why should people engage with sustainable systems or services? They may 'make sense' on a a practical level. But their benefits are hypothetical and generalised to 'society at large'. Appeals to common sense, civic duty or the common good fail to engage most people (IPPR, 2007); this is because they are boring. To fit more effectively into the social-industrial landscape, ARK needs to appreciate its own *less reasoned* appeal - the kinds of qualities readily understood by, for example, advertisers, marketers and politicians. While design research typically steers away from aesthetics - too subjective, ephemeral, complex and contingent - an informed *appreciation* of them at least is, for ARK-INC's purposes, essential. An example is the *durability* of ARK-INC's products. Based in sheer practicality, this ruggedness nonetheless can also be used to situate them within a class of contemporary luxury goods - the GM Hummer, Porsche Design's wind-up outdoors radio (Porsche Design, 2007), and Durabook's magnesium alloy-encased, eminently consumable laptops - sleek, expensive, and meeting US military standard specifications for ruggedness (Durabook, 2007). Another aesthetic aspect of which ARK-INC is acutely aware is its secrecy and potential capacity to be interpreted as subversive: again, a pragmatic initiative that can be 'played upon', amplified for affect (a quality of *inconspicuous consumption* a concept one of us has elaborated upon elsewhere; Singleton, 2007).

Central to the design of ARK-INC's products and services is a consideration of the multiple meanings that interactions with them may have or accrue. They may be thrilling, comforting, anxiety-provoking, even strangely nostalgic, in its appropriation of dormant technology. The organisation does not attempt to enforce one, or a given few, qualities such as these through the design of a particular artefact, but does seek to support their co-existence. An example is the ability to listen to the ARK Movement's abstracted voice through the ARK RADIO;

a byproduct of the technology used, without any strict utilitarian value, ARK-INC nevertheless recognises that such functions are important. The organisation is attempting to offer a *way of life*, and life is not purely utilitarian, even under the terrific adversity of a Crash scenario.

7. Conclusions and future directions

This paper does not propose that ARK-INC represents the only, or even the best, approach to the issues at hand. This is not its intention: for all the pragmatism avowed within it, it is also a critical endeavour. The process undertaken in the research programme demonstrates the extent to which 'sustainability' is a flexible cultural construct, not a given, and the need to take a critical approach to both the projected ends 'sustainable design' seeks, and the means by which it endeavours to arrive at them.

ARK-INC is a platform for a diverse set of future initiatives. In keeping with the project's superfictional status, these encompass both conceptual work and more direct interventions. In the latter category, we are working to create partnerships of different kinds with other groups and organisations whose own agendas intersect with ARK-INC's worldview. Amongst these is the *Phoenix Project* (formally the *Utopia Experiment*), based in Northern Scotland - an ongoing, community-based experiment in self-sustainable living (www.jonardern.com/phoenix/ [beta site]). Such experiments link directly with the concerns of the ARK project, and ultimately ARK aims to be in a position to both inform and be informed by them.

The conceptual side of the project provides a rich space for exploration. The practicalities of systems such as ARKNET are being investigated through hands-on, technological experimentation, and we are exploring how an ARKNET-like system might be coupled with other types of guerilla infrastructure. The potential of 'dormant tech' and 'latent functionality' are likewise being explored through a mixture of conceptual and actual design work. More conventionally-academic research is being undertaken into the *cultural position* of an organisation like ARK-INC, and in deepening an understanding of how economic ideas might inform alternative design strategies, based on projected fluctuations of extrinsic value.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design for the Majority

Designers (Collaborators) As Enablers Of Social Entrepreneurship And Sustainable Product Development

Leslie Speer[1]

Abstract

This paper shares a proposed set of guidelines for designers working independently or within a corporation that will aid them in practising new methodologies and approaches to design that will enable sustainable development in emerging regions. These will be tools that any designer working on developing a product, experience or service for an emerging market will be able to employ. By creating responsible and collaborative methods that are reactive to our current ecological crisis, sensitive to the capabilities of developing regions, and respectful of the inherent knowledge and experience in different cultures, our profession will leap forward into the future in a socially, environmentally, and culturally responsible manner. These methods envision and enable economic independence for all involved.

[1] San Jose State University (USA) – School of Art & Design, Industrial Design Dept., Assistant Professor, Leslie.Speer@sjsu.edu

1. Introduction

"We are all designers now."

–John Thakara, 2005

Today there is an emerging need for design to step back and reassess its role and purpose in the new product development process, especially in regards to sustainable strategies for emerging (developing) regions and markets across the globe. With roughly 5 billion people on the planet that are slowly gaining economic independence (Prahalad 2005, 147-168), how will designers trained in the methods derived from the Industrial Revolution have to refocus and retrain in order to be in step with the new world that is unfolding? If the consumerist world continues to grow, how will design and the earth's resources respond and cope? What will this new world that designer's take an active role in look like? These are some questions that will be addressed in this paper and for which a vision of the future will be proposed.

For the last fifteen years the author has been conducting extensive design research and work in rural areas of Mexico and Central and South America. This research has involved immersion in multiple artisan communities and directly working with cultural institutions, NGO's, professional guilds, local government and businesses, along with non-profit collaborators. The methods used in the research involve ethnographic tools developed by designers, strategy models used in the micro-lending realm, and opportunity qualification models used by some of the world's leaders in business and manufacturing.

Stakeholder analysis (conducting interviews and surveys), ethnographic observation (recording of typical daily methods and habits in the home and at work), empathic research (living within the community for weeks at a time, usually with a local family), eco-system research (working with local industry and community groups), and partaking in storytelling traditions in the community are some of the tools used in the research. These tools and methods have provided information and, after analysis, given the author and the artisans directions that produce results that have aided artisans and product developers in rural regions to become more economically sustainable.

As a point of comparison this research methodology is now being extended to rural craft based villages in Western China through a project with a faculty member of Fudan University in Shanghai, China. Similar methods used in Mexico are being used to understand these creative communities and how they have existed for centuries and how they have been changing over the last decade. The research will lead to insights into the needs and desires of people in these regions and will provide the author a comparative volume of information to aid in understanding the region.

Through a discussion about methods and tools that the author has used over the years in Latin America, about ways in which entry into a developing market needs to be analyzed, about new ways of collaboration, and most importantly about new types of collaborators, this paper will show that there are ways in which designers can harness their knowledge, new methodologies, and skills to work with the developing world in a mutually beneficial manner. Relearning and familiarising ourselves with the types of "appropriate technologies" that have been employed for centuries, along with incorporation of "human labor" and newer distributed fabrication technologies may lead our profession into a new, more sustainably oriented era.

2. Emerging (Developing) Markets

> "The Industrial Revolution made people more than 100 times more productive. People, capital and technology were scarce. What were abundant were resources and places to put to waste. Now we have abundant people and scarce nature. It makes sense to make natural resources 10 or 100 times more productive."
>
> *– Amory Lovins, Rocky Mountain Institute*

What is an emerging market? There is not a universally accepted definition, but on a scale from developed countries (United States, many countries in the European Union, Australia and Canada) to underdeveloped countries (many countries in Africa and South America, Central America, and many countries in Asia), emerging markets fall somewhere in between.

Emerging markets are defined by having three aspects to their economy:

- As is supported by Arnold (1998, 8-10), Prahalad (2005, 85) and the United Nations, the first aspect is the emerging level of economic development, usually indicated by the average GDP per capita, or the relative balance of agrarian and industrial/commercial activity. **Only 800 million of the world population of 6.5 billion live in developed countries.**

- Second is the expectation that an emerging market is enjoying a growth rate that is attractive to an investor. Most emerging markets have an average **annual GDP growth of more than 5%**, and sometimes 10%.

- Third is a system of market governance and the extent and stability of a free-market system; if the country is in the process of economic liberalization from a command economy, it is sometimes defined as a "transitional economy". This can be assessed by looking at national investment risk indices that have been compiled by business information organizations such as The Economist Intelligence Unit (EIU) and Control Risk. (Arnold 1998, 12)

The diagram below represents the world's population separated into its respective levels of income, showing fully 5+ billion people earning less than the equivalent of $9K USD per annum. Fully 2.7 billion of that 5+ billion earn less than $4K per annum; often this is equivalent to less than $10USD per day. Today, the number of people in the upper class – the 475 wealthiest

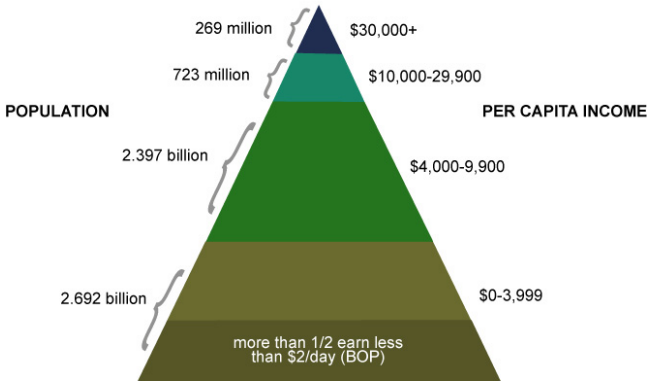

Fig. 1: Global Population/Per Capita Income (Prahalad 2005, 78)

people on the planet who are worth more than the collective incomes of the poorest 20% of the population on the planet, about 1.3 billion people (IFG, International Forum on Globalization, and the United Nations) is shrinking and the number of people in the middle to lower classes is growing.

Why would a designer from a developed country need to know this sort of stuff? As we are educated in today's westernized academic world, we are taught about how to succeed in a world filled with opportunities to work for or be hired by any one of 500 or so multi-national corporations around the world. However these companies only supply products and services to about 10-15% of the global population. What about the other 85-90% of the global population? Who serves them? And by this definition, aren't they the majority? It is true, 85-90% of the global population is not aided by or serviced by any product that the author or most of the other designers in the world ever work on. This should change, but how can this change and how can the design profession be a leader in bridging this huge gap?

Looking inwards to one's own entrepreneurial spirit is the first step in moving towards a collaborative and sustainable future, and a future in which the majority of the people on our planet are better served. Determining if a region is viable for collaboration is the first step, as being able to have an environment that is conducive to change and collaboration is of the utmost importance. Evaluating a region as an emerging market also takes a bit more than what standard business practices require. A SWOT analysis (Strengths, Weaknesses, Opportunities, and Threats) is a start, but isn't enough (Prahalad 2005, 68). More information is needed to determine if entering a region is even advisable. In many parts of the world there is extreme unrest (wars, tribal conflict, corruption) along with a severe lack of basic infrastructure (running water, electricity, roads) that are caused by situations outside of a designers' sphere of influence. It is still possible to work in these regions, it is however, more than ever, important to understand *what* situation one is walking into. A more robust analysis can be obtained by using the Five (or Six) Force Analysis developed by Michael Porter – by engaging in evaluation of competition, new entrants, end users/buyers, suppliers, substitutes, and complementary products/the government/the public (Porter 1998, 32). Using the Five Force Analysis will give the designer and entrepreneur a window through which to look through and to understand how the region operates, before even going there. Other facts are also important to know including literacy rates, influx of communication technologies into the region, women's roles in the community and in the family, recent government election results, and other "softer" information that is often very difficult to source, especially if it is in a foreign language.

However, it is here that the Internet's role becomes a very important resource in the start of qualification of a region. Looking at regional publications and news and being able to translate it from afar is key. Working with translators as collaborators once one is "in country" is vital. Additionally it is here that the designer starts to understand that working alone on a new product development project is no longer possible. Collaboration is key, and whom one collaborates with will determine the success or failure of the project. For decades the field of architecture has utilized co-design methods that incorporate the community into the design process (Day and Parnell 2003, 17-19). Some likely collaborators on a typical design for a developing region have been documented by the company Kickstart in their own company website. Started in 1991 by Martin Fisher and Nick Moon as an NGO, over the last 15 years it has grown it into a business that develops new products based on appropriate technologies that can utilize materials, labor, and manufacturing that is local. They train the manufacturing workforce, market the technologies, and subsequently have grown it into a business that helps to start over 800 new business a month, provides $41M in wages and new profits each year, and has revenues that are equivalent to more than 0.5% of Kenya's GDP.

The secret to this sort of success is being able to evaluate a region, talk with people in the area, listen to their needs, see how they have solved other problems successfully on their own, and then be able to problem solve and discover new opportunities for a community that will not only solve their problem but will provide income and will also provide long-term

sustainability and viability as a business. The needs and desires of people in developing regions show that more often than Westernized (often technologically advanced) solutions, they desire something that is unique to their needs, abilities and cultural habits. Often, their own inventive and entrepreneurial nature has helped them to develop a local solution to a problem that could potentially be applied in an appropriate expanded scale within their own region.

A Myth: Lack of Sophistication of Emerging Markets

From the 1850's to the mid 1900's the masses in Europe and the USA were informed about new ideas and inventions through events such as public exhibitions, World Fairs, and similar venues. With the advent of mass media however, the delivery systems changed (television, radio, variety of printed media, telephone, etc.), and audiences changed accordingly. Information was directed more towards the individual rather than large masses of people (homogenous markets). With the spread of satellite dishes, the World Wide Web and email, global media, inexpensive international travel and communications, the people in many emerging markets are now becoming almost as well informed about new trends and product releases as are people in developed markets (Bell 1973, 78-81).

A significant driver of this sophistication of taste in emerging markets is a large population of teenagers. In 2001 there were 2 billion teenagers alive and well in Asia, Latin America, Africa, North America, Europe and Australia. That is 50 times more than the 40 million that made up the Baby Boom in the US in the 1970's and the majority of these new "Global Teenagers" (Schwartz 1996, 134-142) are in emerging markets. What is different about these Global Teenagers? They are connected, interconnected, and plugged in. They are in-touch and in the know, not just about whom they are with at the moment, but about all their "friends", no matter where they are on the planet. They connect via mobile phones, SMS, email, social networking services, and blogs (Friedman 2005, 192-193). All of this is possible through digital communications systems and networks that did not exist 15 years ago, much less thirty years ago. As communication through digital products becomes the pervasive method (leapfrogging land lines) in the developing world, then no matter what age one is, or where one lives, most people will be able to keep up with what is new in the developed world – and want whatever conveniences and luxuries they have.

At a recent presentation by Iqbal Quadir, professor at MIT (and founder of GrameenPhone, the Legatum Center for Development and Entrepreneurship, and the founding editor of *Innovations: Technology, Governance, Globalization*), a case was presented that proved that understanding how a region functions, and how a new idea can be integrated successfully into it, is the future of how innovation through design will forge a new future. In 1993 Mr. Quadir started Gonophone (Bengali for "phones for the masses"). After only four years of talking with possible funders, Mr. Quadir was able to put together a collaborative team that included a large telecommunications company (Telenor) and financing from a large micro-lending organization (GrameenBank), and as a result, today GrameenPhone has over 18 million cell phone customers in Bangladesh alone, after only 10 years of operation. Mr. Quadir's ability to spot the problem (connectivity = empowerment) (Quadir 2003, 27), understand the economic and political situation in Bangladesh, bring together collaboratively inclined entities that could make his idea move forward, and have the fortitude to keep working at a good idea even though everyone else tells you it won't work, is a model for success in the developing world. This is a very good example of entrepreneurialism and innovation hard at work.

There is a tendency, perhaps, to think of emerging markets as consisting of simplistic, uninformed consumers who want only basic goods. In fact, consumers in emerging markets are highly sophisticated and are informed by many of the same mechanisms (and sources) that exist in the developed markets.

Success ≠ Multinational Corporations in Emerging Markets

Most product designers are under the belief (through education) that the only place for them to work is in or for a multinational corporation. From a product production standpoint, many MNC's have looked at the developing world as a place to produce products at a cheaper rate and quantity than in their own country and so, many MNC's enter developing countries for their manufacturing or raw materials resources only. This approach has been economically quite successful for the MNC's (which is why they continue), but converting emerging markets into stable sources of revenue from product purchases by the customers has proven more challenging (Prahalad 2005, 151).

Historically and through traditional analysis, markets in developing countries did not exhibit enough economic viability for MNC's to develop a consumer market due to extremely low incomes and mostly subsistence levels of existence. In just the last five years that has begun to change, which has led to the appearance of emerging markets (United Nations) where the consumer profile of people living in developing countries is now shifting. They are experiencing a growth in the middle class (though the lower class is still the higher proportion) and the related availability of expendable incomes is starting to grow.

So what do MNC's do when they are trying to introduce products into an emerging market? The typical approach: an MNC will offer a narrow range of established products that have been successful in a developed market. Why? It requires the least amount of time, risk, financial investment, and new product development (for a potentially small market) on their part. They firmly believe in the product lifecycle theory (applicable in their own market) that suggests that the introductory phase of a product should be simple, easily understood, and targeted only at the more innovative market sectors. (Arnold 1998, 6-7) (Reinertsen 1997, 83, 248)

MNCs often erroneously adopt a "less developed countries" mind-set, assuming that these markets are at an earlier state of the same development path followed by the advanced or developed countries, that the game is therefore one of catch-up, and that market evolution patterns seen previously in developed economies will be replicated in the emerging markets (Arnold 1998, 9). This approach will often lead the MNC down a path of failure. What is the missed opportunity? As was mentioned earlier, emerging markets are often close to "Third World" country status in terms of technological infrastructure. This may make a MNC assume that the people are less sophisticated than a developing country market. However, due to the level and sophistication of consumer knowledge (remember, they too are connected), a leapfrogging approach can be used. Technological leapfrogging demands that entrant firms acknowledge a high level of customer sophistication in emerging markets and capitalize on the opportunities for reverse learning. In a rapidly changing social environment, emerging market customers with newly acquired disposable income may be less conservative and traditional than their developed-market counterparts (Khanna 2005, 9) (Reynolds 2006, 133-48) (Thakara 2005, 8-15). MNC's, and the designers working for them, need to learn something about emerging markets as future consumers, and how to collaborate with them during the development process.

3. The Environment

If the product development and manufacturing world produces products for only 10-15% of the world's population now, what will be the impact on the environment when it starts to develop products, in the developed world method, for the other 80-85% of the population? According to the US Geological Survey and UN statistics on global population data, the world is at a turning point. Many natural resources that are used in production of electronic gadgets, transportation products, and other products that make lives easy, are about to run out. Antimony, which is used to make flame retardant materials in the furniture and interiors industry, is

projected to run out in 15 years at the current rate of extraction. Indium, a key material used in computer chips, is projected to run out in less than five years. Silver will run out in ten years, and terbium, used in making the green phosphorous for fluorescent light bulbs, could be gone within eight years (Cohen 2007, 36). So, it is clear that going about developing of products for the developing world may need to be approached in a way that is different from the resource gobbling, emissions spewing, and waste producing methods of the Industrial Revolution.

There have been numerous authors over the last few decades that have tried to communicate ways in which corporations and product development teams can understand our earths' ecosystem. David Wann (1994, 7-10), a pioneer in whole systems thinking, gives a good argument and image as to why we humans should stop considering ourselves outside of nature–and it looks very familiar to the predatory animal world system we all learned about in school (small fish gets eaten by bigger fish, etc.). This diagram illustrates how we humans relate to one another in our manufactured world. If you compare this to Figure 1 shown earlier you will see how closely the roles we play coincide with the economic levels at which we subsist.

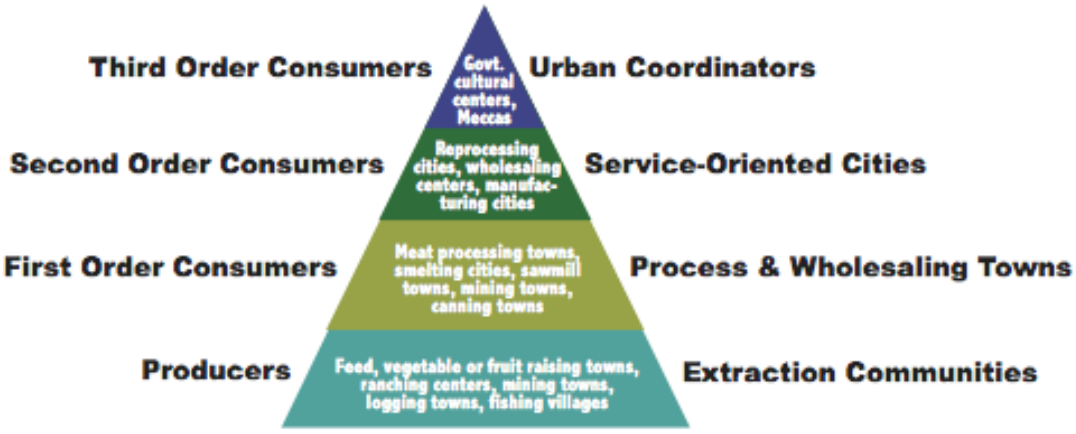

Fig. 2: Human Systems as Nature (Wann 1994, 7-10)

Wann's (1994, 7-10) guidelines for humans, and especially designers, to understand the ecosystem that we are part of includes the following rules for being able to work and produce in a more sustainably responsible manner:

1) Understand basic physical concepts like gravity, nutrient cycles, and the flow of sun, wind and water.
2) Use resources on a sustainable basis – use savings, not the principle!
3) Use the right tool for the right job – no need to thread a needle with a tractor! (Need more diversity in solutions and acceptance of using low tech and appropriate tech where possible)
4) Monitor what goes "in" so junk (pollution) doesn't come out
5) Make a habit of tracing origins and future routes of each physical interaction – cause and effect!
6) Acknowledge uniqueness of location and its inhabitants – all environments are different
7) Use the simplest product or process to get things done
8) Use software (information) rather than hardware
9) Use design solutions that solve 3-4 things at once
10) Account for cost with the full lifetime of product in mind (LCA for everything, not just materials!)

These rules mesh well in content and intent to the seven point agenda developed by the UNDP (United Nations Development Program) in 1998 (Robins 2001, 49):

1) Ensure minimum consumption requirements for all.
2) Develop eco-efficient goods and services
3) Remove perverse subsidies and restructure incentives
4) Strengthen public action for consumer protection
5) Strengthen international mechanisms to manage consumptions global impacts
6) Build strong alliances between consumer, poverty and environment movements
7) Foster synergies between civil society, the private sector and government. These are both good starts and are further supported by Wackernagel's (1996) goals for what are necessary conditions for developing sustainability in industrialized countries:
1) Reduce an individuals' Ecological Footprint
2) Secure a satisfactory quality of life for all

By following these simple ways of thinking about a development project, no matter what stage one is at, designers could be part of moving forward in creating responsible, environmentally supportable solutions for communities already living on the edge.

4. Co-creation

C.K. Prahalad and Venkatram Ramswamy introduced co-creation, or the idea of it, in their book *The Future of Competition: Co-creating Unique Value With Customers* and it introduced readers to different ways of engaging with customers in the product development process. Depending upon one's role on the product development team, the interpretation of how one might use co-creation to create value will be different. It is also important that the term co-creation is not confused with the practice of consumer generated content, mass customization or other similar, but different methods. Co-creation, in its pure form, is just what it sounds like – making something together.

To co-create, all members of the community affected by the introduction of a product or service must be present at all phases of the project. As the planning phase of projects is where the business, research and creative team can push the limits on how they get involved with their customer, it is vital that the user/customer be part of the project at the start. In developing regions, the user/customer could be the "end user", the manufacturer, the local non-government organization, or even the local government. During the final phases of a project, commonly the production and distribution phase, a company can look at new ways of manufacturing and distribution, through using local materials for production, local specialized expertise in manufacturing, and local organizations to aid in distribution. Keep in mind, that in the developed world, many of the products that are manufactured are made by machine, a method that came about during the industrial revolution when there were more people to provide products for, but not enough to make the number required in an efficient manner. In the developing world there is an abundance of people, plenty that lack employment and whom could benefit greatly from getting involved in such a project.

Co-creation requires a bit of rethinking how to structure and implement projects, but more importantly requires a different way of using design tools that have been developed for Westernized cultures. In the past, industrial design has infrequently adopted new methodologies into its practice. The newest is the morphing of anthropology based ethnographic methods, modified to fit our fast pace and low budget projects, into our own design ethnographic models (Taylor 2002, 175-186) (Kelly 2001, 41-52) (Laurel 2003, 28). Designers started to go out and 'observe' the customers, much like sociologists observe cultures, from afar. They shoot photos,

watch, take notes, and sometimes talk to the customers, but with scripted questions that are formed beforehand. These methods have taken designers closer to ‘understanding’ consumers, but again, designers are still able to take some of the knowledge that they personally have about western, developed cultures (where they are from) and apply that knowledge effectively. In developing and emerging regions designers do not have that luxury.

Architecture has long included their customers in the process. Some individuals, like Christopher Day, have always included their clients in on their projects, and, not only does he include them on a basis that informs them of progress, but, he actually brings them into the design process and works with them at the table, drawing, building, researching, etc. He says, “In every other aspect of life, except perhaps the arts, teams have supplanted individuals. Life, after all, is about interactions: teamwork. Businesses nowadays depend on it. Amongst architecture firms, research has shown that the more participatory the office, the more effective, both in business and design quality, are the process and the results. Tycoons and prima donnas are something of the past: nowadays few of us want to hand over the place where we will live to such egocentric personalities.” Unfortunately there is false belief that people untrained in the arts cannot design beautiful things on their own. Yes, this is possible, look in folk museums across the planet – they are filled with beautiful, functional objects. In fact it is shown that people who make their own things look after them; treasure them; they protect them (Day 2003, 205-6).

Participatory design and empathic design are approaches to the front end of the process that were introduced back in the 90’s by computer software companies and have been adopted and applied to the greater product design process. They both have identical foci – getting hidden, or latent desires and needs onto the table (Ullrich and Eppinger 2004, 175). Each is an extension of observational techniques but are done in the customer’s own environment. They look for how end users customize products and services to fit their own needs. They are able to observe honest emotional responses to situations and interactions. By spending some time with the customers they are also able to observe reactions and interactions repeatedly, thus unlocking unspoken and unarticulated user needs and patterns. Observing, capturing data, reflection and analysis, brainstorming for solutions and developing prototypes of possible solutions are all steps in the empathic design process (Leonard 1997, 6). Engineering and product development groups in MNC’s have much experience in using these methods, as do many design firms like IDEO, frogdesign, Jump Associates, and others.

Prahalad’s ideas on co-creation go deeper still – as that is what is necessary in developing countries and emerging markets. Co-creation is empathic techniques plus ethnography plus participatory methods on steroids. It includes the user/customer as part of the team and affords them the same level of importance as any of the other members of the team. In developing countries, as was mentioned earlier, the user/consumer is smart, connected, intuitive, entrepreneurial and a consummate problem solver. Without infrastructures and services to problem solve for them, they have learned how to do it themselves, and have for generations. The funny thing is, we in the developed world used to do it to. The industrial revolution and the machine age took us away from that, and though many good things are a result of it, there may have been some things that we lost.

As Mitchell (1996, 128) points out, though involving users in the design process may seem simple and logical it is a very fundamental challenge to the prevailing school of thought. In fact he says that in the recent past that though the discussion of being responsive to users is at the forefront, few, if any have actually tried to involve them directly in the process. Instead, designers, who set themselves apart from the masses, tend to make assumptions about what people will like, maybe ask them what their preferences are, or even present alternative solutions to them (prototypes) for review. However, the user is never given a true opportunity to be involved in the actual process of design. Integrating the user and customer fully into the process is the near to final step. Sim Van der Ryn (1996, 4-22) argues that design epistemology is flawed, as are a number of other parts of our society like agriculture, architecture and industry.

He argues that we have not given design a rich enough context. The author would argue that getting users and customers involved in the process, along with integrating sustainable development methods throughout could enrich our profession greatly. Even more so however, is the necessity to do this for any work and development done in emerging markets.

In the developing world, users and customers are smart. They problem solve on a daily basis. Why? First, they are economically challenged to the point where they do not have the luxury to go and hire someone to fix their car, their stove, their house – they fix it themselves with whatever they have on hand. Second, the infrastructure to do that, even if they had the funds, is not there. Locality breeds innovation and necessity breeds entrepreneurship. Additionally, since many of the people living in these developing countries are living closer to the land and to nature, they are inherently more connected to how what they do affects their environment.

The idea of co-creation with developing and emerging regions of the world, really getting customers and users to sit at the design table with us, is the future. Users bring a level of intrinsic knowledge of their culture, their environment, nature, problems they and their community face, connections to their system, and ways of thinking through and solving problems that are designed to work for them. In developing countries, working with users and customers, along with working with local organizations, is the secret. For MNC's it might require starting new businesses that can operate swiftly and flexibly. For individual designers it will require embracing new modes of thinking that include collaboration with governments and other organizations, working with users and customers as co-designers, understanding more about sustainable product development, focusing on sustainable entrepreneurship, and also looking at new methods of innovation, production and distribution that more thoroughly incorporate the customer and user.

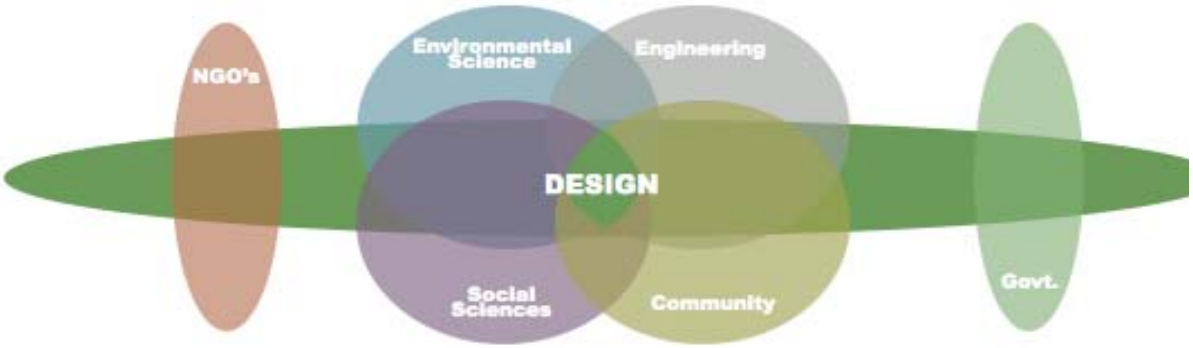

Fig. 3: The "collaborators" in sustainable product development in emerging markets (Speer 2006, 5

5. Guidelines for the Future of Design in a Sustainable World

Designers as collaborators and entrepreneurs that are environmentally focused and motivated by creating sustainable systems and communities, are the new future for the design profession. Rejection of the status quo that design history tells us is the way to be successful is necessary. Looking outside of design to find models, strategies and methods is the secret to updating the design profession so as to fit modern environmental and social demands. Below are some guidelines developed by the author to aid young and older designers alike in moving towards this new vision for design.

Multinational Corporations:

1) Form new businesses and ventures that can operate outside of the normal corporate structure and personality. Emerging markets often require risk-taking tendencies that are not supported by typical MNC's and large corporations.

2) Prepare to learn how to evaluate markets using different criteria and methods that integrate data not obtained off the UN website and similar information databases. Data mining for trends will be more the norm, rather than past use of statistical information about GDP, etc. (Prahalad 2005, 85)

3) Incorporate methodologies to learn more about your customers. Even better yet, go spend time in the culture. Do not go directly to the first urban center, do not stay in western hotels, do not go to Starbucks. Live with the people and learn to understand them as individuals first, as collaborators second, and as a market third.

4) Work with both government and NGO's in collaborative manners so that you can learn from them. Do not look to them for only regulatory data and rules. (Masera 2001, 212)

5) Always think sustainable. Sustainable business models. Sustainable production. Sustainable social models. Sustainable sourcing of materials.

6) Commit to path breaking rather than benchmarking. Disruptive innovation, thinking and acting is often the right way in emerging markets.

7) Be willing to use the right and appropriate technology for the right job. Often the newest technology is not the best one for the situation, sometimes it is.

Individual Designers as Entrepreneurs:

1) Collaborate with entities you are not used to working with. Government representatives, NGO's, local community organizations, trade organizations, and micro-lending institutions. These are the new clients.

2) Spend time in other cultures. Get out of the city. Visit small villages, stay with families, and eat in local restaurants.

3) Learn a culture's language.

4) Think sustainable. Sustainable business models. Sustainable production. Sustainable social models. Sustainable sourcing of materials. Go beyond LCA.

5) Start small and simple. Do not try to reinvent the world in one day. Often working with clients in the developing world requires a commitment that requires years rather than months.

6) Think of yourself as a social entrepreneur first and a designer second.

7) Do not think that you know everything – in fact, assume you know nothing. Your collaborators will be the experts and you will learn from them.

8) View design as a process rather than as a means to an end. Look at it as a "continuous process that defines a system's rules rather than its outcomes" (Thakara 2005, 220-226).

9) Be open to more and more inclusive models of product development. A designer working alone has a limited role. A designer collaborating is empowered (Lewis 2001, 13-24). Designers fill the needed role of environmental and social champion in product development in emerging markets.

10) Do not believe that working for a MNC is the only option. Micro and small enterprises are the backbone of the private sector and account for over 90% of enterprises in the world and account for 50-60% of employment globally.

6. Conclusion

The innovative thinker Larry Keeley best stated it, when he said “For us, effective plans have their basis in a deep and profound understanding of user needs”. Users are not just the people who “use” a product, but are *all* the collaborators involved in a project. From the non-government micro-lending organization that pulls together community groups and businesses; to the government cultural agencies that pull together the producers in the community; to the actual makers themselves; to the designers who innovate new products; all are part of a new paradigm of development in emerging markets in the developing world. By adopting new ways of thinking about who the “clients” are; by engaging with the users (the whole community) as early and as pervasively as possible; by forgetting what designers already know so as to learn better ways of doing; these are just some of the methods that will need to be adopted to work in emerging markets.

As designers in a complex world, how we integrate our talents and knowledge into the product development process is open for speculation. However, with the increasing need for sustainable and socially responsible solutions, it is an optimistic vision that emerges. Within a large corporation, designers have the opportunity to lead through being the holders of knowledge and expertise in methodologies that we currently use and that can be applied to a greater spectrum of the process. As designers with an entrepreneurial spirit, a social conscience and environmental savvy, we can enter into the future as experts in collaborating with customers and users in emerging markets. We should look forward to the opportunities and experiences that await us as we attempt to address a very large group of people that most of us have never designed for – the 5.4 billion people on this planet that live in developing countries with standards of living and modes of working that are very different from ours. And so, as John Thakara stated at the beginning of this paper, and it can be no better said – “we are all designers now”.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

What if the World Were A More Equitable Place

[Would Any of Us (Designers) Be Necessary?]

David Stairs[1]

Abstract

In the pursuit of sustainability and social justice designers need to provide access to their knowledge and resources to people from less developed societies. This can best be achieved through education, with an assist from philanthropic development. The author gives examples of his experiences utilizing altruism as a design methodology.

[1] Designers Without Borders. Department of Art, Central Michigan University.wandegeya@yahoo.com

Introduction

I'm trying to envision a world where technology is not merely ubiquitous, but affordable. I'm told that such a place exists, that designers are applying their abilities to make it real, but I'm still skeptical (Stairs 2007). I'm searching for a world where access to communication is not based upon social caste; where healthful futures for all the world's people are not based upon massive changes, but personal, incremental, community-oriented steps (Stairs 2006). A world where opportunity is so abundant that I am made professionally redundant, but the vision does not arise.

In lieu of this imaginary place, I must be temporarily satisfied with ad hoc efforts to deliver opportunity to those less fortunate, less affluent, less connected. I must suffer the efforts of some to co-opt the world's have-nots into global visual networks. Or accept the implication that disaster relief is the best way to help.

Aims

I'm not trying to re-envision the world in the image and likeness of my culture. Far from it! What I'm interested in seeing is what others do with the same set of tools that are available to me. How will they communicate? Interrelate? Anticipate? Will they lose themselves, their unique culture, or will they enhance it? Haven't others been doing just that (enhancing) throughout centuries of technological exchange? Isn't that what moves us all along, exchanging methods, sharing ideas?

What I'm proposing is what I've been doing these last eight years: Projecting design education and socially just practice into other cultures. Not unsuspecting victims of conquering colonial invaders, but willing partners interested in exchange, expansion, and access.

Education is the master metaphor of human evolution. Through it we create continuity by bridging the past to the future. Design education is my avenue of aesthetic, social, and economic interaction. I am not interested in intellectual privilege, or in the success of a given profession, but in the efficacy of design as an instrument of social change.

Designers Without Borders(Designers Without Borders) is the vehicle, the vision, the means of focusing legal, financial, and technical resources on the goal of social change. It is both aegis and umbrella, providing organization and context for the purpose of development through design. When we speak about economic development through "globalization" I see only the manifest effects: marginalization. Instead of globalization I have begun to strongly believe in localization, a much better metaphor. By marshaling available resources in an effort to assist those less well off, we focus not on the world's difficulties, like the media does, but on its possibilities.

Through *DWB* my colleagues and I have devised curricula and delivered design resources to over 500 students of Makerere and Kyambogo Universities, Mwereerwe and St. Kalemba's Secondary Schools, the Foundation for Development of Needy Communities, the National Committee of Women Living with AIDS, and FHope, to name a few institutions, all located in Uganda.

I will be the first to admit that this is only one of many possible scenarios. After all, as an individual I see only part of the larger picture. But this is how I have chosen to assist those less fortunate than me to seek broader understanding and locate access to opportunity. As a result I have been called "idealistic," "noble," and "unpragmatic."

Collectively we see further and better than individually. I am happy to report that I am only part of a larger movement. *Designers Without Borders* is just one of many such initiatives being undertaken by designers worldwide today.

Africa is key. The birthplace of humanity is today the world's most disadvantaged continent. How this came to be is less important than what we must do to reverse things. We need to find ways to enable Africans to compete on their own terms and from a position of

strength. Design has a place in Africa's recovery. And Africans, natural designers in their indigenous approaches, have a place in the world of design. Not as markets for Asia and the West, or as suppliers of commodities or tribal crafts, but as creators with living design solutions to longstanding everyday problems. Design is transformative. Design and education combined have the potential to be revolutionary.

The *Design-Altruism-Project* (Design-Altruism-Project) is the nexus, the community, the online resource where we test the resilience of a new memeplexe (Stairs 2005, 3-12). What, exactly does this mean? Scientists have speculated about the genetic basis of altruism since Robert Trivers, Bill Hamilton and Richard Dawkins in the 1960s and '70s. The latter's proposal of a "cultural unit equivalent to the gene" makes a great deal of sense when one tries to connect altruism and design. Does the meme for altruism extend to the practice of design and, if so, can it serve as the basis of change for our profession? Can "reciprocal altruism" result in a new model of design practice? Can design for the betterment of society evolve into the predominant paradigm for design professionals? (Hamilton 1964), (Trivers 1971), (Dawkins 1976). In some places, the meme is already actively applied to design education. In some minds, however, it is more a matter for a complete reconsideration of the profession.

Okuwangaala is the book, the document, the investigation of how another culture applies design thinking in its own inimitable manner, not as an import, but naturally, unselfconsciously, as an element of human evolution (Stairs 2002, 70-88).

How do pre-industrial societies survive in the Information Age? Is it possible to jump-start economic development without suffering the same problems industrialized nations have encountered? What are the unique cultural products of vernacular design? What part does it play in balance of trade? Indigenous design wisdom points the way toward possible solutions (Stairs 2006, 81-96). Enlightened assistance acts as reinforcement for these efforts.

If we are to truly be agents of change, we must not be afraid to be confrontational. Some will choose to do this through conventional channels, working to encourage change of the corporate culture, applying old ideas to new problems. Others will be more radical. Either way works. As my countryman Malcolm X once put it, we must proceed "By any means necessary." We must make the choices that will sustain our momentum, encourage universal participation, and respect traditional wisdom.

The ultimate goal is exposure, inclusion, access, the smelly human closeness that occurs when people are mutually excited about a shared idea. This can be accomplished through a variety of means; education must play a role. In many places universal secondary education does not exist. To the extent that design can help to improve this situation, it should be employed. Technology transfer is part of the burden, and generally mutually advantageous. We cannot be afraid to take the risk of giving away what we have or know.

When these things are accomplished the world *will be* a more equitable place. In this way we *will* make the world *more* sound, *more* whole, *more* just, *more* livable for our children. When the world is a more equitable place, our role as designers might not be as necessary any more. By making ourselves hyper-pertinent now we may succeed in diminishing our roles later. But this is OK because when all men and women are rightfully seen as designers, as is naturally the case, then and only then will we have succeeded.

To paraphrase John and Yoko: "Change happens, if you want it."

Let's not just want change, let's actively work to bring it about. Webale enyo. Thank you for listening.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Visions and possibilities of a *transsociation* between design and anthropology

A method for a *glocally* driven product-system innovation

Eduardo Staszowski[1] and Piero C. Leirner[2]

Abstract

The purpose of this article is to reflect upon some interfaces between global and local layers in processes associated with design. Starting from the understanding that production and consumption of goods can be subjected to specific or local appropriations, we attempt to work on certain possibilities of development of a transdisciplinary method which associates design, understood as an operation of cultural mediation between producers and consumers, and anthropology, seen as a possibility of understanding how cultural perspectives take possession of goods. We call this method *transsociation,* taken as a new form of association which respects the specificities and limitations of both disciplines. The paper offers examples of how this mediation can be developed and applied. In synthesis, the paper proposes a tentative method on which design is associated with the anthropological approach aiming at promoting a novel practice, in a world of flows and exchanges that define multiple markets and cultures.

1. Introduction

The purpose of this article is to reflect upon some interfaces between global and local layers in processes associated with design. Starting from the understanding that production and consumption of goods can be subjected to specific or local appropriations, we attempt to work on certain possibilities of development of a transdisciplinary method which associates design, understood as an operation of cultural mediation between producers and consumers, and anthropology, seen as a possibility of understanding how cultural perspectives take possession of goods. We call this method *transsociation,* taken as a new form of association which respects the specificities and limitations of both disciplines.

Two main questions guided us towards the development of this idea. Firstly, creative processes in design, which are similar to many other processes oriented by the contemporary industrial-capitalist logic, do not seem to have precisely qualified points of departure or arrival. Stated another way, this means that the so called 'globalization process' creates side effects and local forms of appropriation or deviant behaviours, which are particularly unpredictable. An example of which would be the well-known case of the Haier Group, a global household appliance manufacturer, which faced a high number of technical problems with a specific washing-machine model in the Sichuan region in China when found out that users were also making use of their washing-machines to wash sweet potatoes. Haier therefore modified the product to respond to the double use of washing clothes and potatoes. Another example was the case of pre-paid mobile phones in Africa which were being used as a tool for transferring money among users using mobile credits; a practice that has launched a new form of microcredit or mobile banking with the emergence of new companies such as Wizzit in South Africa and GCash in the Philippines[3]. Somehow, we argue that a company's inventiveness as well as the modes of appropriation of products shaped by design end up by being transformed by the way these products are locally experienced by people who use them. For this reason, we evoke the idea of an anthropological understanding of design-related products. Secondly, we decided to carry out an exercise of experimentation - yet preliminary – aiming at approaching both disciplines, taking into account their limitations and possibilities.

Therefore, we can first observe how this association can be useful to consider some concepts which are generally very often mentioned but are ill-defined. 'Globalization' and 'locality' are two of them. How do we understand them? Fundamentally, the process of globalization, as it is understood here, does not imply in a loss of specificities or local particularities. Under this perspective, the 'local' is not understood solely as a space of expansion of the hegemonic and homogenizing spheres which try to be placed in the centre of the globalization process. Analogously and furthermore, we suggest that the hegemonic centres are also subjected to the transformations stimulated by elements coming from the local spheres.

By trial and error, it is our responsibility to consider a series of questions which 'denaturalize' these categories: how many centres and peripheries do exist? By assuming the centrality from one point-of-view and not another, what is central? Similarly, if the global exists, where is its centre? And what is local from the point-of-view of the global's centre?

[3] As noted by Sara Corbett in the article "Can the Cellphone Help End Global Poverty?" The New York Times, April 13th, 2008.

2. Copacabana, Rio, New York

One of the points we intend to discuss, inspired by a relativistic notion, which leads our perspective towards the concept of 'point-of-view', is that the local always places itself in the centre and *peripherizes* other relations less perceivable for itself. Even though this is a relatively simple equation, it is hardly ever noticed or perceived by some agents who consider themselves more central than others. As with the example of Wall Street, which considers itself the centre of the world: from the point-of-view of a peddler selling beach towels in Copacabana, this is an innocuous perception and not only does the stock exchange have little effect on his life but also he is not aware that Wall Street traders consider themselves as such. Clearly, one can argue that the stock market determines the flow of tourists who will be visiting Rio, the very same tourists who will buy the towels in the end. On the other hand, beach towels, coconuts and hotels are necessary steps to the realization of capital which has started even before Wall Street. In short, no one is absolutely certain about how a social process starts and ends. It is what Latour would call an 'actor-network', a process in which we only know for sure what we can relate to or make a connection (Latour, 1991). That effect has finally proved its power in the world manufacturing: the larger the number of components, the more difficult to establish their origin. For instance, in a computer or a tyre, the embedded technologies are the result of the concrete experience of the network which invested its labour-power in that product. Moreover, every product is designed to be positioned in a network of consumption or as Manzini points out, in that case we have an extended product system[4], or a space where, subjects, companies and localized communities meet (and clash) in a process of value production (Manzini, E., Vugliano, S., 2000, p.15).

This is a point that has been studied extensively by anthropology for quite some time. Many of the studied relations within, for instance, the so called 'primitive people', considered production and consumption inseparable. For example, eating in many native ideologies is part of the process of conception and production of babies. Nowadays it is considered common sense in many contemporary capitalist societies, but it is relevant to notice that until the 1960's no one mentioned that 'quit smoking' during the pregnancy was compulsory and eating restrictions were seen as a mere superstition. Design, accordingly, joins the world of industrial production, as an area which par excellence must consider the consumer's point-of-view, which is in principle intangible and present in a contradictory subjectivity with the objectification of the contemporary world.

It is worth mentioning, however, that this process has managed to overcome the appalling massification which has always haunted the social theories of the 20th Century. For instance, the internet and the decentralized networks of computers and people, being an unfinished process, is prevailing over the closed networks of communication, which challenges us to reflect upon categories that respond to this multiplicity seen nowadays. Thus, one of the problems we face is the dissolution of those landmarks that were considered absolutely reliable in our way of thinking.

One of the ideas seen here, which supposes an analogy between elements described by ethnology and processes associated with design, is related to the way in which theses disciplines can reason in terms of production and consumption concepts and at the same time in terms of dissolution of canonical dichotomies such as 'interior/exterior', 'subject/object', 'centre/periphery' and, consequently, 'local/global' or 'simple models of push and pull, or of surplus and deficits, or of consumers and producers' (Appadurai, A., 1996, p.32).

In this process, it is appropriate to remember that even Marx, in a less known part of the Capital, considered an imbricated process between production and consumption called 'productive consumption'. This is to be regarded not only because when we produce something,

[4] Product system is undestood as "a system of products and services that fulfils one function, which satisfies consumers' need. Product system development includes product design and design of the service system that minimises the product's environmental impact, as well as analysis of existing infrastructure and social arrangements that help with a more environmentally benign performance of the product throughout its life cycle." (Mont, 2000).

technological resources are also consumed – work is incorporated in goods which produce other goods – but especially when we consume, we also produce a potential labour-power. Dialectically, in the circularity of this process, both steps tend to produce and consume one another. Bearing in mind the intellectual work, especially the one associated with design, this aspect becomes crucial. Design is above all a relationship of experimentation between the potential of consumption and the potential of a good. It must then go through the clash of distinct points-of-view, so as not to become a reference endowed with what we call '100% objectivity'. Objectivity supposes that all points-of-view concur and when the points-of-view are different, it does not mean they are contradictory.

If design is a process which involves perceptions and taste creation, it is something that takes us to levels of distinction and competition, productively as well as consumptively. Analyzing a radical example: 'distinct' people buy great works of art; however, could we say that the works of art create by themselves a distinction which is bought by people? Design taken in its most radical form could be led to this direction: a tool for creation of distinctiveness for who produces it and for who consumes it. Distinction here is the base of the difference or the difference of points-of-view. In this case, we are not talking necessarily about hierarchical distinction but, for instance, multiple tastes or different qualities. It is worth mentioning though that the goods or product-systems exchanged in the market are very different in nature and in some cases tend to be less tangible as in the case of services. The form of a good (tangible or intangible) is not the only aspect that determines the distinctiveness but also, for instance, the quality of the exchange of the good itself and the dimension of the experience involved. This assertion makes us think on the ubiquitousness of design and the possibilities to intervene in a much more complex process of value creation.

Roughly, this idea could be compared to some sort of 'cannibal culture' of the world of goods: it is unknown whether they make people or people make them. How to turn this movement into a practical idea? Since companies tried to understand who are their consumers, it is impossible to predict who precedes whom and where resides the authenticity. Like culture – object of the anthropologists – it is impossible to determine the 'origin' of its elements. There is always one phenomenon behind the other. In this way, culture like objects, can be understood as an element in a constant process of reinvention (Wagner, 1981). By now we could affirm that a brand represents more competently the consumer's identity than the company's identity itself; or is it the consumer's identity which has built the company's identity?

Great part of the cultural criticism on the rigidity of the above mentioned dichotomies is being elaborated in anthropology, for instance, by dedicating itself and for quite a long time to the theme of anthropophagy[5]. Among other things, it is known that cannibalism is associated with reproduction and not only with destruction and death ('I kill and incorporate my enemy') so as to create new relationships in my own world. As a result, it also transforms the world of those related to my dead enemy in a symmetrical way. In this case, the consumption and/or destruction can be understood as production and/or incorporation, and the reproduction can be seen as a transformation. Through this perspective, the 'other', seen as the figure of the enemy, becomes part of the 'self' and the boundaries between what is 'mine' and what is 'exterior' become blurred. This example is helpful when analysing the limits of categories such as 'centre/periphery', 'global/local', as well as 'competition and cooperation'.

This process being understood, it is essential to adjust or polish this vision, in order not to transcend some ethical limits imposed to both disciplines.

[5] The term anthropophagy, was employed before in Brazil by the artistic vanguard of the 1920's leaded by the Brazilian poet Oswald de Andrade in its "Cannibal Manifesto", to defend the idea of "cannibalizing" other cultures and remodel them in a Brazilian way, thus protecting Brazil from cultural domination.

3. Ethical questions

One of the points we are willing to clarify is that we believe that the main purpose related to this proposal of association between these two disciplines is to improve the quality of people's life (the improvement of the social and environmental of qualities of a specific context) and not simply to create another catalyser of class distinction. Therefore, the distinctions that design creates, such as anthropology recognizing distinct points-of-view, must be useful to produce a sort of 'relational multiplicity'. What is this? To some extent, it is the possibility of thinking about how a design-associated process could relate multiple points-of-view in the production and consumption of a good – and not only the one linked with one of the parts: aiming at making profit or its immediate consumption. Hence, we can mention some movements which promote a critical consumption such as those connected with the *Slow Food* and *Fair Trade* associations or the consumer's critical participation in the design of solutions and a globalization, which is based on the circulation of global knowledge, the valorization of local resources and the safeguard of consumers' and producers' life quality. At this specific point, an explanation is required: we do not refer to either an attempt to merely develop an applied anthropology, which is responsible for 'discovering' native logics and pass it on to the producer so that he can make good use of it, or a divagating design, which remains stationed in the possibility of never arriving at the fullest form of subjectivity of those who produce and those who consume.

Above all, we should consider how concepts which belong to one discipline could affect the practice of the other and vice versa. One example to digress: in 1930's Levi-Strauss brought an expedition of Nhambiquara Indians to the city of São Paulo and it was noticed that nothing impressed them; neither skyscrapers, nor department stores or even an airplane tour. Back to their village, he found out that the object which really fascinated them and was incorporated in their stories was a ball used as an ornament at the end of a stair rail. That ball was also incorporated in their ceremonies.

The same perspective can be used to approach wider spheres, such as markets being transformed by similar processes, given that they are also conceived within flows which incorporate 'external' and 'internal' elements that can migrate to the exterior as well. Since markets are also subjected to the movements of appropriations and cultural exchanges, the designer can make use of a vision of the world built by anthropology to innovatively mediate the production and consumption of new products and services. Finally, what makes us believe that this is a possible exercise is the fact that both anthropology and design are cultural inventions and, to a certain extent, they share the same inventive nature.

4. Evidence from the design practice

From the design practice we can draw relevant examples where the *transsociation* approach or the incorporation of different points-of-view in a design process have been successful employed. In this paper we refer to two distinct cases:

Elephant Design

Elephant Design is a product development and design consulting based in Tokyo, Japan that developed a digital platform on the web that "encourages individual users to express their needs as consumers and take part in developing ideal products based on personal requirements"[6].

Using its 'Design to Order' technology (Fig. 1), Elephant Design first invites potential customers to express their needs as consumers, for a product they would like to be produced and then makes a selection of ideas and coordinates the work of designers and manufacturers interested to produce it. The final product is then presented back on their website to attract buyers. Once orders for an item reach the critical mass the product is manufactured.

This case offers an interesting insight regarding the proposed *transsociation* approach. It is related to the fact that the opening of the design process and the improvement of the quality of interaction among many actors involved in a solution can contribute to creating a radical transformation in the relationship between producers and consumers and among consumers themselves.

El Hema

El Hema is a project, which resides in the threshold of art and design, developed in 2007 by Mediamatic[7], a cultural organization based in Amsterdam, The Netherlands. This project which started according to Willem Velthoven, director of Mediamatic, with a typographic matchmaking operation between western and Arabic typeface designers finished to produce an entirely Arabic version of the HEMA[8], a traditional Dutch department store. Through a design contest and an exhibition Mediamatic produced and exhibited 150 new products that interpreted the current portfolio of the original Hema Store using Arabic elements; and the *re-design* of contemporary traditional Arabic artefacts in order to become part of a fictitious Hema's catalogue (Fig. 2). The project ended by promoting a critical debate on multiculturalism, immigrant integration and the cultural gap between eastern and western cultures in the Dutch society.

The interest of this successful project for the *transsociation* approach is that commercial artefacts proved to be a powerful platform to promote intercultural dialogue if we consider products, vehicles of culture and identity. At the same time, this experience revealed the potentiality of crosscultural collaborations and the capability to innovate the form of a traditional artifact when tradition is not seen as something fixed, but instead, drives its force and relevance from the capacity to transform itself continuously.

5. A tentative method

The relationship among producers and consumers during the production and exchange of products, services and communication in the framework of globalization continues to pose a series of questions for the design practice. While companies are already building networks and new forms of organisation to respond, for instance, to the needs of delocalizing their production, the organisation of the design process in relationship to this remains little explored, revealing an area of opportunity for the development of new approaches and methods which can orient the design practice to contribute for the increase of the benefits and to counterbalance the negative consequences (social and environmental) of globalization. In this way, it is our intention to propose the development of a method for what we are calling a *glocally* driven product-system innovation, which is based on the transdisciplinary association of design and anthropological approaches.

In synthesis, the new method aims at the promotion of a novel practice to support the emergence of new forms of cooperation between organizations, individuals and territories in a world where global and local knowledge is exchanged and defined by multiple markets and cultures.

Accordingly, if we accept the rejection of the notion of *centrality* as one of our premises, what we are proposing now with this method is fundamentally the aperture of the design process to all subjects that are part of a specific network involved in a process of value production, which will reflect in the end on the plurality of points-of-view suggested.

At first we would like to induce the disciplines of design and anthropology to a common reflective practice based on *uncertainty*, where there are no guarantees of which relations will be created and which multiple points-of-view will be used or renounced.

Secondly, we propose a sort of 'ordered anarchy' as a method of disciplinary *transsociation* that stimulates the use of open innovation[9] models that make possible the access to the so-called diffused creativity and distributed intelligence[10].

Therefore, we propose that this method and its further elaboration start incorporating and inventing tools that encourage the use of the following tentative guidelines in the design process:

a. *Openness*: to permit drawing ideas and experiences from external practices and incorporate them into a local set of conditions, adapting and combining them with local elements. Openness can also be seen as *open-ended* where the solutions can be constantly modified and upgraded.

   - For organizations, the possibility to open their research activities to external sources.
   - For designers, the possibilty to join crosscultural and pluridisciplinary teams.
   - For users, the possibility to join the design process by expressing their needs.

b. *Hybridization*: to stimulate new combinations of patterns that result in new practices and new ways of doing.

[9] 'Open innovation' is a term coined by Henry Chesbrough to promote the use of external ideas as well as internal ideas to accelerate the process of innovation.

[10] 'Distributed creativity' is a term that refers to the diffusion of creative behaviors in the society and by 'distributed intelligence' we mean, "the new distributed forms of knowledge and decision making due to the increasing computing potentialities generated by the internet." (Manzini, 2004).

- For organizations, the possibility to gain specific insights for innovation in culturally diverse markets and translate local knowledge into products and services for culturally divergent markets.

- For designers, the possibility to incorporate the research of best practices and cross fertilization practices in their creative process.

- For users, the possibility to contribute to the process by transferring fluid or tacit local knowledge.

c. *Feedback*: to incorporate observations, concerns and suggestions which will transform the original solution.

- For organizations, the possibility to incorporate mechanisms in order to reduce risks.

- For designers, the possibility to validate the proposed solutions with final consumers.

- For users, to collaborate or to *co-design* with designers.

Finally, we suggest that the review of the material analyzed by anthropology can migrate to the disciplinary universe of design.

6. Preliminary experiences

This paper refers specifically to an ongoing PhD research[11] carried at the Indaco and Best Departments of the Politecnico di Milano University and also relies upon the Anthropology of Warfare research conducted within the Post-Graduate Program in Social Anthropology at the Universidade Federal de São Carlos, Brazil.

Nevertheless, the *transsociation* approach, has been experimented within some didactic activities through a series of three workshops conducted between November 2007 and May 2008. One of the objectives was to experiment with a new set of tools (a work in progress) that would introduce the incorporation of multiple points-of-view in the design process, specially in the *metadesign*[12] phase.

The first workshop named 'Transpark: ideas for an Ecomuseum in the *Parco Agricolo Sud di Milano*' was conducted[13] in November 2007 with 1st year students from the Master in Industrial Design of the *Politecnico di Milano, Facoltà del Design*. In this workshop, students were asked to design new services ideas connecting the urban identity of Milan to the rural identity of the park through the mutual *contamination* of values, languages and experiences.

The second workshop named 'Super Glocal: design scenarios for the Glocal Supermarket' was conducted[14] in April 2008 with 1st and 2nd year students from the Master in Ecodesign of the *Politecnico di Torino, I Facoltà di Architettura*. In this workshop, students were asked to design

[11] "Design methods for cultural driven product-system innovation" (provisory title). Eduardo Staszowski

[12] If we take the design and *metadesign* subdivision of the design process described by Celaschi (Celaschi, F., Deserti, A., 2007), design is the organization of all the factors that compete to obtain a specific result and *metadesign* is the process of ideation and planning of the design process itself. In practice, *metadesign* can also be seen as the first phase of the design process, or the design of a method that will influence the design process as a whole. A phase that, in one hand, is responsible for identifying and analyzing the constraints defined by the context in question and, on the other hand, synthetizes opportunities that come out of it.

[13] Together with Beatrice Villari and Giulia Simeone

[14] Together with Beatrice Villari, Flaviano Celaschi and Angela De Marco

new product-systems by interpreting the supermarket as an interface between the global and the local spheres.

The third workshop named 'The *Wellcare* Card: service design scenarios for the wellbeing of the contemporary worker ' was conducted[15] in May 2008 with students from the Master in Strategic Design of POLI.design, Consorzio del *Politecnico di Milano*. In this workshop, students were asked to design solutions that would bring the security and functionality of the professional world into our private lives and the identity and freedom of our private lives into our professional world.

In the three above mentioned experiences students were introduced to two *metadesign* tools designed[16] to explore the *transsociation* approach:

- **Brainstorm idea matrix**: it is an interactive matrix, organized around different variables, which can be combined to help students to brainstorm within small groups. The variables in the matrix represent the deconstruction of the problem around the demands of a potential user. The matrix helps students to make choices by associating the different variables and construct different paths that will configure one possible solution (fig.3).

- **Metacards**: each metacard corresponds to the detailed description of each variable of the matrix used to create an idea. The metacards all together become a first set of *metadesign* decisions (or a set of guidelines) which will define the constraints and suggest formal solutions for the next phases of the design process (fig.3).

Briefly, this first experimentation and the initial results informed us that design students equipped with these tools were able to incorporate valuable research data into the design process, giving them more control over the ideation process and enabling them to organize and analyze the plurality of multiple points-of-view used to orient the metadesign phase

In conclusion, it appears to us that new opportunities for further research emerge for both anthropologists, designers and professionals from other disciplines who can benefit from the transdiciplinary association aimed at tackling the complexity of contemporary society in the perspective of a positive globalization process.

DESIGN VISIONS PROPOSALS AND TOOLS

The Slow Design Principles

A new interrogative and reflexive tool for design research and practice

Carolyn F. Strauss[1], Alastair Fuad-Luke[2]

Abstract

We posit a new evaluative tool to encourage design practices to orientate towards social, cultural and environmental sustainability under the rubric of 'Slow Design.'

The Slow Design Principles offer an opportunity to find fresh QUALITIES in design research, ideation, process and outcomes. The six principles of Slow Design are presented here as a powerful tool for designers to interrogate, evaluate and reflect on their design ideas, processes and outcomes using quantitative, qualitative and intuitive means of assessment.

'Slow Design' is a unique and vital form of creative activism that is delivering new VALUES for design and contributing to the shift toward sustainability.

1. Toward a New Evaluative Tool for Design

In this section we discuss the need for new tools and strategies for evaluating design with a view to social, cultural and environmental sustainability. We posit that 'Slow Design' provides a stimulating platform from which to consider, critique and improve best practices in design, while simultaneously putting forward new ones.

What are the standards of evaluation in the field of design? And how, if at all, do they drive design practices to enable a more sustainable future?

The fields of science and engineering apply rigorous standards of evidence and evaluation to guarantee accuracy and 'quality' outcomes. Similar standards exist in the design field, with a focus on functionality, ergonomics, manufacturing efficiency, consumer safety and inclusivity. Since the mid-1990s, there has been a growing, voluntary analysis of environmental impacts in the fields of product design and architecture (for example, eco-design, Design for the Enviornment - DfE, and Design for Sustainability - DfS); however, such practices are not yet widespread and, furthermore, they are not a guarantee of behavioural change that can substantially deliver sustainability.

Recognizing the marginalization of this way of thinking about design, Fuad-Luke raised a rhetorical question whether 'slow design', an approach predicated on slowing the metabolism of people, resources and flows, could provide a design paradigm that would engender positive behavioural change (Fuad-Luke, 2002, 2003). The concurrent emergence of slowLab founded by Carolyn Strauss (Strauss, 2003-present) enriched the dialogue about the possibilities of 'slow design'. A wider public dialogue heralded the positive impacts of slowness (Honoré, 2004) and new conversations about 'slow + design' ensued (Mojoli, Manzini et al, 2006).

In 2006, we posited six Principles of Slow Design (formally reported in Fuad-Luke, 2008) – see below. These principles were the result of diverse research, dialogue and iteration within slowLab and its international network of design thinkers and practitioners. The principles were informed and inspired by others, including diverse 'slow activism' expressions (New Internationalist, 2002), the global Slow Food and Slow Cities movements and threads of the sustainability debate like the Dutch foundation Eternally Yours (van Hinte, 1997-2004) and projects associated with the Faculty of Design at Milan Polytechnic (Manzini & Jégou, 2003; Mojoli, Manzini et al, 2006).

We put forward these principles as an approach and tool for design. We do not regard them as 'absolute truths'; rather, they are GUIDING PRINCIPLES, open to dialogue, iteration and expansion.

2. The Slow Design Principles

Here we present the Slow Design Principles, each followed by concrete examples of design projects created by members of slowLab's network that demonstrate one or more of the principles in active use.

Those brief 'case studies' validate how the principles can work as a set of criteria against which the designer might interrogate and appraise her/his ideas, processes, motives, and outcomes. This should begin at the initial phase of any design project, with the designer returning to these criteria several times during the design process, and applying them again to evaluate the final design outcome and better understand its potential future impacts. In effect this creates a 'shifting brief' and a mutable outcome as the process unfolds.

We have found that the principles of Slow Design encourage and inspire a myriad of understandings, interpretations and uses. The process of applying them is a highly personal one. They provide a lens through which to more intimately understand one's own identity as a designer, to reflect upon the design processes one employs, to evaluate tangible outcomes, and to imagine new scenarios. This process of careful and continuous (self-)questioning challenges the designer to reach for the core of design and her/his role as a designer.

Note: In the description of each case study, we have **emboldened** words that we feel have particular resonance with the values, qualities and practices.

Principle 1: REVEAL

Slow design reveals experiences in everyday life that are often missed or forgotten, including the materials and processes that can be easily overlooked in an artifact's existence or creation.

Architect Karmen Franinovic (Croatia/Canada) uses situated interactive technologies in public architectural space to stimulate social interaction and raise awareness of the surroundings and their diverse ecologies. Franinovic's 'Recycled Soundscape' project (2003-04) [Fig. 1] was designed as a system through which to explore the auditory aspects of experience in the city through a set of "kinetic, human-scale interfaces" which seek to facilitate reflective activity in the public sphere. Within the sonic context of a specific location, people are invited to augment, modify and perform acoustic landscapes by playing with surrounding sounds, tuning the composition of a sonic environment, and listening to/recording noises (human, natural, machine, electronic) that are otherwise difficult to take notice of. The result is 'an interactive system for public orchestration of an urban sound ecology' where anyone can transform the existing sonic characteristics of a place over time, recomposing its 'evolving memory in sound'.' By introducing interactive technologies into physical architecture and immaterial space, she seeks in her work to stimulate **social interaction** and to raise awareness of the surroundings and its **diverse ecologies**. The under-observed phenomena of a locality are **re-revealed**.

In the realm of objects, Julia Lohmann (Germany/UK) believes that acknowledging the origins of a product is the first step towards making more informed and ethical choices about what we consume. The designer finds new applications for otherwise undervalued materials, working primarily with animal materials and byproducts. She designs objects on the threshold between the physical materials of animals and the animal itself, which **probe our attitude** towards the creatures we share the earth with and how we use them to sustain us. Sheep stomachs become beautiful billowing lights, triggering feelings oscillating between attraction and disgust, the former through their warm luminosity and the latter as soon as one learns more about

their material origins. Her ceiling light 'Flock' was made from the stomachs of fifty sheep and installed at the London Design Museum. Meanwhile, a series of unique handsculpted Cow Benches, each with a different name and shape, serve as **memento mori** for the cows that died to make the leather they are made from. The mundane, yet hidden materials of life are **re-positioned**.

Slow perspectives and practices have also emerged in the realm of today's virtual experiments. Tracy Fuller (USA), a Los Angeles-based game designer, has been working for the past several years to create gameplay that "slows the player down and allows time and emotional space for reflection and transformation." In her current work at the USC EA Game Innovation Lab, she is collaborating with artist Bill Viola on 'The Night Journey,' where the core mechanics of the online gaming experience unfold at the extremely slow pace and characteristic visually richness of Viola's celebrated video works (Fuller, 2007 to present). Meanwhile, by much simpler mechanisms, web-based projects 'Shredder' (Napier, 1998) and 'html_butoh' (Endlicher, 2006) reveal unexpected aesthetic pleasures embedded in the seemingly banal coding of Internet sites.

Principle 2: EXPAND

Slow design considers the real and potential "expressions" of artifacts and environments beyond their perceived functionalities, physical attributes and lifespans.

In her doctoral thesis 'Occupying Time: Design, Technology, and the Form of Interaction,' Ramia Mazé (Sweden) points out that, "Design is not only about the spatial or physical form of objects, but the form of interactions that take place – and occupy time – in people's relations with and through [them]. A central, and particular, concern of interaction design must therefore be the **'temporal form'** of such objects and the 'form of interaction' as they are used over time." (Mazé 2008) Her projects at the Interactive Institute in Goteborg included the 'STATIC!' which investigated interaction design as a means of increasing our awareness of how energy is used and for stimulating **changes in energy behavior**. Revisiting the design of everyday things with a focus on issues related to energy use, with the goal of creating a meaningful presence for energy in daily life. (Mazé, Redstrom et al, 2004-05) Her thesis work also considers larger currents in how design permeates daily life, staing that "Increasingly, pervasive technology means that the temporality of form and interaction is implicated in more widespread changes to the material conditions of design and of society. Challenging conventions – of 'formalism' and 'functionalism', 'good' and 'total' design – temporal concerns and implications require new ways of thinking about and working with the **materiality**, users, and effects of design."

German designer Monika Hoinkis is similarly concerned with how we "live with things," but whereas Mazé addresses temporal concerns, Hoinkis searches for **intimacy** and interdependence with the objects around us. In 2005 she created a collection of objects that function only in direct reciprocity with their users: A desk lamp without hinges that begs to be cradled in a cupped hand. An umbrella that stays up only with help, draping over one's head and shoulders. A radio that functions solely in close proximity to a warm body. A metronome that, rather than dictating a beat to follow, instead keeps time to the rhythm of the person who shares the room with it…. As opposed to objects performing discreet functions, Hoinkis' objects must be negotiated with in order to benefit from their full functionality, challenging those who use them to reflect upon whether the other "things" in their lives could have similar **symbiotic dependencies**. (Hoinkis 2005)

The processes of making products are also shifting to reveal new possibilities. Australian engineer and artist Natalie Jeremijenko (Australia/USA) leads an academic initiative for design

and engineering students to trace the histories of everyday products, creating encyclopaedic entries that comprehensively **expose the life of the products**, from where materials are sourced to the labor conditions of those who manufacture them (Jeremjenko et al, 2005 to present). Participating students acquire healthy tools for critiquing consumer culture, as well as new ways of thinking about and executing their own design projects.

Such a rethink is evident in Olivier Peyricot's automobile concept, 'Slow Rider,' where a standard automobile is deconstructed and rebuilt as a purveyor of slow living. Peyricot (France) mounts a stripped-down motor on the back of a vehicle or exchanges it with a refrigerator generator, literally reducing power to **facilitate slowness**. The hood is removed and the chassis sawed down to make way for front-mounted seats. In motion, such a car roams the city like a motorized flâneur. At rest in a parking spot, the car becomes a piece of street furniture that invites the public to relax or **play** on its surfaces.

Principle 3: REFLECT

Slow Design artifacts/environments/experiences induce contemplation and what slowLab has coined 'reflective consumption.'

Product designers are questioning not only ecological values, but also perceptual and emotional experiences that the unique materiality of products can deliver. Dutch designer Simon Heijdens believes that design should, like Nature, unleash a **continuum of expressions** over time. With his project 'Broken White, Heijdens created ceramic dishes that evolve over time to reveal visible **traces** of their relationship with the individuals who use them. As they facilitate the consumption of food and drink over many months and years, the smooth white plates, cups and bowls develop tiny cracks that slowly, very slowly, reveal intricate floral patterns. The varying states of adornment on each plate or cup directly reflects the relationship with its owner, so that his/her favorites have the greatest wealth of decoration while others may remain quite plain. In a world of disposable products, Heijdens embeds new layers of experience into everyday objects, enriching their meaning well beyond mere function and convenience, and thus rendering them increasingly precious to the user over time.

The London design collective Raw Nerve had something similar in mind when they rescued the dilapidated piece of furniture and brought it into their studio. Over time, they began to contemplate its former life, imagining the **impressions** that the sofa may have absorbed, the stories it had heard, secrets whispered, urgent young lovers languishing in its folds. They thought that it might have served as a child's castle and envisioned a collection of lost objects buried in its depths. They saw the sofa not as an inanimate object, but as a living, breathing thing with its own life and its own story to tell. The designers set to reviving that rich history, re-upholstering and imprinting upon it the imagined tales of its life so far. To unravel the secrets of its past, one must interact with the sofa, examining every intimate detail, lifting its cushions and listening intently to soft sounds emitting from deep within. The sofa has moved beyond being a mere functional object to being a **site of discovery**, infused with **layers of meaning** that challenge and delight those who come to sit on it.

While such projects strive to achieve physical and emotional durability, Icelander Katrin Svana Eythórsdóttir (Iceland) explores the **preciousness** that is born of **ephemerality**. Her biodegradable 'Chandelier' (2006) slowly disappears over a period of several months, inviting its owner(s) to savour every moment of its existence. Comprised of a cascade of thousands of highly

reflective glucose droplets, this magnificent light source requires no electricity. The highly reflective nature of the material draws in ambient light and refracts it back out from the object, casting a subtle, warm glow. Lasting only up to three months (perhaps even less if one's local insects opt to collaborate), the ephemeral nature of Eythórsdóttir's Chandelier induces a state of awareness and deliberate contemplation of the object's attributes, functionality and, not least, it presence in one's life. The very lightness of the physical form suggests an ephemerality as well, appearing and disappearing as the light around it changes. Eythórsdóttir says, "It hardly exists, yet it's there."

Principle 4: ENGAGE

Slow Design processes are open-source and collaborative, relying on sharing, co-operation and transparency of information so that designs may continue to evolve into the future.

Collaboration is a critical aspect of slow designing. This is perhaps what industrial designer Martin Ruiz de Azua (Spain) had in mind when he designed his 'Human Chair,' a group of people sitting on each other's knees, propped one on top of the other in friendship and **fragile dependency**. It is 'human', referring not only to the people who are its component parts, but more importantly to the delicate nature of the exercise. At any moment, the 'chair' could collapse, but then it could just as easily be rebuilt again, perhaps with a few more friends joining in. With this simple project, Ruiz de Azúa has given the precious gift of **immaterial substance** to our over-material world: a design 'object' that has no object unless people work together to create it in amity and fun.

Few understand the value of interdependency as well as the folks at the Rural Studio, a design/build program within the School of Architecture at Auburn University that creates homes and civic structures in Hale County, Alabama The projects rely on forging deep connections and **collaborations with the local community** to ensure that **place-based values** and identity are at the core of their architectural projects. The late Samuel 'Sambo' Mockbee, who founded the program, called for "**socially responsible architecture**... to inspire community, or stimulate the status quo in making responsible environmental and social structural changes now and in the future." (Mockbee 1998). He felt is was important that students be involved with materials investigations and technologies which have mitigated the effects of poverty upon rural living conditions. Students engage in"**context based learning**" where they actually live in and become a part of the community in which they are working. Structures are made from **affordable, local materials--** clay, waste materials, recycled glass, scrap metal-- with the students, too, living in structures reflecting the **visual vernacular** of the place as they they learn the critical skills of planning, design, and building in a socially responsible manner. In 1998 Mockbee stated that "The professional challenge, whether one is an architect in the rural American South or elsewhere in the world, is how to avoid being so stunned by the power of modern technology and economic affluence that one does not lose sight of the fact that people and place matter." (Mockbee, 1998)

Principle 5: PARTICIPATE

Slow Design encourages users to become active participants in the design process, embracing ideas of conviviality and exchange to foster social accountability and enhance communities.

With it's project series, 'Slow Ways of Knowing,' the design collective slowLab (USA/UK/Netherlands) has developed an urban design tool to capture local knowledge and elicit public contributions to urban planning debates in their localities. Through **empirical observation, sensory awareness and intuitive imagining**, people are invited to connect with the histories and patterns that a given site reveals. To capture **local knowledge** and public imaginings about the evolving identity of the neighborhood or surrounding area, they are encouraged to annotate local area maps with their thoughts, memories, sensations, fantasies, drawings, and design gestures. By thus revealing unseen or forgotten aspects of those places, generating awareness and participation, the projects remind people of their own part in and responsibility to the life of their localities, and are encouraged into ongoing creative investigations.

In a similar vein, the Netherlands-based social design collective Butterfly Works believes that "structural improvement in people's lives is possible when people have the necessary tools of creativity." The collective has been recognized for their work in several African nations, co-designing new programs with **local makers** and producers, with the ultimate goal of stimulating people to start projects themselves. With 'NairoBits,' Butterfly Works initiated a digital design school in Kenya to train young people from the slums as web designers, with complete transfer of knowledge and responsibilities to Kenyan managers and teachers. While their 'Tyre Trade' project in Morocco got local manufacturers to collaborate on the creation of baskets out of discarded rubber tires, which are now being used locally as well as sold at design shops in Europe. The motto of Butterfly Works multidisciplinary approach is **"Positive Chain of Events."**

Meanwhile, London-based designer Judith van den Boom of Studio Boomwehmeyer strives to bring human relationships to fruition within the processes of manufacturing her own ceramic designs. She proudly goes "below the surface of plain production" in her product development to explore **"warm relationships"** with manufacturers, as evidenced by her current collaboration with a large manufacturer in Tangshan China that includes design workshops and poetry readings with factory workers. (Van den Boom, 2008).

Principle 6: EVOLVE

Slow Design recognizes that richer experiences can emerge from the dynamic maturation of artifacts, environments and systems over time. Looking beyond the needs and circumstances of the present day, slow designs are (behavioural) change agents.

With 'Edible Estates,' architect and social designer Fritz Haeg (USA) proposes the replacement of the American lawn with a highly productive domestic edible landscape. With the modest **gesture** of reconsidering the use of our small individual private yards, Edible Estates takes on issues of global food production, our relationship with our neighbors and our connection to the the natural environment. Haeg is concerned not only with the short-term gains for participants, but also with how this system works as a tool for reorganizing neighborhoods, instigating new community relationships, and reviving the social commons. **Community stewardship** of the project into the future will determine its evolution over time.

Community stewardship will also be key to the ongoing thriving of Louis Le Roy's Eco-Cathedral in Mildam, Netherlands, [Fig. 2] which he expects to endure for at least another 1000 years. It is a site of creative actiivism and **construction of new realities** begun by Le Roy over thirty years ago as a design experiment to demonstrate the potential of human energy interacting

with the forces of nature. There, on a two-hectare site, he has piled up with his bare hands paving bricks, paving stones, kerbstones and other discarded street rubble while allowing nature to proceed about him unhindered. Le Roy calls this fascinating jungle populated by large stacked edifices a ‘cathedral’ in reference to the people who built the great cathedrals and architectural complexes of the past— most of whom probably never saw the projects to completion in their lifetimes. Le Roy believes that “employing all the potential available from all human beings would provide a mega-source of clean energy.” He says that, using such a method, a new habitat could take shape in which everyone could participate creatively in building a **living environment** without a ground plan and without the boundaries of private property. Following his ideas would mean a revolution in designing urban space. The project has spawned a foundation, Stichting Tijd (The Time Foundation) to ensure that longevity while promoting insight and knowledge of the notion of ‘time’ as a condition for the creative development of cooperation between natural and creative human processes. Le Roy says, “The methods of today’s planners will not prepare them for the enormous problems that they will have to face in the next century. One of the first things they have to do is accept **infinite time** within their thinking system.”

3. Case Study: The Slow Design Principles applied as a Re-design Tool in a workshop setting

In adddition to challenging individual designers, the Slow Design Principles can also be effectively applied as a collaborative tool for groups of designers and users alike to evoke new understandings and reinvigorate their design values.

In April 2008, Alastair Fuad-Luke tested this angle in a workshop he led at the Research in Art, Nature & Environment (RANE) research cluster at University College Falmouth. The workshop entitled 'Slowly Re-designing Now' engaged nine participants[3], ranging from fine art to design and architecture researchers, post- and under-graduates. The workshop proceeded in the following steps:

1) The text of each 'slow design' principle was shown to the participants and each one was asked to donate a word to form a 'word circle'. Once the circle was complete then each participant then had to join up two words with one line. This generated a participatory lexicon for each principle.

2) Working in groups of three, the participants were then asked to examine a conventional plastic (1.0 or 2.0 litre High Density Polyethylene, HDPE) milk bottle ubiquitous in UK supermarkets and generate ideas/concepts for its re-design using the word circles representing each principle.

3) The groups present their ideas/concepts and articulated their feedback in a closing discussion.

4) At a later date, Fuad-Luke collated the ideas/concepts into a series of concept sketches, under the fictional brand 'Milkota' [Fig. 3].

1) Feedback from the exercise: word circles

The word circles gave the participants a sense of ownership of the principles and, joining the most important words with a line, gathered the group around important ones for each principle:

[3] Rowena Arden, Rod McLaughlin, Steve Bond, Anne Roberts, Nick Swallow, Bunk, Lisa Fuller, Morye Mamie, Alex Glanville

Reveal – Pause, interval, awareness

Expand – Elastic, being

Reflect – Understanding, natural, calm, contemplate

Engage – Listening, rhythm, communicating

Participate – Love, flourishing

Evolve – Journey, growth, process

2) Mutual learning to generate concepts/ideas: re-designing the HDPE milk bottle.

Key ideas and concepts emerging from the group discussion were:

Reveal – reform the bottle to show the source of the milk, a cow's udder and teats; label on the bottle to explain more about the source (cow, farmer, etc)

Expand – included 'bright ideas' on the side of the bottle; a refund on returning the empty bottle; show possible second-life uses for the bottle

Reflect – this group raised a number of rhetorical questions – Impact of the dairy industry? This is a ubiquitous product but do we need it? If we didn't have it would the other be better? If it continues to exist how can we find better uses for the used bottle?

Engage – again more questions were raised than answered. The most important question was 'Listen to whom?', in a sense enquiring as to who are the actors and stakeholders.

Participate – the group quickly moved to the idea of keeping different materials separate to facilitate recycling of 'mono-materials'.

Evolve – a plethora of ideas was generated on getting second-life uses out of the bottle, e.g. embossing cutting plans on each bottle for a different second-life use or useful measure units for cooking; techniques for cutting and combining the HDPE into other structures (woven, joined).

3 and 4) Design freshness – the value-added of the slow design principles

Outcomes from each group were synthesized into a new design concept [Fig. 3]. Key components of the design include:

a point of sale system that uses passive cooling through evaporation in a terracotta stand-alone cooler that does not require electricity but only requires topping up of the water reservoir.

point of sale systems only available for the sale of *local organic* milk (farmers within 15-20 kilometres) – can be purchased by farmers, farmers co-operatives, shops, and other outlets.

re-usable, re-cyclable thick-walled HDPE bottle that is returned and washed

two detachable components (the top and bottom) enabling colour coding for nutritional/health consumption, making it an 'iconic' design statement in the home – endorsement of the economic system i.e. local is beautiful and viable.

The resulting new brand 'Milkota' represents an improved solution in terms of: eco-efficiency; a better profit share to the farmers, farmers co-operatives and local retail outlets; a local identity milk point-of-sale and recycling system; desirability and eco-iconic status for consumers (signals we support local, fair trading for farmers, we like functional yet 'high design' objects in our lives).

'Milkota' represents a concept with potential for development, one that is grounded in the guiding principles of slow design and that is owned by the participants of the workshop. It represents a different metabolism from the commercial, supermarket model of 'single-use' HDPE milk bottles.

Impressions of the workshop

This workshop successfully demonstrated the efficacy of the Slow Design Principles to facilitate mutual ideation and learning. One of the participants noted. "I'd forgotten the importance and power of words to communicate, to generate strong emotions and guidance." Another acknowledged how the principles had ensured that the object (the milk bottle) revealed itself as part of a larger (milk supply) system, whose efficacy and social equity had to be examined in order to re-design the object. All agreed that the Slow Design Principles allow us to re-adjust our sights, re-evaluate our design values, and bring fresh qualities to our design outcomes (and their legacy for future generations).

4. Slow Design: New Values, Qualities and Practices

We posit Slow Design as a unique and vital form of creative activism to deliver a new set of values, qualities and practices of design. These seem to gather around several inter-related themes, as suggested by our emboldened words in section 2, above. They include:

Shifting awareness and perceptions by creating new awareness (sensory, symbolic, holistic), probing our attitudes, re-positioning the unfamiliar or fogotten, playing with time (temporal form, time in design, facilitating slowness, designed for ephemerality), playing with materials (questioning materiality, the intimacy of material and symbolic layers of meaning), challenging beyond materiality (immaterial substance).

The **values move beyond the materialized object**…stimulating our intuitive imaging while concurrently making empirical observations or invoking a site of discovery.

Focus on **locality, community and Manzini's "local potential"** – materials, needs, community; expose the explicit and implict rhythms of people and place, markers of local identity, community stewardship, and affordability. Mapping local knowledge in new and unexpected ways and then incorporating those values into new planning decisions. Designing to enable social connections and community. Leveraging place-based knowledge.

The long view- a continuum – infinite time

Reciprococity with the human and natural based environment – context-based learning, respecting diverse ecologies, symbiotic dependency. Slowing resource consumption.

Honoring 'slow knowing'/the slow mind: "a type of intelligence associated with what [is called] creativity, or even wisdom." (Claxton), perhaps encouraging more value association with 'slow knowledge' (Thorpe, 2004).

And many more...

5. Conclusion: A Call to Slow Designers

The Slow Design Principles offer a flexible, pluralistic approach for designers to gently evaluate themselves as to the true purpose of their design activities.

With this publication, we hope to encourage a larger movement of designers who embrace these emerging (slow) values, explore fresh qualities in and step forward to declare themselves as "slow designers."

DESIGN VISIONS PROPOSALS AND TOOLS

Design in Public Sector Services:
Insights into the Designs of the Time (Dott 07) public design commission projects

Lauren Tan[1]

Abstract

For design to have a positive impact on the lives of people in our complex and changing world, it must work towards social and environmentally sustainable outcomes for business and the public sector. Many initiatives to demonstrate the value and role of design in this changing context have been launched, acting as experimental ecosystems for Designers to work and explore within, for example the 'Designing for Services' project at Saïd Business School, University of Oxford (Kimbell and Seidel, 2008). The biggest and most recent initiative undertaken in the UK to date has been the Design Council's, Designs of the Time (Dott 07) programme , which took place in North East England between 2005 and 2007 (Thackara, 2007). Dott 07 was an extensive demonstrator of design in the context of designing and developing sustainable public sector services. The public design commission projects tackled issues in the areas of health, education, food, movement and energy. Each project utilised design-led interventions to involve communities in developing public sector services, and in doing so, sought to leave behind a legacy of people-centred and sustainable outcomes. The Dott 07 initiative presents an important opportunity to critically reflect on the value and potential of design in public life.

This paper describes research within a current PhD programme, which aims to understand the contribution that demonstrator initiatives, such as Dott 07, can have on the embryonic discipline of service design. It seeks to do this though identifying key aspects of design methodology and practice utilised in the Dott 07 projects. This paper concentrates on the first, of two qualitative research phases. Each phase involves a critical reflection on the Dott 07 public design commission projects, using a case study method, based on semi-structured interviews with selected stakeholders involved in the projects.

The first phase looks at the project clients as stakeholders. Analysis of this interview data reveals that the design methodologies and practices utilised in the projects have made significant contributions to the legacy of Dott 07. This legacy can be seen as both visible, and embedded in the individuals and communities involved in the projects. The interview data also identifies emerging indicators for design in public sector services, and the paper will begin a discussion on these findings. The paper will conclude by outlining the second research phase, now underway, with the Design Teams of the Dott 07 public design commission projects.

Introduction

This paper, in the context of the Changing the Change Conference attempts to illustrate how design methodology is changing in and of itself, as Designers decide to pursue new and different situations. It uses a case study of the Designs of the Time (Dott 07) programme to reflect on design methodology applied in a social context, publicly commissioned and often with intangible outcomes.

At the time of writing this paper, the main body of research is still a work in progress with the majority of interviews for the data collection completed. It is for this reason that this paper can only start the conversation for indicative conclusions to a growing body of knowledge situated within a PhD programme. It is hoped that this paper will illustrate insight and reflection from research gathered thus far. The paper will draw upon research gathered from both Designers and project stakeholders involved in the Dott 07 programme which was run in the North-east of England between 2005 and 2007. The programme[2], co-sponsored by the Design Council, London and the regional development agency OneNorth East, looked at demonstrating how design and Designers could tackle social issues in five broad areas of:

- Health;
- Education;
- Transport;
- Energy and;
- Food.

The programme identified communities who were keen to learn new approaches to solving social issues and connected them to Designers who had a passion for people and stretching design beyond its narrow definitions of product, fashion, graphics, web, interior etc. The programme, in its entirety, was made up of several components, but the focus of this research has been on a suite of seven public design commission projects. These projects, sponsored by public sector agencies, utilised design-led interventions at a local community level to tackle the five big themes. Each project was unique and different from the others. They therefore varied in their outcomes and impact on the people involved and wider community. The research conducted thus far has included desk research, a literature review, informal dialogue with Dott 07 stakeholders, experiencing Dott 07 events and semi-structured interviews with design teams and selected project stakeholders. In order to provide the backdrop for the discussion in this paper, a brief description of the seven public commissions projects is provided below.

Alzheimer 100

In this project, Designers of public service and communication design firm, Thinkpublic, explored with the Alzheimer's Society, ideas around how people with dementia and their carers could access better services to improve daily life and have a voice to communicate stories of people with dementia. Some outcomes and ideas that emerged from this project included skills

[2] Dott is a ten-year programme, to be initiated every two years in a different region of the UK. Each Dott consists of a suite of public commission projects utilising design-led interventions to "involve the public in designing solutions to local problems" (Design Council, 2006).

building in film-making, production of a film illustrating the daily lives of people with dementia and their carers, a Signposting service to help navigate vast and disparate services available to the Alzheimer's community and a Wondering Garden for people with dementia[3].

Design of Sexual Health (DaSH)

Sexual health services for young people are difficult to access in Gateshead and discouraging for use. The Designers from Design Options gathered insights from young people in Gateshead and proposed a set of solutions to address key issues in accessing sexual health services. This included ideas for the development of a new Genito-Urinary Medicine (GUM) Unit[4].

Low Carb Lane

What began as designing ways to reduce the carbon footprint of a home, ended up being a financial service for tenants. Through insights gathering, Designers at service design and innovation firm, live|work, discovered that in low socio-economic areas such as Ashington, financial issues needed to be tackled before the environment could be addressed. The Designers developed a service that linked energy use to finance by providing a Saverbox financial package for tenants. Tenants would also be able to monitor energy use and financial information on an energy 'dashboard' through their TV[5].

Move Me

In the village of Scremeston, access to transport is a challenging issue. The Move Me project involved Scremeston locals and school children from Scremeston First School to see what they could do to increase the mobility of people, while having as little effect on the environment as possible. Designers from live|work came up with a Lift Share service that provided the community with communication tools, such as a central notice board and lift share cards, to help bring people together to share rides[6].

New Work

Many businesses in the North-east are micro businesses (ie. 4 people or less). Enabling Concepts and live|work helped micro businesses identify key issues, such as social isolation, and helped them design solutions to overcome them. The design team brought together a community of micro business owners helping them to brainstorm and prototype several ideas[7].

Our New School

[3] The Alzheimers Society in the Northeast are currently pursuing ideas and ways to maintain the participation of people with dementia and their carers in future initiatives and activities.

[4] A GUM Unit is currently being built in Gateshead, incorporating ideas from the DaSH project.

[5] The Saverbox concept is currently being realised in North-east England with additional funding and resources being provided by One NorthEast and other public sector agencies.

[6] The Lift Share service is currently being rolled out in a number of schools and many other opportunities to develop the service are currently underway.

[7] The community of micro businesses still exists today, mostly via a social networking website developed especially for them.

The UK Government committed £3 billion, through the Building Schools for the Future programme, to maintain and improve buildings in all secondary schools throughout the country[8]. Designers from service design firm, Engine, helped Walker Technology College (high school students, teachers and parents) develop a vision for their new-build that would see the building facilitate learning, rather than the other way around. The project produced a brief[9] that brought "clarity and completeness" (Collier, 2008) to the vision of the school for the new build, mapped the 7-year journey of high school students to identify support and decision points along the way and developed a board game to facilitate a similar process for other schools also to receive BSF funding[10].

Urban Farming

In the Urban Farming project, a TV producer, artist, and service design firm, Zest Innovations, looked at reducing food miles by getting Middlesbrough residents involved in growing food locally (at home, work, in public spaces and/or in allotments), preparing the locally grown food as meals and celebrating the process at a community Town Meal event which brought people together to celebrate, cook and eat the locally grown food[11].

Why we should reflect on design methodology

Design methodology lays the foundation for how designing is done. It allows non-Designers to understand what is being done and enables the design community to develop ways to have an even greater impact on people and situations. Charles Handy (1993) provides us with a story on the value of being conscious of what we do:

> "I am reminded by a student on a management development programme. He had made half-a-million pounds by his own efforts by the time he was 35. 'Why are you coming here as a student?' I asked him. 'With your success record you should join the faculty.' 'Not so' he replied, 'I have come to find out why I was so successful.' He understood that if he could not explain his success he could not repeat it." (Handy, 1993: 18)

In order to reflect on design, we must attempt to understand methodology. Design theorist, Nigel Cross (1984) states, "Anyone who wishes to reflect on how they practice their particular art or science, and anyone who teaches others to practice, must draw upon methodology" (Cross, 1984: vii).

The viewpoint of design methodology in this paper and the broader PhD programme has been largely framed and guided by the author's own experience in design practice[12] and by the definition of design methodology that Cross (1984) provides where he states that design

[12] This has included design used in organisational strategy, customer experience and services.

methodology is "… the study of the principles, practise and procedures of design in a rather broad and general sense." (Cross, 1984: vii). It is important to make a distinction between methods and process for the purpose of discussion in this paper. In this paper, design methods are known as the different tools that Designers use as they move through the design process. The design process is the broad sequence of design phases over time. How methods and process relate is that design methods populate the design process.

Research into design methodology in Dott 07 has therefore been broad in scope, but deep in its discovery of the project experience from both Designers and project stakeholders. One Designer broadly captures the use of design methodology in Dott 07 saying:

> "… the process is the most important thing about design. It's what it is. It's the journey of all the different stakeholders, the community, the students, the teachers, the Designers. It's how we figured things out, why we figured things out." (Lee, 2008)

A very brief history on design methods

Design Methodology only began to be paid serious attention in the 1960's[13] (Chris Jones, 1992: xviii). Over its 40-year history, the dominant view of design methods has moved through different schools of thought, beginning with very scientific views and approaches of design methodology, which reflected the types of problems Designers were solving at the time. These problems were complicated rather than complex and a reductionist approach to design methodology seemed adequate (RED, 2006; Bayazit, 2004; Chris Jones, 1992; Cross, 1984).

Since then, design problems continue to reflect our social, economic and environmental context. The approach of the design process in the 1960's was recognised as, "simplistic, not matured enough, and not capable of meeting the requirements of complex, real-world problems" (Rittel in Bayazit, 2004: 21). These complex problems were what Rittel called "wicked problems"[14] (Rittel and Webber, 1973). The need to take the "wickedness" out of the wicked problem (Buchanan, 1992: 16) gave rise to "user involvement in design decisions" (Rittel in Bayazit, 2004: 21) ensuring the participation of users in the design process.

Design methods for participation were highly utilised in the projects of Dott 07 but a broadening has occurred as to who participates in this process. The design teams of Dott 07 sought to not just focus their attention on the end-users of design outcomes, but also co-designing (RED, 2006: 13; Albinsson and Forsgren, 2005: 131) with the direct stakeholders of the project, usually those in the leadership and delivery of services to the public[15]. The inclusion of

[13] The very first conference on design methods was held in London in 1962 and was titled, *The Conference on Design Method*s.

[14] Horst Rittel, defined wicked problems as: "1. having no definitive formulation, but every formulation of a wicked problem corresponds to the formulation of a solution; 2. Wicked problems have not stopping rules; 3. Solutions to wicked problems cannot be true or false, only good or bad; 4. In solving wicked problems there is no exhaustive list of admissible operations; 5. For every wicked problem there is always more than one possible explanation, with explanations depending on the Weltanschauung (intellectual perspective) or the Designer; 6. Every wicked problem is a symptom of another, 'higher level' problem; 7. No formulation and solution of a wicked problem has a definitive test; 8. Every wicked problem is unique." (Buchanan, 1995: 14-15)

[15] Albinsson (2005) who uses principles of co-design for innovation within organisations and stated that co-design was about not just about including the end-user in the process, but people within the organisation and/or in management

the direct project stakeholders is where the focus of this paper, and the broader PhD research is anchored[16].

A snapshot of design methodology today

Many design consultancies and design-led organisations have formed their own models of the design process (Figure 1). These include, The Design Council's Double Diamond model[17], Design Innovation Education Centre's (DIEC), Marketing-Fusion model[18], The Mayo Clinic's SPARC[19] model, Carnegie Mellon's User-centred design methodology[20] and models conceived by design consultancies such as those developed by Live Work, Engine, Zest Innovations etc.

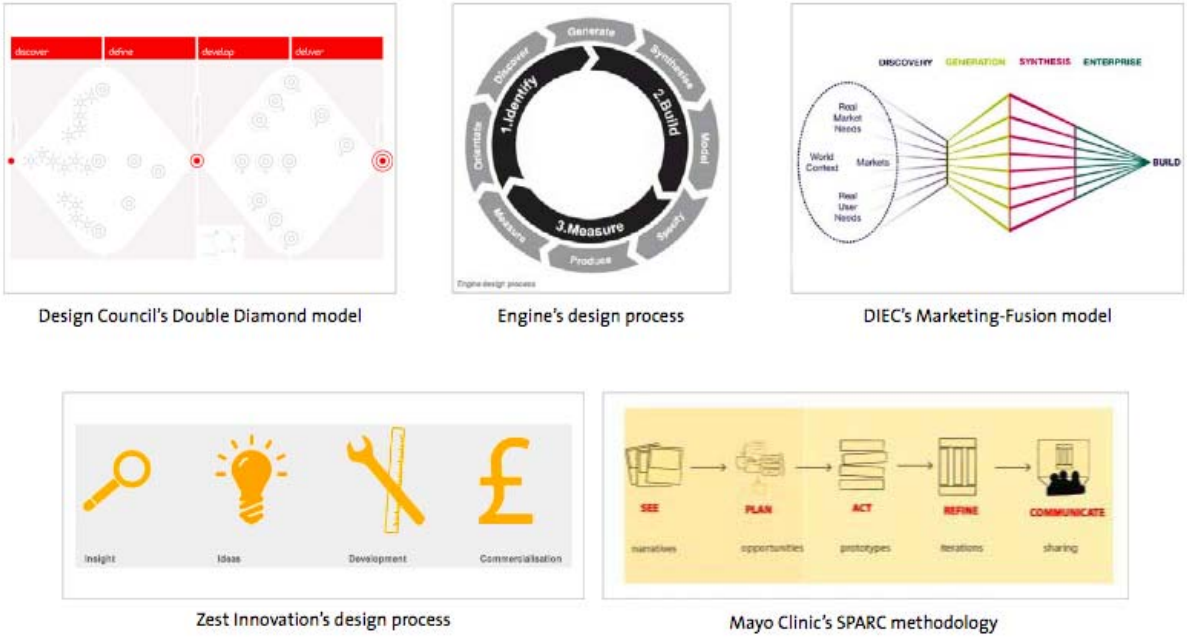

Figure 1. Some models of the design process

(Albinsson and Forsgren, 2005: 131). RED (2006) described co-design in one of their case studies where "Angela wasn't simply the subject of research but an active part of the RED design team. She helped develop ideas, commenting on and participating in a number of prototypes, and making real time suggestions for their improvement: what we call a 'co-design' approach." (RED, 2006: 13)

[16] The PhD research programme consists of two main phases of data collection. The first phase explored the project experience of key project stakeholders. The second phase, currently in progress, explores the project story as told by the design teams involved in each of the projects.

[17] See Design Council Double Diamond model at http://www.designcouncil.org.uk/en/About-Design/managingdesign/The-Study-of-the-Design-Process/

[18] See DIEC model at http://diec.onene2dev.raki.enigmainteractive.net/page/marketing_design_fusion_model.cfm

[19] SPARC stands for See, Plan, Act, Refine, Communicate. For more detail see Mayo Clinic SPARC website at http://mayoresearch.mayo.edu/mayo/research/sparc/how.cfm

[20] The author's previous practice utilised the CMU user-centred design methodology

A review of these models show they are broadly similar[21] and many Dott 07 Designers stipulated this in the interviews saying that "… it feels to be that there are different ways to explain and describe things, but generally they are all much of a muchness for basically the design process." (Telford, 2008)

Models of the design process are valuable in providing a guide to both Designers and project stakeholders for what is to happen during a design process in its broadest sense. Communicating to project stakeholders what they can expect during the course of the project can reduce perceived risk, increase confidence and demonstrate a methodology that has been 'tried and tested' which adds credibility to the work of the Designer or design consultancy[22]. For the design team, a design process can make tendering and pitching for work easier, mobilise and guide the team, assist in project planning and make for more efficient projects where teams can avoid reinventing the wheel. Finally, for both the project stakeholder and the Designer, the benefit of articulating the design process is that it, "… just helps to have everyone on the same page, to have everyone have some general design principles." (Gormley, 2008)

It's not about what it is, it's about how you use it

While there is tremendous value in visualising the design process, it has a somewhat limited benefit when it comes to moving the project forward. The Designer must know how to populate the different phases of process in order to stimulate action to bring quality research into the project, engage and enable project stakeholders to collaborate and participate, and produce valuable ideas. As one Designer put it, "… it's very broad, and it's about what goes into them." (Reason, 2008) Models and frameworks of the design process aren't able to effectively represent how they are to be used, because in use, the design process is not as clear-cut as the visualisations make them out to be. There is a high level of intuition, flexibility and ambiguity brought to the design process by the Designer.

Populating the process

A large part of populating the design process is contingent to the people and context of which the design process is situated. The process is therefore not concrete in delivery, but is instead flexible and adaptable, as one Designer comments, "I think [the process of design] is very flexible and I don't think you will be able to hold people to [it]." (Gormley, 2008)

Flexibility in the design process also facilitates higher levels of creativity, allowing the space for this among people (further on in this paper, more detail will be given in terms of how Designers in Dott 07 adapted the design process to ensure that project stakeholders were engaged and actively participating along the way). One Designer of Dott 07 discusses the need to have less structure in a design process for creativity:

[21] Synthesis of the models show that they usually start with the discovery of people's needs and/or experience for inspiration, followed by brainstorming and generating ideas. Prototyping of key ideas then occurs with several iterative stages. Finally, the refined prototype moves the project into implementation and build.

[22] A marketing person once told me they engaged a particular design firm over another because they could show a methodology.

> "I think with a methodology it's a way of structuring things and [with] creativity […] you don't want to reign it in with too much structure. So again, you need a balance of like, ways to encourage or stimulate without actually stifling, you know, the creative process." (Webb Allen, 2008)

In the Urban Farming project, the inspiration for the idea[23] was derived from a research phase with the Middlesbrough community that included methods of observation, interviews and immersion with the people[24] and place. A Designer on the team described the research phase as doing "things as questions arose" (Belk, 2008). The Designers drew from a variety of research methods from disciplines such as marketing, anthropology etc. Some Designers even have an aversion to framing them as 'design methods' saying:

> "…there are just methods out there that people use to research and find out things, and there are methods that people from all sorts of disciplines use and they all massively, massively overlap. So I think, that saying they are design methods is just annoying." (Singleton, 2008)

Designers recognise that each will carry out methods in their own unique way. "One company would do a different kind of Discovery / Insights / Understanding than another. They might do more market research and less ethnography" (Reason, 2008), which illustrates that the way the methods are carried out, are largely dependent on the design team's modus operandi.

There are also different combinations of methods that can happen and that are an important consideration of the Designer of design teams. In the process, the Designer is deciding, "What discipline, or what disciplines to employ. And then what combination" (Lee, 2008). Some design firms, design-led organisations and Designers help catalyse these decisions by keeping a log of their methods in a 'methods bank'. Many practising Designers refer to these methods banks mainly for inspiration[25]. Some example of these include:

- The Netherlands Design Institute, Methods Lab[26];
- ServiceDesign.org, which live|work formally hosted[27];
- Engine's bank of methods[28];
- The Design Council Methods Bank[29]

[23] This included a 3-part narrative of getting locals involved in growing their own food (Grow Zones), developing recipes and cooking (Kitchen Playgrounds) and celebrating the process at an event (the Town Meal).

[24] This included local residents, farmers, allotment owners, café and restaurant owners, communities involved in healthy eating and food growing etc.

[25] In conversations with Designers, many of them mentioned that they visit methods banks for inspiration.

[26] Found at the back of their book, Presence.

[27] See www.servicedesign.org

[28] See www.enginegroup.co.uk

[29] Design Council's Methods Bank includes 2 methods banks. The first is a log of methods, identified from four design project case studies. The second, an open source website that has members contributing practical methods for inspiration and project planning. The latter can be found at: http://www.methodbank.com/cgi-bin/view

But much like the design process models, methods banks can only provide limited value if Designers don't know how to use them with the right people and in the right context.

Using intuition and adapting the design process

The Designers in Dott 07 often used their intuition to guide decisions for design methods in the process[30] (Thackara, 2005: 213). One Designer commented that, the design process is, "an intuitive approach that people just kind of know, or think they know, their stuff at their fingertips" (Singleton, 2008). In some cases, the design process is so intuitive that they "… don't know it off by heart. We have [our methodology] somewhere, all stored. It's very detailed. I'm not sure of the names" (Gormley, 2008). Designers hold a 'design attitude'[31] whereby they do what they need, to get what they want[32]. It is as furniture Designer Bill Stumpf once said, "The sources of invention and new design knowledge are not in the design cookbooks and menus, but out in the vegetable patch" (Alben, 1997: 9). By getting out "in the vegetable patch" (Ibid), Designers connect directly with people and the context, making decisions based on whom and what they are designing for. The project stakeholders of Our New School understood the value of the Designer's having direct contact with the school saying that:

> "… it was good for the Designers to spend some time in the school really, to fact find. I mean, I guess most of them hadn't been in a school since they themselves had been there. Schools are different animals today, so fact finding was important." (Collier, 2008)

The time spent getting to know the school and the students was important in preparing the design team for bringing students into the design process. One Designer from the project spoke about the difference between high school students and adults as participants in the design process. He stated that in any situation, the Designer must, "really hold the attention of the group of people" (Lee, 2008), but outlines where children and adults differ– "in a meeting in a group of adults there is politeness and there is, you know, more responsibility. When they are group of students, when they get bored, they will let you know" (Ibid). The way that the design team sought to overcome this issue was being aware that plans cannot be set in concrete, and being open and adapting to change. The same Designer commented:

> "… you have to be quite nimble with workshops. There is no point in flogging a dead horse. It's certainly something that we wouldn't want to do with teachers, or adults, or schools, or businesses." (Ibid)

The design team equipped themselves with contingency plans for changing the courses of action as the situation evolved:

> "We have a range of things we plan to do, and we have back-ups as well. Because we never really know … what's going to happen, that's the whole point….

[30] One of Thackara's principles for "designing in a complex world" is to move "From blueprint and plan to serve and respond" meaning having the ability "to respond quickly and appropriately when reality changes." (Thackara, 2005: 213)

[31] Boland and Collopy (2004) state that a 'design attitude' approach would "approach problems with a sensibility that swept in the broadest array of influences to shape inspiring and energising designs for products, services, and processes that a re both profitable and humanly satisfying" (Bolond and Collopy, 2004: 3)

[32] A note take from an informal conversation with a Designer

> half way through an activity, you put something else in to mix it up a bit, a wild card or something." (Ibid)

Our New School was not the only project that included students in the design process. The Move Me project included a younger group of students between 7 to 9 years old. The design team here also saw the importance of adapting design methods and process. A Designer on the project stated:

> "… you kind of have to cut the cloth to fit the particular types of people that you are going to be working with… some methods, you will get a good response for the methods, but with other people, you will just get them rolling their eyes to the back of their head and not want to deal with you." (Telford, 2008)

The Dott 07 design teams that involved children demonstrated how open the design process could be to people without design backgrounds. One Designer stated:

> "… to be involved in that process you don't have to be a Designer, you have to be an open-minded individual to share thinking and ideas and Designers help shape your thinking… facilitate your thinking as you go through the process." (Townson, 2008)

In doing so, the design process can unlock valuable contributions to ideas for the project. For example, the Move Me project found lots of value in the ideas generated by the children. "Some of [their ideas] were very realistic, some of them were very imaginative solutions[33]" (Harrison, 2008). By using intuition and adapting the process to suit the people and context, the inclusion of non-Designers is enabled in the design process to add value to ideas through their knowledge and creativity.

Low or no tech design methods, using the "appropriate 'technology"

To enable non-designers to participate in the process, such as school children[34], the Designers in Dott 07 ensured that the design methods were appropriate to the people. All the projects utilised very modest technological interventions because this suited the nature of the people involved. About half the projects set up websites and/or blogs[35] to keep project communities up to date and informed of the project process. The most technological intervention of all projects was the introduction of film-making in Alzheimer 100, which was well-supported with skills training in film and allowed the Alzheimer community to tell and distribute stories of their daily experiences with dementia. On the whole, the Dott 07 projects utilised methods that encouraged the direct experience of people interacting with people, place and artefacts. For example, in Our New School, the design team took students off-site to a performing arts centre where they could identify with the movement of people around a space and contribute fresh ideas for their school:

[33] Harrison (2008) further added, "The children came up with many ideas for transport and to make public transport more desirable, such as "… Bicycles that would fly over the traffic and things like that, and also ideas about the buses and how they could improve some of the facilities on the buses, so people would be more keen to use the buses, you know like televisions and refreshments… spoken information about timetables… nice seating at the bus stop, just making the bus stop more attractive so that people would be prepared to wait for the bus to come."

[34] And at the other end of the spectrum, Alzheimer100 got elderly people with dementia to participate in the project.

[35] Such as Alzheimer 100, OurNewSchool and NewWork projects.

> "… what we got was a much more fertile group of statements and lists of different things that went on. If we had just done it in school, we would have just gotten a list of what lessons they have and what places are there in the school, and not the interesting stuff like the in betweens." (Lee, 2008)

While communities can benefit from using technology in the project process, the Dott 07 design teams utilised "appropriate technology" (Rowe, 2008) ie. Low or no tech methods that suited the communities involved in the projects enabling them to participate.

Engaging and entertaining people throughout the process

Getting people to participate in the design process, requires the Designer to continually inspire action[36] on rather "unsexy" issues[37]. The Dott 07 design teams approached the project in a ways that "… allow[ed] people to identify the problems and become part of the solution" (Gormley, 2008). Both DaSH and Move Me used a method called cultural probes[38]. This method didn't just succeed in bringing great insight into the daily experiences of the communities, but also engaged the project stakeholders in identifying key issues from which they could then generate ideas to overcome. The use of cultural probes were highly engaging and memorable for the project stakeholders[39] in DaSH. Even stimulating them to think about the application of these methods for their own consultation post-project:

> "I would think to myself as being someone who knows how to consult young people, that's part of my job, and hey, I'm good at that. But [the design team] came up with some really interesting ideas… very interesting stuff… called them cultural probes […] I should develop a lot more consultation tools than I've already got!" (Douglas, 2008)

The design teams carefully and thoughtfully assembled the cultural probe packs, and in some cases, parts of the packs didn't directly produced ideas but were crucial in engaging people to participate in the activity. The Designers in Move Me found this to be the case with the cameras inserted into the packs for the children:

> "… we used some interesting things like the cameras for the kids… And it really encouraged them to do it. While the outputs of the photos… didn't lead to any particular [idea], or added to the output of the project… they were still incredibly useful to get the kids engaged and have something to talk around when they were describing their journey." (Telford, 2008)

[36] Ralph Ardill, Founder and CEO of The Brand Experience talk about design leaders needing to inspire and " keep the why alive, all the way through, not just at the front end" of a project.

[37] Deborah Szebeko, Founder and Director of Thinkpublic regularly refers to the issues in health etc as "unsexy"

[38] Cultural probes were first written about by Gaver, B., Dunne, T., Pacenti, E. (1999), and used in the Netherlands Design Institute Presence project. Cultural probes are packs given to people (eg. they could contain cameras, diaries etc) to help stimulate thinking and capture people's experiences in different ways.

[39] The project stakeholders on DaSH and Move Me stated that the cultural probes were one of the most memorable methods used in the projects.

Adding elements of fun and entertainment to the project experience may not always directly contribute to outputs, but are important to catalyse the process.

Making things tangible

Up till now, this paper has largely focused on the design process, but it is also critical to note the importance and value of the tangible aspects of design. The Designer's ability to make things tangible is one of the most valuable skills of the discipline, and in Dott 07 enabled further engagement of the communities. The project stakeholders in Low Carb Lane stated the benefit of visuals in providing a narrative to engage people in the issue:

> "[The Designer] was just taking photos of like the most bizarre things. And I was taking photos of like the boiler, and stuff, really technical stuff. [The Designer] was taking photos of the sign for Castle Terrace and things, and I actually saw a presentation that he gave… and I had kind of pieced together why he'd done it because he was kind of keen that the audience didn't just view it as a really technical project, it was engaging the public with the whole environmental and community energy theme." (Fowler, 2008)

Some of the projects also mapped current situations being faced by the communities. For example, in the Alzheimer100 project, the design team mapped the 80+ disparate services available to people with dementia and their carers to show the vast array of support available with very little means of accessing to them. One project stakeholder mentioned this as a memorable aspect of the project reflecting, "[it was] very interesting to see that there were loads of services out there, but how do you access them?" (Dewdney, 2008). Seeing the reality in a direct, visual and memorable way can encourage a sense of dissatisfaction to the current situation, inspiring communities to take action for change. Management writer, Peter Drucker, states that unless non-profit organisations create 'doers' within it, "[the] institution has had no result; it has only had good intentions.' (Drucker, 1990: 39).

Visualisations are used not just used for idea generation but also for prototyping, and prototyping was found to be highly appealing to the project stakeholders. Visualisation allows people to "think to build and build to think"[40] and in the New Work project, the design team got the project stakeholders to sketch out ideas they had. "So rather than writing it… getting people to sketch makes them put more detail into an idea" which allows them to "… work through the idea more in their head" (Sim, 2008). The design team found that, "once people [got] hold of an idea… they really kick[ed] off" (Ibid). A project stakeholder of New Work reflected, "I think we came up with something like 20 different ideas. It was amazing…. some of the crap ideas, actually merged to become one good idea." (Cooney, 2008)

Visualisations were an important part of all Dott 07 projects, and were also able to raise the level of engagement of the communities as one Designer observed, "… once people started to see things happen, they got more engaged" (Telford, 2008). Further adding that Designers:

> "Don't just think about the issues and write a report and leave it at that, but actually to do something about it. And that's where I think design has the ability to make things look or feel quite real and just can be used and work immediately." (Ibid)

[40] IDEO Partner, Mat Hunter, in a presentation at the Design Council on design leadership.

One Designer sums up that there are:

> "… two key things [about] design methods. There is one thing, which is kind of action-orientated, qualitative, user-centred research thing, which gives a certain kind of stimulus for either new ideas or improvements.... The second thing is the working up of the tangibles of a thing." (Reason, 2008)

One of the most under-recognised skills of Designers is their ability visualise insights and current situations to move communities forward to take action. Then, using craft skills for visualisation, Designers bring tangibility to ideas to catalyse the process even further[41].

The need for confidence in the process

The flexibility and reflexivity in using the design process brings a high level of ambiguity to projects upfront. Designers must be comfortable with ambiguity of not knowing exactly what might come next, and having confidence in their ability and the process, that their skills of adapting will lead to quality results.

> "We have to be confident about the process. You say [to the project stakeholder], 'Well look, at the end of this, you know at the end of this we would have produced the right thing and that we would have also be able to mobilise a lot of people like you." (Gormley, 2008)

But the project stakeholders often found this ambiguity challenging to deal with. One mentioned, "I like to know the end game almost before I start, and I couldn't work that way on this one and I had to work it through to see the completeness of the vision." (Collier, 2008)

Many of the design teams in Dott 07 involved the project stakeholders along the way, and for most, this helped them feel comfortable with the ambiguity and continual adaptation of the design process, as one project stakeholder said:

> "I realised that actually they would be with us each step of the way, they would support [us] at each step. There would be a lot of contact. They just weren't going to be voices in London, they were actually going to be here, hands-on, doing interviews, showing us how to use design." (Williams, 2008)

Doing it with, not for and embedded legacies

In involving the project stakeholders in the design process, the Designers shift the use of design methodology from doing it *for* people, to doing it *with* them[42] (Hofmeester and de Charon de Saint Germain, 1999: 10-21 and Thackara, 2005: 220-5). By engaging the project stakeholder

[41] Thackara (2007a) comments that design-led interventions are for the delivery of "designed outcome[s] and not just a concept. That there is a kind of sense that the project is informed or shaped by the users of the thing, and thirdly that there is a design quality to the whole package, that gives it life, and a quality that is not a kind of PowerPoint presentation from a management consulting company or a glossy booklet to be read by just managers and clients."

[42] The author's pervious practice recognised the potential of doing it with, with project stakeholders.

throughout the entire process, they are given the opportunity to "identify the problem and become part of the solution" (Gormely, 2008), enabling a greater sense of ownership, establishing the project stakeholders as "guardians" (Belk, 2008) to the principles and ideas, and embedding legacies.

Embedded legacies mean the thinking, ideas and practices that have remained and are currently being acted upon by the individuals who participated on the projects. For example in the DaSH project, the project stakeholders have continued to develop ideas for a GUM clinic using the same principles of the design team in taking a macro and microscope of view the service design[43]. The project stakeholders have held onto seeing their service on a high level, whereby "progressing through a [sexual health] service…. you never go back, to the same waiting room, for instance" and on a detailed level where they now "think about where we put the magazines" in the waiting room because "If you put a magazine in a table in the middle of the floor… everybody has to go up and get it and you hate that because everybody looks at you." (Douglas, 2008)

Embedded legacies are not highly visible and usually manifest themselves in tangential ways for example post-Alzheimer100, a branch of the Alzheimer's Society has been prototyping a couples group service and have been taking inspiration from the methods and approaches used in the project to help develop the new services:

> "… we have just started a new group, a couples group, and we have kind of used a lot of things from the design team… it's helped us to look at the ways that, instead of thinking about the service, let's design the service. Let's work and go out and find out, and use different methods as well." (Williams, 2008)

The other key outcome for designing *with* people, is that it has brought is an awareness and confidence to people's creativity. Harvard Business Review once reported that when we get to the office, creativity gets at left at the door, but the Dott 07 projects sought to engage people in "creative endeavours" (Middlesbrough Council, 2008), and in doing so developed confidence in people bringing their creativity to work. One project stakeholder stated that the Dott 07 project gave her insight into, "skills I probably knew I had, but I had never, kind of, used them. We were always a little bit fearful of maybe taking that step" (Williams, 2008). Creativity is valuable to organisations and communities in the creation of new ideas and is also highly satisfying for individuals. One Alzheimer100 project stakeholder articulated her reaction to seeing their work on display at the Dott Festival as, "Wow! I never ever would have thought I would have ever been involved in producing a piece of work like this" (Ibid). Project stakeholders are now going forward with their ideas for developing and delivering services, but in new and different ways, demonstrating embedded legacies and the impact that involving people in the design process can potentially have.

Creating champions

Many of the Dott 07 projects have had significant impact on the way the projects stakeholders now approach thinking and doing in their work. In some cases, project stakeholders have become "guardians" (Belk, 2008) of principles and ideas. But only time will tell if these project stakeholders become "hosts" (Reason, 2008) for the ideas, actively carrying and sponsoring the ideas in ways where they take on a life of their own. It will be interesting to

[43] In an interview with Designers on DaSH and Move Me, they spoke about their role as taking macro and microscopic views of services, both becognising the big picture and paying attention to the detail.

observe if these project stakeholders evolve into champions for sharing new approaches of thinking and doing, while challenging the status quo in their own organisations and contexts.

Starting a conversation about measuring design

Throughout the data collection, it found that anecdotes and examples were one way to identify the impact of design projects. While this paper does not aim to discuss the measurement of design, the research has started to question what would happen if we shifted our focus from looking at design outcomes, to the impact it has on the people involved. One implication the research has found is that identifying the impact design has had on people needs to happen over time[44]. Interviewing the project stakeholders 6-12 months after the project completion allowed for reflection on how learnings from the projects manifested in other activities that have happened since Dott 07. Learnings weren't exclusive to the project stakeholders either. On the Designer's side, the projects of Dott 07 have, "…just added to our pot of experience and it will manifest itself in other projects in ways that I have not yet considered." (Townson, 2008)

Concluding remarks

The public commission projects of Dott 07 offer a unique opportunity to reflect on the changing nature of design methodology both in and of it self. The conclusions made in this paper can only be indicative (given the point in time of this PhD research programme) but if design is to make contributions to new and different situations, then continuing awareness, understanding and reflection on design methodology is important in catalysing this emergent area of design.

Further research questions and opportunities

The research programme still has a significant amount of time to reflect on research and data collected and to be collected. Further questions that have risen throughout this research programme for reflection and research include:

- Can Designers transform communities of purpose into effective communities of practice?
- Do Designers working in the public sector have the ability to connect people to policy (and in the private sector connect people to strategy)?
- What kinds of new value are Designers bringing, and could potentially bring, to the public sector and public life?
- What kinds of business models are needed to facilitate new uses of design methodology?
- What qualities of design leadership are needed for designing in the public sector?

[44] A wonderful example of how design in public life doesn't stop when just because the Designers job is done is Federation Square in Melbourne Australia. The cultural prescient continues to be widely enjoyed and used by locals and visitors to the city, many years after it's design and construction.

- What is the changing role of the Designer in projects such as these[45]?
- What design skills need to be developed for designing in the public sector?
- What new evidence bases are needed to demonstrate the value of design in the public sector?
- What needs to be down about bridging the language gap between design and the public sector so we can connect better with project stakeholders?
- How do we inspire other Designers, students and professionals, to see the potential for design in this new and different area?

[45] The former RED Unit at the Design Council called attention some philosophical and practical challenges facing Designers working with social issues. These mainly have to deal with evolving from being “traditionalists” to “transformers”. Some of these challenges include: Sharing the creative authorship; “Shaping behaviour rather than form” and bringing transparency to the design process and “exposing the principles and skills of design to enable us to design with people rather than for them” (RED, 2006).

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Social Design:

Exploring the systemic conditions of sustainable change

Suk-Han Tang[1], Louis Klein[2]

Abstract

This paper gives a very broad definition of social design and explore in a narrative way different projects from around the world, presenting the possibilities of what we, as a society could do differently today. On the first chapter, the SocialDesignSite gives its broad definition of social design and framing the approach of the project and the necessity of impact evaluation. Looking at factors for successful change, the second chapter elaborates on awareness as being already a step for change, followed by the necessity of bringing leadership through innovation and facilitating the change process, and at the end presenting an example of sustainable community, ecologically and socially sustainable. This paper identifies the important factors necessary for successful change.

[1] SocialDesignSite.com, Project Manager, suk-han@socialdesignsite.com
[2] Systemic Excellence Group, Consultant, louis.klein@segroup.de

1. The SocialDesignSite

Elaborating on sustainability and directions for change, it is essential to think about social design and explore the possibilities first. The term social design appears regularly in a wide range of contexts across the globe, though it is put to different uses and given very different meanings. In 2006, the Systemic Excellence Group, Independent Think Tank for Leading Practice based in Berlin, launched a non-for-profit project in order to explore the existing conditions of social design and in which form this could take place.

The social world is created as a result of the dynamics of all our individual actions and the term “social” is commonly referring to boundaries of society where social design failed; we tend to focus on issues found on the borders of the society, and not in its central active part. However, by focusing only on those boundaries, we lose the sight of the very heart of what is working in the society and the possibilities of what could be improved, or be done differently not only in the future, but also at present. This is also referring to active practices.

Sophie Dubuisson-Quellier, a French sociologist describes “political consumerism”[3] as actions that take two different forms: one is the passive form, called “boycott” and the other is the action form, known as “buycott”. In the 50’s Martin Luther King organized in the town of Alabama what will be called “boycott”, the action to refuse to buy or take part in an activity as a way of expressing strongly disapproval, in order to protest against the bus that were practising racial segregation toward the black community. The buycott is the practise that is looking to promote production and consumption of products that has an ethical consideration, such as national products, eco-labels, food without genetically modified organism or products from fair trade. That notion aims to restore in the political debate the involvement of consumers that choose producers and products according to their ethical and political considerations.

As such, and in a broader sense, we want to bring back the term “social” in the heart of society and by bringing back the responsibility of every single individual action to the people, we bring it back to the society.

We cannot not be social.

We cannot not design.

We cannot not change the world.

We refer the term “design” to everything that is man-made. “All we do, almost all the time, is design, for design is basic to all human activity.”[4] Design, in this sense, is any circumstance that is a result of and condition for action. It is there whether we are aware of it or not. It is inescapable. In everything we do, we constantly shape the world we live in and any actions will always have consequences on our social world.

Social design is then a great opportunity and at the same time a great responsibility because it relies on the choices we make every day. It is the perception of a man-made reality that consequently can only be changed by man.

We established research in social design in order to gain a perspective, understand and gain knowledge of models, methods and instruments available in order to evaluate the impact on the social world and explore the possibilities of what we could do differently. Our ambition as a think-tank is to illustrate the inescapability of social design and social responsibility by creating a portal that would enable the possibility of social impact evaluation on everything linked to human activities and in establishing a vivid exchange and learning platform for a broader understanding of social design.

Our approach is not defining social design but rather fostering a discourse on the topic. At

[3] Rymarski, Christophe. ‘Etes-vous plutôt boycott ou « buycott »?’ Hors-série Sciences Humaines, no49, July 2005

[4] Viktor Papanek: Design For the Real World, 1971

the launch of the projects, initiators were invited to take part of the project and being asked if they would contribute in defining social design. The SocialDesignSite, was at its beginning consisted of 20 projects from various disciplines, from individual artist work to big communities. At that time, we clustered social design in different categories (social philosophies, social experiment, systems for living, art based, cultural based, modern artifacts, web based, intriguing) categories that have been transformed over and over again and finally dropped. Coming up with such a broad definition, we realized that the content of the website and the definition(s) of social design is an ongoing process and should be processed in a co-creative mode. One year later, in 2008, we involved members in defining social design, by creating a cloud navigation where each registered member can choose and propose any keyword in defining their project. By then, we realized the two words “awareness” and “community” were used by many and to date, we have more than one hundred social design projects and the number is constantly growing.

Some of the factors identified both from a systemic theory approach and from practical approach based on impact evaluation for successful or so-called sustainable change will be presented in the following chapters.

2. Creating awareness

Sustainable change is about exploring the possibilities for creating a meaningful practice of life and in order to understand change, a reflection on social technique is then necessary. Any kind of change starts with awareness. By observing and realizing where we are today, we are already taking the next steps for change. This is what the SocialDesignSite is aiming at. This will allow us on one hand to gather models, methods, instruments in use and give us the possibilities to evaluate the impact on those instruments and feed the evaluations back to the design. One of the first projects we invited on the website was MASSIVE CHANGE[5], a project started in 2002 and calling for greater public discourse and personal responsibility for designers and their projects.

“For most of us, design is invisible…until it fails.” Bruce Mau

Founded by “Bruce Mau Design” and the “Institute without Boundaries”, Massive Change explores and investigates ideas, people, capacities and ethical dilemmas of design in manufacturing, transportation, urbanism, warfare, health, living, energy, markets, materials, the image and information. Using a wide range of media, Massive Change has taken on the form of a blog, an online forum, a traveling exhibition, a book, a series of public events and a radio program. The project attempts to facilitate collaborative thinking among people who contribute to designing the world and manage interconnectivity of the world, wanting to explore to future of design and calling for greater responsibility for designers.

Massive change is not about the world of design; it's about the design of the world. An ambitious effort begun in 2002 to explore the future of design; attempting to chart the bewildering complexity of our increasingly interconnected and designed world. The project is conceived as "a network that grows exponentially every day," states Bruce Mau, founder of Bruce Mau Design and the chief architect of the Massive Change project.

> “Design has emerged as one of the world's most powerful forces. It has placed us at the beginning of a new, unprecedented period of human possibility, where all economies and ecologies are becoming global, relational, and interconnected. To understand and harness these emerging forces, there is an urgent need to articulate precisely what we are doing to ourselves and to our world. This is the ambition of Massive Change. It is a celebration of our global capacities but also a cautious look at our limitations, encompassing the utopian and dystopian possibilities of this emerging world, in which even nature is no longer outside the reach of our manipulation. Engineered as an

[5] http://www.massivechange.com

> international discursive project, Massive Change: The Future of Global Design, maps the new capacity, power and promise of design"

The future of design is fundamentally collaborative so discussions must go beyond the design field itself to the broadest possible audience. Instead of structuring the Massive Change project around professional design disciplines, like graphic design and industrial design, its creators looked at design from the perspective of the citizen. The events, the book, and the growing online community are short cuts to provocative thinking about the power and promise of design and are intended to encourage people to think about and ultimately, influence design.

On an individual inter-action level, "We are We Are What We Do"[6] is a social movement that proposes and promotes small and easy changes to implement in our everyday life and to bring immediate change to the world we are living in. Initiated in the UK, it defines itself as a social movement (not a charity, not an institution), a movement driven by human momentum and an ability to balance artfully on their neighbor's shoulders. The initiative was set up with a modest social design instinct. We Are What We Do are promoting the idea that small and easy changes in our everyday lives can lead to significant large scale change. Their first book, Change the World for a Fiver, contained fifty simple actions that everybody could do. These actions work in isolation. But they work even better when done together. There are actions to compel us to find out how our money is invested, why we should shop locally, to learn a joke and to write to somebody who inspired us. We Are What We Do explain their perception of social design and the situation in the UK like this:

> "We are We Are What We Do, understand social design to mean the way in which people influence each other. If you imagine that people are like billiard balls on a billiard table, glancing off each other, knocking into one another, being pocketed then we would rather not play; thanks all the same. We would much rather believe that people are capable of influencing each other, interacting with each other, standing on the shoulders of each other to create social change and influence this world that we live in.

Although change starts with awareness, the directions for change are manifold and in order to achieve sustainable change, a group of individuals need to share common values and brought together for designing their common future together.

3. Facilitating change

Social systems tend to do what they are used to do. Individual agents provide variation by providing a large range of actions, by doing things differently. In the mechanism, we select things we will never do again, and retain only things that can be part of and integrated in a system. This applies to any kind of human activity. Change can be seen as an ongoing oscillation between self-recognition and self creation. Recognising where we are today, observing the current status, finding the next step for direction for change. It is also about whether we continuously improve within the existing paradigm or we want to do something differently.

The two following examples illustrate remarkably the process of facilitating change in two different disciplines, one in improving the social and interracial conditions of a community and the other as an illustration of social entrepreneurship in establishing and creating businesses in villages in Indonesia.

Crossroads Charlotte[7] is an initiative that uses imagination and storytelling to involve a community in choosing the path of its future.

[6] http://www.wearewhatwedo.org
[7] http://crossroadscharlotte.org

The project began in 2003 in response to a 2001 Harvard social benchmarking study that ranked the Charlotte, NC community next to last in levels of social and interracial trust out of 40 U.S. communities surveyed. This was particularly alarming for a new south city that has struggled for decades with Black and White issues, and now finds itself growing rapidly more diverse, with an exponential rise in Latino and Asian populations. The survey presented a disconcerting juxtaposition: while Charlotte is heavily engaged in faith-based giving and volunteerism, at the same time, it revealed that the generous residents were distrustful and intolerant of people unlike themselves.

Crossroads Charlotte is a civic initiative that presents four plausible stories about the future of Charlotte, NC built on shifts in driving forces such as demography, education, economy, growth and land use, community resource allocation and civic engagement. The stories are presented in live sessions involving actors, poets, readers and facilitated dialogue in a group setting where the community is asked to hear and respond to these stories.

This project is designed to involve leaders and community organizations in meaningful dialogue and to promote individual and organizational actions that will build social capital and promote access, equity, inclusion and trust. They opened an exhibit at the Charlotte Museum of History that features multi-media versions of the stories and highlights from the four stories on dedicated panels. Visitors were asked to view the stories, talk to others and ask themselves: "What can I do to help steer the community towards a positive future and away from a negative one?"

The Seed Program: "Social Enterprise for Economic Development"[8].

The SEED program is a collaborative program of the Asia Research Centre at the Chair of International Mangement (South East Asia), University of St. Gallen and the School of Business Management at the Bandung Institute of Technology. Students participating in the program came from the University of St. Gallen, the Singapore Management University and the School of Business Management at the Bandung Institute of Technology, and are either undergraduate or graduate students.

This project is an example of facilitating changes in business and this program is particularly remarkable in its approach by involving multicultural communities in finding and developing viable businesses. In December 2007, 20 students coming from Singapore, Switzerland and Indonesia gathered to research market opportunities in a community involving 4.000 people living in different villages in Indonesia. Participants lived with the villagers for three weeks, and worked together in finding and developing businesses, taking in account the local resources, culture and climate. At the end of their stay, students and villagers came out with five areas of businesses they could produce (honey production, dried fruits, yoghurt production, organic vegetables, tourism activity) which they then turned in professional business plans and presented the opportunities to Indonesian investment companies.

During the experience, villagers realized their own potential; actively participating in building their future business and at the same time developed their research and market skills. It is also remarkable to note that the program connected the different villages in working together and not competing against each other. The activities developed were financed and a follow-up program will take place again in 2008.

The success of this project lays on the involvement of all concern parties in taking part of the change, bringing in some experts, observers, students, businesses and villagers together in sharing knowledge, implementing new products by taking in account the local resources and cultural ground.

Facilitating change open up the creative process in designing common future. It is about creating common visions, putting together all concerned individuals, taking in account everyone needs and wishes, individually and as a group for shared directions and processes for change.

[8] Daniela Beck, Ph.D.Candidate University of St.gallen, interview

4. Sustainable development

At last, without aiming for sustainability, any kind of change would have a limited impact. Sustainability was officially defined by the United Nations in 1987:

> "Humanity has the ability to make development sustainable to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs."[9]

Applying sustainability to social design, we'd argue that sustainable change is one where all parties involved are aware of what it is, what it can be, sharing responsibility and knowledge, encouraging innovation and participation and developing groups and individuals. It is therefore very much related to creating communities, whether physical or virtual, where all individuals take part in the change process. The following example is the Findhorn Ecovillage[10], providing a tangible demonstration, linking the ecological, social and economic aspects of life and is a synthesis of the best of current thinking on sustainable human settlements. It offers solutions to human and social needs, while at the same time working in partnership with the environment. Thus, the Findhorn Ecovillage endeavours to create a climate and conditions for people to live in greater symbiosis with nature and each other.

Community participation and involvement are integral parts of this human-scale experiment. The ecovillage community has been involved in the erection of buildings, wind turbines and the creation of other physical projects, as well as engaged in the development of community policy. Experiments with alternative monetary systems pay and remuneration, festivals and celebrations, consensus decision-making, conscious governance and leadership, continue to evolve through experimentation and experience of everyday life. A culture of continual learning combined with the intention to help find solutions for a better world, are cornerstones of the community's common ethic developed over four decades of its existence.

The Findhorn Ecovillage is comprised of businesses, non-profit organisations, cooperatives, individuals and families. It includes community-wide, local and international initiatives - all working together as a conscious response to the complex problem of how to transform human settlements so that they are harmlessly integrated into the natural environment. Combining alternative technologies, sympathetic building techniques and organically defined social structures, the Findhorn Ecovillage provides a healthy and sustainable home for its inhabitants within the Scottish landscape and sees itself as a template for living in a modern world.

5.Perspectives

As a portal for social design, situations where several projects compete with each other arise. In order to open up the process of exchange, it is then essential to be as transparent as possible. The evolution of the project will be gathering projects owners to relate, share knowledge and gain experience from each other.

As well as developing partnership, it is important to meet and discuss with social actors, and our participation to and organisation of workshops and conferences is one step toward knowledge sharing.

Such events will help us for continuous improvement and will be made available for everyone as a permanent knowledge and evaluation tool and help future social designers to build up their project or consolidate existing ones.

[9] www.ecovillagefindhorn.org

[10] Brundtland Report, UN-1987

The ambition is to put social design impact evaluation on the agenda of the leading discourses of society, i.e. politics and economics. As all political and economical action is inescapably social, the actors and institutions should be aware of the social impact, creating our social world. Prior evaluation might be recommendable.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Beyond 1000 Suns

The usage of 'design culture' to create a new paradigm for a hybrid heat-and-power solar system

Ezri Tarazi[1]

Abstract

As the population of the world continues to grow and energy demand continues to increase, there is an urgent need for sustainable and renewable energy systems that will satisfy the demand, while reducing the need to utilize more fossil fuel or build additional nuclear power plants.

The role of industrial designers can be crucial for the success of any such solution. By introducing a proper industrial design process to the R&D effort, any project will benefit from the wide range of skills, knowledge, inventiveness and vision of the designer.

The design process of Z10, a new paradigm for a hybrid solar heat and power system, will demonstrate this assumption. It is a 10sqm solar dish system utilizing a new way of concentrating solar power that can provide hybrid power and heat energy by tracking the sun and using a concentration equal in power to almost 1000 suns in mass production ways.

[1] Associate professor, Bezalel Academy of Art and Design (Israel) – Industrial Design Department, Master's Degree Program. ezri@tarazistudio.com

1. Concentrated Solar Power - Background

As the population of the world continues to grow and energy demand continues to increase, there is an urgent need for a sustainable and renewable energy system that will satisfy the demand without the need to use fossil fuel or nuclear power. Technologies of Concentrating Solar Power (CSP) can be a major contributor to the future need for new, clean and affordable sources of energy. Solar power systems use the rays of the sun – solar radiation – as a high-temperature energy source to produce electricity by means of a thermodynamic cycle.

The need for concentrated solar power has emerged due to the fact that solar radiation reaches the earth's surface with a density (kW/m2) that is sufficient for heating systems but not for an efficient thermodynamic cycle through which electricity can be generated. This means that density has to be increased, and that the incoming solar radiation must be concentrated by using mirrors or lenses.

The first commercial plants to accomplish this were designed by LUZ in Israel, and they have been in operation in California since the mid-1980s, with 354 MW of solar power installed. In the meantime, a variety of technological approaches have been developed for different market sectors. These approaches are currently at different levels of maturity. The main concepts used in CSP technologies are parabolic troughs, solar towers or dish/engine systems, which vary according to the concentration devices, energy conversion methods, storage options and other design variables.

The performance of a Photovoltaic solar cell is measured in terms of its efficiency in turning sunlight into electricity. Only sunlight of certain energy levels can work efficiently to create electricity, and much of it is reflected or absorbed by the material that makes up the cell. Consequently, a typical commercial solar cell has an efficiency of 15% — only about one-sixth of the electricity-generating potential of the sunlight striking the cell. Low efficiency levels mean that larger arrays are needed, which means higher costs. Improving solar cell efficiency levels while holding down the costs per cell is an important goal of the PV industry. The first solar cells, built in the 1950s, had efficiency levels of less than 4%, but it is very hard to break the 20% efficiency limit. Newly developed low-cost Photovoltaic cells with thin film produce between 6% - 8% efficiency.

2. Objective

The objective of the project was to achieve a breakthrough in the field of Photovoltaic (PV) cells: to design an efficient solar concentration system which will combine the production of electrical power with twice as much energy in the form of hot water. This will make it possible to produce an affordable product that would compete with traditional energy production even without government subsidies.

3. Global Team of Experts

One of the most important keys for success today is the ability to establish and manage a global team of experts. In order to solve global problems, there are now the need and the opportunity, more than ever before, to recruit, for each project, the best experts on the issues that are at stake. For this project, we put together a multinational, multi-disciplinary team. The CEO[2] of the project has a large experience in the hi-tech industry including the know-how of Venture Capital systems. The Chief Scientist[3] of the project is a world-renowned scientist from Israel with over 30 years of extensive work in the field of photovoltaic and solar energy. The CTO[4] is from Australia with more than 35 years experience in solar concentrating dish systems, as well as a developer and inventor of numerous systems and patents in this field. Another very important key scientist[5], in the team is from Germany and he bring to the project his expertise in development of solar PV cells in high concentration.

The team have a link to an important institutes, like the: Israel's National Solar Energy Center, located at Ben Gurion University, Jacob Blaustien Institutes for Desert Research at Sde-Boqer, the Solar Research Center in Australian National University, Canberra, Australia, and the Fraunhofer Institute for Solar Energy (ISE) which is the largest solar energy research institute in Europe today.

The team also includes other key members from Israel, USA, France, Italy and Germany. Although they are not mentioned here, they all play an important role in the development of the concept, either from a technological point of view, manufacturability, site installations, or with regard to the business development side of the project.

4. The Benefits of 'Design Culture' in a Technological Start-Up Project

The participation of a chief design officer (CDO) and a design studio team in the process of developing a product has a positive effect on any company. When it comes to a technological start-up project, the benefits can be crucial. The design culture is different from the 'engineering' or 'scientific' culture. The synergy between these cultures can create many benefits and enhance to the start-up project's chances of success. Some of the basic principles of the 'Design Culture' are:

- **Vision & imagination:** the ability to quickly and tangibly translate technological ideas into a product concept, scenarios or services, or in other words - the ability to convert this vision into a 'design story' and create a persuasive picture that would convince the partners and investors.

- **Visualization:** the ability to create desirable images that would describe, in an emotional and aesthetic way, the 'future' that the project promises. The ability to visualize the end-product in its natural environment, or as a replacement for an existing product.

- **Human-centered thinking:** the ability to create 'step-by-step scenarios' that would enable the developer to render the human perspective using the product or service in reality. The ability to intuitively guess what the individual would like to

[2] Roy Segev, founder and CEO, former founder and partner at a venture capital firm 'SADOT'.
[3] Professor David Faiman is a director of Israel's National Solar Energy Center, located at Ben Gurion University, Jacob Blaustien Institutes for Desert Research at Sde-Boqer.
[4] Engineer Bob Whelan, former CTO at the Australian National University, Canberra, Australia.
[5] Dr. Andreas Bett, the head of the solar cells III-V group in the Fraunhofer Institute for Solar Energy (ISE), Freiburg, Germany.

have or use or how the individual would like to behave with or around the product. The ability to imagine a 'frustration-free' user-interface and smooth shifts between modes of operation.

- **Wide range of know-how:** the ability to share the diverse technological and marketing information and experience gained from working with various clients. The ability to combine ideas and methods from different and sometimes contradicting fields and disciplines.

- **3D expertise:** the ability to apply the skills of 3D computer solid modeling and graphics to the engineering process. In the context of the solar power project, for example, the optical properties of light and reflections were created by the add-on software used in addition to the solid modeling software that was used originally.

- **Creativity leadership:** the ability to lead creative sessions using various methods, like brainstorming, sketch-storming and think-tank sessions.

- **Culture analysis:** the ability to investigate and analyze social trends and behavior patterns and anticipate reactions.

- **Branding from day one:** the introduction of a design branding and company identity at a very early stage enables the start-up project to establish a strong position vis-à-vis new clients and investors.

5. The "Fostering Goods" Design Process

In this project, it was important for the team to refer to the project as a mass-production system, and not as a scientific 'one-of a kind' prototype. The design process, "Fostering Goods" was used to lead the project through its various phases. This methodology was created by Tarazi Studio, and is used by us with other companies with which the studio works. The process is based on seven phases. Each of the phases is related to a natural process of growing organic plants. This terminology is aimed at focusing the mind to the way nature works.

It is important to mention that the term "Strategy" that we use so often in the design process came to the business world from the realm of military terminology. Strategy is a term that describes "the art of war". Evidently, this metaphor needs to be replaced for the future of the business way of thinking that wants to focus on a renewable and sustainable future. The global economic world should not be regarded as a war zone, but rather as a garden, whose fertility and well-being we need to keep and sustain for our own well-being and sustainability.

The seven phases of "Fostering Goods" reflect this change of metaphor by using the stages of growing fruits. The names of the phases are as follows:

- **Phase 1 | PLOWING** | The preparation of the design brief, setting the project scope, objectives and goals, technological context and research objectives, budget and resources, marketing and purchasing considerations.

- **Phase 2 | SOWING** | Various types of research activities: technology study, materials and process analysis, user observations and interviews, global trends study, benchmark parallel developments, establishment of fundamental territory.

- **Phase 3 | GERMINATING** | Ideation processes of "mind-storming", "sketch-storming" and other creative processes that end up producing a substantial bank of ideas.

- **Phase 4 | BUDDING** | Selection of ideas. Developing several design concepts and creating a visual and emotional vision of the product or product line.

- **Phase 5 | FLOWERING** | Detailed design for each of the design concepts, preliminary engineering and production considerations.

- **Phase 6 | RIPENING** | Full design specifications for manufacturing described in a 3D file and/or by a prototype.

- **Phase 7 | HARVESTING** | Transforming the design into a product and introducing it to the marketplace.

The seven phases of the design process enable the team to change “frequency” according to need. Each phase has a unique taste as well as the freedom to think and to dream. There are other 2 important phases, which comes after HARVESTING, not yet implemented in this case study project, and they are aimed at transforming the process from a linear line to a helix cycle:

- **Phase 8 | COMPOSTING |** Auditing and analyzing the design effect and the true value of it through the various aspects of usability, desirability, reliability, satisfaction and ecological footprint.

- **Phase 9 | FERTILIZING |** New “High View” Introduction Design Brief, and collection of ideas for the next generation of product, system or service.

6. The Design Development of Z10

The development of Z10 was based on a high concentration 400 sq.m parabolic dish that was developed by the Ben-Gurion National Solar Energy Center in Sde-Boqer. Z10 is a much smaller collector, based on a 10sq.m solar dish system utilizing a new way of concentrating solar power that can provide hybrid power and heat energy by tracking the sun. This ability to provide distributed power for domestic demand establishes the technology of concentrating solar power as one of the most promising viable-energy option for the future.

Z10 constitutes a new paradigm in the solar energy field because it uses a hybrid system, capable of concentrating the sun almost 1000 times to generate combined power (2kW) and heat (5kW). In addition, Z10 transforms the industry from one uses flat PV panels to one that utilizes a dish apparatus which, by using simple mirrors, can concentrate the sun 1000 times into small but very efficient PV cells that can convert the sunlight into electricity at efficiency levels up to 30% and generating hot water at 45%% efficiency, which altogether generates energy at 70-80% total efficiency.

By introducing a systematic industrial design process into the R&D effort, the project has achieved a dramatic reduction in costs through the introduction of very large parts using the technology of injection molding. It has also achieved a breakthrough in optical efficiency by achieving almost 5% of flux distribution through the use of over 1000 small flat faceted mirrors, employing CAD systems in a new way.

The new design process intends to deploy the product on the tops of buildings located near houses, in order to achieve proximity to the energy user and to avoid any further damage to the open environment.

Producing electrical power from the sun is still more expensive then coal or gas generators, even when oil prices have more than doubled over the last 2 years. The main reason is that with the current paradigm of flat PV and thin-film PV, the calculation of the price of polysilicon with the low efficiency (~10%) of these panels is not economical. Z10,

with possibly other projects developed in the field of Concentrated Solar Power, may change the formula. The introduction of a ‘design culture’ into the R&D process enabled the project to be directed into manufacturability, and then made it more feasible with a better chance of replacing conventional fossil fuel or atomic power plants.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Metadesign tools

Designing the seeds for shared processes of change

Mathilda Tham[1] and Hannah Jones[2]

Abstract

This paper introduces design tools and approaches developed to invite and support higher levels of synergy in collaborative practice. The tools that are introduced through three individual cases have been used to prompt a proactive and imaginative engagement with the sustainability imperative.

These individual cases challenge the very boundaries of design. The idea of 'metadesign' is adopted to advocate design that operates at systemic levels, that invites interdisciplinary collaborations and that seeds or sets up the conditions for emergent processes of change.

The cases represent the fashion industry at mass-market level in Sweden and the UK, the design, production and export of home furnishings in Indonesia, and an (AHRC) funded interdisciplinary design project in the UK entitled 'Benchmarking Synergy levels within Metadesign'.

1. Introduction

The ultimate context of this paper is the sustainability imperative, and the potentially significant power to yield positive change that design and designers have. (See e.g. Keoleian and Menerey 1994; Thackara 2005)

Although it is gratifying that the sustainability discourse has finally reached the public domain and corporate agendas, the journey towards transcending our current collective conditioning to short-termism, immediate revenues, and a narrow context of decision-making, still lies ahead. The scope of the challenge facing humanity demands imaginative and systemic action and a creative and auspicious organisation of human potentials and natural resources. It necessitates change that not only engages with the substitution of materials and processes, but that addresses the speed and scale of a producer and consumer culture.

The sustainability imperative thus invites the designer into more strategic and systemic territories, and into a more complex set of collaborations; working with other disciplines, with users, and with representatives of wider human and environmental concerns, than what 'design as usual' implies. It suggests the need for a design that invites its participants to operate with fluidity at a wide range of cognitive levels, and to cross-fertilise ideas of different levels of complexity.

Meta-design, the design of design, offers a framework to make such a leap in mindsets and in practice. It can be described as 'a shared design endeavour aimed at sustaining emergence, evolution and adaptation', and 'open-ended and infinite interactivity capable of accommodating always-new variables'. (Giaccardi 2005)

By synergy we mean a condition where the whole is larger than the sum of its parts, where new qualities emerge that were not available from initial components before their *coming together.* The notion of synergy is therefore closely linked to emergence. This paper introduces design tools and theories that have been developed to invite and support higher levels of synergy in collaborative practice.

The tools share four aims:

- To bridge the gap between professional and personal value systems, for a more holistic and embodied engagement with the sustainability imperative;
- To set up conditions for shared learning experiences on several cognitive levels;
- To offer a framework for opportunity focused and imaginative explorations of sustainability;
- To invite engagement with more strategic and systemic designer roles.

The tools that we propose have been developed and piloted through several cases, three of which will be presented in this paper. The first case is situated in the fashion industry's mass-market segment and describes how a rich epistemological framework spurred an extended notion of design. (Tham 2008) The second case, a workshop with designers and manufacturers in Indonesia, shows how the bringing out of tacit knowledge and unspoken values can foster a new sense of community. (Tham and Jones 2008) Finally, the third case, an interdisciplinary workshop, at Pines Calyx in Kent, explores the use of story-telling within a broader framework of tools designed to guide participants through a process of team 'potential realisation' (Fairclough 2005).
('Benchmarking Synergy Levels within Metadesign' project 2007-2009 AHRC funded project at Goldsmiths, University of London.)

Lucky People Forecast, April – June, 2006

Context

Fashion, intrinsically thriving on change – and therefore, according to current modes of doing design, dependent upon a large material throughput. Fashion epitomises wider unsustainable tendencies in society such as the satisfying of needs through surrogates, and a disassociation from the real sites and effects of production, the human and environmental conditions of making everyday artefacts. The fragmented perspective of the fashion system is carried through into the fashion company's structure. Work is highly specialised, which means that designers and buyers rarely work directly with environmental officers and sustainability not appreciated as a shared concern.

Yet, the fashion system also manifests qualities that appear compatible with a paradigm of sustainability, such as an acute in-tuneness with time and space, the sense of empowerment that can come from personal expression and a sense of belonging. At best, fashion celebrates a creativity that operates on rich tacit, visual and experiential levels.

This first case formed part of a PhD thesis, *Lucky People Forecast – a systemic futures perspective on fashion and sustainability.* (Tham 2008) The aim of the study introduced here was to harness positive qualities of the fashion system for more sustainable ends. More specifically the study sought to extend the vision of fashion, beyond product level, and beyond the immediate future. To this end, eight creative workshops with mixed fashion industry stakeholders in Sweden and the UK were set up featuring a range of activities introducing the proposition 'What if fashion and sustainability were compatible or even synergistic?"

The framework for the tools and approaches used in the workshops was threefold:

a) methods and processes that further sustainability literacy – e.g. on a practical level the lifecycle concept; and on an epistemological level the holistic engagement with learning that Action Oriented Research proposes. (See e.g. Heron and Reason 2001);
b) methods and processes in design (e.g. drawing, making, visual and emotive language) and in design research (e.g. the cultural probes approach, Gaver 2001);
c) methods and processes in Futures Studies, such as futures stories and scenario work (see e.g. Slaughter 2001), and a discourse celebrating multiple perspectives on futures (see e.g. Sardar 1999).

Process

Each of the workshops constituted a three-hour session, which took the participants from an initial mapping of fashion and sustainability respectively and together to a scenario task that generated visions for fashion in the context of sustainability in the year 2026.

For the purposes of this paper two of the tools that were developed for and explored in the study are introduced. The first was designed to facilitate group cohesion, and to situate sustainability in the individuals' personal ranges of experiences and skills. The second tool was employed as an evaluative framework of the change that the workshops spurred.

Exemplar tools

- The cultural prop tool
- The four-dimensional attitudinal change framework

The cultural prop tool was inspired by the cultural probes approach, some important properties of which are that of transcending the "understood social roles of researchers and researched…" and eliciting both informative and inspirational material. (Gaver 2001) The new tool uses everyday objects to spur personal narratives on a particular theme. The embryo of this approach was first developed in the Stored Wisdom project. (Sadowska and Tham 2005) The term *Cultural Prop* was coined in the 'Benchmarking Synergy Levels within Metadesign' project, 2007-2009.

In this specific case, the participants were asked to bring into the workshop two objects, representing their personal experience of fashion and sustainability respectively. At the beginning of the session each individual drew the objects of choice and made a list of associated keywords. In a show-and-tell session, drawings and keywords were shared in the group, and all keywords entered on post-it notes that were placed on a big piece of paper. Together the group organised the keywords into themes or 'islands', which were given descriptive names. The result was two maps, or snapshots, of the group's understanding of fashion and sustainability. These documents visualised, embodied and qualified the individuals coming together and their emergent new identity as a group. The maps proved valuable reference points as the group progressed to futures scenarios of fashion in the context of sustainability.

Evidence from the study suggests that the tool can operate on several levels:-

- It can provide a diagnostic framework to quickly get a sense of a group's interests and knowledge;
- It can serve a non-intrusive 'ice-breaker' that quickly draws out the distinctive nature, richness and diversity of a group;
- It can help to situate abstract concepts in an individual and group's personal experience and to integrate new information within an existing body of knowledge;
- It can offer a bridge between personal and professional value systems and identities, and facilitate the finding of common ground between people of diverse professional roles and experiences;
- The situated story-telling approach can facilitate the verbalization of tacit knowledge and foster a shared language across disciplines, professional roles and cultures.

The second tool, the four-dimensional attitudinal change framework is an evaluative tool developed in order to qualify the changes provoked by the intervention that the workshops constituted. By representing a sprawling rather than linear model of change, the tool addresses at least a degree of the complexity that sustainability entails.

The four dimensions of the framework are:-

- Brand/perception - The subjective experience of the compatibility of fashion and sustainability, on a continuum from dichotomy to opportunity.

- Knowledge and awareness - The level of knowledge and awareness of sustainability in the fashion industry context, on a continuum from single issue focus to lifecycle perspective.

- Relationships - The location of personal and professional self in the realm of sustainability, and engagement with the intricate relationships that sustainability implies, on a continuum from partial to holistic understanding.

- Action and activism - The perceived power, and manifested inclination to act and affect change, on a continuum from passive reliance on other stakeholders to personal action and activism.

The four dimensions were translated into axes on a visual map. When an individual or group's statements (in this case data generated through semi-structured interviews) as regards engagement with sustainability are indicated on the map, it is possible to elicit a shape of the particular attitudinal profile. The resulting shape is a blueprint of what we can draw out of this individual or group's metaphorical walk around the particular territory. The shapes can be overlaid with other shapes and comparisons made.

In the figure below the data from all individuals, across the eight workshops, has been collated and formatted into profiles representing the engagement with sustainability before and after the intervention of the workshop. (See Figure. 1) While the profile has expanded in all dimensions, this is particularly pronounced in the dimension that represents *agency*. The least change is evidenced in the factual dimension. While an extensive account of the study results is outside the scope of this paper, a comparison of the profiles shows that the intervention fostered a more rounded, as opposed to deeper engagement with sustainability. The comparison between all participants' before and after profiles also showed that an increased experience of *agency* – however small – was the singular most important factor in achieving a high general change score. Such insights can inform pedagogical approaches in the implementation of more sustainable strategies with students or organisations.

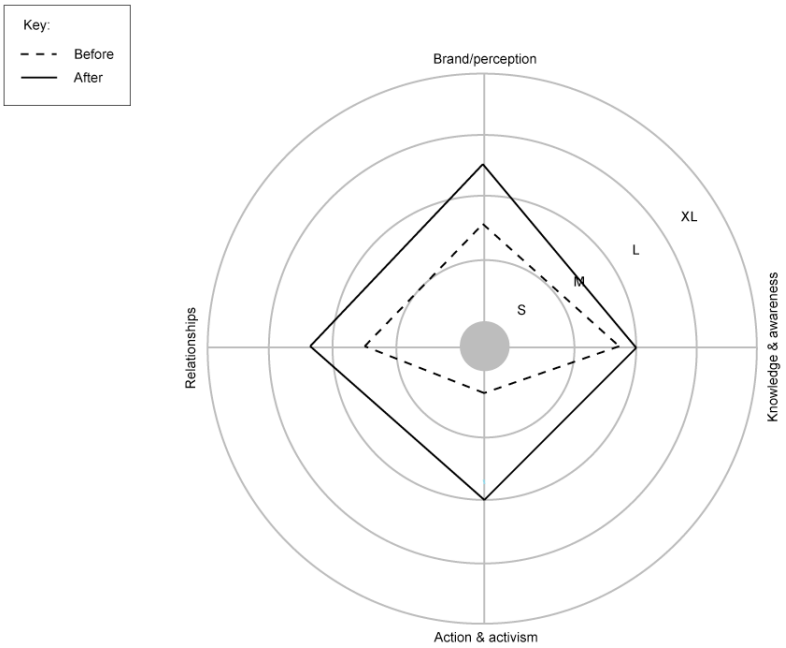

Figure 1. Distribution of responses across the evaluative framework

Seeds of Change

Fashion and sustainability are often perceived as anathema, as while the former popularly implies speed, egocentricity, and wastefulness, the latter implies a slower pace, resource-efficiency and even altruism. In the case introduced above, from the PhD thesis *Lucky People Forecast*, the researcher sought to set up conditions for a more nuanced fashion and sustainability discourse, focusing on opportunities instead of dichotomies. The series of creative workshops with mixed stakeholders groups from the fashion industry served a forum for the proposition “what if fashion and sustainability were compatible or even synergistic?”

The results of the study showed that participants had indeed been able to transcend stereotypes of both fashion and sustainability, and the perception of designer role as mainly operational, and product focused. The approaches also fostered a sense of community in an otherwise highly competitive and secretive arena, and brought a shared sense of purpose and agency to the participants. The study also illustrated that research can constitute activism, as the message of the study spread far beyond the remits of the workshops.

2. Sustainable Indonesia

Context

‘Given that most of the poor are heavily dependent on eco-systems for maintaining sustainable livelihoods, strengthened environmental management is imperative for poverty reduction.’ (UN Development Programme, Country Programme for Indonesia, 2006-2010)

The sustainable imperative in Indonesia has particular poignancy, as anticipated changes in legislation will jeopardise restrictions on natural resources, thus challenging the unique basis and competitive advantage of Indonesian crafts production. Tackling problems at the level of a whole country is not usually the role of designers but for sustainability to work in countries that are rapidly developing, then designers need to be brought in to bring about a step change in negative trends that threaten the country’s self-sufficiency.

During a three-day workshop with designers and manufacturers in Yogyakarta, Indonesia, the opportunities for more sustainable practices were explored, building upon the participants’ own experiences and understanding of both the challenges they faced and their potential solutions.

The workshop was co-funded by the British Council and co-funded and organised by Senada, a non-governmental organisation run by US AID and hosted by Warwick Purser, a creative entrepreneur and founder of Out of Asia, Indonesia's largest exporter of handcrafted goods. The workshop brought together Indonesian manufactures, academics; local handcrafts people, designers, politicians and exporters, all connected to the home furnishings industry. The workshop was, written and facilitated by Mathilda Tham, Hannah Jones from the Department of Design, Goldsmiths, University of London.

This was the first time to bring together different stakeholders in the home furnishings industry into the same room, working together, discussing their work and how sustainability could improve the marketability of their products and motivate the Indonesian design community.

Process

The purpose of this intensive three-day workshop was to present a general background to sustainability and introduce examples of best practice from the design culture in the UK and Europe. The workshops began by grouping the participants in teams and getting each team to produce a shared definition of both sustainability and design. This exercise helped to create a common ground and participants began to realise that they had shared concerns and aspirations for their work. The participants also took part in future scenario mapping in teams and individually interrogated their individual practice with a 'life cycle' based evaluation, helping them to rework more sustainable solutions. Although the participants already had some knowledge of sustainability, the process experienced at the workshop enabled them to actively apply sustainable principles to they own work, whilst generating a collective understanding of what qualities and resources where available for sustainable design and what qualities and resources were need to create more sustainable solutions.

Exemplar Tool

- Parameters for Sustainability Potential Tool

This tool has been chosen from the selection of tools and approaches employed in the workshops to illustrate the awareness of sustainability generated at the level of the whole group. The design thinker John Thackara believes 'We need to design macroscopes, as well as microscopes, to help us to understand where things come from and why'. (Thackara c2005, 6) The Parameters for sustainability potential is a 'macroscopic tool' aimed to harness a collective awareness and evoke a sense of ownership of a culture of sustainability for this community context.

The 'resistance to' and 'support for' sustainability, as pinpointed by the tool are as follows:-

Resistance	**Support**
Communications/ marketing	New market demand
Resource management - materials	Trend (in the media)
Resource management – human	Buyers and users understanding
Cost of eco-production	Education and training
Price of goods	Indigenous knowledge
Access and supply of eco-processes (e.g. finishes for products)	More value and more profit
Lack of education	Natural materials and resources
Lack of political will	The fear of nature degradation
Constraint of economy	Creativity
Individual will	Technology
	Individual will
	Spirituality

To elicit a set of qualities and resources vital for this community's sustainable design practice, the group was first asked to shout out key examples of resistance to sustainability that they experienced in their context and then key examples of support. These keywords were listed on a large piece of paper at the front of the room. Next, the facilitators asked the group to prioritise the key indicators that had been identified. This was done by drawing a line underneath each word and asking the group to bang their

pencils against their tables until they felt like stopping. The longest lines were the highest priorities on the list. This was a highly spirited exercise! The participants shared an agreement for a strong need for management of natural resources and their design community and more education in sustainable practices. Most positively the group celebrated their creative and spiritual interpretation of sustainability and an indigenous knowledge of working with materials that needs to be re-valued and better communicated to their markets.

Seeds of Change

Here sustainability came to serve as a strange attractor drawing together a greater empathy between stakeholders to create a new sense of community. Not only did the participants emerge from the workshop with stronger and more focused visions of the direction of their future practice, but also a new sense of pride and a clearer way of communicating those practices that were already environmentally and ethically sound.

The participants commented after the workshop that this was the first time that people were working together as a community without feeling like they were looking over each other's shoulders. An aspect of the handcraft industry approach is copying popular trends in the west to successfully export designs and so there is a lot of secrecy to secure a competitive edge. The notion of a creative community that emerged moves away from this aspect enabling participants to take ownership over their own trends, taking pride in design.

3. Metadesign Tools at Pines Calyx

The Context

The 'Metadesign Tools at Pines Calyx' case is part of a three-year, government funded (AHRC) research project entitled 'Benchmarking Synergy levels within Metadesign', run from the Department of Design at Goldsmiths, University of London. Over the course of the project we have developed over eighty tools for nurturing, fostering, and harnessing synergy in collaborative practice. The purpose of this two-day workshop was to provide a test bed to evaluate some of our current tools and approaches.

We have defined Metadesign as a comprehensive, inclusive, non-hierarchical, or 'holarchic' (Koestler c1964) design process that also designs itself. This approach transcends the limitations of existing design specialisms by working at a systemic level. This means thinking more deeply about designing for every day life than would be possible in a commercial context. Metadesign works towards attuning political, ecological, economical, socio-cultural, sensual and emotional patterns of living, to create less fragmented and more sustainable cities, services, organisations, etc. This is a highly complex and ambitious task.

Our research aims to go beyond current notions of 'sustainability' by aiming to achieve the more positive idea of a 'synergy-of-synergies'. (Buckminster Fuller 1975) This requires that designers find new ways to work together more proactively to create more affirmative design solutions. The design theorist John Chris Jones, identified at an early stage that the design field has 'become less concerned with the product itself' and 'more concerned with the changes that manufacturers, distributors, users, and society as a whole, are expected to make in order to adapt to, and benefit from, the new design.' (Jones 1970, 6) More recently, John Chris Jones has developed this thinking into the notion of a 'creative democracy' where design becomes a bottom up, co-authored and

participative process. (http://www.softopia.demon.co.uk/2.2/creative_democracy.html) This understanding of the evolution of design also shares its collaborative qualities with the emerging culture of metadesign and is at the heart of the research conducted at the metadesign tools workshop.

The workshop was staged at Pines Calyx, in Kent, the UK's most sustainable conference and events venue. The participants were given 'currency and exchange' as a loose theme to catalyse their design activities. Pines Calyx provided an inspirational local context and reference point for the design teams.

The Process

Twenty-five participants attended the workshop. We employed nine members of the metadesign research team to assume the role of facilitators, scribes and raconteurs. We invited six special advisors from the fields of anthropology and money, design history and philosophy, creative arts, ecology and business and environmental strategy. Finally, we enlisted the expertise of ten designers, drawn from five different design disciplines and cast them individually for one of two metadesign teams.

The metadesign teams were engaged in parallel workshop sessions over the course of the two days. The workshop sessions utilized seven metadesign tools, one of which was the framework of the workshop itself. There were also workshop sessions held by the special advisors to provide vital information about, for example, currency and ecological models used by business. The workshop tools and methods were intended to integrate different specialist design knowledge at various levels (e.g. speculative, intuitive, discursive, practical, etc.). At the end of the first day, the two design groups started working on creating a metadesign brief or designing seeds for the basis of practical designs, for example, re-thinking the idea of currency in a playful, or radical way, these 'seeds' were developed further on day two and presented at the end of the workshop to the whole group for discussion.

Exemplar Tool

- The four-fold integrative framework (Wood, Nieuwenhuijze, Jones, et al 2008)
- The five-levels of processing storytelling tool (Tham, Lockheart, et al 2008)

To highlight the process of change that took place over the course of the workshop it is helpful to introduce the tool employed to provide an architecture for the workshop and one of the tools deployed from within this framework.

The four-fold integrative framework was developed to deploy the other six metadesign tools at opportune moments in the collaborative process. The framework guides the design participants from a 'me' perspective on their involvement in the team to a 'we' perspective on the whole team's involvement in the process, thus, strengthening the team's inter-personal dynamics. The framework also arranges the tools so that they foster and harness both convergent and divergent design thinking to optimise creative synergies in the team's solution finding activities.

The four-fold integrative framework nurtures four different levels of awareness:-

Phase one	Awareness at the level of the self, the designer (my personal involvement, I present MY self, what I am bringing to the table)
Phase two	Awareness at the relational level, 'being with' (reflection on my personal view, 'sympoesis' or creating with the other)

Phase three	Awareness at the level of the team (Each individual identifies with the team as a whole, a team 'potential realisation' (Fairclough, 2005) occurs)
Phase four	Awareness at the level of the wider context (the team as a whole identifies with its wider context/s, potential realisation becomes transferable)

This tool was developed in collaboration with Dr. Otto van Nieuwenhuijze, an expert in living systems and an external consultant for the metadesign project. Dr. van Nieuwenhuijze calls for designers to develop more 'integrative modes of design thinking', believing that when designers act as representatives of a team they need to become 'transpersonal', embodying the values, dreams and concerns of the other members of the team to communicate with external bodies. Arguably, the four-fold integrative framework for metadesigning encourages a more self-reflexive, empathetic, context dependent, inclusive and highly collaborative process than more conventional fragmented and hierarchical design processes.

The second tool to be presented is the five-levels of processing storytelling tool. This tool was deployed in phase three of the four-fold integrative framework. The tool is aimed at enabling individuals to identify with the functioning team as a whole to encourage synergies to emerge. The team participants were asked to recount their experience of a guided walk around the Pines Calyx grounds.

At each level of storytelling, each of the five participants took their turn to speak, whilst simultaneously drawing on a big piece of paper at the centre of the table. Each of the five levels of processing required a different colour pen or pencil to code a chronological, as well as qualitative trace of the team's discussion.

The five levels of processing storytelling tool operates as follows:-

Level 1. The sensual – for 7 minutes
Prompt: What did you see, what did you smell, what did it feel like, what were the sounds?

Level 2. The factual – for 7 minutes
Prompt: What did you learn, what facts did you find interesting?

Level 3. The systemic – for 7 minutes
Prompt: How did what you learnt connect to the outside world, to other contexts, what are the relations between the talks on the guided walk?

Level 4. The futures – what ifs – for 7 minutes
Prompt: How might we build on these sensations, facts and connections, projecting 10 years ahead or more?

Level 5. The synthesis – for 7 minutes
Prompt: How can we summarise the discussion?
Continue drawing. Everybody has to take part.

People at this phase would hopefully fully identify themselves and the others as members of their team. They would also be able to objectively listen to the others whilst

being a part of the group. As the session progressed the accounts shifted from the personal to the interpersonal and shared, and a map emerged that encompassed both individual observations, and a new identity of the experience that was co-owned by all participants of the group. (See Figure.2) As the workshop subsequently continued in a more task-oriented mode – with the design of seeds for alternative means of exchange – the map formed a complex fabric to refer to.

Figure 2. Visual example from the story-telling activity, team one, 2008

The Seeds of Change

To really create a step change in the way people live we need to radically rethink the way people work together; to encourage more sustainable possibilities in the everyday, will undoubtedly require pushing collaborative practice beyond 'interdisciplinarity' to a new culture of 'metadesigning'. In the near future, designers might even be required to set aside their specialist identities to enter into co-authored processes where their role will be as emergent a solution as the actual process itself.

At Pines Calyx the Metadesign tools tested helped to generate a 'seeding process' (Ascott 1995, cited in Giaccardi 2005), marking out a territory to be explored by each of the design teams. The four-fold integrative framework guided the journey from individual contributions to collective endeavors, enabling the ppotential realisation of the whole group.

One month after the workshop, each of the ten design participants were interviewed for 15 minutes on the telephone by an external interviewer. In relation to the overall process that the teams went through, one participant commented how

'…the process and the people in terms of forming the group and how we worked together, were phenomenal… you go from creative to rational very quickly, I don't think we ever got to fully rational in this case, it would be the willingness to live with uncertainty and to enjoy the journey, rather than thinking just about the destination and I think that was fantastically empowering.'

In the case of this workshop 'metadesign allows a sort of creative and unplanned opportunism' (Wood 2000) to take place within the two design teams. Another of the

workshop's participants when asked about how they experienced moments of synergy replied

'I think the moments when I understood more about what my role was and how I could facilitate the group further.'

This indicates that the roles assumed by the team participants emerged as the team experienced moments of synergy.

4. Conclusions

The Ring of Fire model below (See Figure. 3) constitutes a tentative framework for evaluating auspicious and shared learning conditions. It was developed for the 'Benchmarking Synergy Levels within Meta-Design' project and builds upon the study of synergistic moments and processes in the respective cases and beyond. Here the tools form one axis of several 'resources' that we can – to a degree – control or at least plan. Such resources also include casting – the setting up of a group with appropriate dynamics, and facilitation. The other category of axes represents such qualities that are beyond our control, but that we can seek to foster and nurture by fine-tuning the application of resources. All axes constitute continuums between two states, the middle of which signifies the ultimate condition for synergy to take place – The Ring of Fire.

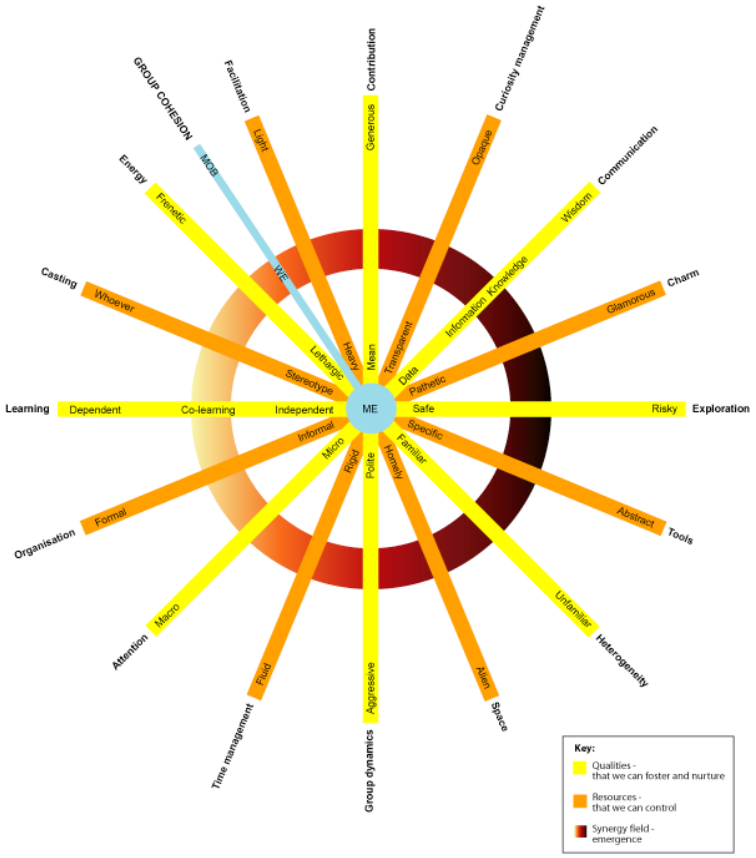

Figure 3. Ring of fire – framework for the evaluation of shared and auspicious learning conditions.

The cases introduced in this paper represent three distinctly different contexts of shared learning. While in the first case the researcher brought into a group of fashion industry stakeholders a distinct agenda, to situate fashion in a sustainability context, in the second case, the workshop in Indonesia, the participants had actively asked for help to address the sustainability imperative. Finally, both the participant base and the aims of the third case were broader, as it served a test bed for design as seeding, or meta-design.

Yet, in all three cases the shared and emergent learning process was in focus, as the expanded notion of design and the designer role, and the auspicious cross-fertilisation of personal and professional experiences and value systems, factual knowing and imagination, and explicit and tacit skills. The tools and the approaches that have been introduced here all seek to foster conditions for such learning, and learning that is contextual. To this end, the tools and approaches that we propose are *partial*; only in situ, with a particular group and a particular focus will they be complete, wherefore the process and the outcomes of the cases have both shared and different identities.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Landscape Ecology as a basis of Landscape and Urban Planning and Design

Siegmar Thomas[1]

Abstract

This paper describes some aspects of design and planning at a regional scale. Actual changes of towns and historic cultural landscapes, also changes of the aesthetic quality of the landscape and urban scenery include: loss of diversity (geo-relief / land form, plant cover, plant and animal species, historic built environment, historic cultural landscapes); loss of naturalness (impoverishment of flora and fauna, impoverishment of the local genetic diversity of plant species, spreading of competitive non-native species); elimination of historic urban ensembles and typical regional settlements, and also older agricultural landscapes; reduction of perception and cognition of the scenery by new filters, new barriers obstructing the view (e.g. new large buildings), increasing disturbance of recreational and protected areas; also by mass tourism.[1]

[1] Technische Universität Dresden (GERMANY) – ARCHITECTURE department. Dr., siegmar.thomas@mailbox.tu-dresden.de

1. Introduction

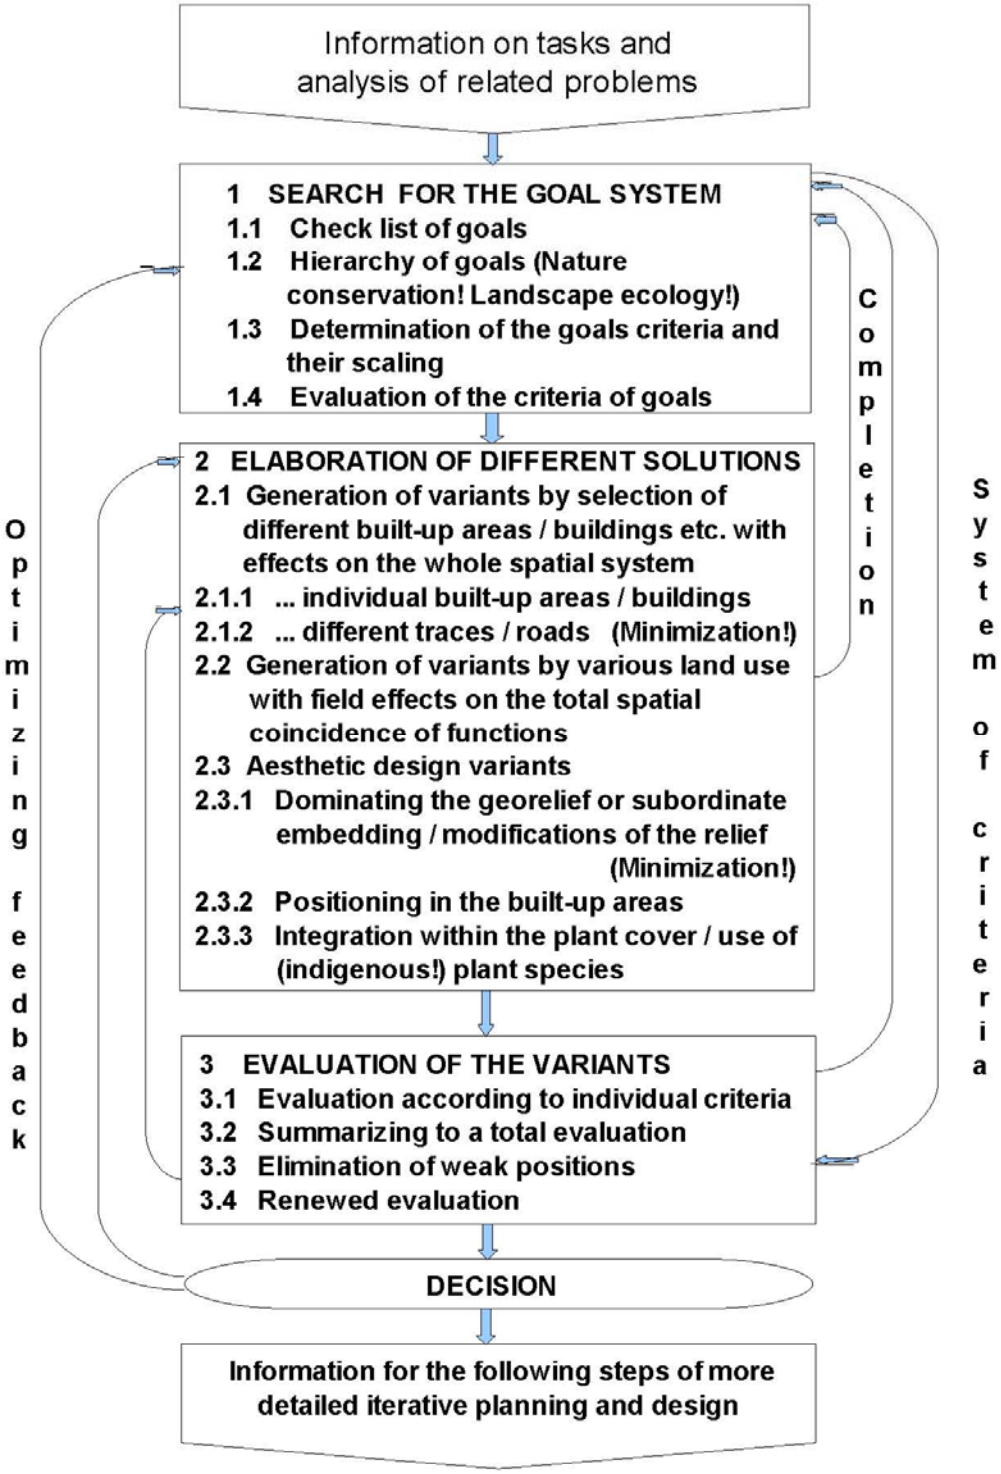
The aims of regional landscape and urban planning / design are to reverse or at least minimize the decrease in landscape and urban diversity. A design at all scales should not be an art work in a pure decorative sense (in extreme cases acting contrary to the landscape ecology principles).
The global climate change will in future worldwide probably more often lead to catastrophic events, e.g. Vb cyclones with heavy rains and floods in Central Europe.
All planning and design must be done under the principles of landscape ecology (towards environmentally friendly and sustainable development). The goal is to reduce negative human impact on the environment. Natural extreme events with worldwide increasing damage potential can become catastrophes for human beings and their goods. They are to be better fore cast to overcome them. All planning and design must take into account preparations to overcome natural extreme events. Learning from nature and use of natural ecological strategies are the best media to avoid misleading developments.

2. Generating and evaluation of different possible solutions for complex landscape and urban planning and design

Landscapes and urban spaces are generally large open systems. For complex problems, e.g. landscape and urban planning and design, we can find almost more different possible solutions. Such variants have to be generated and investigated to find a relative optimum by assessments taking into account all relevant aspects, function, (landscape) ecology (sustainability), economy, form and aesthetic quality. Without investigations about the manifoldness of different possible solutions may be valid: “(Only) one solution is no solution!”

Fig. 1: The following scheme is given after Thomas 1992 (modified).

SCHEME OF LANDSCAPE AND URBAN PLANNING



3. Today's aims of design and planning are to be based on landscape ecology

The recent main goals of landscape and urban planning and design must be based inevitably on landscape ecology (and not primarily on decorative aesthetic design principles by ignoring the essential ecological aims). Some of the main goals of landscape ecology are shortly described in 3.1 to 3.3.

3.1 Protection of areas as large as possible as protected areas (Nature Reserves, National Parks, a.s.o.) and landscape elements within extensively used urban and agricultural lands

The typical spatial land characteristics have to be the basics of landscape planning and architecture, urban planning and design (Kongjian 2007). Areas as large as possible within agricultural and urban land should be preserved in their natural state with only light influence by e.g. routes for ramblers a.s.o. Otherwise they should be re-cultivated to nearly nature-like ecosystems with the indigenous plant cover. The modern aims can not be realized by a type of design that is concentrated only on decorative effects.

3.2 Preventive river flood risk management measures

River valleys are often thousands of years old settlement areas. The river floods as natural extreme events have worldwide increasing damage potential, and become more and more “catastrophes” “if human beings and and their goods are involved severely” (Niedermeyer 2005) by increasing settlement, industry and infrastructure. Global climate change will in future probably more often lead to heavy rainfalls and river floods and mudslides (e.g. Vb weather traces over the Erzgebirge (Ore Mountains, Saxony) and the whole Elbe watershed (Germany, Czech Republic). Different hydro-meteorological sources of river floods in Central Europe exist. Springtime floods are caused by (sudden) snow melting in the mountains and sometimes ice barriers within the rivers. Quite different are other floods, caused by deep air pressure traces Vb (often in springtime and autumn, and in rare cases in summer with humid warm air from the Adria gliding on cold polar air masses coming from North (E.g. deep “Ilse II” 10 – 13-08-2002 from North Italy eastward to the Adria over East Alps to Croatia, Austria, Hungary, Czech Republic, Saxony and Poland = deep trace Vb (classification of Van Bebber 1882; 1891)). This results in high rainfalls some days long over large areas, in the Alps, in the Ore Mountains and other mountains. Then floods and mudslides occur in Germany, Austria, Czech Republic, Poland. The same reasons are valid for the Oder (Poland: Odra) flood in 1997, and especially after heavy rains over the Labe/Elbe watershed – in August 2002 and also the Donau flood during the same time 2002.

Flood protection and nature conservation should be further developed simultaneously – towards natural flood reduction strategies with the following tasks: Natural flooding retention areas are to be redeveloped and enlarged e.g. by new embankments in more far distances to riverbeds. Attention has to be paid to reservoir catchment management in mountainous regions.

It needs re-afforestation especially on slopes in mountainous parts of watersheds; careful agricultural use in hilly watershed areas due to soil protection against surface water flow and erosion; protection of remaining hedgerows, field terraces in mountainous regions, and re-

afforestation there for reducing soil erosion and fast surface water flow in catchment areas with extensive agriculture; protection of remaining riverside forests and re-afforestation; re-naturalization in river landscape. No new built-up areas within flooding zones should be planned or realized. Sealing off in watersheds and catchment areas are to be minimized. Movable flood barriers have to be prepared for temporary use in case of fore casted high floods.

3.3 Protection of landscape (land-form) diversity and biodiversity

Diversity of landscape and urban ecology coincides with land form diversity, in towns modified by the built environment.

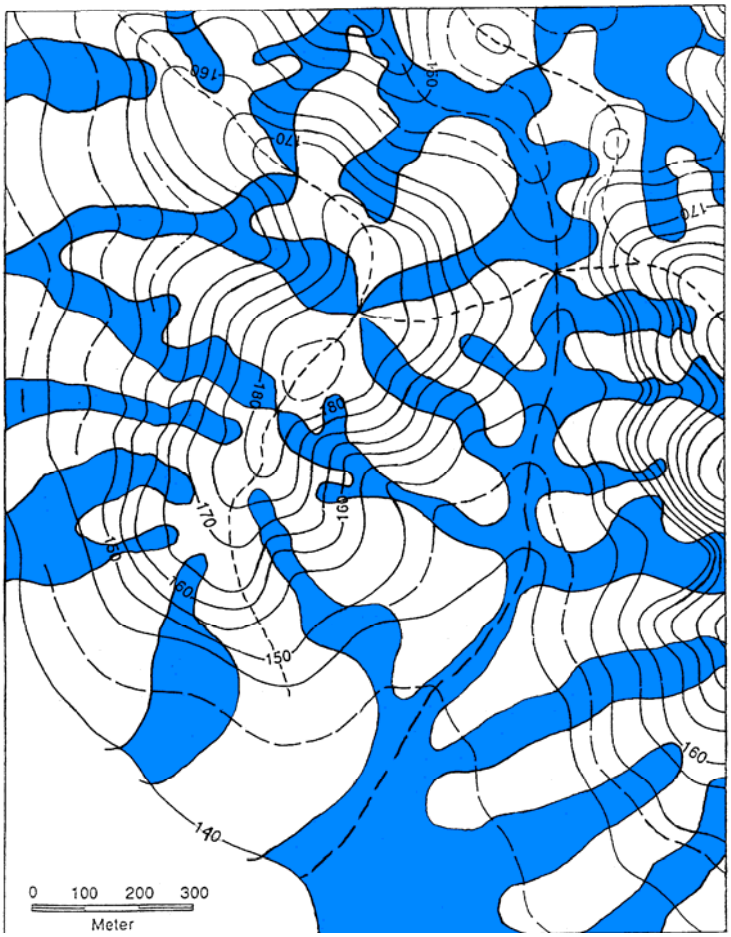
Landform diversity

Land form diversity contributes to the historical development of settlements and to landscape ecology. It also determines the way humans perceive landscape and make aesthetic assessments of the scenery (see below under 4). It influences design and planning of buildings and settlements whether they are dominating the landscape or subordinately embedded into landforms.

(I) Altitude difference of an area, e.g. a watershed, and (II) relief roughness (complementary elevation-depression forms) are decisive characteristics of land surface diversity (e.g. rolling hills with slope ridges, erosion channels).

The complementary elevation-depression forms of land surface are shown in Fig. 1

(e.g. rolling hills with slope ridges, erosion channels).



(white) **elevations**: (remains of) upper plains; (areas of divergent slope curves (= orthogonal trajectories of contour lines; trajectories not shown)

(blue) complementary “dendritic form” **depressions**: erosion channel network (sensu lato); (areas of convergent slope curves)

—— contour lines
— — (“ “ 2.5 m)
- - catchment boundary
— — — deep line

Fig. 1: Complementary elevation-depression forms (after Richter 1962, modified; Thomas 2007)

Landform diversity and landscape ecology

The diversity of landforms is a basic of landscape ecology of a certain region. An inventory of land surface curvature is part of landscape analyses, assessment, and landscape planning.

Observations were done for the different succession stages of spontaneous woody species combinations according to altitude (<500 m to >800 m a.s.l.) on collected stone walls at field boundaries for a part of the Osterzgebirge (Eastern Ore Mountains), a recreational region 50 km away from Dresden, the capital of Saxony (Thomas 1983; 1990; 1999). The potential height growth and the numbers of woody species within the hedgerows increase with decreasing altitude and decreasing relief position within watersheds. The reasons are increasing annual average of air temperature (4.5 °C to 6 °C), decreasing strong wind exposure on – forest free - hilltops and ridges respectively increasing wind shelter within – more plant available water containing – depressions (though the average annual precipitation decrease (<900 mm to 750 mm) with decreasing altitude. Gneiss podsols, - brown earths, -gleys are dominant due to relief positions).

The samples of the spontaneous woody species combinations were investigated for 8 classes of the vertical relief position and of the horizontal curvature-tendency in watersheds / catchment areas after the following matrix:

convex **concave**
horizontal curvature
(divergence convergence
of slope curves)

1 hilltops and (remains of) upper plains;
2 vertical convex upper slope areas 3
of (remains of) upper plains;
4 stronger inclined middle slopes, 5
partially with remains of valley terraces;
6 vertical concave foot slopes 7
and valley ground plains;
8 near deep lines; riversides

(for 8 no differentiation in convex or concave horizontal curvature).

More than 300 representative samples were done from 1970 to nearly 1994 (Thomas 1990).

The potential height growth of the spontaneous woody species combinations increase from < 6 m to more than 30 m with decreasing altitude and relief position within watersheds / catchment areas. The number of woody species increases with decreasing altitude from 4 to more than 25 within hedgerow parts of 20 to 50 m length. The relative maxima of hedgerow height growth (and the number of woody species) are in coincidence with the relative minima of the ground surface and vice versa. This principle is valid for rolling hilly or mountainous (sedimentary or soil covered rocky) landscapes without forests on hilltops and ridges.

The absence of hedgerows after removing results in less attractiveness of scenery for ramblers and visitors (communal area of Liebenau (Fig. 3)).

Disadvantages of non-native woody species in hedgerows on agricultural land

Non-native woody species, planted in the agrarian fields and open grasslands, “can destroy the specific character of the landscape; drive out rare species of open lands and their living spaces appeared; endanger the genetic diversity of indigenous species; change the natural sites of animal species, depending on the plant species (pollinators, parasites, eaters)” (Reif; Nickel 2000). Large masses of non-native woody species occupy a lot of areas and space within the agrarian land which should instead usable for the worth protecting native woody species flora, instead of protection of the natural biological diversity of the landscape, of the species diversity and the intra-specific genetic diversity and differentiation of regional plant species origin. This

may result in appearance of native woody species and eco-types. Native plant species developed special forms and eco-types in geographical regions during evolution without human impact (genetic adaptation of populations of a species). This diversity is also the basis for future evolutionary processes (genetic adaptability). This biodiversity (genetic variability and intra-specific differentiation) must be protected. For example should be used only seed material of regional origin of native woody species for hedgerow plant material (Reif; Nickel 2000). It should be “never used non-regional plant material within the open agrarian landscape” (Reif; Nickel 2000). Plants of seeds from the region are to be used for planting (to avoid introgressive hybridization with eco-forms from other regions and destroying the natural flora.Hedgerows should contain large parts of regional genetic biodiversity to prevent distortion of the flora. This opposes against an increasing uniformity of regional eco-types by introgressive hybridization (hybridization between species, partially from other regions, followed by successive re-hybridizations with parent species) (Reif; Schmutz 2001). Non-native woody species are often not or much less eaten by native animals, insects, birds, mammals a.s.o., because of missing mutual evolutionary adaptation.

4. Perception and cognition of scenery and human preferences depending on land form diversity and built environment

Objective aspects of perception and cognition allow descriptions of visible landscapes. Cognition and aesthetic assessments also contain inter-subjective and personal factors). The complex perception and experience (cognition) of the landscape depends on the landforms:

(1) viewing (the sensory information) and (2) cognition (psychology of perception):

(2.1) symptomatic information: understanding of symptoms of landscape characteristics that can not be recognized directly – due to filter effects;

(2.2) relics of former landscape use: historic cultural landscape and town parts;

(2.3) expression: initiating emotions (individual; inter-subjective);

(2. symbolic meaning: indicates imaginations, ideas, theories, utopian pictures, ideals. Methodological contributions are needed for analyses of the shapes of natural and cultural landscape with the built environment. An overview about the characteristics for objective description and assessment of landscape scenes and urban forms is given in Fig. 2, in connection to tables 1 to 4.

A. Filters of perception and cognition

There are objective spatial, temporal and cognitive limitations to the perception, cognition and emotional processes as a result of so-called filters: spatial, temporal, and situation-specific filters, normative filters on cultural history, and individual moments:

Table 1: **Filters of perception and cognition**

visual: barriers of relief and e.g. buildings, obstructing the view; precipitations and atmospheric clouding; air pollution, global dim; artificial light pollution; sight penetration e.g. into forests of different density, also varying by seasons; pulsation of sight volumes due to day-time, seasons; seasonal aspects of flora (colours, flowering); focussed viewing; selective directed view, following moving objects; optical illusion (Fata Morgana, ...);

aural: power, frequence, distance of point or linear sound sources; sound spread depending on weather and reflecting or absorbing materials; sounds caused by wind and weather; streaming water, surf; animals; humans; production and infrastructure; masking noise; sound barriers;

olfactory: power and distance of odour origins; depending on temperature, field of wind, seasons;

haptic: plants, animals, clothing, materials; movement on foot, by vehicles;

kinesthetic: very steep slope; deep snow or ice on steep slopes; busy traffic; strong winds;

intellectual: emotional, social, cultural-historic: knowledge; spirit of the age; normatives;

each varying due to innate, hereditary and learned associations and reactions; imaginations, ideas, theories

B. Perception: Viewing the landscape scene and multi-sensory experience of the landscape (sensory information)

Perception of scenery in view-sheds takes place in different fields of view in upper relief positions and lower sites:

Table 2: **Fields of view**

panoramic views (from hilltops) over a plain or different valleys	360°
circoramic views (e.g. over some valleys)	270°-360°
partially „panoramic“ (over one or more valleys	90° -270°
sectoral (over one or more valleys)	<90°
views into a gorge, can~on	<<90°

The perception of scenery is potentially realized according to different depths of view, e.g.:

Table 3: **Depth of view within fields of view** (distance zones)

f	**foreground** up to	0.4 - 0.8	km distance
m	**middleground**	0.8 – 8	km
b	**background**	8 - 100	km

The landscape scenery is perceived as – **V** – space-defining vertically perceived surfaces / "walls", varying from confined views to panoramic views. The visible landscapes may contain – **D** – space-accentuating vertical dominants within fore-, middle-, and background (e.g. mountains, rock needles, towers, tower blocks, solitary trees) or elements / areas of different noticeable colours or textures. Description and assessment of scenes can be done using the basic 2:3 matrix:

Table 4: **Description and assessment of scenes** as shown on the basic 2:3 matrix

		f	**m**	**b**
V	vertical visible ranges, surfaces, one behind the other; settlements; forest fringes; (m,b); water areas (mirror effects) (f,m);	Vf	Vm	Vb
D	3 to 5 dominant single elements are immediately perceptible, more seem to be combined to a wall V (m,b); moving waters, animals, (f,m).	Df	Dm	Db

The basic matrix (Table 4) should be completed and extended for the above mentioned fields and depth of view (Tables 2 and 3) according to the four points of the compass, North, East, South, West, 90° each. Additional attention should be paid to the time axis: The above scheme may be sufficient for climatic regions with no seasonal variations (high precipitation all over the year or dry deserts with (nearly) no precipitation throughout the year). In other cases the scheme may be used for the existing seasons repeatedly: two times for regions with a dry and a high precipitation season; for three seasons; or four seasons for temperate climate in the northern and southern hemisphere: spring, summer, autumn, winter (Fig.2). Seasonal changes of transparency of deciduous forests and hedgerows may cause different kinds and distances of the frame confining walls - V - (e.g. forest fringes or hedgerows and deciduous tree rows of avenues are the „walls" during spring to autumn instead of hill-slopes behind them, which are visible and shining through in winter).

So there are seven vectors, describing the objective criteria for the sensory information according to space (I – III); dominant objects, vertical or areas (IV); direction of confined views (V); time (VI); places of historical interest (VII):

(I) depth of view within view-sheds (f, m, b) (indicates length);

(II) horizontal angles of confined fields of view (width); (III) vertical viewing angles (indicates height, not only the altitude difference in the view-shed in relationship to the distance of e.g. mountain ridges, but also the elevated surfaces of vegetation cover, or settlements above bare ground ("V" for vertical "walls")); (IV) number of dominants D for each distance zone (I), viewing direction (V) and viewable valleys (II); (V) direction (N, E, S, W); (VI) temporal vector, number of seasons according to climatic zones (one to four); (VII) historic sites.

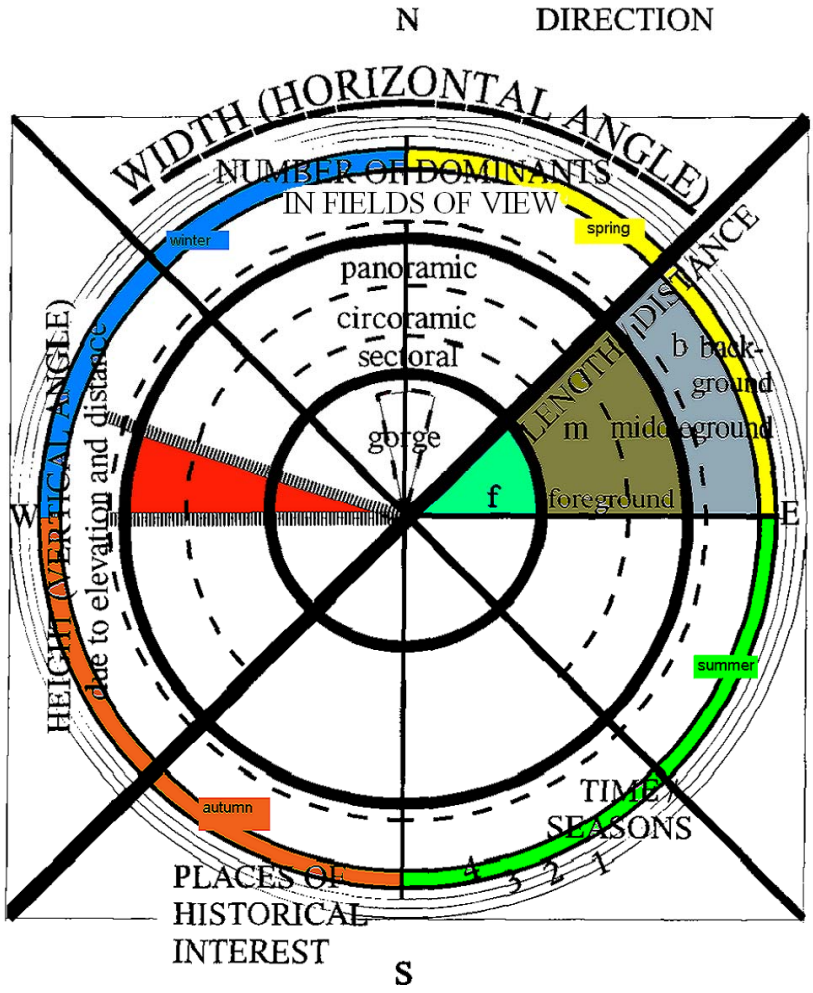


Fig. 2: A scheme for visual landscape perception, description, and assessment (Thomas 2007)

C. Cognition and aesthetic evaluation

The second phase, the cognition and the aesthetic evaluation, contains more subjective aspects (personal and inter-subjective). The scenic beauty estimation attempts to define the visual preferences of humans.

D. Laws of gestalt psychology

Gestalt psychology explains rules of cognition: constancy of perception: constancy of form, colour, brightness (an object is recognized though it is viewed from different perspectives (Goldstein 2002:188)); size-distance relation; figure-ground relation; centre-surroundings-antagonism; ambiguous pictures (riddle pictures); „law of nearness" and spatial effects; „law of similarity" for landscape elements and their gradients of size, density, forms, brightness, colours, contrasts; „law of completion to a simple form"; completion to a "desired" form; „completion to symmetry"; „law of the same destiny"; proportion (e.g. sectio aurea). An objective landscape is provoking a subjective cognition of the landscape scenery (Nohl 2001:233).

E. Imaginary superficial resemblances

Imaginary apparent resemblances („morphisms") are suggestive examples of the „law of similarity": For instance the Sydney Opera House may remind one of

* sailing ship(s) (techno-morphism);
* clouds mirrored in the water (clima-morphism);
* shells (zoo-morphism);
* monsters in moonshine-twilight: "
  sharks, opening their mouths; mystery, nightmare

as an example of ambiguity of cognition and symbolic meaning.

F. The scenery preferred by ramblers based on observations on Whit Monday 2005

For estimations of preferred landscape scenery it is necessary to observe the numbers of visitors in different landscape parts, watersheds / viewsheds, or conduct surveys of a certain number of individuals.

For a part of the Osterzgebirge (Eastern Ore Mountains), a recreational region, we could find: At one extreme, no ramblers could be seen within the flatter open fields of Liebenau, the watershed of the Liebenauer Bach (stream) with a relatively small altitude difference Δz, and crop fields without hedgerows (that were removed a long time ago), and with very small forested areas. Increasing numbers of ramblers were found in the more diverse communal open fields / watersheds, richer in hedgerows and forests on steeper slopes. The greater the altitude difference Δz, and the higher the maximum altitude z_{max} the more visitors / hikers appear in the watersheds / viewsheds in good weather (Fig. 3). The ramblers were counted for entire watersheds (H, Fau, F, Lw). The watershed of the Liebenauer Bach (Li) extends outside the observed area. Only the right sides of watersheds, the right hillsides of the streams Erdbach and Rotes Wasser are included for the small medieval towns Geising (G) and Lauenstein (L). On the excluded left hand sides and also south and west of the investigated region, there are mountains of some higher altitude within the middleground fields of view („m"). In the surroundings of the small medieval towns Lauenstein (L) (with small old fortress ruins and renaissance/baroque castle with a well-attended museum) and Geising (G) the number of ramblers may be greater than that counted during the survey. Possibly more ramblers were hidden on paths within forests on steeper slopes, the hillsides on the right (G, L) when counting was done. Six of the observed areas are nearly 3 to 6 km^2 in area, while only the part of the Heidegraben watershed (H) is smaller. So obviously the number of the ramblers observed is only slightly influenced by the varying size of areas. At Whitsun 2005, in sunny weather, many visitors came to Lauenstein castle and the small market square and also to a wildlife park in the valley of the Rotes Wasser. It

was the aim to count only hikers in the open fields. The results corresponded with similar observations made over several decades and confirmed the expectations.

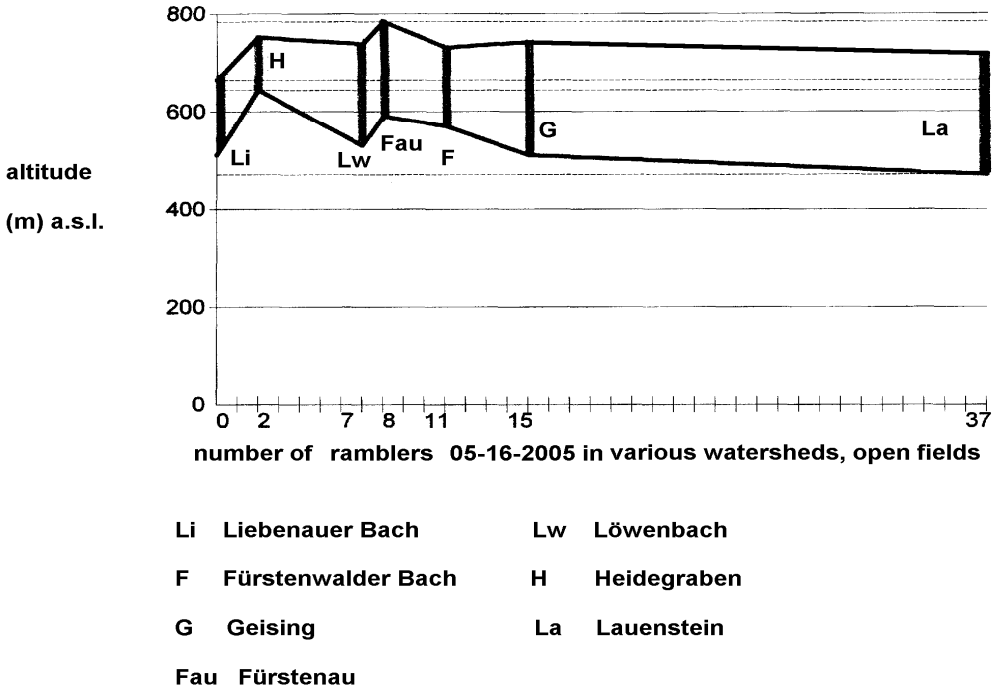

Fig. 3: Number of ramblers in various watersheds of different altitude difference (and correlated relief roughness)

G. Reflections of natural and cultural landscapes in arts (table)

Table : Aesthetics of nature and landscape, and aesthetics of art
Aesthetic and artistic perception of landscape:

Real ***landscape***	***painting*** / graphics	***poetry / literature***	***music***
time sequence	-		**+**
objective	(momentary	indirect,	immediate, model
subjective	representation)	provoking	time-lapse
		imagination,	tempi: peaceful / slow

	architecture / sculpture		folkloristic music, -lied,
	buildings, monuments,		-dance, ... (regional)
	(dance = moving human „sculpture", setting „sculpture" to music)		
	gardens, ...		citations of earlier music
	eclecticism (technomorphism)		
			ambiguity of cognition of symbolic meaning:
	Sydney Opera House: Sailing ship(s) ("); clouds mirrored in the water (climamorph.); shells (zoomorphism)		
agrarian landscape			

"All art constantly aspires towards the condition of music" (Pater 1877).

\- no immediate visual / acoustic reflection, provoking reminiscence of direct perception
\+ immediate representation, models; described objects and processes as direct imitation, with abstractions, variation and thematic processing, included into peculiar music, art
(+) only illusionary reminiscence

5. Conclusion

The more extensive the roughness of terrain carving, the more diverse is landscape ecology, and the more diverse is also the scenery. This is interrelated with e.g. abundance and diversity of spontaneous woody species communities in hedgerows under temperate climatic conditions. The basic principle is commonly valid for all climatic conditions.

A commonly valid scheme for the description and assessment of scenes and planning / design alternatives is proposed. Conclusions could be of interest for analyses of natural landscapes and the planning and design of cultural and urban landscapes.

The purpose is to describe some aspects of design and planning on a landscape scale depending on landform diversity. It helps to manage diversity of landscape ecology and scenery simultaneously.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design as Activism

A Conceptual Tool

Ann Thorpe[1]

Abstract

Although literature on design as *activism* is thin, there is increasing frustration and urgency over designers becoming activists. With participation in social movements and expectations for social innovation on the rise, interest in design activism will only increase. Yet designers are wrestling with the notion of activism: What is it? Can we encourage it? What are its best practices? Design lacks a good conceptual framework for activism, but fortunately sociology has one to offer, a typology of activism. This paper describes research that adapts sociological methods to establish this conceptual tool for design, enabling a more robust debate and use of design activism over time, and across causes and disciplines.

Introduction

Consider a few interesting cases of design activism at work:

- To raise money for landmine clearing, an industrial designer develops handsoap that is a full scale model of a landmine—a landmine that is "washed away" by the purchaser's contribution.
- Architects propose a portable "day laborers' station" to meet the needs of Central Amercian day laborers in California.
- Global Green runs a design competition to solicit proposals for eco-sensitive, affordable housing for New Orleans residents made homeless by Hurricane Katrina.
- Desigers build a set of five secular, mobile "chapels" that rove around offering people contemplative respite from the rush of modern life.

The examples above are all cases from my research on design activism. For the purposes of this paper, I define activism as taking intential action to instigate change on behalf of a neglected group. As the examples above show, designers are working across a range groups and issues, ranging from victims of war or disaster to minority groups. But they also encompass less recognized "groups" and more subtle changes, such as the call to *slow down* embodied in the mobile chapels. Ecological design represents change on behalf of earth's ecosystems, a quintessentially neglected, even wronged, group.

In these cases, sometimes designers themselves are the activists, sometimes they are "activists for hire" working for nonprofit or public groups. In each case the actions have as their bottom line a social or environmental cause, as opposed to a commercial (eg profit-making) cause. This distinquishes my cases from instances where, for example, companies green their corporate headquarters or launch green products. These cases of "corporate design activism" are of less interest in my research—not because they are unimportant—but because I feel they represent the tail of design activism rather than its leading edge.

Activism is a dynamic process. It starts when groups within society call for change, and society responds --either resisting, or incorporating the values encapsulated by activism. Thus as environmental activism proceedes, for example, "green" products (e.g. recycled, reusable, energy efficient) gain a certain normative position and cease to be at the cutting edge of activism. Gradually the public sector steps in and requires a higher "green" performance across all products. This process gradually raises the bar so that businesses do more, governments change policy, and activism pursues yet new areas that have been neglected, but that need attention. My interest in this research is to capture design's role at the leading edge of this process.

Aims

This paper's aims are to:

- Outline design's stumbling blocks with respect to activism
- Provide an overview of how sociologists understand activism and show its relevance to design
- Present initial results from my research on a typology of action for design activism

Design's stumbling blocks

My professional and academic experiences all suggested to me that the field of design is wrestling with the notion of design as activism: what is it? Is there a way to define a best practice for it? How can we encourage more of it? It strikes me that until recently there have been two obstacles in the path of design activism. The first obstacle was the absence of the right context in which to be activist.

The professionalizing of designers as "servant problem solvers" prevents most within the discipline from characterizing themselves as "activists" or advocates, even if that is what they are. Designers typically view themselves, and others view them, as commercial actors. Designers are trained to respond to clients and consumers, and to add value to businesses (Dormer 1993; Heskett 2002). Governments develop policies that position design as a tool of economic growth (Heskett 2002). Professional design associations largely concern themselves with business practices and responsibilities to clients (Thorpe 2007). Even design schools tend to frame their work as educating employees for the "creative industries" rather than as educating change agents. Within the confines of commerce, most designers lack the right context in which to be activists. I have written elsewhere about design's position within the economy and how designers need to actively use the economy (Thorpe 2007, 2008). Fortunately new contexts are emerging, particularly with the rise of the third sector, also known as the nonprofit or "social" sector, but also with the notion of social enterprises (Thorpe 2008).

But it was only when I began to look at how activism is studied within social movements that I understood the second obstacle. In the study of social movements scholars have developed a conceptual framework for activism, allowing them to understand, debate, and critique it across various movements and groups. This framework is the very thing that designers seem to lack. In terms of social movements, this framework is known as the "repertoire of action", a standard range of actions that activists deploy across a range of causes, social groups, and across time, to make claims for change (Tilly 1995). The repertoire is basically a typology of action (I will use the terms "typology" and "repertoire" interchangeably) in which actions are like a set of jazz standards that everyone knows, but that are improvised and combined in many different ways. Activism in this sense is not only what people do, but also what people *know how* to do.

This prompted me to consider whether design also has its own set of "jazz standards" that are used to make claims for change — a set of actions that are relatively consistent over time, that cut across causes and disciplines, that everyone knows how to do. I initially tested the repertoire concept on design activism using my own knowledge and ready–to-hand sources to compile a list of about 50 activist design projects. Analysis of this list suggested to me that there are some "jazz standard" actions for design activism. For example, designers seeking change on social or environmental issues will often organize competitions to solicit new visions or to award prizes that will help implement the best new visions. This action of organizing competitions cuts across all design disciplines and many causes, such as the environment, justice, cultural diversity and accessibility. Other jazz standards, which also cut across discipline and cause, revolve around artifacts:

- service artifacts (eg emergency shelter) that provide humanitarian aid
- demonstration artifacts (eg an extreme green building meant to be a model for others) that offer positive alternatives to the status quo
- protest artifacts (eg the landmine soap mentioned at the start) that may be confrontational or even offensive, but offer a critique prompting us to reflect on the morality of the status quo

Once this framework, this set of jazz standards, is actually proposed for design, it looks almost simple and obvious, belying both its power and the significant task of developing and generalizing it. Although anyone can sit down, as I did, and brainstorm on actions that designers

might take, or have taken to make claims for change, such a list can only be speculative and anecdotal. Without any systematic empirical research we really don't know:

- what types of action designers have actually taken, across the board, over the past 15 or 20 years (eg what actions comprise the set of jazz standards for design activism)
- How design disciplines might be utilizing specific actions in the repertoire and for which causes
- To what extent designers take up "conventional" versus "designerly" forms of action
- Whether or not certain actions cluster together in time or in discipline
- How actions are innovated over time

Once we establish the range of actions in the repertoire and begin to understand some of their patterns, it becomes much easier for future research projects to propose best practices for a given action type, or to critique the effectiveness of various actions, compared to other actions that could have been taken.

Although there are obviously many ways to study the subject of design activism and gain insights about it, my research is aimed at developing a generalized typology of action for design based on systematic empirical research. It is in this sense that the methods and approaches from sociology, which I present below, make the research question possible, particularly since this type of large-scale survey approach is relatively uncommon in design research. The absence of method perhaps explains why a robust conceptual framework for activism is so far missing from design discourse.

Activism and social movements

In sociology terms, activism is the public face of social movements. It is generally taken to be the public display of making a claim for change, in contrast to the day-to-day, behind the scenes administration of groups and causes (McAdam, Tarrow, and Tilly 2001). Social movements are generally defined as mobilized networks of people and groups that, having developed a collective identity, participate in collective action (activism), mainly by means of protest, to bring about change (Rucht and Neidhardt 2002; Della Porta and Diani 1999). Movements may have many participants and run a number of campaigns over a period of years. Though they include organizations, movements are not themselves organizations (Rucht and Neidhardt 2002). Movements run in cycles, and if successful, they typically result in the institutionalization of the change they sought.

Social movements cover a wide range of issues and actors, from gender issues to peace and the environment. There are also movements based around justice, health, poverty, development, mental health, animal rights, and even relatively "dry" topics such as intellectual property. There is a growing body of scholarship on social movements, and three of the pioneering American scholars, McAdam, Tilly and Tarrow, argue that there is by now a "classic" social movement research agenda based around three key theories as to why people take collective action (McAdam, Tarrow, and Tilly 2001):

- Resource mobilization/mobilizing structures: people participate in social movements when organizations and individuals step forward to mobilize resources on behalf of a cause.
- Political opportunity: people participate in social movements when viable opportunities appear.
- Collective action frames/collective identity: people participate in social movements because of the way the issues and actors are framed culturally and emotionally by the movement and because participants in movements can help frame issues and actors.

Among European scholars there is also a school of research on “new” social movements, which adds a fourth theory for explaining social movements, as follows (Dalton and Kuechler 1990):

- Social paradigm: people participate in social movements because they are concerned about the greater good and how it may be harmed by long standing, dominant political goals (such as economic growth) or the way people’s interests are represented in politics and culture (such as direct democracy vs. representative democracy).

A final component of the classic social movement research agenda concerns the strategies and actions that movements use to achieve their objectives. McAdam, Tilly and Tarrow identify these actions as the forms of claim-making, or calls for change, that people use in real-life situations (McAdam, Tarrow, and Tilly 2001). Others call it simply “protest,” noting that protest in and of itself is, “a telling indicator for problems which are neither registered nor dealt with in an adequate manner” (Rucht, Koopmans, and Neidhardt 1999, 8).

Strategies and actions

Social movements are an accumulation of many different actors taking many different actions, but held together by shared beliefs, or a shared claim with some notions of how to achieve it. Jordan describes how activism is in many ways a moral undertaking, in that it seeks to put forward a vision of what constitutes a “good” life, for example, activists might suggest that a good life is free of oppression, injustice or war (Jordan 2002). He characterizes three broad stratregic trajectories for the types of change sought by activists:

- reactionary, or looking to the past for a vision of “the good life” (examples include the US Patriot movement based on civil war times, or religious fundamentalism based on historic religious texts)
- reformist, or looking to the institutions of the present for a vision of the good life (examples include cases where existing representative government controls and determines change: reform to gun control laws, reform to pension laws or reform to environmental regulations)
- visionary, looking to the future and inventing new visions of the good life (examples include the Zapatista and Aboriginal movements that call for the rights of indigenous peoples to be citizens but also to control their lands and communities, or movements to reclaim the streets for all users, instead of accepting the dominance of cars)

In addition, Jordan explains the moral basis underpinning the acts people take for social change. He notes that much of activism intends to make an injustice or oppression unavoidably public, thus forcing those who witness it to “decide if they can live with the moral deficit produced in themselves in the face of an unavoidable demonstration of what is better” (Jordan 2002, 58). The main strategies for accomplishing this demonstration of “what is better” are the non-violent approaches of civil disobedience (or non-cooperation), direct action, and bearing witness. From time to time, violent approaches (sometimes unplanned) also emerge. Within these broad strategies is where we find the standard types of action, the “jazz standards” of activism.

In 1977, based on a study of French protest over several hundred years, Charles Tilly pioneered the notion that there is a “repertoire” of actions that “actors” or activists use and that it is relatively stable (Tarrow 1999). Tilly notes:

> “by analogy with a jazz musician’s improvisations or the impromptu skits of a troupe of strolling players…people in a given place and time learn to carry out a limited number of alternative collective-action routines, adapting each one to the immediate circumstances and to the reactions of antagonists, authorities, allies, observers, objects of their action, and other people somehow involved in the struggle” (Tilly 1995, 27).

Other writers on forms of action have generally embraced the repertoire concept and much literature usefully applies and extends the concept (see for example Olzak and Uhrig 2001; Rolfe 2005; Clarke et al. 2007; Crossley 2002), which gives rise to several major themes in the literature on repertoires. The first theme is of one of constraint and stability. The known repertoire constrains what people do but at the same time maintains a stable body of knowledge about what to do. Tarrow notes, "the repertoire is therefore not only what people *do* when they make a claim; it is what they *know how to do*" (Tarrow 1995, 91). The second theme is of collectivity, including notions of groups and identities and questions as to how to register the rise in what scholars term "individual" activism (Munro 2005). The third theme is innovation; although repertoires provide stability, they are innovated over time as some forms of action disappear or become less prevalent while new actions emerge. The fourth theme is one of modularity; a given repertoire contains a range of modules that are combined and deployed according to circumstances.

At this stage it may be useful to present a list of some of the most common actions that are in the popular contemporary repertoire, such as the following:

- Marches and demonstrations
- Bans and boycotts
- Petitions
- Strikes
- Barricades
- Sit-ins and other forms of non-violent civil disobedience
- Bearing witness
- The formation and offering of "alternative" versions: students offer alternative courses
- Symbols of identity and affiliation: eg the red AIDS ribbon
- Pamphlets/pamphleteering
- Vigils
- Legal obstructions
- Destruction of symbolically meaningful objects

Tilly and others have articulated a number of benefits derived from the repertoire concept. Tilly originally hoped the term would help codify knowledge of the existing forms of collective action, allow a generalization of the question of how these forms change over time, and hypothesize that prior history constrains the current action, "in partial independence of the identities and interests that participants bring to the action" (Tilly 1995).

Tarrow has suggested that the most important contribution of the concept is how it allows us to "disaggregate" the general notion of protest into its conventional and non-conventional forms. Tarrow and Tilly have both used this aspect of repertoire to look for the ways in which repertoires change over time relative to other factors such as political or economic structure. They both agree that innovation in the repertoire typically happens around the edges, leaving the fundamentals unchanged. Tarrow suggests that cycles of protest bring about changes in the repertoire noting, "they [cycles] are crucibles in which new weapons of social protest are fashioned" (Tarrow 1995, 94).

To summarize, social movement scholars suggest that the concept of repertoires benefits our understanding of activism by allowing us to:

- Describe social movements in generic terms such as skills, social forms and so forth, instead of strictly in terms of causes and issues (eg peace, ecology or race).
- Compare actions over time

- Explore patters of activism: how strategies and actions interact, clustering of actions
- Critique social movements in terms of their selection and deployment of actions from the repertoire
- Set innovations of action in the context of the repertoire

Adding to this list, practicing activists suggest that a benefit of the repertoire of action is that it facilitates a proactive approach. Activists can strategically evaluate the actions they take. Let me now argue for what I see as the benefits of the concept for design activism.

Typology of action: benefits to design

In terms of making claims for change, the typology of action enables designers to plan and assess their work in two ways that have not been readily available before. First, the concept directs them to think about actions they might take relative to other actions available in the typology. In a more design-centric approach, architects lobbying for environmental change, for example, typically focus on “green” building and examine the technical, aesthetic and material features it should have. Using a typology of action, they might instead ask, “what does the action of doing a demonstration building achieve in terms of our cause, compared to other actions we could choose?”

The second way the typology enables designers is by directing them to think explicitly about the fact that they are calling for change and to consider how their actions might fit into a broader social movement—should they focus on something that supports ongoing activism in an exisiting movement? Or is there an action they can take that would fill a gap?

As activist Randy Shaw points out, in a campaign for change you avoid tactical mistakes by discussing the possible pitfalls associated with an action and how they might jeopardize the ultimate goal (Shaw 2001). This, he suggests, is the benefit of contemporary “proactive” agendas—it forces activists to think through the connections among various steps along the way to social change. Yet this “connective thinking” in terms of change is something that designers rarely do.

This failing becomes apparent particularly when designers, trapped in a conventional design mode of thinking, try to compare and debate activist and non-activist projects. This difficulty is exemplified in the area of “best practices,” a conventional concern of design. Best practices for commercial design are constrained largely, at the end of the day, by commerce. But what constitutes best practices in design activism? What is the best way to make a claim using the tools and techniques of design given the changes we are seeking? Within the common conceptual framework of design case studies—comparing which green building is best, or how practitioners create products for humanitarian needs—we can get a comparison of design solutions, and these will always be important. But it is only by considering types of actions and social movements, that we can begin to get a comparison of “change” solutions brought about through various design practices. A few more examples help illustrate this point.

Product designers might argue that consumerist design de-emphasizes skills and thus disables users. They might critique labor saving devices and propose new methods for design such as “co-creation with users” or “designing communities,” (see for example Manzini 2006). But by switching to a typology of action, they might consider where and when an action involving self-build is more or less useful than devising a symbol of affiliation for “enabled” users.

A graphic designer asserts that we must use indigenous visual traditions and folklore to develop and apply an awareness of local cultures in the face of tremendous global pressure toward a dominant western design; she teaches classes in which students undertake this kind of research (Blankenship 2005). But without the concept of a repertoire she might not consider other actions such as providing services to those in need as a way of uncovering folklore and visual traditions.

In assembling exhibitions or catalogues of design for a cause, the actions are typically evaluated in a “how to” design sense, rather than a “why to” cause sense. For example, collections of objects made from recycled material typically emphasize issues such as availability and visual quality of material, production challenges, or the whimsy and wit of the objects (Dehn 1996, 2007; Dintenfass 1997-98). Using the typology of action, a designer assembling such a collection might examine how and why these demonstration products perform in the cause to reduce waste, versus other potential design actions for the same cause. Further, how do these actions fit with the broader social movements aimed at reducing waste?

The actions in the repertoire cut across disciplines and aesthetic movements, which also makes the concept significant. It may be tempting to assume that if you’re an architect, your activism will involve making a building and if you’re a graphic designer, your activism will be to make information visually accessible. But empirical evidence dispels this notion, a notion that is only likely to further dissipate in the future. Julier commented that a prominent design activist he’s spoken to describes himself as “media agnostic”—the result might be a building, or it might be a radio station (Julier 2007). Although it’s an extreme example, as all designers pick up more digital media influences, media agnosticism is likely to increase. And this agnosticism is another factor that makes a typology of action useful to design activism, since the typology facilitates discussion of actions that cut across media and causes.

The repertoire concept also gives design a way to reflect on what is new in terms of design activism, rather than simply in terms of a material, a physical form, a method or an aesthetic movement. As Tilly and others have observed, the repertoire holds fairly steady, but where are the innovation in actions? Could designers consciously innovate the typology by borrowing actions from other repertoires? What are the new ways of furthering a cause? Are they relevant to other activists? What cultural or political influences are at work on the repertoire?

The types of debates and questions that I outline above suggest the range of benefits that may result from using a typology of action as a conceptual tool to explore design activism. In the next section I explore how social movement scholars develop typologies and how to adapt their methods to design.

Methods of studying actions

The general method of research to describe and assess repertoires of action is known as “protest event analysis.” It is based on the notion that the repertoire is manifested in real life through a series of collective action events such as protest marches or boycotts. Event analysis seeks to collect and analysze historical information about these events, typically in the context of a country, over a set period of time (Koopmans 1999). Ideally the researcher would have information about every event that took place during the given period in the country. The reality, of course, is much different, and researchers are faced with the question of how to find out about as many of the events as possible so as to paint a representative picture of the actual activity during the period. Typical sources are newspapers and police records. Rucht and Neidhardt have profiled the challenges associated with these sources in detail (Rucht and Neidhardt 1999) based on their German ProDat project, which contains 10,000 events over more than 40 years.

Before looking in more detail at the method of collecting and analyzing data for event analysis, I will consider how the general approaches of “event analysis” or “collective action research” may suit design. How can we take the essence captured by the concept of “event” and formulate it in a way that is applicable to design? And how should we factor in the notion of collectivity or geographic location?

The essence of the term “event” has several components. The first is that it automatically narrows the definition of activism, eliminating all the day to day, behind the scenes work of activists and focusing on the public display of claim-making. The second is that it has specific time-space connotations that also neatly delimit a unit of study. Design, on the other hand, tends

to be organized around processes (eg development, production, use) and their outcomes in artifact form, rather than events. For this reason, the purposes of my study are better served by a term such as “occurrence” or “instance,” both of which suggest something happening, but without specific time-space constraint. I have developed a definition of such a happening in terms specific enough to constitute a unit of study, as shown in Box 1.

Box 1: The unit of study

definition of an instance of design activism

1. Claims are made and directed at other actors, either at political decision makers to change/influence their decisions or at members of public to change their behavior.
2. Claims are made on behalf of a neglected (deprived, excluded) group.
3. The instance can be either client- or designer-led, and for this reason public agencies (often the clients of design activism) are not being excluded as actors, as they often are in protest event analysis.
4. The action is not commercial, that is to say, the bottom line, or priority for the design work is largely environmental or social. Businesses are generally excluded as actors except in the rare cases where their activism is perceived to be on the leading edge of activism as opposed to the following edge.

How should we factor in the notion of collectivity? I contend that almost any designed artifact stems from collective action. In its classic form, the collection of actors would include the designer and the client, possibly the end customers. Most design processes also typically involve various experts in technical and social fields such as engineering, ergonomics, anthropology, psychology and so forth. In design activism, the collection of actors is somewhat different and often includes other activists and stakeholders in a claim (or cause) and “client” organizations are nonprofit or public groups rather than companies. In most cases, therefore, design results from a collective process, although the collection of people may not assemble in the form of an “event.” The important point is that design activism typically does reflect a collective effort to make a claim, and in this sense it represents collective action.

Event analysis research has typicall been country-specific (Tilly’s work on France, Rucht’s work on Germany, McAdams work on America). But choosing the context of a specific country makes less sense in the case of design activism. Especially during the last 10 or 15 years, design activism is probably more closely aligned to certain approaches and ideas (such as eco design) than it is to a specific place, particularly as far as westernized countries are concerned. For example, London-based architects engaged in inclusive design are on the whole more likely to be connected to others around the world working in inclusive design than they are to be connected to other London architects who concentrate on eco-technologies such as straw bale construction.

In the end, I have chosen to let my sources dictate the geography of my study. In lieu of the newspapers favored by social movement researchers, I am using the popular design press, namely three U.S. magazines: Metropolis, Architectural Record and ID (The International Design Magazine). Although I began with five sources, I dropped the two UK publications, The Architectural Review and Blueprint, after a pretest showed that their reporting style generated very few instances of design activism. Using the design press has many of the same strengths and weaknesses found in the use of newspapers.

The widely accepted use of newspapers has several justifications. First, events reported in the mass media suggest actions that have become socially and politically “real” in their consequences by virtue of becoming news (Rucht and Neidhardt 1999). Second, as Hocke notes, an explicit aim for many protest groups is to get media coverage, using slogans, tactics and spectacular incidents to increase the chances that they’ll be mentioned in the news (Hocke 1999). Third, newspapers are typically long running publications, so it is possible to use a consistent data source over periods stretching, in some cases, over more than a hundred years.

My sources are quite long-running publications (minimum 25 years) that suit the time frame of my study (roughly the years from 1987-2007). As with newspaper reporting on collective actions, the very appearance of an occurrence of design activism in the design press brings the occurrence to the attention of the public (albeit the public that reads design magazines) making the actions socially and politically "real" in their consequences. But it also suggests that the activists sought media attention and we can infer that the action may have been reported in the non-design press (eg general newspapers) as well.

On the negative side, the design press will not report on all design activism and it may have a bias about the types of design activism is does cover (eg a preference for activism within a certain discipline or a preference for certain causes). In the end, the presence of a report in a design magazine says more about its interest to other designers than its social impact, relevance to a given cause, or position within a campaign for change. As with newspapers, using the design press is a result of a deficiency, or lack, of other sources, rather than its suitability per se.

Wading into the data

Thus my research is following a classic, event-analysis method with the aim of building an empirically based picture of design's typology of action. I am looking through old issues of design magazines to find reports of design activism that meet my definition of an instance. Upon finding these reports, the next step is to translate, or code, the report into data that can be analysed. I am identifying and coding a range of variables based on two pretests of about 100 cases each. My data, compiled using SPSS software, is non-parametric (meaning that my population of cases does not fit standard assumptions about probability distributions). These are some of the main variables I am tracking:

- form of action (eg a design competition, a demonstration product)
- cause (eg disaster prevention/aid, reduce environmental impact, improve accessibility)
- discipline (eg architecture, product design, graphic design, landscape design, lighting design)
- medium (eg building/structure, product, landscape, interior, 2D visual)
- strategy underlying the action (is it generally reformist or visionary?)
- location (continental region, country, state)
- creator of the opportunity for activism (eg instigated by the designer or by an activist client)
- financer of the opportunity
- whether students are behind the act

Given the nature of design publications, each instance of activism also typically has two or three associated images, so I am also coding my perception of how compelling the images are, as I hope to use a great many images in communicating my results to a broader audience.

At the time of writing, I have coded about 15% of what I expect to be roughly 2000 cases; here I present some of the initial analysis with the caveat that it is only based on a small amount (representing the year 2007) of the yet-to-be-compiled, final dataset. So far, I've found that the prevalence of activism is roughly proportional to the prevalence of the design disciplines. In other words, no one discipline appears to be noticably more activist than the others: architects account for roughly half of the activism, as they account for about half the employed designers (if we exclude graphic designers) according to U.S. occupational survey data (Occupational Outlook Handbook 2008).

In terms of who is using design activism, interestingly so far it appears that close to half the instances of design activism (43%) are instigated by designers themselves or by design-oriented nonprofit organizations. The next biggest group using design activism is nonprofit organizations (which includes schools and universities) at about 25%. Public (government) activist clients run at about 13%. Coalitions, companies and unknown clients make up the remaining. U.S. cases of activism make up about 72% of the total so far, with Europe contributing 10%, and Africa, Asia and the Middle East each at about 2%. About 8% of the instances of activism are characterized as “global” (eg international design competitions).

The typology of action so far has the general shape shown in Table 1:

Table 1: Intial shape of the typology of action

action	% of total	explanation
demonstration artifacts	28%	demonstrating positive alternatives that are superior to the status quo
info/communication	27%	making information visual/tactile, devising rating systems, creating symbols, making physical links, etc.
conventional actions	13%	proposing legislation, testifying at political meetings, writing polemics, conducting research, etc.
competitions	10%	
service artifacts	10%	humanitarian aid
events	9%	conferences, talks, installations or exhibitions
protest artifacts	3%	confrontational, even offensive, prompting reflection on the morality of the status quo

Meanwhile, the causes so far have a distribution along the lines shown in Table 2 below. I expect that over time I will see independent variables, such as natural disasters (Hurricane Katrina, Asian Tsunami) or terrorist attacks (9/11, Madrid bombings), influencing the causes pursued through design activism.

Table 2: Frequency of causes

cause	% of total	explanation
nature	38%	reducing impact, preserving wilderness, regenerative
community enabling	23%	education, user involvement, sense of place, relationships
human rights	13%	justice, affordability, accessibility and democracy
cultural diversity	11%	immigration, religious diversity, ethnic/racial diversity, time (memorial)
disaster relief	9%	
range of causes	4	

	%
health	3 %

Regarding the underlying strategies for activism so far, only about 15% of the cases qualify as “visionary” — envisioning new relationships and new forms rather than reforming existing ones. Eighty-five percent of the cases are “reformist.” Although designers and design nonprofits are responsible for instigating about 43% of the instances of activism, they account for a much bigger proportion—about 65%—of the visionary strategies. This may indicate the importance of designers undertaking activism themselves as opposed to being activists for hire. As proper activists, designers are more likely to help people imagine not just how to reform broken societal patterns, but to imagine and invent new ones. As Dovey notes, “empowerment” for change suggests not only the capacity to identify one’s real interests but also the need to connect those interests to a well-imagined future (Dovey 1999).

Conclusion

In this paper I have argued that by using methods pioneered in the study of social movements, we can develop an empirically based typology of action to aid us in the use and study of design activism. I have argued that this conceptual tool will enable designers to look at activist work in new ways. I have breifly reviewed the sociological study of social movements and activism and described how I have adapted those methods to suit design. Finally, despite the fact that I have only preliminary data, I have described the shape of some of my findings so far as an indicator of how the full study will unfold.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The *Roots of Change** embraced by *local food system*

Design visions, from the sustainable food system to the prospect multidisciplinary key-principles for a sustainable food development

Ana Thudichum Vasconcelos [1]

Abstract

The current paper intends to define the scope of the food sustainability concept. The idea of food sustainability carries a multidisciplinary vision of the problems that are inherent to the foodstuff production and their consumption, in a unique dimensional view composed by a network of complex relations, connections and natural inter-dependences.

Hence, the food sustainability vision is based on a series of principles, transversal to the several areas of knowledge and which have constituted the roots to a new paradigm of food consumption. Here, the design perspective is to contribute to the promotion and implementation of the sustainable food community, based on specific key-criteria. This food community is structured on the reflection of new well-being and ethical values, thus, being a model that is possible to insert in a concrete landscape and cultural reality.

[1] Lisbon University, Faculty of Fine-Art, ana.vasconcelos@fba.ul.pt

Introduction: sustainable food system

What are we talking about when we talk about food sustainability? Does food sustainability mean the consumption of organic products? Is it better to consume organic products even when, these, travel long distances issuing great quantities of carbon dioxide to the environment? Is biodiversity always related to the methods of organic production? Is food sustainability limited to environmental criteria? Does food sustainability include social issues and community-related aspects? Should food sustainability take agricultural issues into account, or simply consumption issues? Should we consider supporting small organic producers and regional food producers, so that they do not surrender and continue dedicating themselves exclusively to conventional agriculture? What benefit can we rip from a system of re-approximation between consumers and producers? What about our health? Do we protect it while consuming food, whose origin and production methods are unknown? How about our landscape? Are we preserving it, while insisting on food systems based on importation? And what becomes of traditional flavours? Are those who produce them a part of our gastronomy? If these producers give up on their fight, don't we risk losing part of our cultural heritage with them? And what happens to the small local producers, when we prefer the specialised consumption of the multinational monopoly-held systems? What happens to economic development?

.

Sustainable food communities

A sustainable food system is one that is sustainable, composed of people with knowledge of the food system, locally based, as economically lucrative for farmers and farm-work, as off-farm labour, participatory, relational, fair and ethical, regulated, sacred, healthy, diversified, culturally nourishing, seasonal, and more concerned with sustainability and equity than profit (Kloppenburg and others Cit. Allen 2004, 80).

The first principle of sustainability will be to think of sustainable development as a complete system of relationships and inter-dependence. This concept of sustainability comprises the establishing of links of a network in itself, composed of several complex systems. This unique dimension of the agricultural food system is interpreted by Jonathon Porritt as "one planet agriculture" (The Ecologist 2007). This provocative sentence, by the Chairman of the biggest British association for sustained agricultural development, the Soil Association, prospects a non-retail dimension of the big problems inherent to agriculture. This means that if the agricultural food system were to be considered one only, probably the planetary benefits would be more than many.

Another statement, which symbolises a harmonious vision embracing the agricultural food problems, was made by Carlo Petrini, chairman of the Slow Food movement, when referring to the *comunità del cibo* (Petrini 2005, 234). This vision involves the understanding of the food system as one only, made by people for people. The *comunità del cibo* refers to the sharing of transversal knowledge of food-related issues, in which the communication channel gives privilege

to social relations, which are inherent to the productive universe and food consumption. Speaking of “one planet agriculture”, or of “a food community” is the same as saying that the agricultural food system is one only, composed of a complexity of relations and connections, based on the several aspects of human life: nature, economics, social and cultural aspects. These several dimensions of the system are often enunciated as the three big pillars: economic, ecological and social sustainability (Mulier, 2), or as the *trinità* (University of California Sustainable Agriculture Research and Educational Program, Cit. Allen 2004, 83) of the agricultural food sustainability. These three big areas of sustainable food development are described as follows,

… Economic, by providing producers with a profitable route market; environmental, by cutting down on the pollution associated with food transportation, and by raising interest in consumers as to how the land around them is farmed; and social, by encouraging a sense of community between buyer and seller, town and country (The Policy Commission on Farming and Food, Cit. Sustainweb 2002, 3).

If we are to consider cultural factors as part of the social/human production, then the parameters of sustainable community and sustainable agricultural food community end up being based on the same key-factors. An example of this is illustrated by the following definition, subscribed by several authors,

A sustainable community is one that has a long-term capacity to regenerate itself socially and economically, and that has the capacity of reproducing itself and being economically, socially, culturally and ecologically involved (Scott, Park et al. 2000; Kline 1995, Cit. Mirata 2005, 3).

This definition can be contested by the concept presented by Allen, which introduces a significant change in the sustainable agricultural food scenario. This author defines a de-codifying matrix of the sustainable agricultural food community, designated by the 3 E’s: “environmental, economic and equity” (Allen 2004, 82). This definition introduces a subtle interpretation of equity, i.e., in this specific food context, the values of justice are emphasised as a means of structuring the social dimension. For Sonnino (2007), *equity and justice,* are the key principles for sustainable development, in the sense that it attempts to meet the basic needs of all human beings while also acknowledging the potential for imposing cost onto future generations. In the agro-food system, this idea of justice refers to the social relations, which involve production and food consumption. This means that, in the scope of food production, social sustainability can be an equation in two ways: (Mulier, pg. 5) one, by including internal factors inside the agricultural community; and the other, by including external factors. Internal factors comprise workers’ rights and treatment of animals in the farm. External factors refer to the benefits that these production units can bring to the surrounding community, by being an opportunity and support to individual farming structures (Gips, 1988, Cit. Allen 2004, 86).

The idea of justice can also be interpreted as a principle of solidarity. The communities which are external to the agricultural community express solidarity. They support the latter by means of conscious consumption and knowledge of the above-mentioned social conditions.

To sum up, the quality of the social environment is determining for sustainable food

production and consumption. However, this aspect cannot be understood externally to the wide economic context. This means that social and economic structures of the agricultural food system, undoubtedly, affect the environment's quality. In a general way, we can say that the interaction between the wide social, economic, environmental and cultural systems, in which the agricultural food system is inserted, influence agricultural production, its distribution and consumption. In more restricted terms, agro-food sustainability system will be possible within a balanced perspective, which can be achieved through understanding the community, where the connection and support amongst members will be the fundamental factor to its operation.

Designations for a sustainable food system

Sustainable food(…) refers to food which matches a number of criteria, including: Proximity(…); Healthy(…); Fairly or co-operatively traded(…); Non-exploiting(…); Environmentally beneficial(…); Accessible(…); High animal welfare standards(…); Socially inclusive(…); Encouraging knowledge and understanding(…)(Sustainweb 2002, 2).

Throughout the times, there have been several definitions to the concept of unconventional agricultural food system. Many of them correspond to diversified trends in the scope of the sustainable agricultural food system; others emerge in the midst of more specific areas of knowledge. The most meaningful terminology is:

_community food security (Anderson and Cook 1999; 2000; Pelletier et al. 2000; Bellows and Hamm 2003, Cit. Feagan 2007, 24);

_alternative food regimes (Friedmann, Cit. Allen 2004, 64);

_alternative food systems (Gottlieb and Fisher, Cit. Allen 2004, 64);

_integrated food system (Clancy, Cit. Allen 2004, 64);

_alternative food streams (Grey, Cit. Allen 2004, 65);

_alternative food networks (Marsden, Cit. Allen 2004, 65);

_alternative geography of food (Whatmore and Thorne, Cit. Allen 2004, 65);

_alternative agro-food networks and systems (Goodman 2003; Watts et al. 2005, Cit. Feagan 2007, 24); alternative or shortened food chains (Rending et al. 2003; llbery and May, 2005, Cit. Feagan 2007, 24);

_the 'quality turn' (Llbery and Kneafsey 1998; Morris and Young 2000; Goodman 2003, Cit. Feagan 2007, 24);

_local food systems (Herderson, Cit. Allen 2004, 64; Feenstra 1997, Henderson 1998, Lacy 2000; Hunrichs 2003, Cit. Feagan 2007, 24; Feagan 2007, 24; Pretty 2001, 1).

Our interpretation perspective of the sustainable food system is one of linking the several areas of knowledge, providing a global vision of it. Therefore, we interpret the food system as a whole, as a system composed by an intricate set of networks, in which some levels of relationship gather, simultaneously, establishing several types of connections. In other words, the idea of food sustainability carries a multidisciplinary vision of the problems that are inherent to the production of food goods and their consumption.

We foresee a planetary vision, where the main point is the quality of human life. This

humanitarian perspective of the food system presupposes co-operation from Man to Nature. This co-operation can become effective through mechanisms that may contribute to the construction of a close relationship between urban and rural communities, between the field and the city.

The building of a food system based on this idea of physical proximity, matches in every way with the presuppositions of sustainable development, in which the resolution of problems begins by spotting them, adding value to local economy and territorial landscape, empowering social interaction. The nearness concept connotes the re-locating of food consumption to a limited geographical area, through social interaction; in which, producers and consumers have a face.

Therefore, a sustainable food perspective presupposes a shortening of the food chain. This means that the smaller the distance is between "from the fields to the table", the bigger the degree of food sustainability. Ultimately, we can say that direct trade between producers and consumers provides the shortest circle, which can be established.

In this sense, we adhere to the denomination of *local food system* to define sustainable food system. This terminology carries a dimension of nearness and the concept of system. Proximity is inserted within the perspective of local sustainable development. The notion of *food system* includes all the aspects related to food production phases, distribution, consumption and food waste.

The roots of change

(Founders agriculture working group 2001, Cit. Pinderhughes 2004, 187)

Organic farming[2]

Organic agriculture is a holistic production management system, which promotes and enhances agro-ecosystem health, including biodiversity, biological cycles, and soil biological activity. It emphasizes the use of management practices, preferentially to the use of off-farm inputs, taking into account that regional conditions require locally adapted systems. This is accomplished by using, where possible, agronomic, biological, and mechanical methods, as opposed to using synthetic materials, to fulfil any specific function within the system (FAO/ WHO Codex Alimentarius Commission 1999, Cit. King, 2006, 3).

The principles and techniques of organic agriculture promote an improvement in human, animal and environmental health and establish a relation of respect for the planet.

Organic agriculture is based on ethical principles and brings about harmony between Man and Nature. Human beings are a part of this natural environment and they should be co-operative with Nature, and not compete with it. Organic agriculture systems produce food items, similarly to natural eco-systems (Quinta da Serradinha 2008), considering the farm as a whole-farm system. The organic farm emphasizes multidiscipline and often develops specific research approaches

[2] Organic agriculture also known as "agricultura biológica" in Portugal, as well as, in Italy "agricoltura biologica", "agricultura orgânica" in Brazil and "ecologic agriculture", in Spain and Denmark, or "natural agriculture" in Japan.

(Allen, 2006, pg. 39).

At an environmental level, the advantages of organic agriculture are of several types. Within the scope of ecological practices, we highlight *bio-dynamics* and *permaculture*, because they incorporate the concept of a complete life cycle in a more effective manner, using renewable energy sources, as far as possible, thus, reducing the dependence on external energetic sources. This way, organic agriculture saves an average of 30 per cent of fossil fuel, when compared to the conventional agricultural system (Steffen 2006, 52). In a general way, it also reduces the quantity of inputs.

This type of agriculture does not use chemicals in food, nor does it use pesticides, antibiotics, or genetically modified food. Organic agriculture harvests using *green compounds*, organic compounds to fertilize the soil, adding nutritive and mineral substances, which preserve the humus. These techniques enable the improvement of the soil, avoiding its exhaustion. Additionally, while practising the principle of seed rotation, organic agriculture contributes to the production of a richer soil, caring for its health, maintaining biodiversity and the capacity of retention of a bigger quantity of water. Last, but not least, because this type of agriculture does not use chemicals, it helps preserve the quality of drinkable water.

Organic practices improve animal quality of life, thus, contributing to a healthier food chain. They promote biodiversity in roughly 30 per cent, as opposed to conventional agriculture, which invests on "specialization and mono-culture as essential to efficiency and productivity" (Allen 2006, 37). In organic agriculture, pest control is done through encouraging predatory insects.

The beneficial action of organic agriculture is extended to the preservation of gastronomic culture and protection of landscape, promoting the variety of plants that are produced in syntony with productive systems, adapted to the diversified locations. Understanding the natural world implies harvesting within seasonal rules, which means production and consumption of fresh products that are produced and preserved in a natural way.

The development of organic agriculture makes up for a scenario of food quality, where the final consumer of any agro-food system contributes to the planet's health and, ultimately, eats better, when preferring products that originate from organic agriculture[3].

Biodiversity

In conventional agriculture, the alternative to the process of specialisation has been promoted by organic agriculture and by several other initiatives that promote food biodiversity, such as, the Slow Food and Nayakrishi Movements (Mander 2006, 22), and many other organizations that dedicate themselves to the preservation of seeds through the production of deposits.

[3] Products of organic agriculture contain a "bigger quantity of dry matter, minerals and vitamins. On average, organic products contain more Magnesium (29.3%), Vitamin C (27%) Iron (21%), Phosphorus (13.6%), Calcium (26%), Copper (11%), Manganese (42%) Potassium (9%) and 15 % less nitrates; their content is richer in fito-nutrients, such as Flavonoid, which have anti-oxidation, anti-cancerigenous effects and protect the cardiovascular system, amongst other effects in human health" (Agrobio 2006).

Organic agriculture increases biological diversity in several ways: firstly, through the type of production, which by itself is based on a wider diversification of plantations. Secondly, it protects regional and traditional productions. Finally, harvesting through organic techniques produces an increase in the amount of living organisms[4].

Lastly, the organizations of seed deposits have helped preserve traditional agriculture, by actively supporting farmers to promote diversity through the prevention of local varieties, guaranteeing abundance and the re-introduction of traditional culture seeds[5].

Sovereignty

The principle of self-sufficiency is based on the creation of a food community that can supply itself without needing to import, i.e., a community that knows to manage its food resources within its regional or national geographical boundaries "as a people's right to decide about its own agricultural and food policy" (Social justice and human rights network 2008). The application of this principle implies a macro vision of sustainable community.

All local, national and regional entities and communities have the inherent right and obligation to protect, sustain and support all necessary conditions to encourage production of sufficient healthy food in a way that preserves the land, water and ecological integrity of the place, respects and supports producer's livelihoods, and is accessible to all people (Mander 2006, 12).

This concept is widely promoted by Vanada Shiva, in defence of the farmers of the southern part of the planet; it is one of the leading policies of the *Via Campesina*, an international movement that co-ordinates organizations of small and medium farmers. The idea of sovereignty is also practised by the Japanese food consumption cooperative: the *Seikatsu Club*.

The principle of food sovereignty promotes the national local consumption, only resorting to the supply of imported products when a certain food variety does not exist in the country. This attitude protects local farmers, their economy and food culture.

Fair trade

The concept of *fair trade*[6] is applied to food products for consumption, imported from long distances, especially from southern countries. The *fair trade* initiative is particularly important to food goods that do not exist in the North of Europe, which have long been introduced in our food system. Initially, such products were coffee, tea, cocoa, and banana. Presently, a lot more food

[4] Around 30 per cent in the number of species and 50 per cent (King, 2006, pg. 4), when compared to conventional agriculture.

[5] It's the case of the Bangladeshi Nayakrishi movement, which has supported around 100.000 farmers in the sense of re-taking organic methods and implementing traditional crops in their areas, using the slogan *freedom zone* (Mander 2006, 22).

[6] Translated into Portuguese as *comércio justo* and into Italian as *mercato equo-solidale.* The *fair trade* movement began in Europe, in the 80's, and it has been supported by 47 countries (Mander 2006, 23).

goods are included in this basket of importation, coming from distant countries. The *fair trade* label defends dignity in what concerns working conditions of workers from far-off agricultural plantations; it promotes the right price, without exploiting those who produce it. The initiatives carried out by this movement are meritorious for implementing this principle of social justice, acting as a means of commercial support.

The promotion of this concept, supported by several associations and institutions that are exclusively dedicated to the activity, and the acknowledgement of its values, by the general public, have enabled the expansion of the concept into the short food chain. Herein, the focus is on social development at local and regional levels, with quality, justice and solidarity towards the rural community.

The *fair trade* symbol seeks to alert consumers to the issues of solidarity and respect for agricultural work. The *fair trade* label sensitizes consumers and makes up for a consumption alternative. While shortening the distance between producing and consuming communities, they make the system of agro-food consumption fairer and more transparent.

From the consumer's part, the acknowledgement of this movement can make consumption become more conscious, both in terms of importation of long distance products, and trade of local food products.

Food links

(F3 2000, 22)

Promotion of the simple concept of link, between consumer and producer, as the starting point for a more sustainable food economy (Local Food and Sustainable Development 2000, 6).

The proximity between producers and consumers promotes a relation between those who harvest and those who eat. The interconnection between these two extremes of the food chain enables the creation of a healthier system at the social and environmental levels and, particularly, it improves food quality.

The establishment of direct contact increases the degree of dependence, through the paving of efficient co-operation ties, thus, contributing to social and agro-food balance. The mutual support, the trust relation and the values of transparency that are built between the intervening parties, enable the increase and re-qualification of quality of life.

The initiatives, which are based on this close relation, make communication easier. This direct contact enables the obtaining of a quick feedback from the system, the perception of satisfaction or dissatisfaction of its partners, thus, allowing the introduction of changes that may improve the system of distribution and consumption.

"From the fields to the table" helps to adjust demand to supply, especially when agreements for supply are established between producers and consumers. On the one hand, this

close relation benefits the consumers, who can gain access to a continuous quality food system; on the other hand, the producers, who sell their products and see them valued.

Participation model

Under the perspective of the agro-ecology movement, participation is a key topic. It means the possibility of the consuming community - external to the rural community -, getting involved in issues of agricultural production. This participation moves towards a system, where the consumers support and improve rural communities, thus, helping to preserve their cultural identity. Participation through the mechanism of sharing information and experimenting becomes fundamental to encourage knowledge and understanding of the cultural food system.

Capra (2005, pg. 20) adds that direct participation in agricultural activity allows the learning of sustainability values.

Buy local

The improvement of individual and public food health depends on the easiness of access to organic products of local production. The enhancement of local food can bring about economic, environmental, nutritional and social benefits.

The access of local food farmers allows the consumption of seasonal products and a great amount of fresh products, with higher levels of nutrients, as opposed to industrially processed food items.

In environmental terms, the consumption of local products minimises food transportation costs and can contribute to the reduction of packaging. Finally, local food trade implies a smaller emission of carbon dioxide onto the atmosphere, thus, improving the quality of the air.

The fundamental consequence of access to local and organic products will be the change in food consumption behaviours.

Plugging the leaks
(F3 2000, 12)

Plugging the leaks refers to the retention of money within the local area. The promotion of local economy can be stimulated through the structuring of a local consumption network, specially, by developing direct systems of consumption between producers and consumers. This network of local and direct consumption networks retains the circulation of money and promotes the creation, or maintenance, of jobs and gives dynamics to local economic development. Keeping the money on a certain territory represents its bigger circulation in that area, whereas consumption through the international food circuit contributes to the production of much less wealth in the local scope[7].

[7] This situation can be illustrated with the Cornwall case (Plugging the Leaks), which compares the result of buying locally originated food and

Apart from developing the local economy, a network of local and direct consumption, brings economic advantages to producers and consumers. A system of direct consumption eliminates the need for intermediate agents. The suppression of the *middleman*, such as freight operators, processors, packaging companies and retailers (Vijoen 2005, 45), means paying a fairer price for food. This type of trade also minimises the cost of transportation, which is also part of the final price that consumers pay for food. It also reduces the environmental cost.

In the social scope, the relation of proximity between producers and consumers favours agricultural stability, this being a particularly important factor for small farmers, thus, promoting dignified working conditions and incomes.

Local landscape

The local landscape suggests the widening of the boundaries of urban perimeter of cities, including their *greenbelt*. Therefore, taking cities 'embedded' in their own *hinterland* into account brings environmental, landscape-related, educational and nutritional benefits. In strategic terms - bearing ecological and economical concerns in mind -, the inclusion of the city in its *greenbelt* can satisfy some of the food needs of urban areas, namely, at the level of fresh products.

Concerning the sustainable food system, from the environmental quality viewpoint, there are good examples of harmony between the city and the countryside, as is the case of Adelaide[8]. It recycles its residual water to supply it to the agriculture in the periphery of the city. It is also the case of Bristol[9], which recycles sewage, transforming it into soil conditioner and fertiliser.

The widening of the city's urban perimeter boundaries to its surroundings, being an integral part of it, can provide for a better relation between the urban area and the countryside. In the peripheral space of the city, named *greenbelt*, leisure activities to benefit from the green areas can be stimulated. Urban population is further and further away from the rural universe, both at a physical level and that of memoir of the countryside. This interconnection of urban spaces with rural ones, provide a gathering between cultivation and food harvesting. Nowadays, there is a growing demand for these green spaces from the urban citizens, thus, materialising this proximity in several ways. In this type of interaction, we highlight pick your own, "le agriculture hobbistiche – in particolare frutteti e alevamenti – le fattorie pedagogiche" (Donadieu 2006, 58).

buying in supermarkets: "every £1 spent in a local organic box scheme generates a £ 2.58 for local economy, compared to just £ 1,40 each £1 spent in the supermarket".

[8] In this Australian city, tens of thousands of hectares of land on the edge of the city are cultivated using the city's wastewater for irrigation, growing vegetables, as well as, grapes and fruit. There is some concern about trace quantities of heavy metals that could accumulate in the soil, but it would take decades to cause any problem. Adelaide's wastewater crop irrigation system is regarded as one of the great success stories of urban agriculture (Viljoen 2005, 38).

[9] Another case illustrated by the same author is that of Bristol, Wessex. Water has developed its own system for turning sewage into a soil conditioner and fertiliser. It dries the city's entire sewage output and turns it into small pellets called Biogran, which are then sold to farmers and land reclamation companies. Again, trace amounts of heavy metals have been quoted as problematic. But this is becoming less of a problem, because cars no longer run on leaded fuels in the UK, and in Bristol, de-industrialisation has led to a great improvement in the quality of Bristol's sewage sludge (Viljoen 2005, 38).

In this context, the preservation of local landscape makes a lot of sense, as Viljoen (2005, 35) refers. This author notices that some cities of Italy and France still have a very strong relationship with their immediate *hinterland*, with *peri-urban* agriculture still much in evidence. This is the case of Florence, which is still surrounded by orange and olive groves, vineyards and wheat fields, where a large portion of its food requirements are grown.

Conclusion: Food network dimensions

We can define food networks as the (physical or virtual) links between different types of actors, that exist for the purpose of carrying out activities associated with the production/ exchange of food, and the development of food related knowledge (Meroni 2006, 52).

Food sustainability involves the creation of a network of systems that promote interpersonal relationships and the shortening of distance between individuals.

This network has a global dimension, in a macro vision of the understanding of sustainability principles, and has the merit of gathering people around fundamental values, enforced by a relation of communication, support and syntony, in what concerns food system problems.

The web unites several communities, using technological instruments to develop connection. These relationships create a circle of influence to the social and environmental issues of organic and regional agriculture. In the scope of agro-food, there are several examples of this type of networks. Due to their dimension and international reputation, they are often named movements, such as the Via Campesina, Urgenci and Slow Food[10].

The micro dimension network acts locally, valuing the economy, the social relations, the food goods produced within, the environment and local landscape. Therefore, this local vision, promote systems a community of food bases on the participation model, considering within the proximity between the intervening food partners: farmers and consumers.

Most principles of sustainability are based on the relation of proximity, through the development of local actions. The development of local consumption and the concept of food community, involve the construction of relationships amongst producers, between producers and consumers, and amongst consumers. This network of relationships can be the key to food sustainability, based on a solid food community, where there is trust, interdependence and promotion of mutual comprehension. It should also feature good communication amongst individuals, co-operation towards nature and provide environmental and nutritional, cultural, economic and social dividends, based on the proximity network.

[10] The Slow Food movement and its 80.000 members, distributed through 45 countries, has been protecting the diversity of species, thus, promoting a renewal of interest for local and regional specialities (Mander 2006, 22).

To conclude, a healthy food community can work, if it is aware of itself and its role in economic and environmental development. Maintenance and spreading of the food community is based on education and participation, thus, stimulating knowledge of food sustainability principles.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Ethically Sound Innovations

The phenomenology and taste of the outdoor elites

Minna Uotila[1], Piia Rytilahti[2]

Abstract

In recent discussion, an ethical attitude towards designing, engineering and consuming has been associated with an alternative and 'socially oriented' – even socio-critical or antisocial – logic of marketing and consuming. Such an attitude could easily be seen as opposite to that of quarterly economics and the principles of economical effectiveness. Yet, the new consumer elite, i.e. the emerging ethically sound elite of Western society, might well consist of diverse groups of well-off and socially aware individuals. The aim of this paper is to illustrate how the study of communities of connoisseurs opens up possibilities for ethically and ecologically sound innovations in which both the exchange value and the unique value of a product are designed into its life cycle.

1. Introduction

‘Average is not enough’ (Male climber)

Alongside the mainstream conceps of ethical design, (sustainable) responsible design (Cooper 2005; Sethia 2005), sustainable or eco-design (Tukker et al. 2001; Mathieux et al. 2001; Beard and Hartmann 1997; Holdway, Walker and Hilton 2002) and ethical marketing or management of ethics (Madsen 2005), one can see the breakthrough of high-design products and services. While these have added value and may even be considered luxury items, the associated production and marketing practices are ethically highly constructed on all levels of business. In the vision of the present study, the long-term success of business may arise from the ethically aware and wealthy sectors of consuming society, sectors comprising market groups and social classes that neither need nor desire to accept anything that is designed, produced or marketed unethically. An approach of ‘learning to generate more with less’ makes it possible to design and produce ethically high-oriented products and create successful brands that carry the idea of environmentally sound design. Within the vision of the two research projects (Sumac and Emergence of Luxury) referred to in this paper, the green industrial revolution needs to take into account both old and new ethics of consumption (Rytilahti, Uotila and Narbrough 2007).

Very little research has been done in the area of high-quality or luxurious products from the point of view of sustainability. The traditional conception of ‘old sparkling luxury’ has become embedded in our attitudes and social structure at the expense of the more sustainable aspects of new luxury. The new luxury emphasises the high quality, durability, and reparability of products (Danziger 2005; Reinmoeller 2002; Uotila, Falin and Aula 2005; Kirig and Wenzel 2005). A shift to the principles of sustainability, i.e. dematerialisation, products becoming services, and recycling (JPC 2005), can be promoted by the meaningful immaterial, emotional and linking values of the new luxury (Cova 1997; Rytilahti 2008). The immaterial values of a product are present after the product has passed its commodity phase (Lehtonen 2008, 98-99; Appadurai 1986, 13-15).

The fundamental and overall theoretical perspective chosen for the proposed project views the phenomenon of ethically sound consumption and design in the light of Karl Popper’s thinking. In his theory of three worlds, Popper distinguishes natural objects as part of World 1, subjective awareness as an aspect of World 2, and cultural products, events and social institutions as manifestations of World 3 (Popper & Eccles 1977). On this theoretical basis, ethically sound innovations could be defined as:

- products and services -- objects of World 1
- designers’, producers’ or consumers’ experiences of ethically sound products, services and their productions -- objects of World 2
- culturally shared understanding or collaboratively produced knowledge of such products -- objects of World 3.

The study views responsible design as mainly associated with subjective experiences and the senses, a choice of theoretical perspective that links the research to the qualitative tradition. Against this theoretical backdrop, the paper goes on to investigate empirically the experiences of precursor users and users as innovators of in the Finnish and the Scottish contexts. The paper also presents a heuristic scenario and a concept with ethical added value for the sport business in particular.

2. Research context and methodology

The aim of the article is to describe the underpinnings of the research on outdoor sports conducted from a sustainable and ethical point of view as part of the project 'Sustainable Innovative Materials in High-Tech Applications' (Sumac). This ongoing project, funded by the Academy of Finland (grant no. 117845), has provided the research data, heuristic scenarios and concepts to be described below. The scenarios and concepts were elaborated in a workshop arranged for students working on their master's thesis on clothing and in a course of product design for first year students in design. The purpose of the scenarios was not to produce a detailed description of a particular sport product but to facilitate the creation of visions for an iterative product design process by engaging students of design in user experiences (see Keinonen and Jääskö 2004).

The research on outdoor sport cultures referred to in the paper goes back to 2004 and was completed as part of the project Emergence of Luxury, also funded by the Academy of Finland (grant no. 205608). The linkage between the two projects lies in the vision that ethical design will act as a driver of sustainable economic development, which will arise through environmentally and ethically aware consumer groups. The two research projects have also provided empirical material that allows us to better illustrate and examine cultural diversity in ethically sound design and innovations.

The research design used in this study draws on and develops the perspectives that have evolved in our previous studies on experiences in the area of sport and leisure (Uotila, Falin and Aula 2005; Uotila et. al. 2005). Data collection in the Finnish and Scottish contexts was conducted in the Sumac project through documentary videos and group interviews during spring 2007 and autumn 2008. The first qualitative case study was carried out during Easter 2007. It is a video documentary of a three-day skiing trek undertaken by six outdoor enthusiasts (n=6) in northernmost Finland; the documentary was produced by the group itself. The informants were advised how to use the camera and what kind of documentation might be relevant for our research purposes. All the practical decisions, such as when to shoot footage and how, were left to be made by the informants in real time, in keeping with the egocentric video method used by Bidwell and Browning (2006). This pilot study was based on the idea of lead-user communities as innovators (von Hippel 2005). The outdoor enthusiasts often represent Pro-Am culture (Leadbeater and Miller 2004), i.e. people whose skills, knowledge and know-how reach – and even exceed – professional standards.

The Sumac project has focused on the target groups' experiences of sustainability in sport and high-quality design products, as very little research has been done in this area. The collection of the qualitative end-user data has been guided by merging the traditional target groups of sustainability research and the new diverse segments of end-users. The audiovisual end-user data was augmented by self-reflective group interviews. The qualitative data-gathering methods used in the pilot study have since been applied with the other focus groups. The informants consisted of women and men who regularly engage in summer and winter outdoor sports. The sample participating in the video documentary consisted of eight ski trekkers, six snowboarders, four snow surfers, eight climbers, four canoeists, and four downhill bikers. With the exception of European climbers involved in the Scottish trek, the groups studied were Finnish enthusiasts engaged in their sport in Finland. They informants were selected using the 'snowballing' technique, that is a method for expanding a sample by asking one participant to recommend others for interviewing (Groenewald 2004, 3).

The self-reflective interviews were semi-structured and focused on the individuals' relationships to their sport as well as their opinions and preferences regarding sport products and services from the point of view of sustainability. The decision to study individuals representing a number of different sport and leisure activities was an attempt to avoid findings that might be specific to a single activity group rather than attributable to the outdoor sport experience more broadly.

The directions given to end-users for videotaping their sport activities advised them to focus on their departure and return, as well as their preparations for the trip, including packing and unpacking. In addition, they were asked to videotape pit stops, lunch breaks, gear maintenance, highlights, events and unexpected situations during the trek. The semi-structured group interviews, which varied in duration between 1 ½ -2 ½ hours, had themes but also gave the participants an opportunity to reflect on the video. Four major themes were used: the personal significance of the sport; the equipment and physical environment; the life cycle and ecology of the equipment; and the social activity associated with the sport.

The video documentaries and interviews were conducted using the focus group method, which has been found to be fruitful in research designs concerned with user experience (Kuniavsky 2003). According to Kuniavsky, at its best the focus group method can be expected to yield knowledge of what the participants think about a given subject, how they think about it, what they value most about it, and why. The main purpose of focus group discussions is not for the participants to produce a single meaning but to share experiences from which multiple meanings can be extracted (Finn, Elliot-White and Walton 2000).

Not all members of the groups documented in the video were able to join in the interview. The number of interviewees is currently 27. Data on two or three summer sport groups will be added, increasing the total number of groups from seven to ten. With the exception of two groups, the age of the informants fell in the range 25-39 years; one of these two groups consisted of women under the age of twenty, whereas the members of the other were over forty. Overall, the groups had more men than women, with eighteen male and nine female interviewees.

The data have been initially analysed inductively with the help of Atlas-Ti qualitative analysis software. The analysis applied grounded theory (Glaeser and Strauss 1967), a procedure in which data are conceptualised and built into an explanatory theory. The unit of analysis was the self-contained description – a narrative told as part of the interview, not an individual sentence or idea (Sheller and Kunz 1998). The goal of the analysis was not to concentrate on particular product characteristics that define sustainable materials and ethical products but instead to highlight the sport experiences and pleasure involved in using ethically sound products.

The first phase of the analysis consisted of open coding of the transcribed interview material and the determination of the categories. These categories were studied as themes that might be relevant in understanding the phenomenon of sustainable consumption. The main categories that emerged from the data during the first round of analysis were sport commodities, unique products, disposal of products, brands and taste. In what follows, the paper organises these initial findings in terms of the Popperian world-view and explicates the values related to ethically sound consumption.

According to Morse (2007, 234-235), data collection and analysis cannot be separated in the grounded theory approach, and sampling schemes change dynamically with the development of the research. Sampling in qualitative inquiry must be purposeful, with participants invited into the study according to their knowledge about the topic being researched (ibid.). In the Sumac project, the qualitative sampling proceeds from purposeful sampling to theoretical sampling along with the data analysis (Strauss & Corbin 1998, 201). For example, it draws on interviews carried out among other skill cultures such as Finnish women's civic organisations (the Martha Organization) from the point of view dematerialisation and recycling used in everyday home economics.

The phenomenological approach seeks to understand things as they are encountered in their context. In this study, phenomenology is applied as a method rather than as a form of analysis. The aim is to attain valid knowledge of the phenomenal subjective experience and to this end the tacit knowledge of connoisseurship is most successfully contemplated through phenomenological interpretation (Anttila 2005, 332; Routio 2000). The phenomenological method and initial phenomenological analysis are situated in Popperian World 2, as subjective experience of the sport.

3. The three worlds of ethically sound innovation

One of the goals of the Sumac project is to elaborate product life cycle thinking and innovative proactive design for sustainability. The present paper does not aim to present extensive results to this end but rather offers a tentative perspective on sustainable and ethical experience as these pertain to products. An initial analysis of the end-user data collected during the research project has revealed three distinct themes: data that deal with the product itself, labelled 'ethically sound product'; data that deal with experience, labelled 'experience of ethicality'; and data that provide insights into what may be termed the 'contexts of ethicality'. One particular focus of the research has been to determine what it is that groups engaged in different outdoor sports conceive of as ethical and what commodities these groups value as high-technology and ethical products. Although the results to be presented are still tentative, the following examples, as well as the scenario and concept, may inform further analysis by illustrating the essential properties of sustainability and ethicality in outdoor sport contexts. The examples are given in the order of the properties characteristic of Popperian World 1, World 2, and World 3. The following sections outline some of the central elements of ethical products (W1), ethical experience (W2), and the context of ethicality (W3).

According to Lehtonen (2008, 85), one problem with the research on consumption is that it bypasses the material aspects of products, although it is claimed that modern life and societies are the most materialistic in history. There are at least three reasons for this tunnel vision. Firstly, the prevailing economic thinking steers people towards defining products as mere instruments in a business transaction. Secondly, the new mind-sets of sustainability and ethical consumption (Beard & Hartmann 1997) are inhibited by methodologies: prices and purchase decisions are more straightforward to study than multiform and transient interaction with products. Thirdly, there is a strong tradition of studying the meanings of products as signs or reflections of something 'more real' (Lehtonen 2008, 86). One prospect presented in this paper is to contemplate a given product in both the commodity phase and the unique phase of its life cycle from the point of view design research.

World 1 – ethical consumption as physical objects

According to our informants, there was not an abundance of sustainable high-quality high-technology sport products. With regard to gear, one of the interviewees knew *'for a fact that not a single one of my garments is made of recyclable materials'*. The weather and other conditions put a great strain on sport gear and clothing, and hence the performance of the material and the product are the fundamental attributes that a product must have. High-tech performance of a product was not easily seen as a sustainable solution, because technological development is fast and innovations are introduced every season. Moreover, the integration of high tech and textiles still lacks one essential feature: it is not easy to wash high-tech sport clothing in a washing machine (Mattila 2006,1).

The end-users seemed to be demanding and criticised the supply on the market. For instance, one climber, who has been involved in all kinds of mountain sports, including mountain biking and snowboarding, described the sport gear as follows: *'usually the stuff is crap, it is just fashion'.* For the skilful enthusiast *'average is not enough'*. This the reason why Pro-Ams create innovations by themselves: '*There are no pros. There is no professional service. But a lot of people work things up themselves, lots of people, creating the solution they find best. Many criticise what the manufacturers put out, they think they can make better gear. Then they put some of their drawings on the net showing how something should be done and put together pretty good things, too'.*

Categories of inorganic and organic materials came out in the group discussions with the end-users. From the point of view of sustainability and ethicality, inorganic materials were seen as high-technology solutions, some of which worked, some of which did not. The end-users were

active and innovative in repairing gear: worn-out trousers used in climbing were repaired in a traditional way with a needle and thread, or more quickly with glue before the day of the climb. Some of the enthusiasts collected durable high-tech materials from their worn-out trousers or jackets and used the leather or thick nylon as a patch to repair their gloves or rucksacks. It is also a functional way of making customised products when you know what materials to add where they are particularly needed: *'Parachute material… I was thinking that sure it can be recycled just like they try to do with everything else – melt it down and so forth. But then I thought that you could make equipment bags or backpacks out of it or something else. You could make Ozone trousers, with a brand label in the back'.*

Not all of the enthusiasts had the time or took the effort to patch up broken gear. When asked about more sustainable solutions in the sport commodity sector, recycling and swap shops were the most common solutions offered by the informants. The secondhandedness (Hetherington 2004) of sport products reflects the consumer ethics: *'I sell a lot of things when they still have life in them'.*

Recycling was excluded more often in the case of high-tech materials that are difficult to repair or recycle. The smaller and cheaper commodities were easier to replace with new ones. By contrast, the more expensive and more technical investments had a 'garage storage value'; as a Finnish male kite surfer put it: *'Their value drops a lot of course, that's the way it is. Their value drops quite a lot otherwise, but it doesn't happen any more to those when they start getting like tissue paper, the material. I don't know where these go? On top of the wood pile... I haven't seen that graveyard'.*

According to Kronenberg (2006, 562), the viewpoint for more sustainable and ethical consumption is to pilot the future where customers are educated about and able to count on the advantages of using better quality products, ones that are more expensive but whose performance and durability are higher. This is illustrated in the next excerpt: *'Do you know Hilleberg, the Swedish tent producer… their tent was absolutely perfect, except this part [points to a tear in the tent] and I sent it back with instructions on what they should do with it, and they did it and send it back to me'.*

Hetherington (2004) has studied the meaning of the disposal of products from the point of view of consumption. He claims that the essence of consumption lies not only in the acquisition, purchasing and owning of the product. The abandoning of a product has just as much meaning for the consumer, but it has not been explored through consumption research. When studying connoisseurs and their enthusiasm for sports, it is very clear that the investment of money, social effort and time in the sport is high. The more money one has put into a piece of equipment needed for a hobby and the more time and skill are involved in learning how to use the equipment, the harder it is to stop owning it even when it is not being used anymore.

World 2 – subjective experiences of ethical consumption

Connoisseurs, i.e. amateurs (Hennion 2007), have a spiritual enthusiasm for the thing they do. This has been the phenomenological starting point in defining the context of the subjective experience of the end-users in sports. The groups have a meaningful relationship with the sport products they use because of the emotionally meaningful leisure context. One of our interviewees summed up the meaning of the hobby: *'You forget everyday worries and the stress from work when you have to spend every minute on surviving'*. Self-fulfilment and pushing one's physical limits create emotions stored in the body, which remain as a unique experiences – 'top kicks' –as depicted in the next excerpt: *'Sport is for fun – you want to reach a great five or great six…it's the level of fear you want to be at'.*

Typical for Pro-Ams and lead-users is that they in one way or another channel their devotion into a business that they can make a living from. That is one rason why the sport products are critically evaluated by these enthusiasts. It also requires a lot of know-how to be able to

participate. Technology and technicality can be part of the sport, but, according to a kite boarder, they are not ends in themselves: *'Can I remark on the terms a bit? I was a bit confused when you asked before if this is a technical sport and I started thinking what the technical sports were. Like sailing, the equipment has incredible importance but skill is the only think that makes any difference. You can kite board even with a really bad kite – with nothing but some rope and a tarp – if you want. But, but without skills you can't really do anything. It is more of a skill sport than a technical one'.*

To end up as a real innovation, existing products must provide good or excellent performance. The role of high technology is to offer a means to survive in extreme conditions. This is why the use value of a sport product is questioned in these communities every time new technology is introduced. Innovations with the most potential are tested by the members and the information is spread by word of mouth or over the Internet. The products that have passed the critical evaluation of the community earn a unique value as symbols of a long-term investment in the life style. For the real enthusiasts the equipment is not just instrumental and stashed in a cupboard or garage when not used. Instead, these products are present in the daily life in home environment, as a female ski-trekker portrays: *'We haven't got a flat;, we have a storage area in which we live. On the bedroom ceiling we have a rack like you find in a garage with sledges, skis and things like that on it – everything is right there, ready to use… The sleeping bags on the wall are an important part of the decoration'.*

One interesting finding is that the enthusiasts were not only devoted to a specific sport. The interests of the focus group mixed with the neighbouring sports: climbers were engaged in other 'mountain sports', such as mountain biking and snowboarding. The kite boarders were familiar with sailing, so they already knew the importance of being able to observe and react to weather and wind conditions. This is where technology usually has its place. As a male kite boarder says: *'[technology] would overcome half of the forgetfulness.*

The purposes in gathering together as a sport group are both functional and social. It is not easy to keep up the standards of the sport by oneself. Figure 1 illustrates a narrative story, a scenario based on the video material and interviews in which the community of climbers are preparing the following day's sport activities. In this short piece, both the commodity and unique levels of content are present. With the help of this story-like depiction we can become aware of the subjective experience that can be attained through distinct time-related and spatial set-ups.

This is what Antoine Hennion (2007) calls a collective technique of taste. She suggests that post-modern tribes such as amateurs or enthusiasts do not believe things have taste. Rather, the analysis of these collective techniques helps to understand the emotional devotion to sensitise oneself to things, to other people as 'us', to situations and to moments. Taste is an opportunism of the moment and of the situation. It is an active way of a people putting themselves into a state where something may happen to them, as can be seen in Figure 1. There are other options for deciding one's taste than either determinism or spontaneity: connoisseurs insist more on attachment in people's activities, less on labels, says Hennion (2007).

World 3 – cultural constructions of ethical consumption

Who are the people that will make up the ethically aware and wealthy sectors of the consuming society in the future? When asked who the people are who will engage in these outdoor sports, the answers were such as: *'I don't know if you can confidently generalise, there are people who have lots of money, people who have very little money, people who are quite old, who have kids…people who sort of enjoy outdoor settings, educated people, ambitious people; it's really not a sport for underachievers I would think. Its quite common for climbing communities to be centred in university groups or clubs because it is quite difficult'.* This type could be identified with Florida's (2002) definition of the creative class or with Ray's and Andersson's (2000) classification of the cultural creative as the new ethically oriented elite of Western society.

A male climber sums up the ethicality of his enthusiasm on a more general level in relation to what might be termed 'conspicuous travel': *'A couple of friends of Sam's flew to the Alps in the winter to climb, for a single climb, one route... ultimately the hydrocarbons that are used for travelling from point A to point B or for the delivery of the products from the other side of the globe, or the recyclability of the single garment regularly used by the end-user do not have that much importance from the point of view ethical consumption'.*

The concept of taste usually goes together with the discussion of class and status. Luxury, elite, class and stratification are concepts with very negative connotations in excluding and categorising human beings in sociology. In this paper, we adopt a more positive perspective on taste as a subjectively experienced choice mediating between structure and action (Hildenbrand 2007, 540), as an interest in self-fulfilment and well-being instead of categories of social stratification. There is a kind of situational stratification that is perceived as positive instead of as envy at not being invited into some form of collaboration, action, or lifestyle (Collins 2004, 338).This is how taste emerged in a more positive way, as a climber advised somebody interested in taking up the hobby: *'You find communities of climbers in communities that are close to mountains… in general most climbing communities are very inclusive, I found, I've never felt excluded by a climbing community, you've just got to find them. Once you've found them you'll meet people, meet people, meet people….The tricky part is meeting the first people; it's really tough but once you have done that you meet people and they introduce other friends and, it snowballs, so to speak'.*

Lifestyles are not just individual lifestyles, but also rituals and thus markers of group boundaries (Collins 2004, 298). Social interaction produces both symbols and moralising about them. Fashion involves materialised commodities that have been created for their throwaway value. The sustainability of fashion emerges as retro fashion or the sign value of the classics. High technology can be used for the purposes of sport fashion. That is why, according to one climber, *'fashion is crap'* and unethical. The sport fashion product does not easily reach the unique level: *'climbers who take this seriously do not mind the look…but there are a lot of people who use the climbing gear as fashion accessories, they are outside the climbing community'.* For example, the group consisting of high school girls were fans of fashion and sport idols. They had adopted the latest trends in fashion and were familiar with the top brands and the colours of the season: *'It sure is pretty much equipment-oriented sport in principle. Textile sport … (laughter) especially in our case. We admire and look at what other people are wearing, saying it's 'way cool' and we have to get gear just like the top athletes have'.* Brands were important for these young ladies, as they have the novelty value of new commodities. The performance of the equipment was assessed by the brand.

Situations and events as cultural constructions of Popperian World 3 are also an essential part of the connoisseur cultures of outdoor sports. The future of the sport was seen as being linked to larger-scale social events where the values and knowledge of the sport could be transferred to an 'audience': *'I thought about gender because there are so few women involved and I have the idea that when they take up the sport it will bring in a anew perspective...it makes the sport sort of socially more acceptable in my opinion – it's not just a guy thing – the audience includes people's friends, they come there – it's not just wives. It's starting to become a spectator sport. There's something to see and people look for chances to watch it and stuff like it'*.

Cultural products, events and social situations can be a starting point for examining the bases of ethically sound innovations. Even though products do not have value, and the value emerges through the subjective experience of the user (Boztepe 2007, 59), the 'value', as Hetherington (2004, 169) points out, 'is the equivalent of a soul for an object'. The experience economy (Pine and Gilmore 1999) – in general terms the tourism industry – is advanced when it comes to in producing commodities that end up having the unique, i.e. experience, level of a product. Ethically sound innovations also emerge from the same type of enthusiasm and emotional energy (Collins 2004) as that seen in what people enjoy doing in their leisure time, especially in the outdoor context, which has been the focus of interest in this paper.

4. Conclusion

The material level of ethically sound innovations discussed in the paper through examples of sport products with physical and emotional experiences presents only a limited view of ethicality as a phenomenon. The analysis of the material objects of ethicality leads us to Popperian worlds 2 and 3 – experiences and contexts of ethicality – which highlight the nature of ethicality as a multidimensional phenomenon. The material level of the ethically sound innovations cannot be studied independently but must be examined alongside the immaterial level of the phenomenon.

The foremost ethically sound sport products mentioned in our video and interview data were related to commodities of conspicuous consumption, unique objects, disposable products, products that enthusiasts had available to them, brands and taste. The sport products interviewees own and actively use play only a partial role in their everyday lives. The data and tentative analyses indicate that ethically sound innovations are not just products made of re-usable materials, commoditised eco-brands or personal decisions not to consume conspicuously. Ethically sound innovation is based on values deriving from a holistic way of living and well-being, and in the future will be based on both the old and new ethics of consumption (Uotila 2007; Rytilahti, Uotila and Narbrough 2007).

We have focused on one way to outline the phenomenon of ethically sound innovation in the spirit of Karl Popper. Our thinking has led us to distinguish two paradigms of sustainability, which define the phenomenon on the level of form and content (Fig. 3.) The point of departure here was to distinguish the paradigm that defines ethical innovation from the point of view of the material use value of commodities (form) and the immaterial status value of unique and meaningful products (content). When a product is on its form level, it has a use value that is exchangeable in monetary terms. When a product is unique, it is meaningful to the end-user in a particular, subjectively experienced way. On the product's unique level, the end-user experiences the emotional and linking value of the object (Cova1997; Rytilahti 2008). The subjectively experienced uniqueness is studied phenomenologically in this paper: the experience of the product is linked with the material existence, i.e. the performance of the sport product and hence its use value. Again, the culturally shared understanding of products emerges from social interaction and is defined through the definition of taste.

On the level of content, the ethically sound innovations of World 1 are immaterial and more abstract: they are unique objects (W1), are experienced as being available (W2), and emerge as a taste (W3). The last term needs to be understood as a collective technique inside the community of connoisseurs. The taste of the outdoor elite is the outcome of the collective techniques that emerge among the groups of connoisseurs. There are collective techniques of managing equipment that combine both the commodity phases and the unique phases of the product's life cycle. We assert that the two parallel paradigms presented in Figure 3 exist equally and co-exist as parts of the phenomenon of ethically sound innovation.

The concept of uniqueness refers to the exceptional quality or customisation of the sport products. The unique immaterial values of a product are present after the product has passed its commodity phase (Lehtonen 2008, 98-99; Appadurai 1986, 13-15). From a sustainability point of view the product should have as many turns as possible from trade-in value to unique value and vice versa. In this sense the material and immaterial aspects of consumption are not concurrent; they alternate instead. The concept of 'availability' refers to the process of signification and could be compared to the term 'experience', which is a value-laden expression reflecting the subject's preferences and his or her personal world-view. The opposite concept on the level of form is disposal as a synonym of waste.

Hetherington (2004) suggests that in order to learn more about sustainable and ethical consumption we should also study how social life is created through disposal of the consumed material. In the literature, disposal is suggesting a too final, singular act of closure, one that does not occur in practice. Getting rid of something is never simply an act of waste disposal. The focus of the rituals of disposal is not only the discarded item but also its value. Accordingly, we have a

two-stage ‘holding’ process through which consumer objects pass before becoming waste. The bookcase, the recycle bin on a computer, the garage, the fridge, the wardrobe, are often constituted more as sites of first burial rather than of second burial. The gap is the space where things are held in a state denying their wastage – where they are kept available to us for a second time so that we can reconcile ourselves with the remaining value. This is also a question of identity: we are not just ‘what we buy’ but also ‘what we do not throw out’. (Hetherington 2004, 169-170.)

The utility of absence is as much a part of the communicative and ordering activity associated with consumption as it is a part of acquisition and use of some object or service as a mark of social membership (ibid.). In Figure 2 , ‘A rotating drum container’ concept created for pack a ski sledge tells us something about this post-modern emphasis on the need for ordering activities, a means of ‘successful doorkeeping’ and that is closely related to the act of disposal. It can be an individual practice, but also a social practice of managing the absence of personal products. There are plenty of situations in domestic and leisure contexts where the ‘absent presence’ – as Hetherington (2004) calls it – could be designed-in in a more socially sustainable and then in a more ethically sound way.

Christensen (2008) poses a central question to be answered if we are to ascertain the nature of ethical consumption: Why is our culture so ready to see sustainability only as an economic-cum-engineering issue? In order to find sustainability and ethically sound innovations, we need a deeper understanding of the kind of deep emotional platform on which products and services will acquire their added value in the future.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Changing a phenomenal change

Reassembling the self through a new ethics of negotiation

Johann van der Merwe[1]

Abstract

The only change we can be sure of is that over which we do have control, when we change ourselves, and even then this *control* is mediated by our interactions with others, by a mediating and normative environment that includes the designed objects we let into our lives. That change, seen against a broad canvas of sustainable social structuration, is necessary, is not in doubt. How to go about effecting this change has to be, even if only for the sake of not making the same mistakes as have been made in the past. Change has to be controlled *from within*, has to be designed into being as a normal part of the individual's ongoing growth process.

1. Introduction

I am an anarchist, but I am also a sunflower. I am contradiction itself, a fact that I have always known and come to terms with. That I am in truth an anarchist, as well as a contrarian, came to me very much later. Noam Chomsky would fain call me an anarchist for my beliefs, and recently I have discovered, through Marco Susani's work, that my structure seems to resemble the networked, and strange, social environment he calls the *Sunflower*. But, more of that below (3. Ontological phenomenology).

First, to this matter of anarchy. According to most peoples' definition, an anarchist is someone who throws bombs and wishes to destroy all forms of government, bad people, in fact. Most decidedly anarchy is equated with loss of control and chaos. However, the Wikipedia definition notes "that anarchy does not imply nihilism, anomie, or the total absence of rules, but rather an anti-authoritarian society that is based on the spontaneous order of free individuals in autonomous communities, operating on principles of mutual aid, voluntary association, and direct action" (Wikipedia). In terms of the aims of this conference, does that sound familiar?

One of the aims of Changing the Change is said to be a strong and ambitious political goal, and to enable this transition towards a sustainable knowledge society, can we do so from within the existing socio-political structures? Changing the Change stands for a new social structure that takes control of its own sustainable future, and what it hopes to motivate is exactly this "spontaneous order of free individuals … voluntary association, and direct action". Whether you prefer to call this anarchism, minarchism, or libertarianism does not matter so much as the argument for rediscovering some of the social structures human societies have historically developed for their local needs, and the fact that what is needed is the anarchistic ideal of *the least amount of control* that any social and long-term sustainable structure can get away with.

According to Chomsky (1995) he was attracted to anarchism as a teenager, and, *as a way of seeing the world*, anarchism afforded him the possibilities of social boundary transcendence. No one would call Gadamer (1975) or Derrida (1993) anarchists, but Chomsky's experience tallies perfectly with their account[2] of social barriers (norms, habits, rules) that have to be transcended for the sake of personal/social development, while at the same time, respecting those very boundaries. No throwing of bombs, then, but always a questioning of the status quo. Chomsky has had no occasion to change his mind since, but, on the contrary, he has made it clear that his goal is to "seek out and identify structures of authority, hierarchy, and domination in every aspect of life, and to challenge them; unless a justification for them can be given, they are illegitimate, and should be dismantled, to increase the scope of human freedom. That includes … our control over the fate of future generations (the basic moral imperative behind the environmental movement, in my view), and much else" (Chomsky 1995).

It is this anarchistic questioning of the status quo that aids my interpretation of Ezio Manzini (2007a), who talks about a 'double transition' taking place, the first (1) created by our social and living / working environment increasingly being underpinned by connective and globalising technology, while, at the same time, and precisely because of this, we are confronted by persuasive evidence of having reached the tipping point of our planet's life-sustaining limits; and (2), since this change is 'deep and fast', a concomitant and second transition is necessary, one that can provide a re-orientation in our very way of thinking. In this paper I will focus mainly on (2), and present a case study that highlights the active

[2] Gadamer and Derrida, in later correspondence, substantially agreed on this issue.

involvement, and the consequent re-orientation they went through, of students of design (3rd year Industrial Design). They will all enter the world of work as, potentially, the future of design itself, and hence also, potentially, as the future of the discipline of design.

The design research results show that an abstract model for a self-organising ontological framework can be applied by individuals, primarily to their own identities, as the start of a catalytic process, with the ensuing re-orientation of design knowledge as a comprehensive end result. It is in this sense that I attempt to answer Jorge Frascara's (2007) question, "How can a new direction be applied to the way things are, and change our culture into a sustainable one?" As Gadamer (1975, 238-239) and Derrida (1993, 919) confirmed, 'the way things are' must be respected, and ways found, rather, to transcend these paradigmatic ways of thinking. Frascara's 'new direction' must come from within the individual, and in this way social paradigmatic thought can be 'transcended'.

However, despite this evolutionary and revelatory process being an individually cognitive one, there are ways of sharing this knowledge among groups of like-minded people, the first methodology discussed being actor-network-theory, also known as the sociology of translation. Latour (2005, 108) makes it clear that 'the social' must be explained, from within, instead of 'the social' being seen as an entity that can explain things. All social groupings, even the newly formed sustainable culture Frascara calls for, will fall back into the trap of normative (fixed) social structuration, unless they pay heed to the insights afforded by actor-network theory. As Giddens (1984, xx) puts it, the "concentration upon epistemological issues draws attention away from the more 'ontological' concerns".

The second methodology discussed in this paper is thus ontological phenomenology, a study of how we look at and experience the world. Mugendi M'Rithaa (2007) asks, "If Africa does not have a lot of money, what then does it have?", and his question implies that we have to look to what each region really has to offer. Like all other regions, Africa's resources are people, and the cross-cultural ethics of *Ubuntu* (being human through others) depends on people – individuals – to uphold the conditions for a sustainable future. Ubuntu is at the same time a social/cultural grouping approach/viewpoint, but, crucially, it depends very much on the individual recognition of the other to work, thus forming a group of like-minded people.

2. Actor-Network Theory

As a way of sharing knowledge among a group of like-minded people, actor-network theory (ANT) is a methodology that works well for designers, but we must remember that, as a theory, ANT is not appicable to anything (Latour, 2005 141). Any good methodology, as a good theory, is not a method for doing anything, and it is not a recipe that guarantees an outcome. Bruno Latour's (173-74) description of how ANT can be useful includes "specific tricks to help resist the temptation to jump to the global", because, in the very act of communication, in forming networks (even if only between one local actor and a second), we are moving ('jumping') from the local (the individual) to the global, to the many, to the away-from-us. "A ploy has to be found to make the two social theories diverge, letting the sociology of the social go its own way while the sociology of associations should be able to keep drawing more and more acurate maps." ANT is, simply put, [1] a way of looking at the roles that human and non-human actors play in any one situation, with non-human actors identified as designed objects, rocks in the road, the snow in winter that will not let your car start, the window that sticks and will not open. Non-human actors are all the external-to-being-human objects (even events) we notice when they do not work as they should, and, more seriously, objects that intrude in our (un)consciousness and our decisions even though we are not aware of the fact. ANT looks at the relationship we have with these objects, and considers the observation of social systems as of necessity having to include both. More to the point, but more difficult to 'see', is the ANT approach to the context of the

social. There is no such thing as 'the social' in ANT terms, because "In the alternative [ANT] view, 'social' is not some glue that could fix everything including what the other glues cannot fix; it is *what* is glued together by many *other* types of connectors" (Latour, 2005 5). When ANT speaks of the social, [2] what is meant are the *associations entered into* by the members of that 'social' – which can be a single conversation between two people, or a whole group of like-minded designers coming together in order to decide on the way forward, for the sake of a sustainable, living future. The 'social' is a temporary concept, which might last for many years, or centuries even, but change it most certainly will, and in our contemporary age change is not only inevitable, but fast.

When we consider the importance of communication, it has to be borne in mind that what is of essence, for understanding human relations, is the *associations being entered into* in the very flow, in the act of true communication. If there can be a glue that holds everything together, it is this. New associations mean new ways of augmenting existing knowledge, in fact, it means that learning takes place, and that means *the new individual* is at the heart of this association[3], or *reassembly*, as Latour prefers to call it. ANT, it must be remembered, is also known as the sociology of translation, and it is well to remind ourselves that the act of communication (any relationship with the external-self) is at the same time a *transportation* of both what we know and of the information we are dealing with, a flow from one contact point to the next, and in this flow *transformation* takes place. Giddens (1984, xx), in focusing more on 'ontological concerns' rather than on epsitemology, meant by this statement that his structuration theory of the social "should be concerned first and foremost with reworking conceptions of human *being* and human *doing*, social reproduction and social transformation". To designers, these 'ontological concerns' should mean, very simply, an ongoing and constant becoming (Heidegger 1962, 359), the crucial point, to both Latour and to Giddens, being that the people making up the grouping, and the designed objects and systems we surround ourselves with, cannot be separated as if they do not structure each other. In this duality of structure, the human need to voice what cannot be seen (human-world experience) nevertheless demands shaped expression, which becomes literature, art (Steiner 2002, 279-280), or becomes design, an outward expression or manifestation of who we are, and what we want or need to become.

That, I believe, can be achieved by making use of, amongst other 'like-minded' theories of being-human, Heidegger's notion of ontological phenomenology, or at least my ANT 'translation' of the term. Phenomenology is the study of how we look at and experience the world, and it is a study of subjective experience, following Husserl, although some have used this approach to deny any experience beyond the concrete objectivity of *what is*. Others have contrasted phenomenology to ontology, which studies the essence, the very nature of existence. Put the two together, and Heidegger's ontological phenomenology starts to make sense, in that individuals can study themselves as developing structures, coming-into-being through a movement away from the *what is* existence of a concrete world, towards a possible existence in renewal. Ontological phenomenology allows each individual to map their own progress, even (*especially*) from within the group, of like-minded people, of course. However, instead of describing this methodology in detail, I would like to focus on one particular manisfestation of looking for the invisible.

3. Ontological phenomenology

We are adept at dealing with things contradictory, and we even deal with things invisible to a remarkable degree. When we make meaning (we usually say, when we make sense of something, but that *is* manufacturing meaning), we are dealing with the not-yet, the invisible that Merleau-Ponty (1968, 215) classified as meaning, emanating from the

[3] This new individual connects ANT to Heidegger's ontological phenomenology.

inner framework of the visible as a *virtual focus* that will not let itself be looked at or looked for, because it will then simply disappear. Contradictory, yes, but also normal cognitive human behaviour, and just because so much of it happens on a tacit knowledge level and as such remains out of sight (but not unobservable), does not mean we cannot investigate this phenomenon. When dealing with the human need to voice what cannot be seen, we are trying to find ways to make sense of the world, not simply as it presents itself to us in concrete fact, but in non-material, relational meaning, and especially in terms of the effect of our communicative networks. How does this outward, shaped expression come into being, and how do we voice the invisible? How do we talk to each other?

Marco Susani (2002) begins this descriptive journey through the different stages of networked communication by starting with the *Womb* and ending with the *Sunflower*. Susani began his presentation at Doors of Perception 7 with a quote from Herman Melville: *It is not down on any map. The true places never are*. Communication between two people, two systems or entities, creates new places of meaning, with a virtual focus, as Merleau-Ponty (above) stated, because these true places are not on any map,and cannot be seen, yet we have to voice these places, or rather, we have to voice what happens in these virtual spaces. A very difficult thing to do, indeed. We are continually speaking of things that do not yet exist, which is why Susani (2002) is "trying to map places that are intangible and invisible; the flows of communication and the places where they happen". These true places are in peoples' heads, and Susani appreciates this phenomenon as very rich in possible content, and he even labels this human phenomenon as "wireless, networked ubiquitous communication", because each individual phenomenal communicative event depends on at least one other, hence the first phase called the *Womb*. Our language use is largely dependent on the use of metaphor, which is possibly why Susani and his colleagues decided on a list of named forms to describe the communicative patterns being established when two or more people join in a networked effort to make sense of the world, beginning with the *Womb*, a space of communicative sharing that, in belonging to the two people so intimately sharing that meaningful space, begins to take on this shape that seems enclosed and inward focusing. As more and more people in different configurations join the network of communications (closely resembling the networked effects of actor-network theory), the shapes or forms of these intangible and invisible places begin to vary, taking on the configuration of the actual network of communication, taking on the shape(s) of the consequential possibilities, of these communications, as it were.

It would be impossible, here, to deal with all of these permutations, but I would like to focus on two others before arriving at the *Sunflower*. The next form, for my purposes, is the *Infinite Star*, a recognisable network of communications that resembles the space of flows – Felix Stalder (2002) gave a descriptive example in likening this structure to the Dutch East-Indian spice trade: there has to be a medium through which things flow (the oceans), the stuff that flows (spices then, information now), and the nodes between which flows happen (the harbours that served as starting and end points for the ships). The *Infinite Star* has groups of people as the nodes, between which groups the information flows, but all the nodes are in principle, and usually in practice, connected. Susani sees these nodes as communities that are broadcasting to each other in a peer-to-peer network of communicative flows, overlapping, because every node is connected to every other node in the system, forming "a continuous space that connects infinite points" (Susani 2002). The content, Susani states, is what holds these groups together. The spices (their entailments) held the trade between Amsterdam and Batavia together, bound them in communities of practice, in the same way that groups of designers (design students!) need, not actual 'content' but purpose, new associations, to help them create an *Infinite Star* continuous space of learning.

This, it has to be said, is too easy. On the way to the next form I refer to (the *Flames*), Susani deals with an increasing complexity of communicative flows, because, being human and not being able to do anything else but participate in a group *as an individual*, we cause the stuff that flows to keep on adding to itself, and we are dealing with augmented upon

augmented individually interpreted/translated narratives that circulate between nodes, *collectively as group narratives*, and between the individuals that make up each node, to again be augmented individually. Susani (2002) speaks of "a kind of viral diffusion. Sending the message of the message is a kind of social space that is infinite: we call this the *Flames*". A veritable fractal space that networks in an almost biological fashion (as opposed to the clean, linear, controlled diagrammes we usually see purporting to represent these networks). Where the *Infinite Sta*r is still easily 'managed' as a network of communicative flows, in reality communication flows where it will, and in education terms, must be allowed to connect, augment, and be virally diffused as it needs to, given the 'harbours and ships' at its disposal at any one time – the designers in the group of like-minded people, the members of the public that share a common goal of everyday sustainability, or the students in a design class, this potentially infinite social space that links formal with informal learning, this discontinuous space of learning.

"Now imagine the same structure with the same flames going around, but combined with the idea that then, at a certain point, they gather, they return back to a single space" (Susani 2002). This is the *Sunflower*, a networked, and strange, social environment form. We are dealing with a circularity (true to the essence of cybernetics and design) that finds order in seeming chaos[4] (have you tried *counting* the tiny florets in a single sunflower head?). That order, or comprehension / understanding, that is the relational principle behind this networked communication, begins with the individual and ends with the individual. There is no such 'thing' as a group, just as there is no such thing as the social[5]: there are only individuals and there is only communication[6]. We, all the individuals who make up the sunflower head, need to find a way to deal with this very compact, very complex mix of communicative flows, and we need to do so in this new, *single space* (Susani, above).

Oh, dear. Now what? First we had the *continuous* space of learning, then the *discontinuous*, and now we're back to a *single* space? At this point many a student gives up, or it might seem that way, at first. I am trying to find out why they do not lose their way completely (cf. 4. Student case study), despite these very intricate and complex issues being discussed in class. How is it possible to speak about complexity theory, to discuss Heidegger's ontological phenomenology and Bruno Latour's human and non-human actors with a class of third year design students, and, heavens forbid, keep their interest? There is, only and ever, the individual. Everyting else is manufactured, socially constructed, and increasingly difficult to comprehend.

True and sustainable *group* understanding of important social issues depends very much on *individual* understanding and endorsement of those same issues. The group does not exist, the social does not exists, except through the individual. Alain Findeli (2001, 12) called for a renewal of design education, because he believes that "A system, and especially the human or social system, is best understood from within, through a qualitative, phenomenological, approach". My version of this injunction is to focus on the new individual, within the old self.

4. Student case study

[4] Sunflowers, daisies, and the beautiful Echinacea purpura are contradictory flowers, since what we see as the 'flower' is, in fact, not. The head of a sunflower is composed of many florets densely packed together, in this *single space*, which, on closer inspection, turns out to be very ordered indeed, according to the mathematical, yet biological, logic of Fibonacci numbers (the Golden Mean or Golden Section, derived from the spiral shape of i.e. the Nautilus sea shell and the head of a sunflower, is an example, one that has always inspired artists and designers).

[5] Latour (2005, 7-8) reminds us that 'the social' is an invisible entity that only exists because of the participants, and these 'elements' are themselves not 'social'; Latour defines *the social* "as a very peculiar movement of re-association and reassembling".

[6] We are who (we think) we are through communication (negotiated, interactive building of relationships, above), or as Luhmann (2002, 156) puts it, "only communication can communicate" in the networks we have to build, and the resultant actions we decide upon are the result of our understandings generated within these networks of communication.

Humberto Maturana (1980, 2) asked this question: *How does it happen that the organism has the structure that permits it to operate adequately in the medium in which it exists?* (discussed below). That question had a more practical focus, namely: *how is it possible for pigeons to deal with the world of form and colour*? Maturana, being a biologist, at first wanted to know what form and colour looked like to a pigeon, but he got no answers. The world intruded (in the shape of student riots in Chile) and he changed his observational position; instead of asking a semantic question, he asked a structural one: instead of asking *how does form and colour present themselves to the pigeon*, he asked, *what does the pigeon need to observe the world out there*. Ergo,the Project 2 design theory essay question[7] to my group of 3rd year Industrial Design students: *How could students acquire a structure enabling them to operate innovatively in a modern design environment*?

Apart from introducing the students to systems thinking[8] early on, and then moving on to cybernetics[9], I deal with Alexander Manu's The Big Idea of Design, which asks of them to strip away everything (to do with 'objective' detail) and instead look for the essence of any object, to look for the origin of a designed artefact and the role that this non-human actor initially played in our lives, and the (possibly) changed role that its progeny now plays. Having done that, we move on to questions such as, *What is the Big Idea of a "self / identity"?*, and for good measure, *How does education and self/identity relate to each other (relationship of what purpose?)*. To put some more pressure on them, I have them read Anne-Marie Willis's *Ontological Designing* (1999), which deals with both Heidegger's notion of *becoming*, and the life worlds inhabited by both objects and people. Having come so far it couldn't hurt to introduce actor-network theory, could it? I purposely try not to give the students too much information (aka 'prompting'), but try to give them access to as much relevant sources as possible, and, because they have to do quite rigorous research, *and* work in groups (always, in the initial stages, to share data and in developing information platforms), we also discuss their developing understanding of the topic(s) as much as possible. The students, in fact, have to regard themselves as their own product, and observe where, how and why they acquire the structure just right for them to deal with the world of design, and *then* they are able to tell me (and themselves) whether they are still of the same mind (mostly not!), or whether they have discovered their own Alexander Manu moment of change. I am, in fact, asking the students to deal with the complexity of communicative flows (Ezio Manzini and Felix Stalder on the Space and Pace of Flows), networking (Maneul Castells), rhizomes (Deleuze & Guattari's organic networks), Wolfgand Jonas's *groundless field of knowledge* and Edward .O Wilson's *consilience* ('jumping together'). Oh, and complexity theory, of course. They hate me.

The fact that Donald Schön[10] promised this would happen is no great solace, to begin with. But perturbation does work, in a kindly, anarchistic kind of way, even though it must appear as utter chaos to the students at first. Too much information, too new, and too fast! they cry, not realsing that they should be lamenting *I do not have the structure that can deal with these new worlds opened up by this information*, hence the Project 2 structural research question: *who are you and what's your knowledge-acquiring structure like*? It is not the content of the course, not the information they work with, and not the articles I make them read that is the focus of this theory class, but the individual. The students have to learn how to learn, and to do that, with self-knowledge, they have to learn about themselves first. These are some of the insights they reached, as individuals, supported by group discussions:

---

[7] This is not an English class, so I expect, and discuss, the necessity of working from a research-based proposal structure.
[8] Peter Checkland's Soft Systems Methodology (cf. also Donella Meadows' *Dancing with systems*, 2001).
[9] Second-order cybernetics differs from first-order cybernetics, in that it does not deal with predictable and ordered systems, but studies the observation of observing systems, i.e. *us*.
[10] Schön is famously credited with believing that students need to be 'frustrated', because they have to learn to work in the "indeterminate zones of practice – uncertainty, situations of confusion and messiness where you don't know what the problem is" (Schön, 1987).

- Somewhere along my development I made the transition from being taught to teaching myself [and] the way in which the individual react to this shift in responsibility seems to differ from one person to another;

- [I have learned to] look at the holistic picture and direct my vision away from purely relying on my own opinion and presumptions;

- Some people believe that the ultimate goal in life is self-fulfilment, however the only way in which to really create one's own happiness or reach 'completion' as a human being is to make others happy;

- My purpose for wanting to learn continuously is tied up with my outlook on life and my purpose as a human being;

- Every product that I develop must have a purpose and will always have consequences.

The fact that these comments are centred on individual viewpoints – the first person perspective - is mitigated by the realisation that the 'I' is here dependend on the 'other', that the students clearly see their roles, as designers, intertwined with their roles as human beings among other human beings, and not just as designers v. users. To understand the human social system from within, as Alain Findeli (above) urges us to do, is to understand the individual inside the communicative and learning system, and here I can refer to Fig. 1: *The wickedness of design education*. My design theory classroom is a social constructivist space for learning, and this illustration tries to make sense of the invisible, in fact tries to map Susani's (2002) "places that are intangible and invisible; the flows of communication and the places where they happen". What should be a straightforward input / output with-feedback-loops structure is anything but linear and easy, and very difficult to 'map'. Susani's communicative forms and actor-network theory's relational principles make it rather more understandable, from the viewpoint of seeing this on paper, but what if you were *inside* this process, right now, and couldn't see anything for the 'chaos', the *oh, this is too much* stuff swirling around your head? Imagine a student with an education-sponsored 'map', trying to find her way towards what we would like to call 'knowledge'. Instead of the relatively easy to navigate situation of Drawing 6, the direct interaction between teacher and student (comparison with Susani's the *Womb*), this poor soul finds herself in Drawing 10, which, if anything, resembles Susani's *Sunflower*. For a 'map' to be of any use whatsoever, it must be drawn by the student herself, inside the group, with the help of the group members, of course, and especially if she, no, *when* she reaches the point of being able to make full use of this 'single' *Sunflower* space, she will be able to handle any situation in the real and complex world, because the new 'map' coming-into-being is her new self and the new strucure *enabling her to operate innovatively in a modern design environment*. That new self emerges from the wavefunctions (below) of all the individuals in the *Sunflower* single space merging, when "they return back to a single space", because sometimes, as Arato (1994, 130) said in discussing Luhmann's work, we are looking at "a whole which is paradoxically conceived of as its own part". As another student reported, "a conciliate model for my design thinking can only be created when all my experiences and influences cease to be … only then can this 'jumping together' and blending of information become conciliate", only then can he experience Susani's *turning back to a single space*.

In Fig. 2 we can see another version of both Susani's *Sunflower* space and Drawing 10 from Fig. 1, a system that works on two levels, depending on your observational position. You can either look at the whole classrooom as one entity, and see all the students following this same system of discovery as a group, but you can also, and should also, see all of them, at the same time, dealing with their own Fig. 2 systems, while linking into the growing network, and becoming each other's data-into-information inputs. "By conserving [making the distinctions and choosing] tested and examined information, I will start to form

my own design identity", while seeing education as a reaching outwards to the rest of the group, and beyond, in this discontinuous space of learning turned back on itself.

5. Discussive afterwo/ard

I spoke of the African cross-cultural ethics of Ubuntu earlier on, a notion that depends on people, *as* individuals, to uphold the conditions for any sustainable future. *Sawu Bona* ('I see you') is an example of this, but it can only, effectively, happen between individuals, and emerge, willingly, from within each individual, and, like this friendly greeting between two human beings, cannot be enforced from 'outside', but is a constant becoming, an awareness of the phenomenological effect of an "open atmosphere of learning" (Grant 2005, 564). As Seamon (quoted in Grant 2005, 564) found, it (this phenomenological cross-over between the self and the other) can become an "intersubjective verification … to establish generalizations about human experience". What Grant is advocating (my 'sociology of translation' reading of Grant), is a phenomenology of practice , a cooperative responsibility that becomes the "transcendental intersubjective essence of all audiences" (Grant 2005, 576), or another way to share knowledge among groups of like-minded people, a way to transcend the difficult social boundaries that too often 'follow' (are persuaded to obey) economic and political agendas other than the direction advocated by this conference.

The *Sunflower* single space becomes Grant's phenomenology of practice, within which the intersubjective essence of each individual can be shared among the members of a grouping (actor-network), as Grant's *audience*, the members making up this audience listening to each other, and collectively saying *Sawu Bona*, I 'see' you, I acknowledge who you are, what you stand for. We are dealing with a collective paradigm shift, in everyday knowledge generation, from individual 'knowledge' to group 'knowledge', but this process then shifts back to the individual, again; the new individual, within the group, that is not, just as the flower of a *Sunflower* is not (an individual flower, that is, but a collective). This is totally contradictory, and totally quantum physics: two states of existence can be 'true' at the same time, depending on your observation position. When each individual reaches a state of augmented, enhanced participation in knowledge generation (which, as I am sure you will agree, can only happen internally, hence individually), then the wavefunctions[11] of all the individuals within a group such as the *Sunflower* begins to merge, and we can understand why Susani could ask us to "imagine the same structure with the same flames going around, but combined with the idea that then, at a certain point, they gather, they return back to a single space" (Susani 2002). Merleau-Ponty recognized transcendence in the new becoming-self that is always just beyond existing borders, and as Lingis (1968, *I-li*) states, Merleau-Ponty regarded 'the visible' (compare Susani's *Sunflower* single space, but envisage the real group) not as an assembly of individuals fixed in space and time, but as a field, a moving, human landscape ('topography') of possibilities that unfold by making distinctions[12], but instead of disintegration, a *re*integration takes place "through the reflections, shadows, levels, and horizons between things (which are not things and not nothing, but on the contrary mark out by themselves the fields of possible variation in the same thing and in the same world)". The individuals make the group, and the group makes the (new) individuals, as long as we remember that these flows of communication can be effective only when we realise that "this system of lines of force, are not *what* we see; they are *with which*, *according to which*, we see". When wavefunctions merge we are within reach of this new single space.

[11] A wavefunction is a term describing all the information content of what is being observed, at that time. Compare this to the information / knowledge content of each individual, at any one moment.

[12] Luhmann (2002, 3), in a statement reminiscent of the development of second-order cybernetics, affirms that "we are no longer in the realm of a foundationalist 'first' philosophy but rather in the realm of a 'second-order' philosophy of observations of the observations of self and other".

Complexity theory gives us an insight into what has been happening to human networks, on an everyday level, for as long as we have felt the need to gather as a social group for a defined need, such as now. My argument is that our central nervous system, as a sensing organ, and on a metaphysical level ('activated' by the memory knowledge of physical phenomenology), uses the projective functions of our consciousness in a deeply biological way that follows the structural understanding of Maturana's (1980, 2) question, *How does it happen that the organism has the structure that permits it to operate adequately in the medium in which it exists?* How does it happen that the individual has the capability of operating adequately within the group in which it finds its (new) self, i.e., where the individual finds a sense of place / belonging*?* Monod (1997, 155) speaks of a non-verbal mental reflection that, as a projection, imagines or simulates an experience (of the 'outside-self') based on forms, forces and interactions. That means the 'structures' (Susani's *Womb, Flames, Sunflower* forms) encountered in this 'outside' social space become the structure of the organism, initially, and on further development, both sets of structures 'recognise' each other. *Sawu Bona*.

Based on the work of Davies (2000, 43; 243) and Prigogine (1980, 89-90), my argument is that the complexity of quantum physics makes this possible, and even though a wavefunction is known as a mathematical object, it does represent the information content of any existing state, and most importantly, it is non-local, i.e. ubiquitous, and ideally suited to a model of social structuration. Furthermore, to complete the correlation between complexity and human knowing, atoms have both particle and wave-like properties: socially, we can *be* the system and the environment, an individual *and* the group, at the same time. We can be our own autopoietic system, self-organising and 'closed off' from external forces, but we are also the environment that sustains us through 'natural' interaction. We are our own internal information for own consumption, but we also 'identify with the object itself', becoming part of the environmental information, sharing *with* the group and sharing *in* the group. In that sense human knowing is (at least) two wavefunctions that collide, two information structures that form a new entity via a phase transition[13]. Individually, as the collective, we *are* this new single space.

Reassembling the self through a new ethics of negotiation, it seems to me, becomes the new student body politic. They now *comprehend* their own identities by reassembling what they thought they knew, about the world, about knowledge, about themselves. Actor-network theory, networking with ontological phenomenology, allows them to map their places (of negotiation) *as* they map their journeys of discovery and learning, and seemingly as a matter of course locating ethical responsibility as "… more than [being individually truthful] … something much more than making wise choices … Our moral obligations must … include a willingness to engage others in the difficult work of defining the crucial choices that confront technological society" (Herkert, 2002). Reassembling the self in this fashion can create Manzini's deep and fast second transition, that crucial reorientation in our very way of thinking.

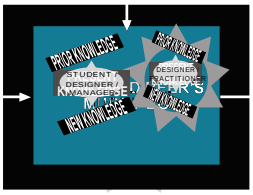
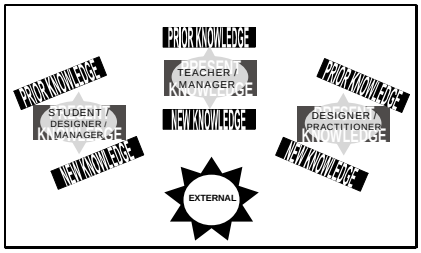
1. The constructivist classroom depends on feedback loops as a measure of calibration

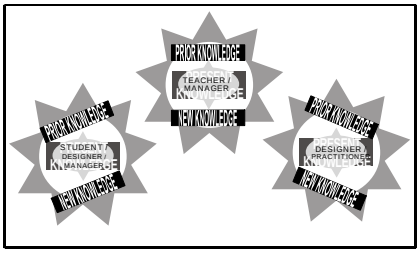
2. Design is, however, not so neatly linear, but quite grey and wicked



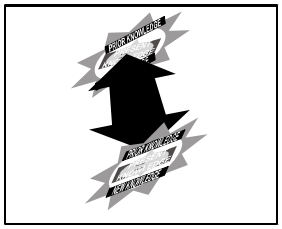
3. To make sense of the active and re-occuring patterns, we artificially slow the process down to see what's going on



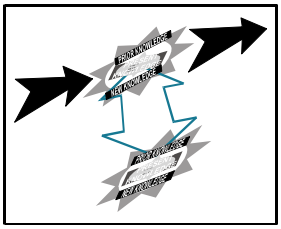
4. Simplistically, the classroom contains three units: student, teacher and external information. But each of the three units consists of prior & new knowledge; each deals with its own input/output feedback loop



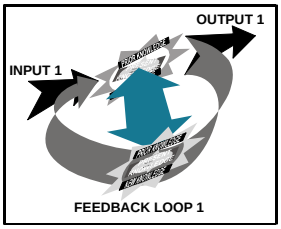
5. Even this is too neat and controlled, because each of the three units also have to contend with many other external > internal inputs in real and retrospective time



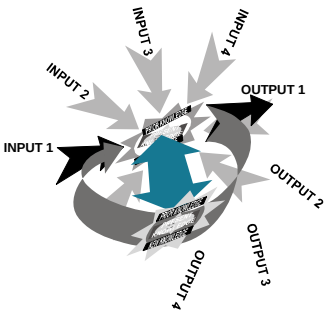
6. Besides the real/retro & internal/ external influences on each unit, the teacher as classroom manager has to foreground the interaction between teacher & student
"THE WOMB"



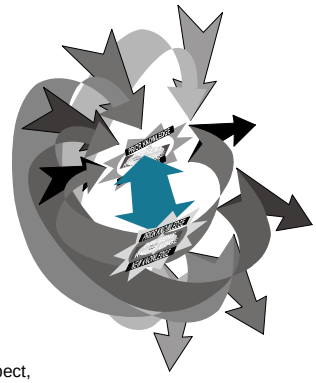
7. This direct link also depends on managing the input/output feedback loop, which, on a macro level follows the design curriculum ...



8. ... but on a micro, classroom dynamics, level follows the active design learning situation, with the teacher/student interactive link, calibrated to the output, changing the input in real time



9. How can the student learn to manage the input in real time, plus add to the original input in retrospect, when each of the many possible feedback loops are active, and effective, at the same time?
"THE FLAMES"



10. In real time, this is what the picture looks like: this is Rittel's Wicked Problem Situation, seen as multiple input/output + feedback loops, or Activity Theory in action. This seeks to understand the unity of consciousness and activity, since the input/output relation between the student and information is neither mechanical nor given. "A much richer depiction of the user's situation is needed for design and evaluation" (Nardi, 1996)

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

CONCEIVING THE DESIGN CENTRE OF THE FUTURE

Design vision

Transforming the economical and social landscape through multidisciplinary projects and integrated user-centred design research

Mark Vanderbeeken[1], Jan-Christoph Zoels[2], Michele Visciola[3]

Abstract

In this paper we present our vision of a future design centre with a high economical and social relevance, brought about by its ability to develop concrete, design-driven local and regional solutions, departing from the current and future needs of people.

The introduction describes the context in which this vision came about.

The second chapter presents the design research methods and results that formed the basis for this vision.

In the third chapter we elaborate on the vision, mission and concrete functioning of what has since become the “Transformation Factory”.

The fourth chapter contains examples of how the Transformation Factory will be of concrete economical and social significance for companies, government institutions, semi-public organisations, educational institutions and designers.

In the fifth chapter we point out the next steps that need to be taken in order to realise the Transformation Factory. The sixth chapter contains conclusions.

1. Introduction

As many other places, the Belgian Province of Limburg is under pressure to evolve towards a knowledge economy as soon as possible. Within the last twenty years, Limburg has had to deal with radical changes in its economical and social tissue. One of the major economic setbacks for the region was the closure of the local coal mining industry. Larger locally situated companies such as Ford are increasingly relocating their activities to foreign countries. The region is suffering from relatively high unemployment rates, problems with integrating a large immigrant population, and a relatively low educational level. In addition to that, it will soon have to face the economical and social consequences of a rapidly ageing population.

In addressing this context, both the public and private sector are counting on innovation with an emphasis on creativity and multidisciplinarity. Reinforcement of the region's development is needed in order to create new processes, services and products to address current and future needs and meet the demands of future national and international markets.

Since July 2007, Experientia has been working with the Belgian City of Genk, the Belgian Province of Limburg and the Media & Design Academy (M&DA) in helping them to define a future design centre that will stimulate and support creativity and innovation within companies, cultural organisations and social institutions. It will be located at C-Mine, a former mining area that is being transformed into a creative hub for creative institutions (such as the Media & Design Acacemy) and innovative companies (Jaga).

2. Emphasis on research

To ensure the concept we were asked to develop would be of relevance to the needs of the region Experientia applied a user-centred research approach in the development of the design centre concept.

Stakeholders and end-users were actively involved during both the research phase and the vision and concept development phase, which included:

- A benchmark study of 70 design centres from around the world;
- Twenty in-depth interviews with various stakeholders about the region's social and economical characteristics, current and future needs, and their vision on what the design centre should be. The interviewees were key figures in the fields of politics, industry, design and the social sector from within and outside the region;
- An analysis of existing studies about design centres, exploring developments and current and future trends;
- A co-creative workshop with a selection of key stakeholders;
- User-centred design research has also been integrated into the functioning of the design centre itself. Putting user needs and the way people interact with products or services at the very centre of the design process will be the central working method according to which the design centre will handle all its projects.

The results of the research phase were very encouraging. The literature study pointed out that even though most design centres are currently mainly focussing on promotional activities, workshops and direct consulting, there are new developments taking place on an international level:

- There is an increasing emphasis on project based support for companies ("design management"), instead of focussing on promotion and design in itself;
- There is a growing importance of design as an instrument to create social and cultural change;

- The use of design to create and stimulate human focussed changes within the social sector.

In addition, there are certain themes that are gaining traction: User-centred Design, Sustainability and the intrinsic relationship between a broader design vision and innovation.

The increasing importance of the developments outlined above – company support, social and cultural change, design and the public sector – and the new themes also emerged from the benchmark. This study showed the role that design can play in the reinforcement of thematic communication and in an innovative branding of regions. It also became clear how important it is to have an integrated and strategic approach to design promotion and support, ideally in the form of a well-structured design policy.

The in-depth interviews have also generated a number of insights in what the needs of the region were and how the functioning of the design centre could be of relevance. This is described in the examples in the fourth chapter.

The research phase was followed up by a co-creative workshop from which the principle ideas for “the design centre of the future” originated, that are presented in the rest of this paper.

3. Vision

Our concept for a future design centre is called “Transformation Factory” (TF). We decided for that name because it implies the bringing about of concrete results and change. The TF will create positive change and facilitate progression, through design.

The Transformation Factory will create economical and social value for companies, government entities, semi-public organisations, educational institutions, and designers in Limburg and surrounding regions. It has to become a high level centre that is strongly focussed on the characteristics, needs and future development of the region, as they have emerged from our research.

Mission: The Transformation Factory will become a dynamic structure of the highest international level that develops scalable and multidisciplinary design innovation projects for (clusters of) regional companies and public organisations, to generate diversification and renewal within product and service development.

The TF will engage in coordinated projects with local partners. The projects will relate to specific themes, which will change every two years. These projects will be handled professionally through contracts and executed by a multidisciplinary team of local, regional and international professionals. The companies, public organisations and designers involved will benefit directly from these projects.

The first three themes the projects will relate to are mobility, wellbeing and social change.

Before we illustrate the mission and the functioning of the TF with a few examples, we will first describe the type of activities and its target groups six basic principles of the centre,

The TF will have three unique core activities:

- **Experience prototyping** - The TF focuses on the creation of products and services based on people's needs and contexts, and on the testing of the user experiences of these products and services that have been developed with them. In other words the TF focuses on understanding, designing and communicating the way in which the user interacts with a product or service by using a simple inexpensive prototype of the product or service.
- **Mentorship** - Limburg has numerous experts in business, government, public organisations and education. The TF brings these people together in multidisciplinary projects with the best students, young designers or young companies transferring knowledge, skills and experience from "mentor" to "apprentice".
- **Creative incubator** - The creative incubator offers - for a number of years - office facilities and guidance to those starting entrepreneurs who are from disciplines and backgrounds that are consistent with the mission and vision of the Transformation Factory and who want to work around the themes that the TF has chosen. These entrepreneurs are involved in the projects of the TF. The TF in turn enables these entrepreneurs to collaborate with other companies and supports them in their daily company management.

The action radius of the Transformation Factory will cover the Province of Limburg and the adjacent areas in Wallonia, the Netherlands and Germany (a.k.a. the EUregion). However, it will also aim at further international European collaboration.

Target groups:

- **Small and medium sized companies** - The geographical working area of the TF has numerous SME's with a company culture where creative innovation is not placed very high on the agenda. The TF offers the opportunity to set up projects with these SME's that will give them new added value, also in collaboration with employers' organisations that can further stimulate the SME's.
- **Government and semi-public organisations** - Many governments, on a local as well as a provincial and regional level, take initiatives to improve the conditions for economical growth and quality of life. For example activities have been planned in the fields of mobility, company infrastructure, regional strategic sectors (tourism, logistics, life sciences), care for the elderly and social housing. Also hospitals see their tasks change as they have to approach the growing group of chronically ill patients more as clients who rightfully demand these institutions to better address their needs.
- **Schools and universities** - The TF will provide new possibilities to students and graduates of the Media & Design Academy and other schools and universities. Project based experience at the TF can serve as useful input for the curricula of, and as crucial practice-based learning for these educational institutions.
- **Designers** - Professional designers will regularly be involved in the project based functioning of the TF.

The activities of the centre are based upon six core principles:

- **Project based** - By working on concrete and realistic projects in the region, in collaboration with companies, public organisations and multidisciplinary design teams, the TF will differentiate itself from other Flemish design initiatives and can also position itself internationally as a cutting edge institution. The projects will be of such an innovative character that they will not compete with the work of local designers and

design agencies. On the contrary: they will provide new possibilities for professionally activity in a renewed manner. As a project oriented organisation, the Transformation Factory will engage in a constructive and structural collaboration with important strategic partners, including other design and innovation structures.

- **Thematic structure** - The projects and activities of the TF will fit into specific themes that are driven by the needs of the local context and will change every two years. The focus on a series of broad, clear themes that are easy to communicate will structure the functioning, simplify the communication and increase the possibilities for de facto realisation of concrete and useful concepts, solutions and products.
  Each theme will run for two years and will be preceded by a preparation phase and will be followed up by an implementation phase (see Fig. 1).
  During the central execution phase, a multidisciplinary team of consultants and designers will work on the project, while during the first and the last phase, only one project member will be involved with the project.
  This allows time and manpower to be already allocated to the preparation phase of a new project as soon as the previous project is entering its implementation phase. This parallel process enables every new theme to start off well prepared with a first series of projects. Furthermore, the implementation towards similar contexts, companies and organisations afterwards will become easier, given the fact that time and resources are set aside for project implementation. It finally guarantees that there will be one responsible person for each theme who will become a point of reference for the entire project duration (from preparation to implementation). See Fig. 1: Thematic project structure.

  The first three themes are already defined but are still very broad in concept:

  - **Mobility**: this comprises public transport, traffic, logistics, automotive, bicycle traffic, walking trails.
  - **Well-being**: healthcare (ZOL, one of the main hospitals of the region, is a very interested partner), care for the elderly, tourism, leisure time, food, body care, sports etc.
  - **Social change**: sustainable development, renewable energy, social integration, multicultural society (with Genk as a laboratory).

- **Multidisciplinary approach:** The problems and challenges for companies and public organisations are often not resolvable within only one particular discipline or field. An increasing number of companies and organisations are asking for a multidisciplinary approach in addressing their challenges. Also educational institutions and research centres are grouping and organising themselves in multidisciplinary clusters (e.g. UK, Denmark and Finland). Also the TF will work with a multidisciplinary approach. The collaboration of experts from diverse disciplines will result in new, creative and innovative concepts that can be converted to relevant and useful solutions.
- **Radical choice for the end-user:** The most effective way to design a product, service or system that people really like to use and that they can use efficiently and effectively is to start off the design process by departing from the actual needs of the end-users. The M&DA and the radiator design company JAGA, both to be situated on the C-Mine area, have already implemented this design approach in their activities.
- **Company focussed:** The companies in the region of Limburg want more opportunities for project based experimentation and innovation. The same goes for public organisations such as government and healthcare institutions. A company focussed design innovation partner, such as the Transformation Factory would be of great value for these organisations.
- **Research based:** The hands-on approach could possibly leave little time and space for an in-depth thematic orientation in which research plays a central part. It is of

importance to create strong forms of collaboration with universities, sector organisations and innovation entities.

Legal structure, staff and finances – The TF will have the legal setup of a company structure. The design centre will profile itself as a business structure that aims to in time become a full-fledged economic entity with self-sustaining activities. Choosing for a company structure underlines the conviction the founding partners have in the economic viability of the TF. Also a private structure makes it easier for other entities to participate in the shared capital and in the managing bodies. The majority of the shares will belong to the private sector, which enables the structure to obtain enough capital to avoid liquidity problems when it becomes operational.

The founding partners are the City of Genk, the Media & Design Academy of the Katholieke Hogeschool Limburg, and the Province of Limburg. They will sign a partnership agreement in which they declare to agree with the mission of the Transformation Factory. The City of Genk, the Autonoom Gemeentebedrijf Genk and the Media & Design Academy will be the public shareholders of the company and will also be members of the Board of Directors.

Regional design and innovation structures Flanders InShape, Design Flanders and Innovation Centre Limburg will sign a collaboration agreement with the TF to become its strategic partners. Participating companies will also be a part of the legal structure. The funding for the TF will come from the founding partners and the companies that participate in the projects.

The TF staff will be limited to a small professional team with expertise in business management, general management, design innovation and technical commercial skills. For the execution of projects and assignments the TF will also hire external know-how. A limited amount of staff keeps the fixed costs low and offers the flexibility to hire a variable number of personnel.

4. Examples of themed projects

Mobility – Project: Spartacus

Spartacus is an extensive mobility project for the province of Limburg. It concerns the development of an entire express transportation system consisting of a network of trains, fast trams, trams/streetcars, express buses and buses that covers the whole of the province.

At this point in time, the Spartacus project is still in its phase of technical and financial planning. However, it will be an enormous opportunity for companies and organisations in Limburg. Not only because it will create a better mobility infrastructure, or that it enables them to work on the project by means of contracts, but especially because this project can serve to boost innovative thinking and stimulate the development of new services and products, which, after this project has finished, can be applicable to other regions, other contexts and other clients.

Spartacus will become operational in the year 2012 or later. Project concepts that could be developed by the TF in the period of 2009-2010 are therefore crucial and could have an impact that will last for several decades. In its approach, the TF will start from a number of questions that are in fact all design opportunities:

What is the future of mobile transport? How will the needs of the passengers evolve? What kind of technologies can we anticipate to satisfy these needs? How can the products and services that will be developed and implemented for this project, also be relevant for other future transport projects? How can those services and products be part of a broader vision for sustainable mobility? How can we test the use of these services and products thoroughly before they will be implemented on a large scale throughout the whole system at high costs?

Relevance to companies – How can the furniture for trains and waiting areas be imagined for the year 2020? How can the building materials such as steel, glass, concrete and wood be reconceived, in order to make a sustainable investment in the future of Limburg?

A design answer to such questions implies the development of innovative products, which companies can also propose to other clients. It is likely that in such a large scale, future oriented and multidisciplinary project, companies will develop new working methods and procedures and form new partner networks that can also be used in other contexts.

Relevance to government and semi-public organisations - Government institutions are by themselves no experts in the development of mobility projects. They will have to collaborate with private companies and other organisations. The classical top-down approach is not always the best approach for such future-oriented projects, because it often simply departs from existing models and seldom leads to real innovation that can provide competitive added value for the broader economy, apart from the project itself.

A project-based, multidisciplinary and strategic design approach allows these (semi) public organisations to be acting as team leaders within this very innovative project. This will renew and reinvigorate the relevance of these public entities, and create a positive communication for the region. Moreover, the organisations involved can assign some of their best people to work as mentors with designers and young company executives from the creative incubator in a project based collaboration.

Relevance to schools and universities - Schools and universities engage in socially relevant research. They want to realise projects with practical relevance and prepare their students for a concrete labour market. It is possible to do all of this with much more impact within an existing project that already features collaborations with an academic institution (Media & Design Academy), companies and government institutions, and where good quality research is of great importance.

In this concrete context students will be able to learn the more complex tasks of their discipline from mentors, and can work with companies and government institutions before they graduate. Research can be executed within the project and deliver results that immediately have a social relevance. New study and research methods can be developed that will lift these educational institutions to a higher level, also internationally.

Relevance to designers - Local, national and international designers will be able to work on future-oriented projects, applying the most up-to-date methods, and working within a multidisciplinary project team, together with companies and government institutions.

This will allow designers to greatly expand their knowledge and network, skills and experience. Moreover, their work will be of high communicative value because of the importance of the project. This will help them in finding new projects and clients.

Social change – Project: Master Plan for Great Sledderlo

Great Sledderlo, a neighbourhood within the City of Genk, consists of two areas – Old and New Sledderlo. In many ways the area is an uncompleted part of the City of Genk. Almost fifty years ago the City had the idea to build a major satellite city for 20,000 inhabitants, consisting of five neighbourhoods situated around the city centre. In practice, only half of the planned area was realised. It is called New Sledderlo (which is next to the historic Old Sledderlo). Over the last few decades this isolated area with about 2,230 inhabitants had to confront several problems: the quality of the social housing is not very good; there is a physical and mental separation between Old and New Sledderlo; there are few public and commercial facilities; there are social problems between the different population groups that are mainly of foreign origin; and there is a high unemployment rate and a low level of education.

The creation of a number of support initiatives (neighbourhood development, youth wellness) has raised the self-supporting capacities of the population somewhat, but the

fundamental issues have not been resolved. Old and New Sledderlo have remained separate worlds and the area cannot really be called a proper city district.

In 2007, the local city authorities and the inhabitants came up with numerous ideas and plans to elevate the quality of life in both areas. A new Turkish mosque has already been realised and a new school and new houses will be built in the near future.

These were good reasons for the city administration to start with the development of a “Master Plan for Sledderlo”. This plan will need to contain the outlines for the future spatial planning within the area within several fields: redefinition of the social housing area, private housing development, public facilities (education, sports, culture, youth, well being), public infrastructure, the development of local commerce, the reinforcement of the economic structure, the relation with the surrounding industry, and the cohabitation of the different populations.

The city administration sees it as essential that the master plan can count on the support of inhabitants and local actors, as they will be the plan’s future users. Inhabitant participation will therefore be of great importance in the realisation of the plan. It also has to have an inviting character to public and private partners.

The future TF can make a great contribution to this planning process by addressing some of the following questions:

How can the general quality of life be improved, socially as well as technically? How should renovated and new houses look like in order to support the social mix of the population structure? How can the communication between the population groups be improved? Which new concepts can be developed for education, sports, youth, culture and wellbeing facilities? How can these services become part of a broader vision on multicultural cohabitation in the future? How can these new concepts be integrated and implemented in other locations with similar problems?

Relevance to companies - What will future classrooms for toddlers and children in primary schools look like? The way that classrooms are organised and furnished, as well as the choice of materials are of importance. This could be a good opportunity for potential suppliers to start working on renewing their products and services. The same opportunity would arise from the potential development sports, youth, culture and wellbeing facilities, or the renovation or construction of houses. Also the external surroundings are important when it comes to improving quality of life; think about park furniture, waiting areas for public transport, wireless communication, etc.

Relevance to government and semi-public organisations – It is clear that the city administration and the social housing organisations would benefit from the master plan being successful with the inhabitants and the local actors. The participatory approach is a crucial method to involve the future end-users in the whole realisation process. The local administration has a chance to create a maximum level of involvement in the development of the master plan. The TF can gather a multidisciplinary group of specialists, who will, together with the end-users, turn concepts into prototypes that they can experience – an approach of strong innovative value.

Relevance to schools and universities - The master plan is not a fictional “what if” project but provides a real “on the ground” opportunity for students who are in their last year or graduated recently to obtain professional experience and establish a link with the reality of the everyday professional world. In this setting, project proposals can be tested on their usefulness. Collaboration between educational institutions, students, recently graduated students and companies offers many opportunities for creativity and innovation.

Relevance to designers - The master plan will not only be focussing on the here and now, but also on the more distant future. That is why it is of importance to work with talented designers with a broad vision and an eye for national and international approaches and methods. Working under the guidance of experts who act as mentors, will be a tool to achieve that. The realised concepts, products or services will serve as touchstones. For the designers it is an ideal opportunity to show them selves to the world and to be able to create opportunities for their own professional development and career.

Wellbeing – Project: The Hospital of the Future

The European population is ageing dramatically and healthcare is shifting from providing acute treatment to becoming a service provider for the chronically ill. Internationally, design engage in service design approaches that are increasingly relevant for the healthcare sector.

ZOL (Hospital of East-Limburg) is one of the most progressive and future oriented hospitals in Flanders. Recently ZOL stated that the hiring of a hospital futurologist would be a likely next step. This futurologist could possibly work within the Transformation Factory. Hospitals need to continuously decide about investments for medical equipment, or the furnishing of hospitalisation rooms, waiting rooms and examination areas etc. Often this involves substantial amounts of money and decisions will have an impact for decades.

The decision makers are often the hospital authorities themselves, in collaboration with their financers (the government) and their suppliers (companies). This context does not always lead to innovative thinking. Governments would like to save money, companies want to sell their existing products and the hospital authorities have the tendency to envision the hospital of the future as a “more modern” version of their current hospital.

A project regarding the hospital of the future can be an enormous opportunity for innovative thinking and the development of new services and products.

What does it mean concretely to have to imagine a hospital of the future that will mainly treat chronically ill patients? What is in fact the future of the hospital? How are the needs and expectations of the people going to evolve? And how will we have to organise the hospital to meet those needs and expectations? How can we involve patients and relatives in the creation of a healthcare system that is of relevance to them? And how does such a hospital fit within a broader vision on healthcare?

Relevance to companies - Hospitals are dependent on numerous suppliers: architects, contractors, manufacturers of medial devices and products, producers of furniture, suppliers of food, hygienic facilities and cleaning companies – just to name a few examples. What does this new definition of a hospital mean to these companies? How can they help create a constructive vision about the hospital of the future? How can a multi-disciplinary, collective and experimental process to create a vision of the hospital of the future become a win-win for both companies and the hospital itself, thus benefiting them for many years to come?

Relevance to governments and semi-public organisations - How can a hospital transcend a way of thinking that is determined by a conventional vision of what a hospital is supposed to be, or by the restrictions set by too strict a financial target? Fresh and innovative ideas emerge by assembling a multidisciplinary team that does not immediately start its thinking from existing structures, or wants to apply a financial or product-focussed style of reasoning. Such a team has to be led by a progressive and open management team, such as that of the ZOL (Ziekenhuis Oost-Limburg), and should be guided by a number of strongly motivated government mentors.

Relevance to schools and universities - Schools seldom collaborate with hospitals and universities often only conduct basic research there – usually outside of Limburg. A university can approach this “hospital of the future” project as a research project with a practical relevance that will prepare students for a concrete labour market. A strong, progressive project can also lift these institutions to a higher international level.

Relevance to designers - Designers seldom get the opportunity to work directly on projects related to healthcare or hospitals. Still, their human-focussed way of thinking can contribute in a very unique and valuable manner. An in-depth project experience can help set professional designers on the right track, and demonstrate the possibilities of design thinking to student designers.

5. Next steps

The City of Genk has recently assigned the Experientia team involved in the visioning to also set up the structure legally, organisationally and financially.

In addition, the Cities of Genk (in the East of Flanders, near Maastricht/Eindhoven) and Kortrijk (in the West, near Lille) are currently in the process of developing a project proposal to obtain Flemish and European funding to stimulate entrepreneurship in their local economies and in the surrounding regions of Limburg and West-Flanders, based on a strong design driven approach. The Limburg part of the project would be the launching project activity for the Transformation Factory.

6. Conclusions

The design visioning process that we described above have led to a new definition of a “design centre” that achieves on-the-ground transformation through concrete projects, guided by six core principles: project based activities, thematic structure, multidisciplinary approach, radical choice for end-user, company focussed commitment, and research based analysis.

Design and user research was the founding basis for the vision of the Transformation Factory. The needs of the region and the people who live and work there came first in the vision development and also in the themes around which the TF will end up working. The core objective of the Transformation Factory is in essence to bring about concrete social and economical change in the region through the application of research and design in the broadest sense.

Our House:

Interior Design and Sustainable Consumption

Gabriela Varanda de Castro[1]

Abstract

Brazil's social and economic context involves some issues that could be considered contradictions: conservation and economic progress, technology and tradition, industrial and huge natural areas.

Brazilian sustainable design also reflects these expectations, searching for contemporary solutions, but also using local resources and skills to keep some traditions alive.

Nevertheless, the social learning process, which conducts Brazilian designers towards a constructive critical attitude able to reach sustainable society, is not an isolate one, but also a collective process that encloses the views of those who acquire products.

This paper presents insights from a research project that examines the notion of responsible consumption, and its implications for interior design in Brazil. Quantitative and qualitative methodologies were used to investigate Brazilian consumers' behaviour and expectations.

[1] Catholic University of Rio de Janeiro (BRAZIL) – Arts & Design Department. MA Student, gabriela.varanda@terra.com.br

1. Introduction

Sustainability seems to be the watchword for society of today. Therefore, we are everyday bombarded by news from newspapers, magazines, television channels and Internet vehicles, which address this issue.

Despite looking simple, the concept of sustainability is complex and has been understood from different points of view, by different researchers. One of the most complete definitions is the one given by Ignacy Sachs. For the author, it is necessary to consider, simultaneously, five dimensions, for a complete apprehension of its meaning (Sachs 1993):

- Social sustainability: improves the rights and living conditions of populations and reduces gaps in social groups living standards;
- Economic sustainability: makes feasible the efficient allocation and management of resources, evaluated much more under macro-social than micro-business criteria, and by regular streams of private and public investments;
- Environmental sustainability: involves attitudes to reduce resources consumption and waste production, to intensify research and the introduction of cleaner technologies and to establish rules that permit an adequate environmental protection;
- Spatial sustainability: contemplates a more balanced configuration of rural and urban issues and a better distribution of territory, involving, among other concerns, the excessive occupation of metropolitan areas;
- Cultural sustainability: searchs native conceptions inside each culture, respecting the peculiarities of each ecosystem, of each culture and of each locality.

Nevertheless, in which manner the sustainability concept is embedded in a design product? And how sustainable value is perceived in furniture and decorative objects, from the perspective of consumption?

This article investigates the way sustainable value is assessed by furniture and decorative objects consumers, showing results from a poll taken among customers from three interior design stores in Rio de Janeiro. This research includes a conjoint analysis – a statistical technique used in market research to determine how people evaluate different features of an individual product or service – and a qualitative interview, that determinates people's expectation and impressions about the relationship between products, design and sustainability. In addition, this article analyses the notion of responsible consumption and its implications for design in Brazil.

2. Sustanaible Design and Consumption

Accordding to Mary Douglas and Baron Isherwood, each person is a source and an object of judgments, each person is in the classification process whose discriminations are helping to establish. The flow of consumption goods leaves a sediment that constructs the culture structure as chorale islands (Douglas and Isherwood 2004, 119-147).

Therefore, consumption goods are an instance of the material culture. As other types of material culture, they allow the public and visual discrimination of cultural specific categories, codifying them into a set of material distinctions through the goods (McCracken 1991). Bourdieu also thought that goods join and classify groups. For the sociologist, they are elements that establish lifestyles. Economic exchanges are symbolic ones (Bourdieu 2001).

The consumption culture uses images, signs and symbolic goods to evocate dreams, desires and fancies that suggest authenticity. The new heroes of consumption culture transform the style into a life project and reveal its individuality and sense of style in a set of goods, clothes, experiences, appearance and corporal disposals intended to compose this exact lifestyle (Featherstone 1995).

The creation and the production of consumption goods – and dreams, desires, fancies and lifestyles – are close to design activities. To consume a product is also to consume its design and the previous intentions that originated it. But what is the role of the designer in this symbolic trade? Design is, in last analysis, a process to embed meanings into the objects (Denis 1998, 24-30).

Branzi also believes in a neo-primitive design approach. For the author, designers pursue the construction of an identity, of a language, acting as the old tribal chiefs. The tribalization of the cultural society, with its cultural groups or tribes and its specific consumption goods, is the result of this neo-primitive condition (Branzi 1989, 38-39).

Curiously, in his article *The idea of comfort,* the Argentine philosopher Tomás Maldonado asserts that we only decide the organization and the position of the domestic objects in the microenvironment of our houses, where we stamp our perceptions related to these products. If in the exterior world we remain in a blasé attitude, perceiving but not apprehending the demand around us, in our houses, this small segment of the huge material culture society, we have real autonomy and an actual relationship with close objects (Maldonado 1995, 256).

It is in this context, in respect to environmental and social questions, that sustainable design appears as a new proposal for contemporary design.

Design has to be responsible in terms of the ecology and the society. And also has to be revolutionary and radical. It must be dedicated to the principle of the minimum effort of the nature, in other words: A minimum inventory guided to the maximum diversity (Papanek 1985).

Therefore, considering sustainable concept, what is the collective code that categorizes sustainable products and services, allowing sustainable value consumption?

In other words, what is the symbolic meaning of embedding sustainable value into a product?

To embed sustainable value into design product is to show its origin clearly, to tell its history, to inform on its use, to satisfy a real necessity and to collaborate with global economic and social development, allowing consumers/users (who really choose and legitimise a product) to identify and share this new cultural proposal (Castro 2007a, Castro 2007b).

As we know, it is part of design job to create symbolic goods to evocate desires, fancies and dreams. And sustainable products and services are symbols of a new lifestyle to be fully achieved.

3. The Research

This study was conducted among a group of thirty furniture and decorative objects consumers, from three well-known stores in the city of Rio de Janeiro.

The Elementos da Terra store, located in Copacabana district, offers a selection of crafts produced by designers at NGOs (non-governmental organizations) and cooperative associations, from different regions of Brazil. The store has products manufactured with natural fibres, wood from demolition and other natural raw materials.

Fernando Jaeger´s showroom, in Jardim Botânico district, offers, specially, wood furniture and accessories for decoration. Fernando Jaeger is a designer who uses certified and alternative wood in his projects. He is one of the furniture designer pioneers in the development of products with low environmental impact in Brazil.

Daqui Design is a small store in Leblon district, dedicated exclusively to the contemporary national design. It brings together many of the Brazilian newest design names.

The selection of the interviewed customers was defined by non-probabilistic sampling, to achieve information in a quick and low-cost way, due to time and budget limitations. The used criterion was to interview clients who attended the stores as eventual or potential customers, or assiduous clients indicated by the shops owners.

As part of research, two surveys were prepared, a qualitative, made up of a separate interview in depth, and other quantitative, using the conjoint analysis technique.

The in-depth interview allows the collection of data and opinions, interests, perceptions and attitudes faced with the central subject of the research: the perception of sustainable value in interior decoration products. A pre-determined script in an interview form was established without exposing initially the central issue that was being investigated, avoiding induced responses by the persons interviewed.

In addition, in the interview script, visual stimuli was included with products offered by the stores, for an assessment of aesthetic perception of the sustainable value in design products.

The quantitative research used the conjoint analysis technique. According to Malhotra and Birks, if you choose this technique, you should identify the relevant attributes, to determine their levels, define the attributes combination to be used, choose the presentation form of stimuli and select the approach of the analysis. The attributes must be relevant to influence consumer's preference and choice (Malhotra and Birks 1995, 554-557).

According to Malhotra and Birks, attributes are characteristics that describe a product or a service, i.e., what a consumer evaluate at consumption act. In the conjoint analysis, the respondent is asked to make a choice: to select attributes that overlap each other, in a situation very close to the purchase scenario, when the consumer is forced to consider all these characteristics at the same time.

To reach the definition of which attributes were relevant to the research, it was used, as a secondary source, the Planeta Casa Prize, which is held annually by Casa Claudia magazine, a Editora Abril's publication (Azevedo 2007).

The Planeta Casa Prize is an event that recognizes sustainable initiatives in design, architecture and decoration fields, rewarding the winners in the following categories: Product, Construction Material, Social Action, Architectural Design, Interior Design, Student and Real Estate Venture.

The poll attributes were defined and gathered on cards, from an analysis of the furniture and decorative objects winners in the category Product, in the last five editions of the Planeta Casa Prize.

The four attributes, and their respective levels, were defined as follows:

1) Material:

- Recycled, renewable or recyclable: A material that was reused from another product, was made with renewable resources or can be reused in new products.
- New or non-reusable: Materials which are virgin or cannot be reused in new products.

2) Aesthetic:

- Rustic style: It uses natural fibres, rough wood, it has a straight relation with nature.
- Contemporary style: It follows present trends, it is modern and urban.

3) Way of Production:

- Craft: One that was created manually, by craftsmen from various regions of Brazil.

- Craft with signed design: One that was created manually by craftsmen from various regions of Brazil, with the guidance from a designer.
- Industrial: One that was produced industrially.
- Industrial with signed design: One that was produced industrially, with the signature of a designer.

4) Price:

- Low ($): In offering, in promotion.
- Middle ($$): Average market price.
- High ($$$): Above the average market.
- Very high ($$$$): A lot above the average market.

Since that there were four attributes (two of them with two levels, and the other two, with four levels), the total number of combinations would be 64 (2x2x4x4). This number would make the task very costly.

According to Curry, the minimum cards number with attributes combination is given by: minimum cards number = attributes levels total number - attributes total number + 1 (Curry 1997).

Using the previous formula, the minimum cards number would be nine. But, considering that the recommendation is to use about 1.5 to 2 times the minimum cards number, it was decided to use 16 cards.

4. Results

It was verified that 87% of the interviewees were women and 13% were men, once decoration consumers are predominantly female.

Most of the consumers researched has age between 26 and 54 years and family incomes exceeding 3,000 reais (the minimum salary is 415 reais in Brazil), and more than 77% present a complete graduate or post-graduate level of education.

The qualitative research analysis also found that, for those consumers, ecological products are those that:

"... are *made with recycled material, are reusable, have non-industrialized appearance, are crafts, simple and cheap.*" (interviewee 1 - Elementos da Terra)

"…are made with material extracted directly from nature, such as fibres, straws, leaves, more rustic woods." (interviewee 7 - Elementos da Terra)

"... *come from rehandled forests, with supervisory control, from planted forests. They have fabrics that do not depreciate the nature*." (interviewee 10 - Fernando Jaeger)

"... *are made with recycled or recyclable materials, from reforestation woods, they contain non-aggressive materials to the environment*." (interviewee 12 - Fernando Jaeger)

"... *come from the nature, don't destroy the planet*." (interviewee 20 - Daqui)

"... *come from the nature without its degradation, such as authorized wood and paper*." (interviewee 21 - Daqui)

As regards to products that carry a social value (they are socially responsible), it was found that they are those:

"... *that pay craftsmen in a decent way, come from fair trade, are recyclable, you can know the origin of its material*." (interviewee 1 - Elementos da Terra)

"... *who value, above all, the work of a craftsman*." (interviewee 8 - Elementos da Terra)

"... *produced in an environment of fair work, with the labour laws of the country being met, with good working conditions, without exploitation of workforce*." (interviewee 10 - Fernando Jaeger)

"... *made from recycled materials, usually considered 'trash', by cooperatives that help to create jobs for the people of low income*." (interviewee 16 - Fernando Jaeger)

"... *produced by companies who are concerned about the type of workforce employed, about the qualification of the staff members*." (interviewee 21 - Daqui)

"... *that do not attack the nature, as indigenous products*." (interviewee 28 - Daqui)

These assertions were further supplemented by the visual perception of products with social and environmental value, selected by customers from the three stores (Figure 1).

Using an Excel application, the conjoint analysis showed that among the four attributes evaluated (material, aesthetic, way of production and price), the decoration shopper was more sensitive to the way of production (Figure 2). The conjoint analysis also generated comparative charts for the levels of each one of the attributes.

When analysing the levels of the "way of production" attribute, that one with greater weight, it was realized that the "craft with signed design" level is the most quoted, followed by "industrial with signed design" one (Figure 3), which confirms the appreciation of the designer work. But this observation also points to another direction: the sum of the results of "craft" and "craft with signed design" levels shows that the crafts production is very relevant at purchase.

The "price" was the second attribute with greater weight, since a low or medium cost has superior importance faced with the quality or origin of the material used. The recycled, renewable or recycled materials were preferred to new or non-reused ones. As regards to "aesthetic", the attribute with lesser weight, the "contemporary" style was positioned before the "rustic" one.

5- Craftsmanship and Natural Materials

The importance of the "way of production" attribute in the research carried out helps us to understand the weight given to the designer's work and its association with the crafts production. Handicrafts, undoubtedly, go through a time of valorization in the Brazilian decoration market.

However, it is the social matrix that is given to craftsmanship as seen in the qualitative poll which interests us in this study. The recognition of the craftsmen work, the perspective of a better income distribution, the recovery of regional techniques and cultures, the development of urban and rural areas, all of these contributions are part of the greater sense of the sustainability concept, as defined by Sachs (Sachs 1993).

In the Brazilian context, sustainable strategy based on the pyramid base approach, as suggested by Prahalad and Hart (Andersen and Tukker 2006, 383-384), is a very interesting alternative: the rethinking of poverty as an attractive opportunity for growth, generating income and satisfying the basic human needs of certain populations. In this case, the social dimension is more important than the environmental one (UNEP 2006).

The tradition of a place may, after all, survive in a globalised world, and a sustainable design product should carry this possibility (Manzini 2007). The anthropologist Nestor Garcia Canclini brilliantly defines this moment in his book *Culturas Híbridas* (Canclini 2003).

According to Canclini, the modern development (or contemporary development) does not suppress the popular cultures. We live a hybrid culture, where craftsmanship has a complex interaction with modernity, renewing its work, but also respecting certain traditions. The increase of craftsmanship in industrialized countries shows that economic progress does not necessarily mean the elimination of productive forces that do not serve for its expansion. The reproduction of the traditions does not require being unaware of modernisation.

Another interesting observation is that not only the craftsmanship adhered to the rules of modernity, but the inclusion of crafts by industry also points to a double road. It is very common to see designers appealing to crafts techniques to add quality and exclusiveness to his pieces, mainly in the fashion and the decoration market, which also influences the crafts production.

For some, the reminiscence of craftsmanship is often a romantic desire to rescue another time, another era, when the artist was local and the world was summarized to his town, still far from a small globe, imposed by mercantilist practices. The recovery of the crafts could be seen as a search for identity, a safe harbour, in the frenzy of contemporary life.

The existence of new projects for the countries and the consequent change of its economic and cultural role has changed its place in the social relationships, in the definition of national identities and their own identity as objects. But you cannot say that the modernisation trend is simply to cause the disappearance of traditional cultures. The re-elaboration of traditions could be a source of both economic prosperity and strong symbolic affirmation of their identity:

Being the sum of functionality and beauty, a craft object can return us to the lost synthesis. It equals not exactly to the opposition of an era to another, but the reaffirmation of the basic needs of human beings, which, actually, leads to a re-identification, a review not only as a being able to make multiple things, but as a person ‘belonged' – not rootless, but included in an own and proper system (Ribeiro 1983).

Therefore, the crafts production lets to the roots, both for those who makes and for those who purchase them. According to the anthropologist Antonio Arantes, in this search for cultural value in crafts production, however, we must accept some demands, to meet the premises of sustainability (Lages et al. 2004, 124-126):

- Singularity: The aggregated differentials must be effectively rooted in local cultures and be recognized as significant differences, both by producers and externally, fighting forgeries production and shop window identities induction.
- Traceability: The safeguarding of links between products, producers and territories makes possible the consumer contact with the social and cultural environment of the original product, which is essential to build the credibility of the cultural value aggregated.
- Quality: The development of technical and material conditions of production, as well as the upgrading of products which are created for external consumption, should respect the producers’ cultural arrangements and their social organization.

Finally, the "aesthetics of nature". Such as in sustainable architecture, which shows on its "skin", for example, green roofs, it is reasonable that somewhat similar is expected from a sustainable interior design product, "one that recalls the nature", as observed in the qualitative research. For some persons, sustainable products are those made with natural materials (at Elementos da Terra and Daqui stores), and for others, those created with natural materials and with an appropriate origin (at Fernando Jaeger’s showroom). It is also interesting to note that there is room for the contemporary style, even within the "aesthetics of nature", since this is not associated, necessarily, to the rustic style.

Therefore, the great opportunity for sustainable interior design in Brazil is to merge the concepts of "nature", "tradition and place", and also the concept of "social innovation", in a new aesthetic approach of desirable products, which promise changes.

6- Conclusions

No artefact survives without culture, without being significant for those that conceive and utilize them. This sense has probably been the product design original point of interest, as designers promote the relationship between people and the material world, seeking to adhere particular meanings to their projects, and suggesting new models for the future (Margolin 2007, 4).

The knowledge of the meanings of an object can be built from some categories. Some of them are related to the user context, where he is inserted: their motivations, emotional aspects related to the use of the object, the characteristics of this user, the contribution of the object in the explanation of the identity of its owner, how this object serves as social communicator, the role of this object as an element of discrimination, social integration or ordination.

In current days, the word aesthetic is no more exclusively linked to the idea of good taste and beauty. Our aesthetic perception is relative and dependent on our cultural system, and there resides the important of the cultural factors or the functions of the products. The way we see and feel depends on our habits, our knowledge, i.e., on our life in our society.

The inherent product characteristics involve the materials, the technologies and the costs related to the product manufacture, which can also apply significant changes into the product image, as they concern to the production.

However, the extrinsic characteristics, which include the emotional, social and cultural, semantic, symbolic and aesthetic aspects of the product, have vital importance in regard to the product image faced with the consumer/user.

The products don’t exist outside the human involvement, because we do not react barely to their forms and functions. The fate of an artefact is not determined solely by its aesthetic and functional qualities. It is believed that the search for an identity of the Brazilian design cannot be exclusively anchored on physical aspects but also on symbolic ones, which allow Brazilians to recognise themselves. After all, the idea that people's behaviour play a vital role in moving towards sustainable development (Jackson 2004; UNEP et al. 2005).

In this search for the sustainability visual language, Brazilian designers create products using traditional skills and materials, exploring local resources, forging a connection with their client's customers or communities and elaborating a design proposal that can be locally recognized and useful in the Brazilian society transformation. It is precisely this union between craftsmanship and design that best communicates this Brazilian proposal: by the ideas of "nature", "tradition and place" and even by the concept of "social innovation".

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Knowledge Communities

The actions of design for the construction of knowledge-based territorial systems

Rosanna Veneziano[1]

Abstract

This paper intends to describe a planning methodology for the strategic and services design to put in evidence the importance of sharing strategies to increase the territorial development and the participation of local communities on the project process.

In complex territorial systems where universities and research institutes create and spread knowledge, the link with the geographic site is very important.

In this context, thanks to the strong integration between local communities and universities, it is possible give birth to the “Knowledge Based Communities”, that through an active participation in decisional processes can have a determining role for the territorial development.

This paper presents the case study “*Suniverse. University services system*”, a services design project for the Second University of Naples.

[1] Seconda Università degli Studi di Napoli (ITALY) – IDEAS department of Industrial Design, Enviromnet and History . Phd, rosanna.veneziano@unina2.it

1. Introduction

The design studies, with its scope of action, have a crucial role in building innovative models for the development of a territory and management of territorial resources.

In the project process, the design is able not only to realize new production scenarios, but to start up a general participation of the community in planning-operating, project and experimentation phases.

The design, through the strong connection with the “environment” in which it operates, analyzes the territorial, social and economic characteristics and develops the material and immaterial aspects. The continuous innovation needs that come from the territory and from the social body, find an answer in different actions and strategies.

On one hand the design contributes to the development and the enhancing of the local resources, on the other hand supports the spread of new cooperation models and initiatives that provide answers to social problem. The design is the tool, particularly in services and strategic area, to develop collaborative services systems. In this system the local communities aren’t only a role of users or end-users but they are producers or co-producers.

Through an action system based on the sustainable approach and projects related to solidarity and exchange, it is possible to address the community towards responsible behaviors. Sharing initiatives, that face and solve a local problem, increase the belonging feeling to a community and activate a relationships system of local capabilities and individual competences.

This type of social participation, spreading shared and self-management services, even develops spontaneous initiatives and is able to transfer more quickly those values essential to change lifestyles and consumption in a sustainability perspective.

Thanks to projects born from community’s creative processes and that start from the bottom, it is possible to share and experiment proposals that act not only on environmental quality of processes and products, tangible and intangible assets, but on the ability to spread a new idea of welfare-oriented sustainability.

In this scenario projects with a strong identity emerge because they born in life contexts in which the results are immediate by “doing”.

The design approach based on the cooperation is continuously adjusted and the final result is verified by communities from where the demand for innovation emerged.

In this context the sustainable approach is a project experimentation process about strongly contextualized needs with an active community participation that express local identity.

For this considerations the design can play a crucial role and can certainly be the mastermind for the development of a territory, offering solutions for the community needs and spreading ethical and social values.

2. Social networking: creative communities and knowledge communities

In the "network society", defined as a social network that spread through the network logic and that is powered by information technology emerge a new form of communication based on horizontal networks of communication (Castells 2007). In this context the distributed systems widespread over time and for different areas. These systems are complex shapes with a strong interconnection but which have their own autonomy.

The distributed systems were considered as possible structures of innovative developing models for a sustainable society. In recent studies they were reported as the infrastructure of the so called *"multi local community," a society based on new ideas on communities and places* (Ezio Manzini, the Ezio Manzini's blog, *From distributed intelligence to distributed economy via distributed energy generation: an emerging distributed model of development?*, paper posted to on October 5, 2005).

In this context the qualities and characteristics of a place, its human and territorial resources must be considered not only at a local scale but also, at a larger scale, as part of a connected system in which each element is a knot in a network.

In the social scenario the relationship between social networks and virtual networks is more and more widespread. In fact through the unlimited connections, the information, ideas, experiences and knowledge are spread.

The more interactions between the knots, the useful is the network: "… the usefulness of the network and its proportional growth is a function of social groups that have access." At the same time the network value is multiplied with the increase of knots that compose the network. The network efficiency is guaranteed by a process of reconfiguration and replacement of those knots that are failing the task of providing value information. (Castells 1996, 70-75).

In recent years through the network communication we see the spread of new models solving common problems or defining complex project on very large scale. Institutions such as Design Council, spirit of creations, since years, activate virtual communities to analyze specific topics to find solutions about social problems.

These practices are based on virtual communities, on connectivity and on the individual participation to solve common problems or discuss specific issues.

The collaborative networks are complex forms of organization in which a group more or less numerous of people exchange information to obtain a result. This type of flexible structure is based on the individual experience of someone sharing ideas with a group of people through peer to peer dynamics. (Manzini and Jegou, 2003).

Another social phenomenon, developed in recent years, is that of the *creative communities*. Those communities, born locally, have a strong and global interaction and participate actively to the design process.

The creative process is born from the need to solve a problem particularly felt at the local level and is concretized with the identification of alternative solutions and new ways of social acting in everyday life.

These self-organized communities experience and solve problems through shared ideas and collaborative models with high social innovation contents. (Ezio Manzini, the Ezio Manzini's blog, *Creative communities, collaborative networks and distributed economies. Promising signals for a sustainable development,* paper posted to on January 6, 2006).

The design capabilities of *creative communities* are activated around an emerging need and they give rise to an interaction system towards new types of social learning. These forms of creative groups are a strong signal that identifies an awareness of a changing towards the sustainability, sharing new ideas of "welfare".

Today there are many creative projects that identify solutions able to respond to the growing demand for lifestyle changing. The problems arise from social services inefficiency or from the need to make best use of local resources or even to promote local know-how.

These communities have faced in a very efficient way problems such as mobility, housing, food, social services, education, work, identifying different and sustainable solutions. (Meroni 2007) The project approaches starting "from bottom" and spreading through social network, through solutions such as car sharing, co-hausing, producer markets, construction of associations for food distribution and sale, of groups coordination to respond to a request of social services.

The design tools used are activated in a contest where the responsibilities and skills of the person are a founding value. In this way the subject is a consumer but also a creator of concept and a co-producer of a service.

Considering that collaborative networks and creative communities are distinct phenomena generated with different intents, and considering that both phenomena are important for social changing, it is clear that, in this context, the *knowledge based communities* have a more important role (Ezio Manzini, the Ezio Manzini's blog, *Creative communities, collaborative networks and distributed economies. Promising signals for a sustainable development,* paper posted to on January 6, 2006).

The *Knowledge Based Communities* develop in places where strong is the interaction between local communities, university research institutes and enterprises. The system of interactions between the territory and the university predispose to the social changing and to new complex relations systems.

In areas whose economies are closely connected to knowledge, the contribution of the *knowledge based community* is fundamental to attract new economies enhancing the territorial and social resources while promoting sustainable development strategies (Thackara 2005, 24-26).

In places where universities and research institutions set up, the so-called knowledge poles, we see the "territory cultural contamination" becoming a more complex system of relations.

The role of knowledge poles in the dissemination of best practice towards the sustainability is to contribute to build connectivity networks between communities, businesses and institutions, and to implement actions and projects with the common objective of respecting cultures and environment.

Universities, defined as "engines of innovation" (Richard Florida, the Richard Florida's web site, *The University and the Creative Economy*, document posted 2006) create important synergies with the actors and the communities in the places where they are active and the surrounding areas. By means of policies oriented to strong links between Universities and the territory and the implementation of diversified strategies, devised together with the local communities, processes can be set up to disseminate knowledge and enhance the development of creative communities, which are a source of innovation and growth for local realities.

It is possible to create a Knowledge based territorial system implementing projects using the landscape potential in the right way and starting from the local field to share the global results. These systems are characterized by strong links with communities participating actively in the design process.

Actions should be addressed to the enhancement of local resources through the exchange, the sharing and dissemination of knowledge and of best practices of territory development. (Thackara and Verwijnen 2004)

3.The territorial resources enhancing: the communities interaction. *Suniverse* case study

The case study explained below, experiment a model of cooperation between knowledge communities and local communities. The services design project is based on the social participation and on the construction of a complex system of relations between public institutions, research institutions and local communities. The services design project promotes the territory development thanks to the of real and virtual network potential.

The Second University of Naples (SUN) has a special organization, because the various faculties are distributed over the territory of Campania. The multi-centre system is build up with the aiming of locating the research centres in the most suitable specific area.

Therefore the SUN appears as a complex system of competences and a place to experiment projects aimed at making the University-territory system more and more competitive.

In the *Suniverse*[2] case study, through strategic and services design the university and the local communities devises an action strategy characterized by a variety of actions to be included in a common program: enhancing local, territorial, landscape and social resources by constructing a global network applied locally and transferring the know-how developed in the university's laboratories all over the territory.

The project aim is to enter the SUN and the linked communities into highly competitive systems, through implementation, in an out-sourcing model, of a services system which uses and promote the already existing skills and resources.

The project provides for the application of an operative methodology oriented to the complete cooperation of public and private stakeholders and to the integration of measures and actions leading to the achievement of tangible and intangible services.

Through different and coordinated services the project activates, on one hand, an intangible services network, which use the same potential of the network, on the other hand, builds welcome places facilitating the meeting between demand and offer and promoting local and cultural activities.

As the *SUNiverse* project is implemented over time, it makes the services available and constructs wider relationships, which are needed for the enhancement of the human and territorial resources and for the development of a *knowledge based community* that is perfectly suited for a global competitiveness scenario.

The project includes six fields of action:

SUN Hospitality, an alternative accommodation service which identifies different levels of accommodation using existing structures on the territory and organizing them into a network;

SUN Mobility, a mobility system which experiments sustainable solutions and encourages the use of collective transport systems;

SUN Café, a gathering place equipped with advanced communication technologies that encourages cultural exchange and hosts the collateral scientific activities of the university;

SUN Lab, a virtual environment dedicated to communication of labs research activity;

SUN Card, an tool to access the project services;

SUN Agency, a physical place, located in the university areas, that welcomes users and promotes activities and their services.

The institutions and communities involvement is particularly significant as part of a project to hospitality and mobility.

SUN Hospitality aims to build a network valorizing, at different levels, the hosting structures in any faculties municipality. The network enhances local resources and also encourages the housing sharing by a system of exchange between students and the aged persons.

The objective is to internationalize University activities, and to increase the number of users in extra regional areas. It is necessary to ask an immediate reply in terms of hospitality to propose the implementation of alternative and sustainable strategies going beyond the economic difficulties related to the building of new structures.

The obstacle that strongly influence the spread of initiatives and the international experience is determined, on one hand, by the inability to adapt university building in an accomodation structure in short terms. On the other hand, the obstacle is determined by the small economic

[2] Research Team: Patrizia Ranzo Team leader, Rosanna Veneziano, Migliaccio Davide, Chiara Taddia, Patrizia Silvestri, Ivan De Francesco.

funds available to build new hosting structures. The increase of housing needs, for short and medium periods, the growth in demand by offsite students and the dissemination of international projects, make very important to carry on a plan about hospitality.

The hosting service experiences a different type of hospitality at various reception levels and quality indicators. From the analysis about the housing supply and demand the project chose to follow what was already done in other Italian cities (communities low) encouraging forms of shared housing, low cost or even free of charge accomodation, among people of different generations.

The first level, *Indoor Services*, includes rental services, and a selection of hosting resources in the territory (hotels, bed and breakfast, residences, farms, houses to rent for students and host family). The first level allows the construction of a network with an on-line access. A specific site section, a blog, will be used to collect hospitality demand and supply at low cost or free, exchanging domestic partnerships. The project involves the development of a *SUN Hospitality* quality mark, granted to the structures included in the hospitality network. The mark includes all those residences with high levels of quality promoting local development starting from small businesses. It is also planned to conclude agreements with institutional bodies to cut the rental costs and to spread initiatives of shared accommodation.

The second level, *Personal Services*, includes services related to the person about health, fun and spare time. It gives useful information about hospitals, medical site, chemist's, theaters, cinemas, sports facilities and also promotes events at interesting prices.

The third level, *Outdoor Services*, includes services about meeting the territory, with on-line tourist itineraries, promotion of agri-food experiences and cultural events.

SUN Mobility is an action aimed at achieving a network for the optimization of private transport and for the easing of traffic on the roads of the university municipalities. Every day about 28 thousand users SUN move from different part of the region, with unsustainable travels because of the inefficient public transport service. Consequently, it is necessary to implement optimization strategies of travelling.

The service gives awareness to sustainable solutions and encourage the use of collective transport systems. In particular, the first actions of the project are the optimization of trade by different means of transport (train-bus), the introduction of collective mobility system such car-pooling and car-sharing, bike-pooling with deposit stations and also the creation of a customer service.

By the agreements among the University, the municipalities, the public institutions and the private partners, the *easy parking* service will be activated. It is a low cost parking service for SUN users travelling together in one car. The aim is to promote the use of private cars, reducing the number and therefore the demand of parking space.

By using a software it will be possible to send the request of sharing car to a server that will dispatch the requests and will send by e-mail or sms the travel offers.

In this case study the relations about the service are an essential element for the project goal. The construction of complex social relationship promote an active involvement of users and spread choices and shared values.

Knowing the area in which the services are developed, enable a continuous service adjustment; in this way the service implements its performance adapting itself to the needs of its users.

4. Conclusion

The design actions, in the field of design services, are able to build a interaction system between the productive texture and territory. So the design activities concur to define a

cooperative process of production that is oriented to the development of places with low resources.

The dissemination of design services, that support the integration of knowledge communities and local communities aims to collect the following results:

- activating a communication between research institutes and manufacturers that recognize the research as a point of reference for the development of the territory;
- adding human and territorial resources value meeting cultural and productive activities on the territory;
- developing the *Knowledge based territorial* system.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

From sustenance to sustainable living in India

Elements of vision based on collaboration with local NGOs.

D'Silva Sabina[1] and Jégou François[2]

Abstract

The research *'From Sustenance to Sustainable Living'* explored possibilities of moving from means of sustenance, revitalizing traditional social structures and consolidating existing forms of services to foster the development of sustainable lifestyles in the communities that Indian NGO's are currently working in. The paper discuss different established or emerging initiatives, how they could be improved, diffused and made viable in the long term. It is the combined result of a series of interviews, seminars[3] and workshops[4] that were undertaken in India, in collaboration with Indian NGO's, between 2006 and 2008.

[2] Strategic Design Scenarios, Brussels, francois.jegou@solutioning-design.net
[3] a collection of promising cases, interviews with local experts and a expert seminar with local NGO's have been conducted within the Creative Communities for Sustainable Lifestyles project. CCSL is supported by the Swedish Ministry for Sustainable Development in the framework of the Task Force on Sustainable Lifestyles within the 10 Year Framework of Programmes on Sustainable Consumption and Production, usually called Marrakech Process.
[4] workshops with representative of local NGO's have been held during the 'All India NGO Summit' held at the Art of Living International Centre in Bangalore from January 31 to February 03, 2008

1. Introduction

Indians are at the crossroads of a big change in their way of living. Economic liberalisation, a large pool of young and educated workforce and a middle class consumer base of 300 million, has propelled rapid economic growth in the country. However this growth tends to be concentrated in its cities. Cities are growing uncontrollably and are in the throngs of infrastructure development with new mall construction, mass-transit infrastructure, condominium housing complexes, attracting more migrants from the rural areas, with people changing their lifestyle from more traditional and sustainable to Western-inspired consumerism. On the other hand rural populaces, which constitute nearly 70 percent of Indian total population, are still struggling for basic essentials of survival, reaping little or no benefits of economic liberalization or the consumer society. In both urban and rural situations, NGO's are acting on the field, since a long while, helping to counterbalance endemic extreme poverty as well as new effects of booming urbanisation and uncontrolled economic growth.

The main objective of the research was to examine how to move from more *'transitional solutions'* to more *'sustainable ones'* in the various communities.

For different dimensions of daily life activities, examples will be described and analysed in the paper. It will show which solutions are more than 'transitory sustenance' and have a potential to diffuse to the larger share of the population and across social layers and shift the on-going trends toward consumerism and unsustainability.

The overall factors that contribute to certain solutions being accepted more readily than others in this context will also be examined, be it cultural, traditional or social norms, economic factors and availability of existing service infrastructure.

This paper has been developed from various research projects conducted in the area of sustainable living:

1_SEP and the activity of collecting/documenting social initiatives promising in terms of sustainability to enrich a 'catalog of cases' towards sustainable lifestyles. SEP is a part of a research study called EMUDE; EMUDE (Emerging User Demands for Sustainable Solutions) is a programme of activities funded by the European Commission, the aim of which is to explore the potential of social innovation as a driver for technological and production innovation, in view of sustainability. To this end it seeks to shed more light on cases where subjects and communities use existing resources in an original way to bring about system innovation. From here, it intends to pinpoint the demand for products, services and solutions that such cases and communities express, and point to research lines that could lead to improved efficiency, accessibility and diffusion. Emude has been promoted and developed by a Consortium of European universities and research centres. In order to identify a collection of promising cases it has set up a network of observers, known as Antennas, encompassing teams of researchers and students from 8 European design schools.

2_The activitiy of researching/compairing/discussing cases in India through the CCSL Indian Programme. The Creative Communities for Sustainable Lifestyles (CCSL) is an on-going project of research that deals with creativity and sustainable lifestyles. More precisely, it discusses the potentialities of collaborative everyday life creativity (the creative communities) in generating and diffusing new and more sustainable ways of living in the urban environments of the emerging countries (with a focus on Brazil, India and China). Examples of these creative communities initiatives are: self-managed services for the care of children and the elderly; new forms of exchange and mutual help; alternative mobility systems; socialising initiatives to bring cities to life; networks linking consumers directly with producers, etc. The CCSL India exercise was held in September 2008.

3_The CCSL presentation at the All India NGO Summit Sangam held in January 2008 in Bangalore, India. The presentation was held in 2 sessions, urban and rural, each comprising 25 to 30 NGOs from different parts of the country.

The approach adopted was to present and share cases on sustainable living from around the world, focussing on cases relevant to the Indian context. The focus here was to dilute the specific context of each case, especially global cases, and make them more relevant to the context. Cases were selected in different areas of everyday living, namely neigbourhood care, new food networks, childcare and mobility. Each case was represented by four pictures in an A3 size poster, with the main service ideas being highlighted in text. The people in the drawings were lined in pencil, to make them appear more ‘generic’ and 'readable' by an Indian audience. The audience was introduced to these cases and asked ‘how relevant they were in the Indian context’, ‘if they existed..in what format’, and ‘if they didn’t…why not’.

2. Beyond transitory solutions...

The main concept that this section would like to demonstrate is the notions of 'transitory' solutions: for instance the traditional and more recent solutions based on creating value and employment through recycling initiatives are win-win solutions combining sustainable benefits (developing recycling) with social benefits (creating employment). But these solutions have a 'transitory' character toward a sustainable society based on fare and reciprocal solutions...

We will examine 3 cases in the area of waste management/recycling.

The first case is an example of a traditional service called the neighbourhood ‘Bangarwalla’. This service is an informally organised, urban neighbourhood, door-to-door service, of collecting used recyclable objects from homes and shops, and selling them further to a scrap wholesaler or back to the manufacturing factory.

The service is usually rendered by a person or a family, immigrants from the rural areas, who collect objects door-to-door once or twice in a month, or on demand. They are always seen in the neighbourhood and even if they are not visiting a certain residential society on a particular day, they can be called for an impromptu service by spotting them in the neighbourhood. The objects vary from glass and plastic bottles, tin and plastic cans, newspapers, books, clothes, household electronic items, furniture…basically anything that is not wanted and is recyclable! The bangarwalla purchases the items from residents by weight or by lot.

He tows the items away by handcart to either a small store of his own in the neighbourhood or directly to the scrap wholesalers. At his store, he sorts out the objects, sometimes even doing further recycling like melting the metals objects. The sorted items fetch more money and are sold further to larger scrap dealers or directly sometimes to the manufacturing factories (eg alcohol and softdrink bottles back to bottling companies). Sometimes the store also renders a small/medium size service of a neighbourhood library (from old books/magazines collected) or of a little odd objects/spare parts store. The libraries are frequented and popular particularly among students.

This example is extremely well diffused in urban areas in India, both big cities and mid-size towns. The service still thrives in urban areas. Mostly uneducated, unskilled rural immigrants coming into cities take to this profession, as an easy one to start with no entry barriers. However recently few restrictions have been placed on previously easy accessibility of the service. Eg a lot of residential societies do not allow the bangarwallas into the residential societies for security reasons. Moreover this kind of service is mostly carried out during the day and was more accessible when at least one member of the family was available at home. Now with more and more working couples in the cities, there is nobody home for the bangarwalla to visit. The service has also not been able to upgrade itself to improve the earnings of the service provider.

Bangarwallas make anywhere between Rs 2000 to 5000 per month, but still retain the social stigma of a job to be done by one less privileged or a rural immigrant. It is an essential service but not given its due recognition and not upgraded to a value added professional one.

The second case is also a traditional example of the 'Urban Ragpicker Community'

Urban Ragpicking is an informally organised service, where individuals pick up recyclable items such as plastic, glass, paper, wire, cans etc. from public dumps and garbage bins, and further sell it to scrap dealers.

The ' urban ragpicker community' in India consists of poor immigrants from rural areas, typically from particular villages in the South of India. Each group informally adopts a certain garbage route consisting of public dumps and waste bins. They start off at 4 am in the morning with a gunny sack and start picking out recyclable waste like cans, plastic bags, bottles, papers etc. from the bins. Not armed with gloves or any other tools, this job does not suit all because of the health hazards associated. By 7 am they wrap up their rounds and take their sacks to nearby scarp dealers who pay them for their collection of the day. The rest of the day, they are occupied with other more organized jobs, like residential colony sweeping or domestic housework. This job is typically carried out by women. Interestingly, the particular tribal, rural communities that get into it have displayed above average health immunity that this job demands.

Again, this example is highly diffused in all urban areas in India.

Entering dumps and bins with no proper safety equipment increases the health hazard of this job. The service does pay enough for survival needs, but has a high social stigma attached to it. However the contribution of this community to the urban waste management system has been recognised by some city municipalities. In some municipal wards they have been provided with better tools like gloves and an overcoat and in some cases, also day wages. However, this is still the exception and has a long way to go before becoming part of the formal system.

The third case called the Daily Dump is an example of a contemporary service started in Bangalore, a big city in India..

The Daily Dump is a Home Composting Solution, proposed by the Shristi School of Design, Bangalore, selling composting products and tool kits to residents and also services to help start and maintain the composting activity at home.

The solution is proposed as a system, which includes composting technology and products, with service maintenance plans to support. The composting products and containers can be purchased by residents. In addition, start-up and maintenance services are also available whereby residents can avail services of an expert to visit them at home and maintain their composting planters on a regular basis. The solution is supported by a website which encourages users to share information and experiences on composting. The service is promoted via local clones in different cities, the website, local stores and events on composting and ecology.

This is a new service started in a single Indian city and is just gaining ground as a replicable idea. It is still mainly active in the origin city that is Bangalore, but is now also being offered through a quasi-franchise route in few other cities in India.

The service is currently only being promoted by the original entrepreneurs, is the Shristi Design School, Bangalore, so its reach is limited to that of a private service. It involves a behavioural change on part of residents, where in the past, they have been used to dumping wet garbage into garbage bins, now they have to put efforts to sort out the wet garbage. Moreover, the technicalities of composting are not widely understood and it is seen as a messy activity attracting flies and smell. It is also perceived as an activity that requires a larger space or an outdoor space, which is a constraint in most urban apartments.

In synthesis, what is interesting to note is that though all the 3 cases are interesting in terms of sustainability i.e. enhancing recycling or composting, but the first two are more 'transitory' whereas the last one is more in line with 'sustainable lifestyle'. The difference lays essentially in whether or not the solution is based on cheap man-power and hazardous working conditions.

In the first case, there is much more potential and reach for this service if it becomes part of the formal municipality-driven recycling chain and people are encouraged to recycle-exchange more. And very importantly if this becomes a means of offering fair wages and social inclusion to the ‘bangarwalla community’.

The spin-offs from an initiative like this could be a second-hand store in the neighbourhood for tools, furniture leasing or second hand clothes, games store, that helps re utilize neighbourhoods objects within the same neighbourhood, thereby eliminating the need for transportation of waste to scarp dealers and factories……The currently run bangarwalla second hand stores could get a makeover, as a neighbourhood leasing store, promoted by the residents as solutions for more sustainable living.

Again, the bangarwalla case is more of a post-recycling nature….and if garbage was sorted out at source, this step would no be necessary at all. This service is therefore is also more of a transitory nature in a society leap to more sustainable solutions. As pointed earlier, although it does generate income and employment for rural immigrants, (that is a social benefit in a country like India), it does not give them better working conditions or ensure fair wages, two very important conditions to qualify as sustainable lifestyles. However, it is worth pondering if there is a more long-term way of incorporating the services of this community, who are like a specialist community in these services, towards more sustainable waste management solutions.

The Daily Dump encourages sorting of waste at source and hence is more sustainable. This service is by far the most sustainable of the three, since it is based on a spirit of more of "collaborative services" and fair wages to all Again if recognized by the municipality it could offer a wider spread reach. It also actively encourages micro enterprises by training people in the delivery of such a service to start their own businesses.

Each of the above solutions has a role to play in the transition from Traditional sustainable to Long-term sustainable solutions for a changing Indian society with changing needs. The Bangarwalla case brings to light the existence of a local infrastructure available for waste management needs. Collectively pooling together these services for each neighbourhood, recognizing and fortifying it with government and resident cooperation, finding news ways of accessibility, delivery and value addition can make this service relevant and useful to contemporary society. The Ragpicker community services can also be effectively used in the transitory phase, and can eventually be clubbed together with a better service idea like the Daily Dump. This community can be encouraged to start micro enterprises in different neighbourhoods offering services like the Daily Dump and other sorting, recycling of waste at source, more like waste Management Cells in various residence. For at-source service. The key is to use the infrastructure already available, club it together with the efforts of the municipality and get resident buy-in for more recognition, wider reach and value added innovations….towards more sustainable solutions.

3. Revitalising traditional solutions...

The main concept of this paragraph is to show that emerging contexts still have traditional collaborative structures but that they tend to disappear behind the progress of the western-like consumption society. In order to have a chance to 'leapfrog' from these still existing potential of sustainable solutions, they should be revitalised through new ideas...

The activity examined here is Food Supply Networks, both traditional and merging in India.

The first case is a traditional example of a 'Neighbourhood Bunya Store'

The store is of a neighbourhood grocery store, small-scale, usually run by a family or relatives from a particular community, stocking dry groceries and daily household consumption goods.

Residents can buy their supplies from the store or also avail of home delivery of the same. The home delivery option was started because of increasing competition from new retail formats like Food Supermarkets. The local stores also offer goods on credit, small quantity purchase, special items ordered on demand and a relationship-based service that one can bank on even for emergency purchases or sourcing one-off products. This has a high diffusion level in all urban cities in India

So far the emergence of big retail food supermarkets has not dramatically impacted the small grocery stores. But as time passes, they are beginning to feel the impact. Once again, change in the lifestyle of people and more working couples, means less time on weekdays. They are preferring to do their grocery shopping at one go, in bulk over the weekend. The big format stores are a convenient option to do all shopping at-a-go and also offer better prices for larger quantities. Moreover big format stores, spend large amounts on marketing, with high visibility through TV advertising and promotional fliers in the newspapers, often tempting buyers into buying things they do not actually need. In India, where Mall cut lure has just emerged, weekend mall visits are becoming a part of a family outing trend. The air conditioned environment, movie complexes and food courts are seen as a good getaway spot for families. So it's easy to complete the grocery shopping there as well.. Big format stores also offer larger shelf varieties and the latest product offering and promos, with cheap pricing.

The second example is also a traditional one – The local sabziwallas/fruitwallas

This service is very similar in nature to the above case and works on the same lines, but is offered for fresh produce. The service is provision of fresh fruits and vegetables from individual stands or carts, either static points like local vegetable markets, or mobile on carts. Again offering home delivery and customised ingredients, based on client requirement. The local sabziwalla is usually a rural immigrant from a particular community. He sources his supply of vegetables every morning at 4 am from the local wholesale market, which in turn gets its fresh supply of fruits and vegetables from areas around the city on a daily basis..

The third case is a New case emerging called the Navdanya organic food supply initiative,

An NGO called Navdanya runs an organic food store and organic food home-delivery service based on subscription in New Delhi.

Navdanya has direct links with organic farming communities and cooperatives from where it sources fresh organic produce and dry grains. It also sells processed organic products. Its flagship store is in New Delhi and it has also expanded recently to Mumbai. Residents can buy at the store or can subscribe for weekly home delivery of organic produce, including seasonal fruits and vegetables. The store also has a restaurant which promotes freshly cooked food.

Navdanya directly faces competition from big format grocery outlets who offer better prices and larger varieties to the urban middle classes. In India the trend is that a population traditionally used to consuming organically grown produce, are now aspirational about consuming processed foods, imported ingredients and MNC brands as symbols of a more affluent aspirational lifestyle. The Navdanya format also breaks from the traditional wholesale food supply network, hence is more expensive to manage and adds to the food cost. Besides, it can only be offered in areas where organic farming clusters are present or can be developed.

Finally the fourth case discussed is the Satvik Food Festival as an emerging food supply example.

This is an event that brings together local organic farmers from around Ahmedabad to sell fresh and locally processed organic food to urban residents of Ahmedabad.

A fair or mela is organised once or twice in a year and organised by the famous educational institution, IIM Ahmedabad on its campus grounds. The event is targeted as a weekend outing to urban families and brings together farmers and residents looking for fresh organic food together directly. It enables building of direct links between them, cuts food supply costs and also encourages local food culture.

Currently the event is an annual/biannual feature and hence can only suffice for occasional food buying and not regular food supply. After the event, there is no link or relationship maintained between farmers and residents for longer term or more regular services.

In synthesis, the key ideas that are important here are to find ways in which to revitalise traditional solution like in the first two cases. And in the latter two, to find possible routes of furthering the benefits offered, namely, Navdanya in providing high level quality (organic) and service (subscription delivery); Satvik Food Festival in desintermediation (direct access to producers and short distribution circuits)

In the traditional examples, the advantages of credit facilities, buying small quantities, home delivery and offering specialised ingredients still hold well in favour of the small bunyawallas. If these services are further strengthened and new more sustainable options like organic food supply and local ingredients are added, these formats can continue to stay profitable in contemporary society.

Educating people on the benefits of organic food needs to go hand-in-hand with promoting a service like Navdanya better. Creating local networks of people interested in organic fresh foods, who can play a role in the support and delivery of fresh foods in their locality and possibly also co-manage local delivery points for food would help diffuse this service wider and make it more viable. This will bring down the cost of the food and ensure wider reach. Getting the support of the agricultural ministry and other natural food associations will also help bring better recognition and quality assurance to this service.

Events like the Satvik Food Festival can be used to encourage building of direct links between farmers and residents. Subscription based service could be offered and residents signed on at the fair. The farmers could form a collective and promote their services through a website, thereby maintaining direct links with the residents and possibly offering more regular service for daily food needs.

A widely diffused service infrastructure already exists in Indian cities in the form of the local bunya store and local sabziwalla. This infrastructure already offers localised services, customisable, and operate based on one-to-one relationships. If these infrastructure were tapped into and revitalised to provide organic food, they would be infused with a new life and more competitiveness on one hand and they could offer sustainable food options for local residents on the other. NGOs like Navdanya could take on the role of a franchisor, procuring the food and offering it to these local stores for delivery. Festivals like the Satvik Food Festival could also open up new routes for food delivery, new direct links between farmers and residents. Organic farmers could also have direct links with local grocery stores/sabziwallas, and use them as a value-added interface to serve residents.

4. Beyond "fix-it" service society...

The concept in this section is to explain the challenge for India to pass from a 'spontaneous service society' based on over-population, cheap labour and particular traditional cultural specificities to a 'mature service society' based on both sustainable solutions (reducing environmental impact and promoting fair trade activities) and robust solutions (more professional and reliable services through organisational and technological improvements).

The activities examined here is Mobility Solutions in urban India

The first case is a traditional one, that of the neighbourhood school childrens pick-up and drop service

A group of families in an urban neighbourhood often get together and organise a single taxi or autorickshaw with a driver, to pick up and drop their kids from school. Mostly the person hired for the job, is a known one from the neighbourhood. The service is hired on a yearly basis for fixed hours of the day. The driver goes to drop the school children before his usual rounds of public taxi driving, and picks them up on his way home or as required. He is paid a fixed amount for his service by each family, normally monthly, and this sum works out much cheaper than each family hiring an individual taxi or autorickshaw. And in turn the family feels comfortable, knowing that their kids are with a familiar person from the neighbourhood.

Sometimes, this service is also initiated by an entrepreneur from the area who will have a fleet of two or three mini vans, hire drivers and offer this service to families. This service is widely diffused in cities in India.

The drawback with this service, is that often these vehicles, whether the taxis, minivans or autos are not designed specifically for this purpose, and hence do not have the necessary safety in place to transport children. Also, parents tend to compromise and these vehicles are normally overstuffed with children, beyond capacity, further reducing safety. There have also been instances of accidents due to reckless driving with these services.

The second case is that of a public-private partnership for car pooling called CarPoolmumbai.com

An online Carpooling service being offered in Mumbai, where residents can pool a car via email, sms or telephone.

The main platform is a website wherein interested users can register and offer or avail their services for car pooling. This initiative has been given a boost by being adopted by the Mumbai traffic department. The traffic department has negotiated with one of the main banks and insurance providers, ICICI, for a variety of incentives to promote this imitative. ICICI Bank offers rebates on insurance premiums for car poolers. In addition it is planning to come up with a chip that will trace registered cars and their locations. Thereby if a single occupancy car is passing by a certain locality and a user is interested in taking a ride, he/she can call an ICICI Call Centre who will trace the nearest car and connect the two. Users also get deals and discounts from Movie Multiplexes, Coffee Shops, and Restaurants. Safety of the passengers is also ensured since all car poolers are registered with their details.

In synthesis, can such informal, improvised services like the neighbourhood pick-up, be turned into more structured and sustainable ones? The first case illustrates the 'fix-it' level (Metha 2007) of solutions, wherein solutions have been adopted as a reaction, by the sheer need for them, but lack the progress towards a more professional, safe and quality approach.

The second case of car pooling, on the other hand, shows how an informal practice of car pooling could be turn into a more organised one. The car pool service has already taken off

very well, due to the support of the Traffic Department and now a large corporate entity like ICICI Bank. The initiate is doing very well among users, especially women, who previously would have had to travel by public transportation. The boost given by the traffic department has given this recognition and has helped the numbers pick up quite well. However, getting individuals to switch from the comfort of having their own car (and sometimes driver) to car pooling will be a challenge.

The service if interfaced with a car tracking technology will work very well for both subscription based and more spontaneously car pooling. Tie ups with other service providers and incentives for using this service have also proved popular.

Car pooling as a service has come into existence to combat excessive traffic congestion of cars on Mumbai roads. However, it is a reactory solution that may ease part of the problem. Again, looking for long term sustainable mobility options, newer services that offer a combination of car share/car pool will need to be introduced with sophisticated and professional delivery platforms for ease of use and accessibility of the service. thereby helping larger number of users migrate from owning individual vehicles and driving with single/double occupancy.

Conclusion

This is a critical time for Indian society. The economic reforms introduced and subsequent liberalization, have led to an Indian economy that is growing on a bullish fast-track of more than seven percent annually. Most of India is young, (over half is under twenty-five years of age) and aspirational of an affluent lifestyle – more often than not inspired by Western lifestyles through media.

The process of globalization has also impacted Indian tradition and culture. A society whose tradition and culture has revered nature and promoted restraint in consumption, is today changing. Traditional, more sustainable choices in daily living are no longer seen as Progressive,' 'Modern', 'Glamorous enough' or sometimes even 'Relevant' to modern-day life. However, in the current state, the traditional Indian service infrastructure and the services they offer, are not eroded and still very much alive.

The challenge of this 'booming' Indian society is to 'leapfrog' from the current situation to more sustainable lifestyles; among other issues, through the rethinking of certain existing social practices and services;

This challenge is exciting and also shows a counterpart of opportunities for Indian strategic design to develop these sustainable lifestyles such as:
- the existence of still strong traditional communities providing participative and collaborative solidarity frameworks;
- spontaneous and natural skills to develop services that could consolidate in agile infrastructures supporting daily living;
- a availability of strong ICT development capabilities to support social collaboration and synergy.

The right interception in time, through services designed for the contemporary context using the available service infrastructure, could infact help 'Change the Change' from 'Sustenance to more Sustainable Living' in the Indian Context.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The Learning Network on Sustainability

A mechanism for the development and diffusion of system design for sustainability in design schools

Lara Penin[1], Carlo Vezzoli[2]

Abstract

The LeNS project is an action of curriculum development involving seven partner institutions in Asia and Europe that will jointly design, produce and implement new modular and adaptable courses and teaching subsidies in Design for Sustainability with a focus on product service system innovation, contributing to the transition towards sustainability.

The paper will describe LeNS as a mechanism to develop and diffuse system design for sustainability in design schools in a transcultural perspective, where design educators in industrialized and emerging countries share knowledge and come out with a design education agenda able to respond both to local and global sustainability challenges. LeNS output will be an open artefact, allowing a decentralised and collaborative production and fruition of knowledge.

[2] Politecnico di Milano INDACO Dept. carlo.vezzoli@polimi.it
Lara Penin wrote 2, 3, and 6. Carlo Vezzoli wrote 1, 4, 5

This paper also incorporates inputs from LeNS partners: Jan Carel Diehl, Duygu Keskin , Marcel Crul (Delft University of Technology, Industrial Design Engineering, Design for Sustainability); Eija Nieminen , Tiina Laurila, Cindy Kohtala, Tatu Marttila , Aila Laakso (University of Art and Design Helsinki, TaiK); Amrit Srinivasan (Dept. of Humanities & Social Sciences, IIT Delhi); Cai Jun, Liu Xin (Tsinghua University, Industrial Design Department, Academy of Arts & Design); Sompit Moi Fusakul, Pwinn Rujikiatkumjorn, Praoranuj Siridej (King Mongkut's Institute of Technology Ladkrabang, Industrial Design Department, Faculty of Architecture); Poonam Bir Kasturi, Mary Jacob (Srishti School of Art, Design & Technology).

1. Introduction

Approaching sustainable development from a global perspective, there is a very clear need of shifting of consumption and production patterns of industrialized, emerging and low-income countries. This shift or transition will have to respond to the challenges of radical reduction of resources consumption and emissions, not to mention socio-ethical aspects such as poverty reduction and increase of wellbeing. There is an emerging understanding that a great deal of this change can be directly linked to decisions taken in the design phase of products, services and systems (system design understood as both the design of the mix of products and services jointly capable of fulfilling a given demand, and the design of the interactions among the stakeholders involved in the offer).

Along the last decades, the role of design has increased in relevance and recognition, and the approach of *Design for Sustainability* has been evolving in research and has started to be recognised in many parts of the world. It is clear that designers must have a theoretical background as well as know-how that enable them towards a practice committed with these pressing challenges. Design schools have therefore to be able to provide design students with a broad knowledge base, as well as effective tools so a new generation of designers can have an active role as catalysers and enablers of the transformation of our consumption and production patterns.

Under this perspective, there is a pressing need of mechanisms that act at the education level, enabling design educators in industrialized, emerging and low-income countries to share knowledge in this field and come out with a design education agenda able to respond both to local and global sustainable development issues. This paper will present the concept of a multi-polar network on education for design for sustainability involving design schools in Europe and emerging countries in Asia, as an effective strategy in this direction. This concept has been formalized in the project ***LeNS: The Learning Network on Sustainability, Asian-European multi-polar network for curricula development on Design for Sustainability focused on system innovation***, funded by the European Commission programme Asia-Link[3].

The LeNS project proposes curriculum development in seven partner institutions in Asia and Europe that will jointly design, produce and implement new modular and adaptable packages of curricular courses and modules. This will include teaching/training materials, teaching tools (including distance-learning), guidelines for courses/modules design and implementation and illustrative examples.

In practice, the design of this curriculum package starts from the analysis of the current state of art (i.e. how *Design for Sustainability* is currently approached in the partners institutions and in the respective regions) and takes in consideration the local needs and constraints of each partner context as well as the global agenda of sustainability. From this initial verification, the partners will jointly design the didactic pilot courses/modules to be implemented in each partner institution through an exchange modality that combines two kinds of flows:

- content flow, with students from European partner institution designing for an Asia partner campus; and students from Asian partner institutions designing for European partner campus,

[3] LeNS is an action of curriculum development funded by the Asia Link programme, under European Commission's EuropAid Programme. It is a 3 years project started on 15th December 2007 coordinated by Politecnico di Milano University INDACO Department (Italy) and has as partners Delft University of Technology, Industrial Design Engineering (The Netherlands); University of Art and Design Helsinki, School of Design (Finland); Indian Institute of Technology New Delhi (India); Srishti School of Art, Design and Technology (India); Tsinghua University, Industrial Design Department, Academy of Arts & Design (China) and King Mongkut's Institute of Technology Ladkrabang, Faculty of Architecture, Department of Industrial Design (Thailand).

- experts flow, with European partner institutions hosting Asian partner staff; and Asia partner institutions hosting European partner staff.

This unique combination of content and experts flows will allow of the flourishing of innovative forms of collaborative didactics that explores both in-situ and distance-learning, configuring a *transcultural* didactic process, an effective approach for design education, where design schools become labs for experimental research and education. In this perspective a sort of osmotic process between open-front research and experimental didactic is created, creating a continuous flow that contributes to develop and verify new hypothesis on design approaches, methods and tools for sustainability. And, through this process, sensitise and empower a new generation of designers worldwide to reach design practice through an embedded sustainability approach.

The LeNS project has the ambition of being a catalyser for actions and exchange on education in design for sustainability worldwide, through the production of an open-source curriculum package (***OLEP: open learning e-package***), a strong dissemination and communication strategy (through prizes, conference, exhibition publications and thorough on-line exposure) and finally a replicable web-platform to be easily reproduced in a worldwide scale.

2. LeNS process and approach

LeNS is an action of curriculum development in the field of Design Sustainability and PSS innovation design. Its starting point is that a new generation of designers is formed with the right conceptual and operative tools to be able to cope and contribute to this transition towards a sustainable society. For that, design educators across regions should be able to create and incorporate new learning resources into existent or new curricula. In the LeNS project, the focus is on Europe and Asia, but its ambition is to reach worldwide design educators and schools through the production of an output that follows an open source model, allowing users from around the world to use and transform it.

The benefit thus of LeNS project are in the first instance for the partners institutions but it can and hopefully will be expanded beyond them.

The LeNS process foresees the development of new curricula reflecting both a shared macro agenda on sustainability but also localised, contextual sustainability agendas that respond to local needs and demands in the economic, social and cultural levels. It takes in consideration also the experiences and expertise at each partner that may emerge under different forms. The partners will analyse what is their state of art in terms of didactic and research in DfS and PSS and express what are the main demands not yet covered. The partners will then collect and develop new subsidies for new courses and come out with a first (beta) version of the Open learning e-package (OLEP). OLEP beta version will be used (tested) along 8 pilot courses at the partner institutions following an exchange modality: each partner will host a guest teacher from another partner and each partner will play the role of guest teacher at another partner, according to an exchange agenda. The logic of this process is that of refining and expanding the beta OLEP along its implementation in the 8 pilot courses, feeding back the original pack. At the end of the pilot courses implementation, a “final” version of the OLEP will be primed and opened to external diffusion.

This process can be summarized as follows (see fig. 1):

1. State of the art

State of the art of current practices and experiences on DfS and PSS in partners (*available*): each partner will gather and exchange their own knowledge, previous didactic and research experiences in the field and share specific priorities and approaches.

This work is done according to the verification of *DfS needs of each partner* according to its own *sustainability agenda* and establishment of localized PSS agendas and approaches (*need*).

The results will be the basis upon which the teaching modules will be designed and teaching subsidies will be developed in terms of disciplinary content and structure and exchange modalities.

2. Design of the didactic pilot modules and teaching subsidies

Development of all the necessary inputs for the implementation of the didactic pilot courses and teaching subsidies.

Didactic pilot courses will be designed and the necessary and teaching subsidies will be gathered or developed *ex-novo* according to expressed needs and demands, including methods and tools.

The process takes further the assessment of need areas of DfS/PSS at partners (*need*) and matches *available* with *need*.

The result is the first (beta) version of the OLEP (open learning e-package) ready for testing. The beta version will be continuously updated along the implementation phase (3).

3. Implementation of pilot courses

The implementation of the didactic pilot module will be carried out within a total period of 18 months. This time span will allow in progress assessment of the teaching materials (OLEP) and consequent improvement for the remaining academic semesters.

Teaching modules will be as much as possible integrated in normal curricula activities; this will both reinforce the institutional commitments and provide reduction of costs by establishing synergies.

The exchange of teachers will be carried out so to implement in each of the partner institutions the didactic pilot courses to be done in collaboration between the local teacher (*host*) and a *guest teacher* in a transcultural learning/teaching process. It is foreseen that a third teacher (the *observer*) will follow the pilot course implementation at the hosting schools (see fig. 2) reporting back the results to the OLEP development.

The pilot courses will be focused on PSS design for food, mobility and healthcare/well-being and will use as design ambit the university campus of each partner.

4. Preparation of OLEP “final version”

According to the results of the implementation process of pilot courses, a “final” 2010 version of teaching subsidies will be formalized. It is a final version regarding the LeNS project (that lasts three years: from December 2007 to December 2010). But, since it will be an open package, it foresees its continuous updating and development to be done by users after the termination of LeNS project.

At this point, the teaching package (OLEP) assumes an open-source model: an online platform for sharing learning objects on DfS, open to external users who will be able to use and transform the original material, and contribute to its further development. In addition, the platform is thought to be reproducible i.e. using the original code, users can reproduce its architecture in a localized version, for example in different languages or focused on specific regions.

During the whole process, an evaluation process will be carried out in parallel, through both external evaluators and internal evaluators (the *observers* of the pilot courses). Dissemination activities are foreseen along the process and in the last phase to increase the diffusion of the in-progress and final results.

3. Need for local PSS agendas in design education

The LeNS project starts from the following assumption on PSS potentialities:

"A system innovation (PSS approach) may act as a business opportunity to facilitate the process of social-economical development in an emerging context - by jumping over or by-passing the stage characterised by individual consumption/ownership of mass produced goods - towards a more "satisfaction-based" and low resource intensity advanced service-economy, characterized by the development of local-based and network-structured enterprises and initiatives, for a sustainable re-globalisation process aiming at a democratisation of access to resources, goods and services".

It starts thus from the assumption that PSS approach is not only valid as a potential sustainable strategy for industrialised countries but it is also a potential leapfrog strategy for low-income and emerging countries. PSS and system innovation bibliography has been almost exclusively produced in and for mature industrialised countries, notably Europe and to some extent the United States. An effort to adapt and verify PSS approach in developing countries in general and in the particular economies of each country is imperative.

This is an effort that started in 2000 by the United Nations Environment Programme (UNEP) involving a group of international researchers to start disseminating and exploring the concept of system innovation in a worldwide scale in particular in the so-called low-income and emerging countries[4]. At that moment, some potentialities of PSS for low-income and emerging countries are highlighted:

"First of all, if PSS are eco-efficient at system level it means that they may represent opportunities, at least at a macro level, for a context with fewer economic possibilities to respond more easily to unsatisfied social demands.

Secondly, PSS offers are more focused on the context of use, because they do not only sell products, but they open relationships with the end user. For this reason, an increased offer in these contexts, should trigger a greater involvement of (more competent) local, rather than global, stakeholders; fostering and facilitating a reinforcement of the local economy.

Furthermore, since PSS are more labour/relationship intensive, they can also lead to an increase in local employment and a consequent dissemination of skills.

In addition, since the development of PSS is based on the building of system relationships and partnerships, [it is] coherent with a democratic re-globalisation process.

Finally, they are coherent with the development of network enterprises on a local base for a bottom-up re-globalisation. This last consideration is quite important since its connection to the potential for convergences between environmental and socio-ethic sustainability."[5]

Another base line is the recognition that PSS already exists in emerging Asia. In India, we observe the share use of artefacts as the norm, as well as productive and social organisation based on "spontaneous services" very much related to micro-entrepreneurship[6]. In China, car-pooling became a very popular practice across the country, responding to traffic congestion of the big cities (even if not recognised by the public authorities as a legal service). In Thailand, sustainable practices are more recognised in traditional lifestyles that are greatly based on resource saving principles. But as we know, the rapid process of industrialisations have imposed changes of traditional production and lifestyles and so forth demands new models and conceptual keys that allow putting in perspective the complexity of these countries. These new models and concepts will not reflect tradition alone, but on the other hand cannot simply mirror the industrialised countries' processes.

[4] Vezzoli (2007 pp 134), Vezzoli and Manzini (2008), see also UNEP (2002).
[5] Vezzoli (2007)
[6] As revealed for example by the project Creative Communities for Sustainable Lifestyles, www.sustainable-everyday.net/ccsl/

The initial challenge for LeNS was therefore starting a process of a more localised in-depth appreciation of PSS and system innovation in emerging Asian countries, considering the great diversity of each country economic, social and cultural model. LeNS has proposed establishing a dialogue amongst its partners so to determine a multipolar and extended knowledge base from where to start the development of curriculum that would respond to these localized PSS views.

The first step of the project was then to understand the main sustainability drivers and agenda at each partner country and region and confront these with their current didactic and research practices, identifying gaps and demands that will inform the development of curriculum and teaching subsidies so to cover the identified need-areas.

In practice, LeNS proposed a mechanism starting from the collection of data at each partner (presented as reports) covering the following points:

- General vision on DfS and the particularities of Df/PSS in partners' context (country and region). How the contextual situation of the partner city/country/region affects the construction of a local sustainability agenda and description and critical view on how the school is dealing with the issue.
- Description of previous experiences on DfS (Eco-design, Life-Cycle Design, Social Innovation, Strategic design, Product-Service System (PSS) Design, etc) regarding teaching and research on education, whether entire courses, modules, short term workshops for under or post graduation students, materials and tools used with students, support tools for teachers, projects and networks, etc.
- Best practices of educational (and research) experiences on DfS, cases and inspiring examples from other institutions.
- A draft map of main design schools in the countries and regions involved where design for sustainability is taught, under different areas or sub-areas such as Product Life Cycle Design/ecodesign, Sustainable (Product-Service) System design, Design of Services, Strategic Design, Design and Social Innovation, Sustainable Consumption and Production, etc.

This information collected at each partner was then collated resulting in some synthesis and tentative maps:

- An overview of the sustainability agenda in the involved countries and regions
- Visions of Design for Sustainability between Asia and Europe, articulating commonalities and variations
- Preliminary hypothesis of country-based PSS relevance areas (localised PSS)
- Map of existing didactic and research experiences on Design for Sustainability and PSS innovation
- Overview of existent methods and tools

These results will provide then insights for pilot course subsidies development (contents and teaching materials), ensuring that existent expertise and experiences and expertise at each partner (that may emerge under different forms) is taken in consideration as well as the new material are developed so to respond to expressed needs of each partner. It should also ensure that the development of new curricula reflects both a shared macro agenda on sustainability but also localized, contextual sustainability agendas that respond to local needs and demands in the economic, social and cultural levels.

4. Transcultural pilot courses

A cross-learning mechanism for design educators

The 8 pilot courses foreseen in the LeNS process will occur through an exchange of teachers of the partner institutions (experts flow). European teachers will teach in Asian design schools and Asian design teachers will teach in European design schools.

The pilot courses will be as much as possible integrated in normal curricula activities or within new courses or workshops, structured so to maximize the interaction between the ***guest*** teacher and the ***host*** staff and students.

The exchange scheme foresees that one ***hosting teacher*** will receive a ***guest teacher*** coming from the counterpart institution within the thematic cluster and in a second moment will be received as a guest in the counterpart institution (the roles of guest and host are inverted and the same procedure is repeated) see fig.2. The thematic clusters determine the exchanges, as follows:

- **Food-chain A: pilot courses 1 and 2.** One partner hosts a guest teacher into his/her course. Students at the host partner will design new sustainable **food** solutions for the university campus of the guest teacher.
- **Food-chain B: pilot courses 3 and 4.** One partner hosts a guest teacher into his/her course. Students at the host partner will design new sustainable **food** solutions for the university campus of the guest teacher.
- **Mobility 2: pilot courses 5 and 6.** One partner hosts a guest teacher into his/her course. Students at the host partner will design new sustainable **mobility** solutions for the university campus of the guest teacher.
- **Health-care/wellbeing: pilot courses 7 and 8.** One partner hosts a guest teacher into his/her course. Students at the host partner will design new sustainable **health-care/wellbeing** solutions for the university campus of the guest teacher.

Each exchange is followed by a third party, the ***observer***, a teacher coming from a third partner. The role of the Observer is monitoring and annotating the development of the activities along the period of implementation of the pilot course at the host institution. The observer will be in-site during the visit of the host teacher at the guest institution and follow the developments of the long-distance collaboration. The aim of the observer is that of assessing the process of implementation of the didactic pilot module and reporting its results to the work package leader.

The observer can intervene and contribute along the process of implementation of the courses whether during the ‘on situ’ phase or the virtual (long distance) phase. This will happen in accordance with the 3 involved partners (guest teacher, host teacher, and observer). At the end of each half cycle of exchange, the observer will prepare an evaluation report, that will feed back the teaching pack, that can be updated transformed for the following pilot course implementation.

The implementation of the 8 pilot courses will be carried out within a time span of one and an half year, so to allow in progress assessment and consequent improvement for the remaining academic semesters. The OLEP therefore will be constantly evolving along the implementation of the pilot courses.

The exchange activity aims as a whole to promote a process of mutual learning, intended as a **cross-learning mechanism** among the partners: each teacher learns form each other, not only in terms of contents, but also in terms of teaching views and approaches. This process of sharing is extended throughout the whole project. The pilot courses will be the highest point of the cross-learning process, where the guest teacher and the observer will follow how the host teacher conducts his/her course. The other partners (not present) will learn via video-recorded lecture.

A transcultural design exercise

LeNS' exchange mechanism foresee also a content flow, referring to the exchange that will take place in terms of design subjects: students from European partner institutions designing for an Asia partner campus; and students from Asian partner institutions designing for European partner campus triggering a collaborative international design process.

The strategy of using the university campus of other contexts (countries) as the design ambit for experimental learning courses can be justified in two levels.

First, adopting the university campus as the design ambit:

At the theoretical level, if we assume the whole experienced based on the approach of system innovation and transition for sustainability, the campus is a peculiar restricted community, an ambit for which it is effective to design (and implement) sustainable innovative solutions in technological, socio-cultural, organizational, economical and environmental terms. We can say thus it could be thought as a "community-lab" for sustainable innovation. At the same time, campuses could represent an optimum "community-window", because of their potential to showcase and disseminate the sustainable innovations and ideas later to be spread to wider communities (and to society at large).

At a practical level, the approach is effective because is easier for participants to collect information about the campus since they are working in the campus, and at the same time students living (and/or spending great part of the day) in campus should be well motivated and aware. Even in cases where the campus is restricted to a building, there is a community of student and teachers eating, moving to and from, taking care of wealth, etc.

Second, adopting a (campus of a) different context (country) as a design ambit:

An initial clarification is necessary. It is certainly not our idea that a designer who is alien from a particular socio-cultural context could alone design sustainable products, services or a system for that context, unless when part of an international ad-hoc team.

The intention instead, is to promote an experimental learning design exercise for students. The focus is on the learning process for students, where the value is not only the strict feasibility of the students' concepts, but rather the process of confrontation with other socio-cultural context in a design process (even though experimental). In this sense, proposing students to design for another country's campus enables:

- students/teachers (designing for other campuses) to discover a different context from their own through a strategic analysis of the information provided and through direct critics and evaluations of local teachers.
- teachers/students (when evaluating/criticizing the concept designed for their own campus) to discover another's culture interpretation of their own (and even be surprised by unusual ideas)

Said in other words, we enable a "transcultural" learning process by introducing the students (and teachers) to an approach able to "decentralize" one's own cognitive references and values, and direct oneself towards other cultures returning to one's own culture enriched by the confrontation experience. This process should also give the students the perspective of an international design practice and an enriched cultural experience. Since it is an experimental process, it does not embody or express a consolidated truth, but are a testing ground for some hypothesis, and will reveal for sure some limits to be understood.[7]

[7] It is also worth mentioning that this approach has already been tested in previous experiences: since 2002, POLIMI has been partnering with IIT Delhi and the Tsinghua (together with other universities in Brazil, China, Turkey and South Korea) in an informal educational network on the theme of Design of Sustainable Product-Service Systems for their respective university campus, named LENS (formerly known as DECOS). These experiences are the basis of the EC funded LeNS project.

5. An open source learning model

As it has been initially described in section 2, the main final output of the LeNS project is the Open learning e-package (OLEP) on System design for sustainability. We can enter now a little bit more in detail of the OLEP's nature and mechanisms.

The OLEP can be described as an e-package composed of a set of learning resources targeted at design educators, to facilitate the activation and implementation of courses on design for sustainability (DfS) with a focus on sustainable (Product Service) Systems innovation. The learning resources of the OLEP will be easy to be used and free being based on the open-source and copy left logic: users (mainly teachers) can download, modify and reuse the available set of learning resources. The OLEP will be targeted also at students, designers, entrepreneurs and interested persons/institutions. The OLEP will be located within the LeNS web platform.

Generation and acquisition of contents

The open learning e-package contents will be produced during the LeNS project, but can incorporate other existent or future material considered as interesting and relevant. Most part of the materials will be developed within prior to the pilot course implementation and will evolve in synergy with the courses implementation (see figure 1). It will be edited into its final shape after the pilots' implementation.

The teaching materials will be developed based upon the identified needs. They will be also partly based upon the teaching materials of the partner institutions developed prior to the LeNS project, as well as new teaching materials to be developed *ex-novo*. Each topic will be covered by a range of different supporting media. These activities will be concentrated before the beginning of the first pilot course, but will continue along the whole implementation process, that is spread in an 18 months time span.

Next to the teaching materials developed and collected in the preparatory phase, the core of the OLEP will be constituted by the materials used in (selected to/developed for) the 8 pilot courses. In practice, each partner teacher holding a course will develop (as normally for any course): a programme for the course; a series of computer presentations to support the lecture; a series of video-recorded lectures. And each teacher holding a course will make available for his/her students: a series of texts (course bibliography); a set of tools for the design exercise, whether new or existing tools.

After the implementation of each of the 8 pilot courses, an evaluation will be carried out (based on the observer report) to assess the impact of each of the teaching materials used. This assessment will inform the teachers of the next pilot courses as well as the progressive development of the OLEP final version (indicating for example if a given tool needs to be adjusted, materials that work better in a given context, etc).

Any existent educational support material considered as interesting and relevant will be also incorporated (e.g. tools, texts, power point, etc. used by teachers outside the Lens consortium). Finally, a final conference is foreseen to the presentation and discussion of these results. The conference proceedings as well as a selection of the outcomes of the award, exhibition and other dissemination activities will be incorporated to OLEP final version.

OLEP general requirements

The open learning e-package (OLEP) aims at facilitating the introduction and implementation of Design for Sustainability (focused on product service system innovation) in the educational curricula of design schools and universities worldwide (starting form the LeNS consortium).

In practice, the open learning e-package contents will be:

- Indications, guide-lines and examples of courses (programmes, supporting materials, expected results, etc) targeting teachers who wish to activate new courses or renew

existing ones on system design for sustainability (incorporating it on the school/university curricula)

- Materials and tools to support teachers in holding courses and didactic modules, on system design for sustainability.
- Materials and tools to support students who follow courses on system design for sustainability.
- Materials and tools to support designers in incorporating DfS thinking into their practices.

The OLEP is meant as a modular package of learning modular resources (or learning objects). Any interested design teacher is allowed to: **download, modify/remix and reuse**. The aim is to allow any design teacher to adapt and use the learning resources he/she finds useful, according to his/her specific didactic needs, institutional requirements or local context particularities. Also students and designers are welcomed to access the OLEP to support their learning activities (linked or not to a given course).

The OELP contents will take different formats:

- Texts in different formats, such as print-on-demand from the publisher (with ISBN code), printable in common printers (whole or partially), readable on screen, editable files (for open-sources documents, modifiable by the user)
- Slides presentations
- Composed presentations that integrate video-recorded classes (teachers classes and students presentations) with slides presentations
- Audio or audio/video files (e.g. recorded lessons)
- Software and other tools
- Archives and databases of best practices, examples, etc.

The e-package will be hosted at the LeNS web-platform, to be directly downloaded by users (typically registered teachers and students). On-line visioning should also be possible (with the possibility of streaming audio-video). To allow greatest diffusion and penetration to teachers (and students), all e-package contents should:

- Be free-access (preferably)
- Have a modular structure
- Be developed with an open-source and copy-left logic (preferably), with intellectual property rights (authorship), but without restrictions to diffusion (i.e. Creative Commons license).

The system architecture will facilitate the access of teachers (and students), allowing optimal fruition. A pragmatic and user-friendly approach will be followed and a guide will be prepared and made available identifying different users profiles to properly guide them throughout the OLEP use (teachers, students and designers). Nevertheless, learning resources could be accessed as **single** objects or grouped objects as related to a particular course/teacher. More precisely, a pre-selector and three modalities of access have been so far identified:

- a language filter will be available as pre-selector
- access to all learning resources of a particular course/teacher (e.g. a teacher who wants to start a course from the beginning could have be interested in an overview of the organisation of all the contents within a course; and a student who wants to receive support for the course he/she is following could have them gathered);
- access by content regardless the teacher/course (e.g. allowing a teacher who wants to improve a course to get direct access to all that has been produced/collected related

to a specific issue; and allowing a student who wants to deepen a content to get direct access to it independently from the teacher indications);

- advanced access by other tags/metadata typical of learning resources; the list of tags to be associated to learning objects are listed at the end identifying a proposal for compulsory; suggested and optional.

Teachers who are part of the LeNS consortium will be able to update the e-package during and after the project duration. They will constitute the OLEP scientific board. Teachers and users external to the LeNS consortium (the wider network) will be able to use the package through an open-source logic as described earlier, but the update will be controlled by the LeNS scientific board, safeguarding the scientific reliability of the new materials. External teachers and users of OLEP can apply to become members of the scientific board after the project termination (rules to be defined).

6. Conclusions

LeNS aims at becoming a mechanism for the development and diffusion of system design for sustainability in design schools. It appears to us that this is proposed in the right moment, when sustainability is being incorporated in the worldwide agenda and in all levels and there is a clear perceived growing demand of design for sustainability, especially in Asian emerging economies. It appears also that it is the right opportunity, of interfering at the education level, since education is very much the base of every change.

Contributing to this process of transition towards sustainability requires facing the complexity of the current dynamics of a changing society, where global and local drivers are in permanent dialogue but not always find balance.

In this framework, LeNS ambition is first of all that of being in itself a transcultural learning process. Design educators will be confronted with different learning approaches and different approaches regarding DfS in relation to both global and local interpretations and priorities of sustainability. Design students will be confronted with design subjects that are different from their usual design situations. In both cases, a cognitive challenge is created, in a vision of a *cosmopolitan localism* (Sachs, 1998, Manzini, Vugliano, 2000, Manzini, Jègou, 2003), a condition where actors find a positive balance between localization (being rooted to a place, a community, cultural values and socio-economic conditions) and the "global flows" (Appadurai, 1996) that characterises the contemporary society.

In the long term, LeNS ambitions to offer an ***open*** output, a platform for storing and sharing knowledge (learning objects in design for sustainability, courses, guide-lines and examples, teaching materials, methods, tools, presented through different supports texts, slide presentations, video, audio, etc) among design educators, students and practitioners. It is intended also as a **reproducible platform**, allowing interested users to reproduce its architecture in localized versions, in different languages or focused on specific regions.

This final result: the open learning e-package (OLEP), is intended as a true open source artefact, allowing users to freely **use, modify, remix and reuse** the OLEP material according to their needs in the framework of decentralised and collaborative production and fruition of knowledge.

DESIGN AND NEW HORIZONS OF SYSTEMIC INTERACTIONS

Technology and application innovation for a holistic approach to problems

Riccardo Vicentini[1], Luciano Bruno[2].

Abstract

The main purpose of this study is to show how the **systemic application** of innovative technologies is particularly effective for solving problems that are normally "resistant" to traditional, specialized approaches.

This study was conducted using a problem-solving methodology and developed according to the principles of **systems design**: rather than using a linear approach which often creates solutions that are **isolated from their context** and so sometimes ineffective, we defined the theoretical model from a systemic perspective which could **enhance the relationships** between each element and create new ones within the scenario.

We chose **Radio Frequency Identification (RFID)** as the technology platform. This technology uses radio waves to read and write data that is invisible to the human eye on special electronic supports.

1. Introduction

It is easy to observe that RFID is arousing a great interest in universities, companies and society.

Understanding why the approach to this type of technology is often made more of words than of facts is less easy, even for those fields in which the use of RFID application is more consolidated; at the moment, these cases are quite restricted, since they rarely tackle more than one problem at a time, and they never go beyond their current application domain.

Generally, the solution to a problem is found **only from the technological point of view,** and problems are addressed in an extremely **specific, vertical** way: as a consequence, issues are analysed as **isolated from their context**, with the risk of generating effective but “closed” solutions, which prove useless when applied to wider issues.

The main purpose of this study is to highlight Radio Frequency Identification suitability to a **holistic approach**, providing a possible support for the analysis and simplification of complex systems.

Consequently, a **systemic** approach can become an added value, allowing to range from situations of simple traceability, logistics and operation management in the industrial field, to the identification of solutions which, thanks to the contribution of universities, industries, society and citizens, can become elements of remarkable innovation and integration of both traditional and innovative technologies, to solve problems “resisting” to specific applications.

It is clearly outlined that solutions are no longer aimed at a single application, but **are tailored according to the needs of actual end users**: common citizens, but also tourists, or weak social categories such as children, elderly and disabled people, thus giving to this project an additional **high social value**, as well as importance for the public opinion.

It seems clear that RFID technology, essentially flexible and providing a high versatility if approached with a systemic vision, can become the starting point for the creation of structures which could be easily compared to **autopoietic systems**.

2. Research background

Social, production and economic change has remarkably characterised our life in a short time, crucially contributing to the arousal of new problems. These problems were unknown until that moment, and ad to be addressed in some way (at different social levels).

Technological innovation, along with the globalisation of markets, has extended to a great number of persons the possibility to access goods and products which were not concretely available before, creating a series of problems related to **safety**, the **identification of responsibilities** on products and the **valorisation of product provenance** as a qualifying element.

During last years, in this context, the theme of traceability has come to the fore, drawing attention drastically and connecting to many subjects regarded as "sensitive" by both public opinion and Institutions.

Though underlining the difficulty to find a univocal and shared opinion about this concept, traceability - at least in the meaning which is investigated by this study – can be defined as a process taking place in the field of agriculture and food production chains. The concept of traceability was created in conjunction with the increasing interest of consumers in foodstuffs

provenance, and represents an added value assessing quality, as well as correctness, awareness and ethicality of production techniques.

A temporal dichotomy arouses when making an attempt to define univocally what traceability is, defining two separate domains. These two domains are represented by two separate concepts: **traceability** and **retraceability**[3].

Traceability is the process which follows a product, good or service, from its "birth" (and, in some cases, from the raw material stage) to the final user, so that, **at every crucial stage, the products leaves clearly identifiable "traces".**

Retraceability is strictly connected to traceability, being its mirror process. Thanks to retraceability, it is possible to **get back to the history of the product itself**, retracing its path and gathering information along it.

Besides the best-established application domains, such as agriculture, food processing and industrial process logistics, a field which is still quite new though arousing a great interest is the so called "service traceability", on which this study is focused, paying a particular attention to hospital procedures. This was due to the topicality and social value of the subject.

A hospital constitutes a highly complicated structure, presenting interpretation and management difficulties. From a certain point of view, it is a **constantly changing** structure, like a body needing an inner regulation to compensate any anomalies that may occur.

This organic, **systemic** vision as we might say, is the basis of the approach which must be adopted by anyone wanting to perform an analysis of activities and procedures inside a hospital.

The hospital is seen as a body, and, likewise, is constituted by a great variety of elements interacting with the whole system in different, **complementary** ways: besides doctors, nurses and patients, there are also other personnel categories, such as administrative staff, secretariat, technicians, medical orderlies. Finally, the patients' relatives and helpers often interact daily, though for short periods generally, with the hospital structure, playing a role which is complementary to that of patients.

The problems analysed by this study can be divided into four macro-categories:

- **Safety**, involving all aspect of sanitary procedure, including outpatient treatment, surgery, medication and transfusion bags administration, meal schedule, patient movimentation activities and procedures aimed at preserving hygienical standards;
- **Management of patients' personal details:** doctors need to have the greatest amount possible of data about the patient's clinical history, and patients must always carry with them a sometimes uncomfortable amount of documentation.
- **Logistics:** this category involves the management of materials and services flows from and to the hospital, and the so-called "patient logistic", that is the management of the patient's movements.
- **Costs** which are strictly related to the quality of services provided by the hospital, as well as to structure level, directly involve not only the personnel, but also the patient.

Particularly, this study focuses on a transversal theme for the mentioned issues: **adverse events**.

In the health system field, an adverse event occurs when, **after being discharged**, a patient undergoes **permanent damage or diseases due to therapy** mistakes or hospital inefficiency.

[3] *Fondamenti dei sistemi di tracciabilità nell'agroalimentare. http://www.indicodecr.it/prodottiservizi/index.php?id=22*

Some studies at an international level, which are comparable because they share the same methodology from the Harvard University, based on the California Medical Insurance Feasibility Study, have highlighted how the phenomenon of adverse events is widely spread, even in extremely developed countries from the medical point of view.

Particularly, these studies highlight how the majority of adverse events are classified as preventable through the institution of correct procedures, and that the total amount of hospitalisations ending with adverse events have taken place in different countries with the following percentages: New Zealand: 35%; UK: 47%; Australia: 53%; USA: 58%.

In Italy, according to a study carried out by the Ministry of Health[4], on about eight million hospitalisations in a year, approximately 320.000 patients are discharged and undergo an adverse event. Of these adverse events, 35.000 (about 11%) result to be deadly. Some studies have shown that, **40%** of these adverse events **are preventable**.

In order to fully understand the meaning of these data, it is necessary to specify that the incidence of adverse events on the balance of United States health service is estimated to amount to **37,6 billion dollars** and that the only preventable adverse events cause a yearly expense charge of about 17 billion dollars.

In Italy, the situation is not better: in fact, insurance companies estimate that the yearly charge caused by adverse events for the National Health System amounts to **2,5 billion euros**.

3. Radio Frequency Identification

RFID is the acronym for **Radio Frequency Identification**. This expression defines all those technologies employing radio waves for data transmission, used to trace a particular object, or, more specifically, to perform a particular function.

Though RFID technology has come to the fore in quite recent times (at least in Italy), it was already known from long ago. Obviously, like the majority of technological instruments which are employed in everyday life, it started developing in the military domain.

During World War II, along with the development of new Radar (Radio Detecting and Ranging) instrumentation, the British Army implemented a system called IFF (Identification Friend and Foe) aimed at the identification of aircrafts by the anti-aircraft artillery. The system was quite simple, consisting in the installation of a transmitter on board of British aircrafts (and successively also on the allies' ones).'This transmitter emitted a signal which could be captured by aerials on the ground, allowing to distinguish a "friend" from a "foe" aircraft.

However, the real predecessor of RFID was an instrument created for espionage in 1945 by Russian inventor Leo Theremin. The "bug" (or "the thing", like it was nicknamed) created by Theremin, was the first device of this kind to exploit electromagnetic energy induced by radio frequencies on a defined frequency range to transmit an audio signal to another.

Between the Seventies and the Eighties, many studies and researches contributed to the development of this technology, but the concretely implemented applications were restricted to the military field, or to the civil one, but only in the aeronautics and navy field.

Finally, in the mid-Nineties, also thanks to the acquisition of new technological miniaturization skills, fully implemented RFID system applications are available on the market. These are essentially used in the warehouse logistics and goods handling fields.

In more recent times, the attention towards this kind of technology was finally aimed at the valorisation of its remarkable development potential, related to its great flexibility of use, as well

[4] Commissione Tecnica sul Rischio Clinico. 2004. *Risk Management in Sanità. Il problema degli errori.* Roma: Ministero della Salute.

as to the possibility of integrating it with other technological systems. Thanks to these characteristics, possible application contexts have significantly increased[5].

A RFID system exploits radio waves to send data which are read (and sometimes written) on appropriate electronic supports called Tags or Transponders. The basic version of these devices is constituted by a micro-chip which can be rewritten hundreds of thousand of times, on which data to be traced are stored; a miniaturized aerial, generally made of copper or of other conductive materials, has the double function of condenser (to supply power to the chip) and of data transmitter/receiver; all this is contained in a support which, on the basis of specific requirements, can be made of different material (paper, different kinds of plastic, etc.), can be adhesive or even integrated into the object to be traced. It only needs a surface of a few square centimetres and a thickness equal to that of a cardboard sheet.

This type of Tag is a **Passive Tag**, lacking an independent power supply source. It works exclusively in Low Frequency and High Frequency mode and is characterised by a limited signal scope, as well as by a relatively low data transfer speed.

There are also two other types of Tag: **Semi-Active** and **Active** Tags, operating in Ultra High Frequency (UHF) mode and with microwaves.

Semi-active tags are characterised by the presence of an internal power source, which doesn't feed the chip directly, but other devices connected to the Tag, such as, for instance, sensors for the execution of additional functions.

Finally, Active Tags have their own internal battery and, as a consequence, they send independently the data they contain; they have a wider signal scope and a higher data transfer speed.

Besides the Tag, a FID system is made up of at least two other elements: an **aerial** which sends the signal at radio frequency and receives information contained in the Tag. A **Reader** is connected to the aerial; this is the device converting radio waves captured by the aerial in a binary language readable by any computer.

The reader feeds data to the computer, which manages the entire process, elaborating data through an appropriate software and performing functions for which it has been programmed.

As said before for tags, various models of aerials and readers are available on the market, presenting different characteristics according to their application.

A distinction is essentially made between fixed and mobile devices, that is between "gates" through which RFID tagged products pass, placed in strategic points of the process to be traced and constituting fixed points for the collection of information.

On the other hand, some mobile devices, generally made of instrumentation integrating reader and aerial in the same object, which is possible to carry or install on fork lifts or material handling carts, through which it is possible to perform picking, inventory and advanced logistics operations on the spot.

The basic functioning of a RFID system is relatively simple: the aerial connected to the reader (which will be called "main aerial" from now onwards), emits an electromagnetic field at a determined frequency and, in quiet conditions, receives its feedback signal unaltered.

When an object with a RFID tag enters the magnetic field generated by the above mentioned aerial, its own miniaturized aerial, acting as a condenser, is charged with power which is transferred to the micro-chip; when the power level surpasses a certain limit, the chip is capable of transmitting the information it contains.

[5] Vicentini, Riccardo. 2007. RFID + sensori e nano-tech. Il Giornale dell'Architettura 56: 7.

At this point, the main aerial will receive information and send it to the Reader, which, after codifying them into binary language, will send it to a computer, which will carry out all the operations established in the software regulating the process.

The above-described procedure involves the use of a Tag known as “read only”, or of a “write once & read many" tag, that is a device containing information that, once entered, can be no longer modified.

More complex systems involve a second information exchange stage, in which the reader, according to the received data, writes new data on the microchip. In this case, it is a “read & write" tag, generally presenting a series of fixed data which cannot be erased, as well as other information which are constantly updated as the traced process continues.

4. Methodology: Systems Design

As previously mentioned, this research and the resulting project are based on a systemic approach to problems.

To explain the way this work is rooted in the Systems Design principles, a short historical excursus on the evolution of scientific thought is necessary.

At the end of the XVI century and during the XVII century, new scientific discoveries in physics, mathematics and astronomy brought to a significant change in common scientific thought. Old philosophical and theological conceptions gave way to the new vision, determined by important figures such as Galileo, Newton, Descartes etc.

The interest of science exclusively focused on the study of those phenomena which were directly measurable and quantifiable, turning an organic and spiritual vision of the world into a new vision in which everything (included living beings) was part of a machine-world vision, which could be measured and quantified.

Descartes theorised this mechanistic vision through what is commonly known as "reductionism", that is the necessity to divide complex natural phenomena in simpler sub-sections, directly observable and measurable, in order to explain them.

The explanation of scientific phenomena of every nature through the principles of physics and chemistry resisted all along the XVII and XIX centuries; during this last one, also thanks to the improvement of instruments such as the microscope, the theory of Descartes provided the basis for the study of molecular and atomic science, for microbiology etc.

However, during the XX century, many currents of thought opposed the reduction of biology to chemistry and physics, through dissertations in which all living beings were seen as parts of organized "systems", which it was not possible to avoid when explaining phenomena.

The ideas proposed at the beginning of the century from these scientists are the basis of what is currently known as **Systemic Thought**, according to which "the essential properties of an organism, or living system, are properties **of a whole**, which are not held by the parts alone. These properties come from the interactions and relationships between the parts, and are destroyed when the system is materially or theoretically broken down into isolated elements. Though we can distinguish single parts of a whole, these parts are not actually isolated, and the nature of the whole always differs from the mere sum of its parts”.[6]

The element characterising the properties of an analysed system is represented by internally occurring relationships, that is ordered relationships between elements belonging to the system. Moreover, in the systemic vision, those elements have a secondary role if compared to relationships, being regarded as their sub-systems.

[6] Capra, Fritjof. 1996. *The Web of Life. A New Scientific Understanding of Living Systems*. New York: Doubleday.

Systemic thought articulates itself in terms of connection networks. According to this theory, in fact, connections characterise a system and its context, and it is through connections that a system weaves a network of information and matter. As a consequence, the vision becomes of an **holistic** type, and defines various system levels. Particularly, every system is part of a bigger system and contains smaller sub-systems. The analysis of a system level cannot ignore the context to which it belongs: for this reason, systemic thought is also known as "**contextual**".

As a consequence, mechanistic and systemic theory have an opposite approach: the first sees the world as a group of objects characterised by specific properties; though they interact with each other, relationships have a secondary importance. On the contrary, according to the systemic vision (as already said), objects themselves are groups of relationships inside wider connection networks, where material boundaries of single objects become definitely a secondary element.

During our analysis, it has been noted that the majority of RFID applications currently available on the market and, more generally speaking, industrial applications including the implementation of innovative technologies, have a linear, traditional approach, in which technology is included in a specific domain in a quite restricted, vertical way. The solution is consequently titrated to a single problem, regardless of connected elements.

This kind of approach is thoroughly analysed and highlighted as a great limitation to solution effectiveness by British expert Ken Robinson[7], who defines it with the term "**Septic Focus**", that is the tendency to see a problem as a single element, **isolated from its context**.

Through this way of acting, every application field is a self-standing element, exclusively connected to previous and successive fields. In this case, the application must adapt itself to the limits of technology and to any possible changes or adjustments; this is also valid for positive results, which will be strictly limited to the specific field, just because they were conceived excluding an interaction with the rest of the system.

This is a quite rigid scheme, where it is difficult to make changes, if not through interventions involving the application as a whole. In a structure like this, it is difficult to operate feedback when needed and to adapt to the change of a company's requirements, which occur continuously and unexpectedly.

On the other hand, the point of view at the basis of this research is the elimination of limitations brought about by a linear approach.

By applying the previously illustrated principles of Systems Design, it is possible to avoid septic focus phenomena in the implemented technological application.

The systemic application of a technology means first of all that there is no need of adapting the problem solution to the imposed technological limits; on the contrary, the instrument itself adapts to the specific case requirements. When using a systemic application, all crucial elements in a system are analysed not as isolated elements, but as parts of a connection network of which the goods, information and service flow has been analysed. The same system is seen as a part of a wider system network, interacting with all other systems. This communication can take place both between systems in their complex, and through single crucial points interweaving specific relationships with external systems.

The possible consequences of this approach are, first of all, the implementation cost breakdown between all subjects belonging to the system, as well as an **overall positive effect overcoming the sum of the single benefits deriving from vertical-type applications**, because they involve the whole system and not merely a single element.

[7] Robinson, Ken. 2001. *Out of our minds*. Oxford: Capstone Publishing Ltd.

In this way, the application is extremely flexible and horizontal to the greatest extent possible, that is referred to the whole structure. This allows a constant feedback and adjustment to make it more and more effective for all crucial elements and systems involved.

Finally, it must be pointed out that, especially in particularly complex domains such as a hospital, a methodological approach of this type generates solutions that, besides having quantifiable positive effects from the financial point of view, involve another series of benefits, which are not numerically quantifiable: positive effects in the social field, positive feedback from citizens, support to more feeble individuals; in other words, all that can be summarised with the word welfare.

In conclusion, it is necessary to point out that, though a systemic approach may seem difficult to implement, because of its apparent management complexities, it provides a further advantage related to RFID applications: every crucial element in a system is connected to the others equally. In other words, there is not a fixed departure point for implementation to make the project work.

As a consequence, various systems can be involved during successive stages, choosing freely the most suitable departure point and implementing, through the common criteria previously explained, all those domains that during the study stage have proven to have connected elements, or the contexts which, as a consequence of the network enlargement, are spontaneously touched.

5. Project solutions

The project constituting the final step of this research is the application in the health care field of a theoretical model, seeing the instrument of technological innovation not as a mere technology change inside a specific, vertical field, but as **an instrument generating systemic interactions**, where technology is the means to attain the objective, and not the objective.

The project's guidelines are the following:

- A **Systemic Approach** as a methodological basis for the elaboration of solutions.
- The employment of the same Tag to perform **more tasks**.
- **Tag reuse** for the highest number possible of procedure cycles.
- The involvement of **external systems** with respect to hospital domain.
- The possibility of implementing solutions for **successive stages**.

Moreover, some basic application devices are estabished. These are passive or read&write tags at 13,56 MHz to trace patients and objects, palmtop readers used by medical staff and a wireless Lan line installed into areas where procedures take place.

The elaborated solutions include the real-time check of the correct blood bag-patient correspondence, with automatic feedback forwarding to the Blood Bank on the actual use of the blood bag; the automatic management of refrigerated blood banks; the automatic verification of the correct administration of medications and meals. All these applications won't be managed as single solution to single problems, but as a common platform providing support to patient and helpers for specific exigences.

By extending this "platform" to the exterior, it will be possible to involve and integrate other systems inside the application, such as, for instance:

- **Transport system:**
  not only for automatic ticketing, but also as a support for weaker users, to create an integrated management of traffic flow according to the necessities of single urban areas.

- **Waste management:**
  "intelligent" collection points communicating with collectors, a "collection on demand" system could be implemented, to perform waste collection only when necessary. This system could be extended to the whole urban context; this could lead to a more accurate management of waste collection and disposal, as well as to a smaller number of movements for collection means. This would result in a lower fuel consumption, lower harmful emissions level in the air, lower transport means maintenance expenses and so on.
- **Medication management:**
  creation of a management and monitoring platform for medications, exploitable by all subjects involved in the system: industries, chemist's shops, hospitals;
- **Public Administration:**
  make available all data contained in the patients' Tags, so that Public Authorities (e.g. registry offices, municipalities and health bodies) can consult them if needed; this could be useful to speed up bureaucratic procedures and to create personalised services for subjects with special requirements.

6. Result evaluation

Making an estimate of an application such as the one proposed in this research is a quite difficult operation. This is due to the previously explained reasons, as well as to the nature of the approach and to the complexity of the application field.

On the basis of the previously underlined considerations and of the subject nature, which is clearly social-oriented, it is evident that the most important obtained results are probably the "non-material" ones, which are not financially quantifiable.

However, an attempt has been made to quantify the "material", or financially quantifiable results. This calculation is incomplete in any case, because, at the present state, it is not possible to foresee all financial effects on possible external systems involved. In brief, since the project can be implemented in subsequent stages and with no precise and mandatory departure point, the estimate is obviously not definitive.

A tentative overall financial view, obtained on the basis of present data, can help to evaluate at least partially the possible relevance of the project implementation.

For this purpose, some assumptions have been established. Through these assumptions, it is possible to elaborate a cost estimate referred to the current situation, as well as to compare it to the situation after project implementation.

The first is that, since adverse events generate a yearly financial burden of **2.500.000.000 Euros** for the National Health System**,** the total number of adverse events classified as preventable are estimated to be 40%, the financial burden caused by preventable adverse events for each of the about 8.000.000 yearly hospitalisations in Italy amounts to **125,00 Euros.**

Before going on, it is essential to interpret correctly this figure: in fact, it does not represent the financial increase generated by adverse events in each single hospitalisation (luckily, not all hospitalisations involve adverse events). Actually, it represents the repartition of the increase due to preventable adverse events, against the total amount of yearly hospitalisations, including those with no successive adverse events. In other words, it is possible to estimate that the cost of every hospitalisation to the Italian Health System is 125 Euros more, due to the occasional occurrance of preventable adverse events.

By saying this, and establishing the number of patients served by the Blood Bank in 2006, which amounts to 11.493, of which 395 in the internal ambulatory and 11.098 at the Molinette Hospital and in other related structures, the financial burden for society, generated on the basis of

the before-mentioned 125 Euros, has amounted to 49.375,00 €/year for the Blood Bank itself, and even to 1.387.250,00 €/year for other structures. This means that the financial burden for society is of **1.436.625,00 €/year**, which are an additional cost for the National Health System.

It must also be considered that, according to surveys carried out during research, about 75% of patients of the Blood Bank need to be accompanied. According to the same estimate, 25% of helpers are in their working age, so they have to renounce to working hours to accompany the patient. This generates a yearly lost income of 60.596,59 Euros.

The same reasoning can be applied to the patients of the Molinette hospital and of related structures, where, however, it has been estimated that the number of patients needing a helper is lower (20%). Anyway, this generates a yearly lost income of 227.004,55 Euros, which, summed up to the previous figure, makes a total amount of **287.601,14 €/year lost income.**

Finally, another cost related to hospital can be estimated with sufficient precision: this is the cost generated by the two employees responsible for the control of blood bags, dividing them in usable and quarantined bags. According to the estimate, the direct cost for the hospital, due to this procedure amounts to **70.000,00 Euro per year**.

The three previous figures represent three single cost entries for the National Health System, lost income and direct costs for the hospital in present conditions. Summing up these three values, though connected to different subjects, the amount of the total costs inserted in this financial account is obtained; this figure will be useful to make some important considerations. Total costs amount to **1.794.226,14 Euros per year**.

First of all, to evaluate the “To Be” after the implementation of the project, a calculation of the direct costs for the new technological instrumentation necessary to the system functioning has been made: on the basis of the previously highlighted number of patients with a medium frequency of about 24 transfusions per year per patient (defined through a survey), and considering that the price of a tag is 0,25 Euros, the total yearly cost for Tag supply would be **117.228,75 Euros.**

To this, other costs have been added: 900.000,00 Euros for new systems and technological infrastructures; 200.000,00 Euros for the change of the system management; 150.000,00 Euros for general expenses, for a total of 1.250.000,00 Euros a five-year amortization period, generating a **250.000,00 Euros** direct cost for the hospital.

As regards costs for society, it has been estimated that, through the implementation of the system, it is possible to avoid about 80% of preventable adverse events. The remaining 20% is related to those adverse events not related to the project, because they are due to a patient's accidental fall or other similar events. The prevention of those events is related to planning interventions which are not involved in this research.

The remaining cost for this type of events results to be 9.850,00 Euros per year, referred to Blood Bank direct patients (internal ambulatory) and 227.450,00 Euros per year for patients of the Molinette hospital and other structures related to the Blood Bank, amounting to a total of **287.325,00 Euros/year.**

The remaining costs to be considered are costs for lost income of helpers: obviously, it is impossible to completely avoid this cost, unless other services are exploited (a support service financed by the Public Administration; patient tutoring projects, etc.); it is estimated, however, that the application of the project stage described in paragraph 5.4.4, can reduce of about 75% the time in which the helper must actually stay into the hospital, thus reducing costs for lost income of helpers to 15.149,15 Euros per year for helpers of Blood Bank patients, and to 56.751,14,00 Euros per year for the helpers of patients of the other hospital structures, generating a yearly expense of **71.900,29 Euros.**

The analysis of the difference between present costs and costs after the implementation of the system underlines that the only increasing entry is represented by direct hospital expenses, due to the investment related to technological instrumentation and management of the new

system. All other entries, from the cost for society related to preventable adverse events, to the lost income of helpers, highlight a yearly cost decrease which, through an algebraic sum of factors (positive and negative) underlines a saving, generated by the implementation of the project, amounting to **1.067.772,10 Euros**. However, the most significant element is constituted by the **1.149.300,00 Euros** that can be saved by the National Health System (and consequently by citizens) which, alone, could justify the investment to implement the project.

Besides, it must be taken into account that the importance of highlighted economic results can legitimate any possible investment aimed at the project's implementation, even in case the real expenses exceed the estimated figures.

In conclusion, it is our strong belief that the most interesting result of the application of the systemic model illustrated in this work is not the financial one, but is represented by those benefits defined as **"non-material"**.

In fact, the advantages related to society, to the support given to weaker subjects, like elderly people and patients, at whom the research is aimed, and to the creation of a common communication platform between Health System stakeholders, as well as to the increase of safety levels in hospitals and to all relationships and possible positive results for external systems, are the real asset and added value of this project, with respect to similar implementation experiences presenting a linear approach.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Business Idea Design

Supporting tools and services for start-up design-oriented companies

Arianna Vignati[1], Michele Carriero[2]

Abstract

The aim of this paper is to introduce an innovative approach to the problem of the start-up phase that design-oriented companies (project companies, and manufacturer & services companies, which are based on design as a differentiation and competitive asset) face.

The thoughts, the tools and the working method introduced in this paper are the result of a Research& Development project, carried out by the INDACO Department, as part of the "SATURNO 2007" initiative – a financial plan of Lombardia Region, Ministry of Labor and Social Welfare, and the European Social Fund, coordinated by the Lombardy Chambers of Commerce and Unioncamere Lombardia, and ended in February 2008.

1. Introduction

The creation of new companies has always been a significant data for the economic development of a Country. The social and economic dynamic which are positively referred to this factor are related to the generation of employment and most of all to a tight relation between new companies and renovation/innovation of the industry in which they operate (Dringoli and Boccarelli 2004). In fact the new companies are more and more a trigger for the introduction of new technologies, and for the product, process, service innovation. And not only. More often new companies support the traditional ones in terms of offering innovative service and in terms of diffusion of incremental innovation in the production line.

The "micro-entrepreneurship" phenomenon, meaning the creation of small and very small companies, especially in Italy, is partially due to the parallel phenomenon of reduction in the number of employed by the big companies. To be ambitious, have ideas and to be eager to face challenge means, in our country, to often deal with the challenge of starting an entrepreneurial or self-employment action, as it would be difficult and different to do the same things when employed by a company. In Italy this eagerness leads to the creation of 400.000 new companies per year[3], bringing our country among the leaders in creation of new companies, especially individual and small companies. When looking at the current economy, it is evident that a successful innovation, which generates a long-lasting flow and a consistent economic value, rises from individual initiatives that can gather a system of skills, ideas, opinions, attempts (a wide network of companies, bureaus and institutions that get more and more over the regional and national boundaries). In fact, it has been some time since innovation was coming from an isolated inventor, of from the R&D process of a single company (Plechero and Rullani 2007).

In the current competitive context innovation, thus that push and that chance at the basis of all business and entrepreneurship opportunities, is (and it will be even more in the future) an emerging factor (rising from opportunities and circumstances tied to different real factors), very dependent on contextual circumstances and especially to the *animal spirit* (as Rullani defines them) of the people involved. The innovation is developed in an area between the technological and economic system. A sort of "no man's land" where the processes don't follow any purely technological and economic logics (Plechero and Rullani 2007), but where individuals and their knowledge are determining factors. The level of innovation of a new business as well as the growth opportunity in the years after the start-up depends on these assumptions. The continuous innovation process is crucial since the very beginning. An innovative process where the capability of making decision is very important. The new businesses have to be based upon innovations rising from the ability to envision, and to create shared meaning, and generate virtual worlds. These variables derive from the creative skills of the subjects, which are at the basis of an innovation process (Plechero and Rullani 2007). This creative skills aren't improvised manifestations of the individual fantasy or brilliance, but they become the way in which the intelligence of people and organizations deals with complexity, trying to find its meaning in its growing process.

The space of new and possible is opened and accessible to innovation, to become the space for everybody's freedom and experimentation, which through rules and relations are reshaped in maps an reusable networks (collective intelligence) (Lecy 1996). The open innovation (Chesbrough 2008) becomes the *modus operandi.* The design companies and those that base their innovation on design have in their DNA the competencies and knowledge to make it "daily active".

A crucial role in this collective intelligence and in this open innovation model is played by the human capital, which in the creation of new entrepreneurship significantly contributes in long-term innovation: the entrepreneurial development is in fact the growth engine of the network. As

[3] According to an investigation by Unioncamere published early in 2008, and the data Movimprese 2007, 436.025 registrations were made in 2007 (the highest since 1993, when the investigation was sterted).

Stewart states (Stewart, 2002): *No tangible goods are needed to access to an entrepreneurial activity. The special and differentiating asset, isn't the machinery: it is software and wetfare (neologism meaning "humid goods", to indicate the brain) […] There was a time when the possibility of gathering material assets used to determine a competitive advantage and explain why the companies were established where they could use the physical characteristic of the territory […] In terms of material assets, purely knowledge-based societies (such as professional services companies, publishers and financial groups, not to forget the internet and design companies) can have requirements which don't go far beyond some computers and desks.*

This introduction on the competitive and economic context which for the years to come will represent the path which many and new companies will have to follow, allows us to look at the phenomenon of the design self-entrepreneurship as an original and innovative element of the whole industrial system. This because design, especially the Made in Italy, has always been a complex system of services supporting business innovation, and the core of the market competition.

1.1 The creation and growth of design oriented companies

The business start-up, especially in the first and most difficult years, brings innovation and positivity to the economic system, but it is also quite critical. Its issues are tied to several factors: inside the company (training the entrepreneur, finding the qualified human resources, organizing and managing etc...) and outside the company as regards the turbulence of the market (legislative changes, changes in the interest rates and in the cost of raw material etc...). Since many and different factors influence, even dramatically, the stability of start-up companies, several actors have nationally activated policies and projects to support these issues. The principle of these initiatives is bases upon the firm belief that to support institutions and universities can lower the impact with these difficulties and allow the young entrepreneur to find their way in the scenario of the global competition and open innovation.

It's been a few years since, in this framework, Regione Lombardia (through fundings of the European Social Fund and the Ministry of Labor) has activated Saturno, a project to support the business start-up in Lombardy. 25 Lombardy operators participated in the call in March 2007 and, on the basis of a unitary proposal by the Chamber of Commerce, as many projects were activated.

The Business Idea Design (BID) project, promoted by Dipartimento INDACO of Politecnico di Milano, supported by Organizing & Consulting[4], was part of the initiatives "Saturno 2007" and focused on the investigation and testing of tools and methods for the creation of design oriented companies (design companies and companies aiming to base their competitiveness on the design driven innovation).

The aim of the initiative was to support 15 start-up companies with significant innovative contributions to the service design sector and to traditional sectors, leveraging on product, communication and service design.

The BID project also allowed to define a model and a service, education and consultancy platform to support these typologies of company.

2. Business Idea Design: tools and methods for the start-up of a company

[4] Companies that carries out supporting projects for the business creatin, especially in the disadvantaged areas in the South Italy

The Milan and Lombardy areas are an extraordinary fields for continuous innovation for the Design System. In the Milan and Lombardy area there is a high concentration of design schools, design companies, professional associations and design related services. This is why new design companies and companies which use design as a competitive asset are created and grow here more than anywhere else in Italy. More in general there is a substantial trend, in this very particular field, as regards the design discipline: design is leaving once and for all its dependency from the production and consumption system, to find its way towards a wider system of values. This system shares a life project socially and environmentally sustainable, and it plays a proactive role, able to generate shared wealth scenario (Zurlo 2003). In this logic companies have recently been created (and the phenomenon is increasing), thing which opens up new cultural, social, civil problems (Bucci 1998).

The Business Idea Design project allowed the identification of a supporting action to design startups, divided in two main business typologies and models:

- design companies: they base their core business on the offer of design related activities in all the design fields (product, interior, communication, etc...)
- companies that use design as a competitive asset: they use design (at the product system level) as an innovation and competition element in the traditional sectors or the new technology and new economy ones.

On the basis of these two models, the project laid the basis for creating a platform of services, education and consultancy, to support the design startups, and generating the condition for a future interaction model.

2.2 Education: management and design

The education and training of the human capital is one of the crucial elements to support the business development. Some studies have shown that a specialized university education risks to lead to a reduction in the entrepreneurial development in our Country (which was until recently supported by a wide and multidisciplinary university education) (Femminis, Martini, 2004). Thus, knowledge transfer and education had to be the basis of any action to support the company start-up.

The first step in the activities suggested and organized within the BID project referred to the definition of a short educational program targeted at groups, which would focus on the knowledge transfer in the management and design areas and on sharing the business ideas. The candidates (around 40) studied topics related to strategic design, marketing, communication, distribution and business organization, and used the suggested tools and innovation models to reshape (and in some instances radically) the business idea. The interaction within the class allowed an ideas cross fertilization which in the following months helped establishing a stable interaction network. At the end of the educational program 20 innovative ideas were selected, to be developed in a further step: organization and definition of the business plan.

2.3 Consultancy: evaluate the feasibility of the idea and define the business plan

The premise for any activities of evaluation of the business ideas is the evaluation of the innovation degree of the idea itself. The opportunity to start an investigation to define a business plan has to start from a real evaluation of the possibility of success of the idea. The more the possibility of success is foreseeable the more the qualities of the entrepreneur are intelligible, the more the role and the identity of the company in the society and market of reference are clear (Zurlo 2003). The mission, the strategic plans and the actions of a company have to be based upon a unique factor, and not only upon a competition. The competitive advantage doesn’t come from a differentiation effort, but from exploring unknown dimensions. The more this advantage is acknowledged and shared, the more the strategy needed to be gained it will be clear. The 20 potential entrepreneurs were led to the definition of the business strategies in a series of personalized revisions, during which the economic and financial information of the initiative were evaluated. Scheduling personalized meetings allowed to:

- isolate and clearly identify the business idea and to clarify the suggested focus of innovation (in comparison with the market and the current economic system and with a vision of what it could become in the medium-long term);
- once the business idea was defined, carry on with:

  1. verifying the technical and economic feasibility (through tools of economic analysis);

  2. creating the network of actors needed to activate the business (with special attention given to the relation with the Design System and the management competencies).

The creation of synergies among young designers and potential entrepreneurs was strategic for the success of the project, many of the business ideas in traditional sectors were in fact created by entrepreneurs with a strong technical background (mainly engineers), which would consider design as a determining factor for the competitiveness of the new product/service, but which didn't have any competency in the field. The BID management team had to enable the relation among potential entrepreneurs who, since the very first steps of the business development, worked together with designers, who could visualize and communicate the visions on the product system.

On the other side, to support young designers (designers, architects, communication designers) in their company start-up meant to focus on supporting the management and organization model of the new business (contracts, company architecture, managing the investments, etc…). the synergy among the competencies of the potential entrepreneurs also allowed to define shared innovation platform.

2.4 Services: community building and network creation

The Business Idea Design project was developed according to the process and constraints given by Regione Lombardia to all the operators. At the same time as the educational and consultancy program, the team developed a service to support and stimulate entrepreneurs to grasp logics of continuous and open innovation. This support was developed in two different services: funding opportunities search and involvement in research activities.

The regional and national funding opportunities for start-up companies and research projects involving universities and SMEs were constantly monitored, and companies were helped and supported in writing and filling the participation forms. Thanks to this service some companies, even after a month since their creation, were financed without security, or at a very convenient rate.

As regards the participation of the startups in networks of innovation and research, the newly born companies were involved since the very beginning in research and collaboration projects between University and SMEs. This allowed to strengthen the platform shared by University and regional production, and to make the process of technological innovation accessible to the new companies.

The result of the BID project was the creation of 15 innovative startups and of a community building platform coordinated by the university. The platform is part of a wider network of actors operating at a national and international level (incubators, research centers, companies accelerators, scientific and technological parks, etc…), aimed to support the creation of new companies. With one specificity: design.

2.5 The strategic areas of the startups

The strategic areas of the startups are many and different. They draw an interesting picture of reference for the direction that design might have in the future of the national economy.

Integrated design: **Marchingenio,** company that combines the design competencies (the participatory design and the development of sustainable projects included) with the architecture and interior design and the development of "key in hand" solutions. They not only suggest projects, but define themselves as "the bearer of new cultural scenarios" focusing on energy efficiency, material and space sustainability, individuals' psychophysical wellbeing. Web services: Diego Giuriani created **MyVetrina.com** (www.myvetrina.com). He was able to leverage web design to create a stable network among companies in Valchiavenna (area with several logistics problems, which is thus very suited for technology-based services such as this one). New product solutions which aim to take to the extremes the relation between crafts and haute couture: Gabriella Frigerio (young fashion designer with a wide experience in the prestigious haute couture brands) created **G:Lab_27** and designed a hand made collection of bags. The collection takes the role of the high quality handicrafts in the Como area to the extremes of the production for international market. Products for specific users: **Aquabrik** (fig 1) gets in the swimming world as an innovative system, which opens up new frontiers in the field of the psychomotility of specific users (children, people with handicaps etc…) and in the field of the post-surgery rehab. Products combining technological innovation and design: **Rizlab** is created as a new young company designing and producing integrated computer systems within design solutions. A Lab in which original ideas are developed and translated into computer tools characterized by the use of unconventional shapes and materials (through a continuous research, extreme customization and attention to the current trends) (fig 2). Specific design consultancy for SMEs: The **muvin'** product manager is the new profession created by **Paola Marincola** to answer the need of SMEs to manage the product and communication innovation process in a strategic way. The concept is to take the idea of "open innovation" (Chesbrough, 2008) to its extreme, through a flexible and moving figure tied to project management. Products for specific users: the specialization in designing and producing playing grounds for children (especially normallyintelligent ones) is the core business of **Stileurbano**. Design for food: packaging, innovative banqueting solutions, food design are the focuses of **Boxing catering** and **Le Kanary**, companies in the catering and food fields. Identity communication, branding: the company communicates its identity through the integrated communication of its value, offer, innovation, etc…; **Visulamade** offers communication design services especially to SMEs, exploring the new virtual communication world such as Second Life.

3. A network model for a stable relationship between University and new design companies

The service, meaning the relation among the different actors of the production line is currently very important when talking about innovation (even though for several years it was considered a useful but not leading activity, like those which "consume" the added valued produced by others) (Rullano, 2007). In order to innovate, exploring the world of what's locally possible in an immaterial way, producers and consumers, specialists and system analysts, material and immaterial, local and global have to be *linked* in a dialogic manner, mixing the traditional manufacturing and services roles.

In order to create all this it is necessary that the innovators act within a network that makes others' knowledge and production resources accessible (which then allows to share the weight of innovation costs and risks). In a polycentric system where innovation reaches different point of a network a self-organized management system is needed. In this way, the pioneering innovation can be amplified and become fruitful by the propagation in the network. The propagation is managed by leaders and public policies through a process of self-regulation and bottom up (Rullani 2007). In this vision of the innovation model, in which the newly born companies operate, the University plays a pivotal role, like a ring in the chain that can spread information, knowledge and innovation.

Once the Business Idea Design experience ended, the aim of the project's evaluation process was the test and possibility to shape the network. First of all a network among the project participants, to create a stable dialogue between new companies and University. An internal network which looks outside, at a model of continuous innovation and at the support to the creation of new design companies. Several design and research occasions, activated within the University, have actively involved the new companies, putting them in relation with SMEs and systems of national, and in some instances international, companies. The model upon which the network is created involves several actions:

— Knowledge transfer (good practices, innovation and new research boundaries that the University puts at the companies disposal);
— Consultancy (support to the definition of new design business ideas and design business plans);
— Services (support to the identification of bans, funding and research);
— Stable network among startups, innovative companies involved in research and applied research processes and university (community building).

Final objective of this process to build a stable network is the development of a virtual space to give visibility to the community of young entrepreneurs and that could be involved in a wider network of relations among designers, companies and universities. Besides the support given by a technological tool as a platform for knowledge sharing, the life and growth of the network depend on two main variables:

— The first is the human capital, the basis of any organization and any model of know how and innovation exchange and transfer;

— The second is the organization institution, which together with the University, manages the communication platform and the service supply. To support the company accelerator at Politecnico di Milano (Acceleratore d'Impresa, AI), together with the educational activities of the Facoltà del Design and the research and innovation activities of the Dipartimento Indaco, the developed model suggests a subject which can act as a reference point for potential entrepreneurs (first of all young design graduate) and the new startups. (fig 3).

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design by Components

An operative methodological tool for the ecocompatible industrial design

Andrea Virano[1]

Abstract

While until yesterday design development processes were based on the creation of few product families, today the increased welfare and the abundance of a product-park overloaded with objects, is asking for changes in the way of “doing design”. Recently there has been a clear need rising, the need of adopting appropriate strategies/tools/operative methodologies, so to redirect industrial productions towards quality and not quantity. In this always changing scenario, the Design by Components methodology propose itself as a powerful instrument supporting the environmental sustainable industrial design. Through this tool, that follows the concept of the reverse engineering, it will be possible to get to a redefinition of new design criteria able to meet the current environmental needs.

[1] Politecnico di Torino, (ITALY) – 1 Facoltà di Architettura, DIPRADI department (Dipartimento di Progettazione Architettonica e Disegno Industriale), architect - PhD in Technological Innovation for Architecture and Industrial Design, Lecturer in Industrial Design, fellowship researcher, andrea.virano@polito.it

1. The methodological tool

The methodology presented in this paper is the synthesis of many experiences gained over the years, through courses, national and international workshops, by the industrial design work group of *DIPRADI*, *Politecnico di Torino*.

It is necessary to show a simple but involving approach, if we wish to show how to work.

We start by concretely dismantling a commercial product, interacting with an object, not only theoretically but for all purposes, triggers a mental and operational process leading towards a deep understanding of the same object, the technologies adopted and of the planning process.

By dismantling the product it is possible to perform a spontaneous application of the so called “reverse engineering”, that being an operation enabling an understanding of the problems arising from the analysed product. The dismantled object must be, therefore, represented in an exploded axonometric view which highlights all its parts and peculiarities.

If, on top of this analysis, we add all the materials the object is made of, it is possible to see on the same table all the parts it is formed of, ease or difficulty of disassembly (caused by several issues, such as the one of safety) and materials. As a result, we can perceive the object in its complexity.

Before it was only a shape, now it is no longer just that: it is a component system.

This different type of focus allows us to understand the “underlying whys and wherefores of things”. The following step is to define what its components are.

The component is the resolution of a function (an electric wire is a component, for it transmits electricity; a switch is a component, as it “accepts or refuses” the passing of power through a wire). At this point, the understanding that we have gained makes it possible for us to outline the general operation scheme of the product, without analysing any further operating object, and to relate the several existing components, getting to its essential scheme, once we have understood all its possible redundancies.

If we analyse them within their homogeneous whole, we can see how each table focuses on specific analysis. The awareness of the complexities observed, results in increasing knowledge, that is fundamentally important, because we can confront ourselves with a concrete reality where all the theoretical baggage suddenly materializes.

The theoretical study of the manufacturing technologies is extremely useful and educational, but even more beneficial is to see and handle the produced parts, as we can immediately discern all the problems we could not see before with one’s mind’s eye.

With this approach, it is possible to observe a foamed component or an injection mould and to understand all the problems arising both from its realization and its assembling. We can see bulges, indentations or supports and we understand the reason. By touching screws, washers, joints or gaskets we can guess how easy or difficult it will be to assemble or dismantle them.

This is “learning by doing”, it is like going into a craftsman’s shop, seizing his secrets.

Moreover, by dismantling the object, figuring out what the difficulties may be and reporting the latter on the tables, we may understand the different existing types of users, such as production users, management and maintenance users and consumption users.

This means there are three types of accessibility, production staff must easily assembly parts, management and maintenance staff deals with disassembly and repair difficulties and users wish to use the produced goods as long as possible, as well as doing small repair works.

If we look at the matter from this point of view, also components will take “different” positions which can, however, generate planning benefits.

The explosion of parts, that can be illustrated on a disassembly table, is not very effective if it is considered individually, uprooted from the relationship occurring with the other ones. Instead, if

single parts are conceptually connected, one with the other, so as to understand their functions, it is consequently possible to materialize the different components.

Combining previously undifferentiated portions may now determine well-outlined “focuses”.

A component table has to emphasise the individual functional parts (components) forming the product and has to help, in such a way, to detect and determine the relationship occurring among the parts, that being the possible general working scheme.

The above mentioned scheme becomes easily discernable once the relationship and assemblage system of the different components has been fully understood.

Cross-reading the tables, starting with the initial complexity, until the final essence, caters for the ability to relate all the pieces in such a way they can actually “communicate” with each other.

If such communication is coherent, we can easily provide a detailed analysis of the object in question.

It is now possible to configure an essential scheme which can, differently from the previous one, eliminate all the redundant parts and volumes. This synthesis leads towards an abstraction, by means of removal of the formal waste concerning the previous product, and open the way of a new coherent planning system, operating in compliance with the components, that are indispensable in order to perform a given function. It is the first synthesis of the object.

The following step takes place within the specific filed of cognitive ergonomics.

It is the subjective definition of the perceptive and emotional contents, with reference to the essential scheme of the identified components, that this time have been analysed from the user’s point of view. Following this additional but essential detailed study, we can configure and outline the guidelines, inferred through the different passages,as requirements for: the end-of-life cycle, the right interconnections among components, the good maintenance and management, the functional relationships and the perceptive relationships of the new product.

The shape raising from a number of analytical passages, entailing choosing among different possible solutions, will not be the creation of an extemporary imagination or of a preconceived idea. It will be the result of a well conceived and aware planning process and the object produced by these detailed analyses will be the result of a conscious choice, with regards to functional, technical environmental and perceptive principles.

An example of the results that we can achieve applaying this methodological tool is the wall gas boiler. Over the years the object has lost its peculiar connotation and its original machinery appeal. An initial formal decision caused the whole planning process to adapt itself. This consisted of a parallelepiped to be hidden inside a wall or a piece of furniture, but, can a burner or the fire configure a parallelepiped shape?

Only by dismantling the boiler one can figure out what the product-related problems may actually be. When we analysed a boiler we saw that, in order to get to the expansion tank (that being the part that blocks the whole system, in case of damage) in the occurrence of a breakdown, it was necessary to dismantle the whole object. Time, materials and electric power waste related costs, become unaffordable, not only for the expenses users need to face, but also for the environment.

An expansion tank is the “lung” of a boiler and of the whole heating system.

Also its shape ought to be conceived bearing in mind what its function is. It ought to be circular, rather then elliptical or, even worse, square, so as all its points receive the same pressure, not any lesser or more. By placing the expansion tank in a comfortable position easy to reach, the whole object may have a whole new appeal. Why does a burner need to be rectangular?

Bearing in mind the fire is not rectangular, it is appropriate to consider that also a burner will be shaped in a way to be strictly connected to the movement of the flames, rather than the one imposed by the need to hide the function in a box, as if to conceal it.

The planning process is now winding, as parts making the whole are analysed on two different fronts, those being the individual components and the relational system occurring among them.

The synthesis of the two results in the product.

Nowadays, the manufacturer entrusts the designer the only task to refine the previously ordered shape, and to dress up a technical set, just like when an architect conceives an architectonic shape to be raised by someone else.

The designer is not a stylist, at least not according to the meaning and definition the word is currently given.

We may have forgotten that, in the past, a stylist was a tailor sewing clothes himself, or a sheet metal worker shaping the car he had himself built, with a hammer. The first coachbuilders would have never misplaced a component, as it was their job to dismantle and fix their own creations.

Changing attitudes would probably help solve many problems, with ease and deeper awareness.

It is necessary to create a widely spread culture in a planning, technical and production field, that belongs expressively to the individual actors of the whole production chain, where everyone is aware that a new “know-how” is being achieved and shared.

If we have “strong” components that are endowed with a strong identity, we will not always need to dress them. The possible aggregation will differ from the one that is currently provided for and, as a consequence, also its dress will have a relevant connotation; it will no longer be a mere cloth used to cover pieces of furniture during the seasons when we do not use them, or an “installation of Christo”, but a veritable outside shell, coherently designed with the inside.

2. Didactical testing

It is difficult for a learner to understand how to move confidently within a planning filed, as he has not gained enough experience to proficiently approach such complexity. Every time he ought to make up his own strategy.

In this chapter we want to underline all the different passages of this operative methodological tool in order to explain step by step how our students approach to the project.

Gathering information regarding an object for use, begins by making currently existing knowledge explicit. It may be effective to note and photograph, together with a table approach to the object, how to use it, the performed functions, the environments affected by its operating, and in general whatever exemplifies the culture we have, in relation to the objects analysed in the study. Disassembling the object is the first step to make if we wish to get close to it, to be in tune with it and understand it. Through an analysis graphed by means of an exploded axonometric view it is possible to highlight all the elements the object is composed of, the materials and all the different kinds of tools used for the operation.

The accessibility analysis table looks at the different elements identified during the dismantle and classifies them according to the degree of ease, the order in which they can be dismantled and whether the latter operation needs to be performed by the user or the maintenance man. In addition, this table serves the purpose of revealing all the different connection modes, such as screws or rivets, as well as to find out if it occurred by aid of joints, bonding agents or welding. As a result, we can check whether an individual element may be disassembled or if we absolutely need to destroy it.

The analysis of the components delves into the parts the dismantled object is made of. Such parts are arranged and classified so as to identify the different functional systems which contribute to define the performance of the object. Components are the elements, or sets of elements, endowed with those functional features which help the object achieve its objectives.

The current working scheme of the object explains the connection occurring among the parts during the operation and makes them explicit. It pays particular attention to the inputs, the flows running inside the “object system” and to the generated outputs.

The general scheme explains the connections existing among the different components. Flows, connections and circuits existing inside the object are arranged and organized in order to emphasize the areas to be used for individual functions or groups of functions. The initial object is now totally dematerialized and schematized by the whole collection of systems enabling its operation. In this way we have moved away from its initial shape. We have lost every connection with its look, that is its “shell”.

The essential scheme is the maximum possible synthesis. It is composed of the main components, that cannot be eliminated if the functional qualities of the object in the study are to be preserved. This scheme detects all the components and fundamental relationships system. It is now possible to rethink of the object free from all formal and cultural ties. The “shape” of the new object will be mainly determined by the features and organization of the components that form its essence.

The table referring to the correspondence between shape and function examines each component and its functional features in relation to the formal characteristics. This assessment aims to find out the existence of any kind of correspondence between the two aspects and identify if the shape is generated by the function performed by the component or by other factors. Other aspects are being evaluated, such as the possibility that adjacent components may be formally inconsistent or contradictory with each other, as well as how the object can possibly be improved, aiming to increase the level of performances or make maintenance and disposal easier to accomplish.

The perceptual and sensory analysis explains the way components and functional systems are perceived by the user, on the basis of the general scheme. This analysis shows the importance of understanding the diverse aspects of the interaction between users and components.

The survey on the emotional relationship between the user and the object points out what the users’ functional expectations are, with regards to the object. The emotional analysis supports and completes data gathered until now, showing the need to move on by making on-going “zooms” back and forth from detail to general.

Inquiries on objects for use cannot be restricted to the object themselves. We need to go in depth within the background analysis where they are adopted. In this way it is possible to deepen the knowledge of users’ uses and needs, the times and the modalities of use and the link with the environments where the objects are used. The more this analysis is deepened, to the point where it represents the foundation of the project, the easier it is to define new elements concerning the use and traditional functions with regard to the initial object.

Guidelines summarise the new requirements deriving from the previous analysis and form the requirement table of the new product.

After a detailed study of every single passage, it is worth noticing how, by grouping them together along a logical/planning sequence, it is possible to really see how a designer’s mental process becomes articulated, when applying a methodology of Design by Components. Alongside the previously defined general and essential schemes, possible solutions are now being individually looked into, thinking in terms of parts, components or areas of influence. Each solution needs to be commented on, reporting both positive aspects and possible criticalities or degree of severity.

We are now provided with a full range of well thought-out possible solutions for each point examined; we will need to rely on these indispensable tools, whenever we make planning choices or during the feedback. The appropriate modes of representation, the use of models of study adopted to assess the object individual features in details and comparing them with different users, enable us to approach a more objective verification of the solutions to select.

Once we have chosen the selected solutions, we proceed by acting on the initial scheme. As we go along, the project acquires physicality, dimensional characteristics and some of the qualities and properties of its parts are outlined. The on-going assessment of the choices made, jointly with the notes written directly on the drawing, allow us to verify the appropriateness of our choices and to possibly test other solutions.

Communication of the project has to be displayed by means of front, side and top views, providing thoroughly explained details and sections, in order to gain deep understanding of all physical-dimensional aspects of the object. Using axonometric displays (preventing measurement distortions), producing real scale models and other types of layouts (exploded, films and so on) may help remarkably in visualizing the project.

The choice of production-related materials and technologies will occur only when the object performances and quality have been appropriately defined. The designer can now, objectively search for interesting opportunities, free from constraints and conditioning; under other circumstances we risk to rely exclusively on the technologies and materials we are already familiar with.

3. Design by Components, other possibilities for the tool: application in architecture

The planning researches, that have been carried out up to now, have been interpreted as experimental chances of conveying know-how from the field of design to the one of architecture. The approach of Design by Components (also in the architecture field) requires that the answer to a planning related question must be obtained through a process, which starts from the definition of a complex relational scenario, concerning the specific thematic area we are going to act in.

According to the ecodesing principles, where it is regarded as a transversal discipline of an object conception, planning and production activities, each existing serial product can be considered as a an interrelated and complex component system. The methodological tool of design by components makes problems readable and analysable according to a logic including all possible cultural and scientific contributions, which are brought also by specific experts, intervening with the objective to provide the designer with further support. The emerging scenario presents complex features rather than being characterised by disciplinary monotony. At the same time, the targeted users directly or indirectly involved in the fruition process of the products, are under analysis. The human factor is an additional variable which makes the problem remarkably more complex, it outlines further performance needs which are related to the nature of the perception of the product. The processing of the production and consumption scenarios determine further performance needs connected to the quality determination of the product, from an economic, sociologic and environmental point of view. It is up to the designer to analyse this complex system of required performances, as well as to identify priorities and emergencies.

The previous experiences, culture and ethics, jointly with the ability to go beyond the apparent cultural borders, traced by the schematic subdivision of knowledge, are important tools for the designer. Firstly he uses them reliably and knowingly to define the families the previously outlined objectives are in relation with. Secondly he analyses the nature and the mutual relationships and chooses the most appropriate metaplanning configuration, this research will go on through subsequent re-deliberation processes until the moment the designer faces planning definition and execution phases. The innovative aspect these themes have helped experiment, is

the new consideration of houses and existing architecture, equal to any other serial product. They are therefore, regarded as complex systems, which are as such, decomposable in functional and then in essential schemes, to be subsequently analysed.

In the following text are presented four cases (reserches and applications), that would represent a critical testing contribution and should be considered as a useful dialogue proposal in order to start a positive and constructive contamination between parallel fields of architecture and design.

The Motor Village project[2] in Mirafiori in Torino, Italy.

The work group had to decide if it was necessary to demolish an "old" industrial shed for realize a new structure or refurbish the old one, in order to realize a new nodal point for *FIAT*, creating the prototype of *FIAT* branch office all over the world.

The whole building has been carefully examined in its state-of-the-art conditions and the "broke-up" into parts and components. This approach has enabled the work group to understand the elements to be changed and those to be preserved. This situation arised, as it usually happens in the event of common use products, because of the presence of one-sided parts: certain components could be used as they were, others couldn't. The planning group delved into the structural whole that showed to be made of a metal framework, with a roofing in pre-insulated/corrugated metal sheets panels, perimetric walls made of brick with steel wire drawn frame and bar windows. In this case, the planning group did not proceed by replacements of components. We understood, on the contrary, that it had the chance to intervene following a precise logic. The architecture, an old "shed" structured saddlery, consists of repeated modules made of columns and two pitches.

Instead of taking the "low-high-low" module of the cover, according to the scheme, the group, on the contrary considered the "high-low-high" one, according to the scheme, by simply sliding the modularity by half a span. This reinterpretation has radically changed the perception of the whole, also reinforced by the underlining of the perimetric walls which have also undergone this change in perception: going from to, the module obviously broke in half and radically changed the global perceptive approach. Alternated full brick painted backgrounds with other empty ones (new full field windows) have once again helped consolidate this view.

This allowed us to give to an "old" structure, in the process of being demolished, a new life, and, at the same time, this way to proceede could become a model to reproduce, when dealing with the planning and construction of other "old" industrial buildings.

Maintenance in popular building trade[3]

The turning point for an environmentally and technologically sustainable future, consists of the opportunity to approach maintenance with a substitute logics, where the greatest number of obsolete and damaged elements are replaced by new products and components that are obviously up-to-date. This would be unlike the current regulatory and requirement framework trend. This would help reduce energy consumption, extend the useful life cycle of the building, and consequently, delay the building dismissal without having to face the environmental and economic costs that a new production phase would entail, when natural resources would consequently be eroded. It is therefore necessary to rethink of the building trade as of a maximally reversible production and assembly process. This is even more true where big maintenance works are performed, in replacement of scheduled and periodical maintenance operations that are difficult to perform for economic and logistic issues. We absolutely need to think in terms of components. This implies realizing, also within the building practice, that

[2] Work group for *DIPRADI (Dipartimento di Progettazione Architettonica e Disegno Industriale)* of *Politecnico di Torino*, Italy, that has developed the planning concept: L. Bistagnino, C. Campagnaro, A. Virano.

theoretical schematisation at the basis of the categorisation provided by regulation UNI 8290-1[4] describing the build up product as an interacting complex of technical classes of elements. The project must make decomposability of the technological system feasible and allow individual components to be isolated, compared to the other ones, by leading building production practice towards endless reversible unions.

The research on façade systems has permitted us to test the degree of severity encountered as we go along, consistently with the principles of Design by Components, the management of deterioration phenomena affecting external vertical partition systems. Starting with the observation of the current status, based on the evaluation of the performance requirements the technical elements need to meet, we arrived at outlining a façade component that can be assembled in compliance with a specific technological program. The front component, as the smallest technological and semantic meaning unit, becomes the basic module we begin with, in order to "redesign" the build-up product. The project allows to check and manage the distribution of individual performances or a homogeneity of the same, in relation to the building packaging, both on its superficial extension and in its depth. The value of the component consists of its ability to combine with complementary modules, that can be assembled as well as isolated and replaced, where each item has its own performance. The project intervenes, through the construction of complex systems, at different scales. During their exchange, it is possible to realize the positive relation between what is known, the fruition moment at the component scale basically functional to the performance response, and what is new, that being the perceptive moment at a building and suburb scale, which the secondary function the component system outline, prevails on.

It is therefore possible to carry out linear, punctual and superficial interventions, in addition or supplementary to the functions destined for the buildings façades. Such interventions, if they are coherent with each other, help restore the performance efficiency and value of a built-up product, with regards to consumption users' and management waiting times. Furthermore they would give buildings more meaning within the contemporary city.

An integrated project to introduce sustainability principles into building maintenance activities of existing building stock[5]

The research is aimed at obtaining innovative building components which introduce sustainability principles into maintenance activities and facility management of real building stock. This goal is justified by the awareness that nowadays the building sector is one of the main responsible for resources consumption and impacts in the environment, especially during its usage phase.

This issue is expressed in the recent European Directive (2002/91/CE) concerning the energy performance and the application of energy certification of new and existing buildings. For this reason an extension of building life span with an high level of eco-efficiency, focusing on components maintenance and replacement activities, is an indirect strategy for improving environmental and energetic performances of buildings according to European or national directives, but also regarding zero energy and emission principles. On these assumptions, the research has been started with an analysis on background factors such as, the influence of sustainability principles both in the project of a new or rebuilt construction and in the European and domestic legislations, the adoption in the Italian context of facility management methods and systems for real building stocks, and an overview of the average age of the existing buildings and of construction market trends in Italy, which lately is more focused on renovations rather than new constructions.

---

4 The norm UNI 8290-1 of September 1981 supplies, in the field of the residential building, the classification and the articulation of the technological units and the technical elements in which the technological system is decomposed. It unifies the terminology used in normative, program, planning, operative and communication activities.

5 Taken from architect Cristina Allione's PhD work, *Politecnico di Torino*, Italy

The research results that have been collected so far are, above all, the importance of the study of the weak points, made on a format basis, which can highlights the recurring problems for each selected component of buildings, the fixed requirements for each element not only according energy efficiency, but also for the inhabitants' well-being, and the most common maintenance activities for each one, with an indication of their frequency. This analysis it will be possible to define the following steps of a research aimed at designing an integrated project for these components which combine maintenance with sustainability principles.

Road Side System[6]

The "road system" is currently characterised by a complex homogeneity of parts and component, standing out from the "crowd" for the observer may have a different perception, according to whether he is moving along the road, or out of it. In the current situation, although for different reasons, the parts making up the side of the road almost always coexist independently, but are distinguishable, one from the other, as they all have separate functions, as well as being classifiable into continuous or discontinuous components, depending on how they are distributed along the road. Therefore, the focus has been shifted from the individual component to the road side system. From this point of view it is no longer important to churn out a new component (among many of them) hoping it's (finally) the problem solver.

During this analysis it was determined that we cannot shut ourselves away, inside the typological horizon of "anti-noise barriers", instead we need to hypothesise and petition for a systemic logic which, starting with the current status, looks at a wider horizon and outlines a modus operandi to overcome the current cumulative procedure consisting of: guardrail + anti-noise barriers + road signs + information + lighting, and so on.

We need to think about an integrated-integrable system which has the objective of becoming an evolutionary trend line (beginning with the constrains and the objects existing in the market) and also to a system, capable to organize components of the road-side, that is as open as possible. This is an important feature as it enables designers to enjoy great freedom, when facing problems arising from situations such as, the introduction of the object in the environment, maintaining sound device performances, using a single framework for more components and an adequate cost control.

The road side system needs to coexist harmoniously with the surrounding environment, taking into account that drivers and external observers may perceive it in different ways. It should also perform the perceptive integration of the linear road sides, to be dealt with in compliance with products generated by a unitary calling. Doing so is necessary if we wish to cater for different safety, comfort, appeal and landscape-integration related requirements.

The analysis carried out shows that we need to deal, in systemic terms, with the relationships occurring between different components (or a mix of components) that constitute infrastructures. This study points out that we cannot imagine solving problems, one by one, with individual technical solutions.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The Vision for Mississauga's City Summit

Collaborating for Change

Julia Walden[1]

Abstract

The power of social networks has the potential to create consensus among diverse groups and can be harnessed to create transformational change. For the Missississauga City Summit, Sheridan's Visualization Design Institute modeled a design solution – a collaboration tool adapted from a social network application to engage civic and industry leaders in discussions about important issues. The summit themes: energy, economy and society are challenges shared worldwide.

The collaboration tool was a catalyst that moved summit participants to solve problems and create new visions for their city in the form of their own personalized mash-up movie. Summit participants were keen to take home their mash-ups on a memory stick to distribute their messages among friends and family. The change begins…

[1] Sheridan Institute of Technology & Advanced Learning (CANADA) – Visualization Design Institute. Director, julia.walden@sheridanc.on.ca

1. Introduction

Sheridan's Visualization Design Institute is dedicated to innovation in visualization design. The Institute's professional team situated within Sheridan's renowned high tech, animation environment conducts applied research. This dictates a practical rather than theoretical design approach conducted one vision at a time.

The design team has considerable creative and technical capacity. In its ten year history, the team has undertaken an eclectic range of projects including: e-learning, health, bio-tech, municipal infrastructure and all genres of gaming from web 2.0 through four dimensional, real-time environments that integrate scanned objects and cultural artifacts.

This impressive record has left an important message track: no matter how talented the design team, it is critical to work collaboratively to represent what is imagined in someone else's mind. Perfect vision is difficult, if not impossible, to achieve. This difficulty is compounded when the vision like that for Changing The Change, is to influence change in multiple minds or stakeholders; however, as we have demonstrated in our project for the Mississauga City Summit, a practised multidisciplinary team can come close.

2. Background

When Summit leaders approached Sheridan's Visualization Design Institute last summer to help them realize their "the vision" for the city's future – a vision that would stimulate dramatic change in civic policy and planning, they had a few short weeks and no budget. Nevertheless, we were able to create a deceivingly simple solution – a collaboration tool that adapted, combined and "mashed-up" existing technologies with new relevant, "on-the-message" content produced by both professionals and amateurs. This achievement relied on three factors:

- the considerable creative and technical resources of an experienced design team comprised of artists and programmers with complementary skills;
- the willingness of summit leaders to experiment and take risks and;
- the enthusiasm of summit participants to play a serious game.

Summit Vision: An Urgent Proposition

Summit leaders needed a way to stimulate discussion among influential civic and industry leaders who in the course of one day were to reach consensus on issues of importance to their city and to carry that message forward to their community.

Their sense of urgency was for good reasons. Mississauga, located west of Toronto along Lake Ontario, is a suburban sprawl whose citizens' lifestyles once consisted of single family homes supported by the requisite car. But this is changing. The cost of energy is soaring. Crude oil prices are up 40 per cent already this year and even though the city is mobile and booming with 80-90 thousand commuters driving in and out every day there are concerns that any economy overly dependent on fueling the individual vehicle is unpredictable and may not be sustainable. According to the city's official web site, roads and transit are at their capacity during peak hours, creating air pollution as well as traffic congestion. These issues were reflected in the three Summit themes: energy, economy and society.

Fig. 1 Mississauga traffic at peak rush hour

Immigration and mobility patterns have seen the city become one of the most culturally diverse in the world. In March 2008, the city's Commissioner of Planning and Building reported that based on Canada's 2006 Census, "the immigrant population represents 52% of Mississauga's population… (whose) mother tongue that is not one of the two official languages;" e.g. English or French. More than half of Mississauga's immigrants are from Asia and the Middle East. The Commissioner identified the need for newcomer services and housing affordability and intensification for this diverse new population.

The Visualisation Design Institute's solution for the Misisssissuaga Summit in 2007 also works in the context of Changing The Change. In both cases, the challenge, "the vision," is to discover how design can create change towards a sustainable future. Our practical solution, due to the short time line and diversity of the audience, was to adapt a social networking application, an ideal method to facilitate the change in a mass audience. Our premise – that incenting change works better through collaboration – still holds true. We will use it as our touchstone as we move forward with an ambitious new visionary project in collaboration with Mississauga to create a Digital Corridor.

3. Rationale

Mississauga Summit leaders inspired by the Creative City Network Conference held in Toronto in the fall of 2006, recognize that in this time of massive social and environmental change it is critical to act now to sustain their city's economic advantage and citizens' wellbeing and quality of life.

Toronto is five years into a ten-year action plan to use its arts, culture, and heritage assets to position it as a global cultural capital – to incent a creative economy through the leadership of urban theorists such as Meric Gertler, Project Director of "Imagine a Toronto…Strategies for a Creative City" and Richard Florida, author, proponent of the "creative

class" and now Professor of Business and Creativity at the University of Toronto's Rotman School of Management. Both cities are located in the province of Ontario whose overall goal is to transform the economy from its reliance on light industrial and automotive industries through innovation to one based on knowledge and design through innovation. In fact, the province has a dedicated Ministry of Research and Innovation founded by the Premier. Mississauga has Hazel.

Hazel McCallion is Mississauga's 87-year-old mayor who has held office for 30 years. Early in her tenure, in 1979, Mississauga was the site of a train wreck involving explosions of dangerous chemicals, chlorine and propane necessitating at that time, the largest peace time evacuation of more than 250,000 residents. It is not surprising that Hazel's Mississauga has prioritized infrastructure and mass transit. In the mayor's own words on her web site, "I encourage you all to get out of your cars and onto Mississauga Transit."

Rather than a creative clusters model like Toronto, Mississauga's Summit leaders envision a competitive business ecosystem that is networked but extends beyond one industry or type of industry; e.g. the creative industries. The city's official web site claims home to 50 of Canada's Fortune 500 offices. Local industries and organizations represented at the summit ranged from information and communication technology to biopharmaceutical to social services such as hospitals. More than 100 industry, academic and civic leaders attended including university and company presidents, senior urban planners, municipal and federal government representatives and executive directors from arts, multicultural councils and social and health care agencies.

This sets the scene for Mississauga's Summit, establishes who was in the room and sets the challenge to create a design catalyst enabling such a diverse group to reach consensus. Here are three key considerations that influenced our choice of the mashup tool:

- the popularity and power of social networks, especially in the greater Toronto area;
- do not build what you can borrow;
- the ready availability of a web 2.0 widget.

4. Tool Selection

From the perspective of an applied research institute we had to arrive at a practical solution working from known rules:

- Rule One: Social Networks Are Popular And Powerful

The Toronto area ranks as one of Facebook's largest user groups boasting more than half a million people or ten per cent of the population, according to a report on the CTV news web site in May 2007. As practical designers, we could leverage this network both at the front end by modifying a widget or small application tool designed to enable amateurs to create content for social networks – and at the back end by using it and other web based communications to disseminate key messages virally.

Facebook arguably is part of the game paradigm and we were counting on the mashup to engage summit participants to discuss and reach consensus on issues in the same way that players of massive multiplayer online games draw on the energy of many minds to win. Psychologist Nicole Lazarro who is internationally recognized for her expertise in player experience in games, describes the collaborative capacity of social networking as a kind of "social calculus." Speaking at the 2008 Games Developer's Conference in San Francisco, she described how the "Poke," the Facebook widget that lets users get their friends' attention has been augmented to create the super successful, "SuperPoke." According to Lazarro, the model for social network design is: "One application designed by committee at any one time. If you don't get it right, millions will not come."

The Visualization Design Institute was aiming to create a SuperPoke. Among the hundreds at the Mississauga Summit, we had one chance to get it right.

- Rule Two: Don't Build What You Can Borrow

The design team proposed to adapt a beta stage web 2.0 tool developed by iBloks based in San Francisco, California. The iBloks tool demonstrated in June 2007 at the Under The Radar, Entertainment & Media Conference in Mountain View, California, was designed primarily for the advertising market as a tool to self-serve rich media. It targeted companies who want to maintain a fresh, updated online presence by providing an easy way to cut, paste and load proprietary media assets such as still images, logos, music and audio clips to create a simple, user generated "movie." The client could do this without relying on a professional ad agency or web development team. Since then, iBloks has modified their product for their target market.

Summit leaders were not easily convinced. They had envisioned a conventional movie that would inspire multiple "Aha" moments; however, the Institute's team experience is in creating three dimensional immersive environments involving interaction. Put simply, the design discussions centred on issues of:

- Technology: push versus pull;
- Originality of content: professionally produced versus hybrid professional and user generated.

Credit goes to Summit Co-ordinator Maureen Latocki who saw the potential of the proposed application and was prepared to take a risk and graciously bridged these two disparate visions.

5. Collaborative Design Theory

These discussions reflect ongoing dialogue and design questions of importance even to the applied research practice. For instance, whether in a design economy, amateur content, or hybrid amateur/professional content, is less creative than professionally produced content. Or whether technology is less valuable because by it is mashed-up or combined with other software and technology and not necessarily patentable. New creative and business models involve considerable risk. Likewise, design that opens up to user generated content is unpredictable as well as powerful.

Evidence of this is collected through several blogs maintained by Bill St. Arnaud, Senior Director Advanced Networks for CANARIE Inc., Canada's Advanced Internet Development Organization. He tracks collaboration efforts ranging from the arts to politics. For an example of a successful art collaborative, a film, his blog post on billstarnaud.blogspot, May 8, 2008 describes:

- Wreck A Movie, a new initiative by Finland based Star Wreck Studios creators of the world's first feature-length collaborative Internet film, Star Wreck: In the Pirkinning released in 2005 has more than 8 million global downloads.

According to St. Arnaud: "This niche film with Hollywood quality special effects, subtitles in 30 languages (was) all made in collaboration going against every industry standard and for only 15000 €… With today's technology, people cooperating across the Internet and now instant global distribution, the crew of 5 and 3000 of their friends across the globe proved the old model of film making and watching is not the only way. The success opens the door for any niche film to get made and then seen by millions."

St. Arnaud also is a believer in next generation democracy. In his May 1 blog post on next-generation-democracy.blogspot he predicts that "Wikis and web 2.0…have the potential to fundamentally transform the way we are governed and radically reshape political philosophy," by allowing people to track their tax dollars so that they vote on the services that are most important to them or through "personalized behaviour."

In the business context, Forrester has predicted a dramatic increase in business spending on web 2.0 applications or “Enterprise 2.0” according to analysis by Sarah Perez on the ReadWriteWeb blog, April 20, 2008.

Just as the Mississauga mash-up identified the importance and effectiveness of mash-ups among Sheridan’s student population and extrapolated it to a conference setting, Forrester predicts that Web 2.0 is ready to graduate from "Kids' Stuff.” According to the ReadWriteWeb blog post: “Right now, it's people between the ages of 12 and 17 that are the more avid consumers of social computing technology, with one-third of them acting as content creators. Meanwhile, only 7% of those 51-61 do the same. However, this is another trend that is going to change over the next few years. By 2011, Forrester believes that users of Web 2.0 tools will mirror users of the web at large.”

6. Design Process

Once the direction was green lit, artist Jonathan Eger rendered an idealized visualization, or representation, of Mississauga’s city hall as a backdrop, or digital canvas. Programmer Matthew Rogers combined the iBloks movie-making widget with several other softwares, then loaded media assets relating to the Summit themes; for example, images of traffic, local green spaces and social services such as hospitals along with music by local artist Gurpreet Chana.

A partial list of software deployed (all under academic licence):

- 3D Studio Max
- Maya Unlimited
- Adobe Creative Suite 3
- MSDN Premium
- Sony Sound Forge 9
- Visual Assist X
- Nero
- Quicktime
- WinRar
- EditPlus

A group of 24 people without specialized computer knowledge was trained to use the tool to ensure the technology would facilitate rather than impede discussion. The training took 30 minutes. After internal trials using the media assets alone, programmers retro-engineered a Microsoft word pad into the collaboration tool. They programmed the tool onto laptops that Summit participants including Mayor Hazel McCallion used in breakout sessions to visualize and brainstorm solutions.

Break out session participants use the word pad to create their collaborative narrative or mash-up story before layering in the media assets in cut and paste mode. A mouse click automatically generated a dynamic movie that each table could share with those at other tables. Participants took home their personalized “mash-up” movie on a memory stick so that their collaborative solutions could be communicated virally to those who did not attend the Summit; for example, their children so savvy in social networking.

Fig. 2: Mississauga Mash-Up Tool Created by the Visualization Design Institute Team

7. Execution

Here is a summary of observations by the design team:

- Participants were focused and engaged when their presentation/movie was being played.
- Many people, including high ranking CEOs and the mayor of Mississauga were impressed with the quickness and efficiency with which their ideas were converted into their own custom movie.
- After seeing the presentation, some participants assisted in creating the next iBloks movie when the second roundtable discussion concluded.
- Some roundtables were going above and beyond what they were trained to do; they were exploring the program and using it in ways we did not even think of.
- Participants voluntarily returned to the roundtable hall to pick up USB keys with the iBloks tool and their three presentations. They were excited to try it for themselves at home.

And here are first person observations by Summit Co-ordinator Maureen Latocki: “I spent the entire Summit day in the Idea Incubator room so was able to observe what occurred including people’s engagement during the three sessions. What I observed and what I heard from many throughout the day was the high level of energy in the room. I believe the use of the technology had a lot to do with sustained interest in the three conversations. People kept coming back to see the mash-up of their ‘big’ ideas.”

8. Results

There are several ways to measure the impact of the Visualization Design Institute's design solution for collaboration among summit participants including:

- Anecdotes: "buzz" in the room indicated engagement of participants who took their movies home via a USB memory stick to distribute to friends and family;
- Awards: Mississauga's mayor presented the Visualization Design Institute with an award for its role
- Surveys: participants ranked the break out sessions at the top of the list of Summit highlights;
- Media coverage: A *Toronto Star* article on September 26 was headlined, "Transportation stole the show," citing as proof that the city's transportation commissioner, "was shocked at how the issue took over roundtable brainstorming sessions at the Living Arts Centre in Mississauga, between panel debates and moderated discussions."

Sustaining the momentum of the summit and Sheridan's relationship with Mississauga, the Visualization Design Institute, working with representatives of Mississauga's Office of Arts and Culture and Bus Rapid Transit Offices, have developed a proposal to the Ontario government to develop the Mississauga Digital Corridor. The Digital Corridor is an exciting, ambitious project that the potential to transform the city by making a major contribution to its sustainable future. The Mississauga Digital Corridor will promote energy efficiency, clean technologies and products:

- Wireless connectivity is planned as part of the rapid transit communications infrastructure.
- This project creates the potential to extend free wireless already in Mississauga's public institutions—such as libraries – to commuting public citizens.
- The Visualization Design Institute will develop and deploy software (typically used in entertainment) to communicate relevant content in visual formats instantly understood and managed by the citizen on the move. Such content could include public data; e.g. weather information, traffic forecasts and local social/health events as well as entertainment.

Such features of the Mississauga Digital Corridor will, like the Summit mash-up, engage diverse citizens to interact with or "visualize" their journey on the new Bus Rapid Transit System. The goal is that by enriching the journey more citizens will opt for public transportation and take the mayor's advice "to get out of (their) cars."

Activities will take place first in the Institute's lab and immersion studio and then extend to the Mississauga Bus Rapid Transit creating a distinctive research test bed within the Digital Corridor. Each unique technological innovation and related visualization can be a demonstration project on the commercialization track with measurable outcomes. The ultimate goal is to advance digital media through technology and design innovations that that go beyond current point and click – cut and paste to explore various modes of interacting – step, jump, wave – move your body, use your muscles, your nerves and senses to generate joyous and precise engagement – to give meaning to the journey.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

sermons in stones

argument and artefact for sustainability

Stuart Walker[1]

Abstract

This study focuses on the values, priorities and arguments needed to advance 'design for sustainability'. It critiques conventions related to innovation and technology and offers an approach that emphasises minimal intervention, integrated thinking-and-doing, and particularities of place.

These themes are discussed in relation to sustainability and clarified through the design, production and use of a simple object that is, essentially, a symbolic sustainable artefact. Although fully functional, its usefulness in contemporary society could be seen as marginal.

Its contribution as a symbol of an alternative direction prompts us to consider aspects of our humanity that are beyond instrumental approaches. It challenges initiatives that fail to question the underlying values and social drivers that affect how we act in the world.

Introduction

> And this our life exempt from public haunt
> Finds tongues in trees, books in the running brooks,
> Sermons in stones and good in every thing.
>
> William Shakespeare
> As You Like It, Act II, Scene I

Changes in our modes of living, away from our highly consumptive lifestyles and towards ways that are both preferred and less damaging, will require not only changes in our activities but also a shift in our attitudes, values and priorities. These issues are considered in terms of the need for, and qualities of, such a shift, and what they imply for our approaches to product design and production – which is illustrated here through the design and creation of a symbolic sustainable artefact.

The discussion begins with a consideration of the dominance of technology in contemporary society, its relationship to sustainability and some of the concerns it raises; this is a question of emphasis and balance. The links between technology, consumerism and growth are discussed, along with the promises of capitalism and our notions of progress. An alternative perspective is proposed based on 'being' rather than 'having', which is rooted in long-standing philosophical and spiritual traditions. This places 'sustainability' firmly in the here and now - rather than viewing it as a goal to work towards in the distant future. The relationship between changing our activities in the world and 'inner' change in our attitudes and perspectives is related directly to sustainability and linked to the role of 'the local'. These concepts are then translated into a set of considerations for the product designer and applied through the development, design and production of an illustrative functional artefact. The result is a sustainable object, and the issues it raises offer a basis for re-thinking many of our priorities and approaches to product design. Thus, the process of creating the object and the object itself both serve to inform the discussion and throw light on the relationship between functional objects and sustainability.

Techno-Utopia

One of the most emblematic features of our current age is the prominence given to technological development. It commands enormous efforts, resources and investments in our universities, in private corporations, and in government priorities. Advanced technology fills the homes, cars and even the pockets of most people living in the affluent countries and, increasingly, in the less-economically developed countries. It is seen as a major factor in wealth creation, jobs, security, competitiveness and progress, and has become virtually synonymous with the term 'innovation'.

The development of technology is strongly linked to the potential for profit through the manufacture of consumer products – which in turn is linked to resource and energy use, waste and pollution and, all too often, social injustices. Hence, technological research and development are not neutral activities but are, in many ways, significant aspects of the 'sustainability' question; the term sustainability referring to the now familiar three-pronged relationship between social, environmental and economic issues.

Advanced technologies have brought enormous benefits to many areas of our lives – from medical research to communications, and some new technologies help

reduce environmental impacts by offering more energy efficient solutions and less polluting products. However, it must also be acknowledged that the emphasis given to the development of consumer goods based on advanced technologies, and their consequent production and global distribution, is creating very severe environmental problems together with many social injustices and inequities (e.g. Waste Online, 2008; Cafod, 2008). Therefore, if we are to seriously address the challenge of sustainability, it will be important to consider the emphasis placed today on the development and proliferation of such consumer goods; goods that quickly become discarded and replaced because of the speed of technological advance.

Furthermore, technological research and development tend to be well supported by government (i.e. taxpayers') funds through research councils and regional development agencies (Guardian, 2007). When preferential support is given to science and technology over, say, the arts and humanities (in the UK by a factor of over twenty to one[1]), based on a rationale of creating competitive advantage, growth, jobs and wealth then, despite the benefits, there arises an imbalance in our priorities and our efforts – one in which instrumental value is favoured over intrinsic value.

Unsustainable Development

The relationships that exist between technological development, short-term government agendas (i.e. jobs equal votes), and the production of short-lived, hi-tech consumer goods, all serve to encourage consumerism and reinforce a fundamentally unsustainable system. It is irrational to think that we can reduce our environmental impacts and advance social and economic wellbeing, equity and justice (i.e. conform to the principles of sustainability) through unbridled development of more and more increasingly sophisticated technologies. Within a free market, capitalist system, investment in R&D is only justified if it is likely to turn a profit in the future. This invariably means the commercialization of the technology through saleable products, often in the form of mass-produced consumer goods, which, in turn, intensifies environmental damage and is frequently associated with social exploitation. This route to economic prosperity and societal wellbeing is based on:

- the fallacious, increasingly precarious and damaging ideology of *continuous growth* - in production and consumption - and hence, too, in resource and habitat depletion, pollution, waste and human exploitation (see Korten, 2001, 43-56)),

- the misguided attempt to attain happiness through ever higher material standards of living, and

- aggressive competitiveness within a global economy.

To continue to pursue such methods only maintains the same kind of thinking that has characterised the past century or more. This is not innovative thinking, it is just the same thinking applied to the continuous development and production of ever new, often trivial, consumer goods. At one time it may have been justified to produce any and every kind of product we could imagine as long as it created wealth and jobs. Today, however, the cumulative impacts and harmful effects are only too evident, making the continuation of such practices increasingly difficult to justify. However, the messages of marketing persistently tell us that we need, indeed deserve, these technological 'marvels', and the shrewd talent of the advertising industry is to even turn critique of consumerism into persuasive advertising copy. A recent collaboration between the U.K. department store Selfridges and American artist Barbara Kruger is

one example (Douglas, 2006), where in-store banners boldly proclaim, “Buy me, I’ll change your life” and “You want it, You buy it, You forget it” (Fig. 1). Similarly, the U.S. auto manufacturer Hummer, which has received criticism for its oversized vehicles aimed at the consumer market, launched a TV commercial that focused on a man buying vegetarian produce who is later seen at the wheel of a Hummer, accompanied by the line “Restore the Balance” (Hummer, 2006). By employing irony and humour, such examples demonstrate the infinite adaptability of capitalism, which allows it to undermine virtually any form of critique (Miller, 2005, 2).

Of course, a major objective of commercial corporations is to create and continually grow shareholder profit**,** and technology linked to consumerism has become a primary means for creating such profit. Governments usually support this, seeing it as positive for the economy. However, despite the plethora of ‘green’ rhetoric that emerges from corporations and governments alike, approaches based on continual growth in consumerism, resource use and energy use are clearly at odds with any serious understanding of the term ‘sustainability’.

Flawed Perfection

When manufacturing is combined with marketing the result is often a technocratic version of societal wellbeing. The implicit message is that some kind of future Utopia of sustainable perfection is actually attainable, where our environmental and social problems will be solved through the ingenious application of advanced, super-efficient, non-polluting technologies. Such a notion is clearly idealistic, patently false and flies in the face of both logic and the teachings of all the major philosophical and wisdom traditions down the ages. Yet, the unerring message of corporate commercialism is, in effect, that this product or that service will fulfil your dreams and make you happier.

These flawed notions are being taken ever further as corporate interests remorselessly create dissatisfaction and stimulate desire – from the gaudy trappings and superficial ‘splendours’ of the modern shopping mall (Figs. 2-4) to the increasingly exclusive and outlandish goods and services on offer. Both are meant to appeal to our vanities through their suggestions of elitism and status. At a recent conference of the Industrial Designers Society of America (IDSA, 2007) keynote presentations included a high performance electric sports car (Straubel and Hatt, 2007**;** Tesla, 2008) and the planned commercialisation of space tourism (Seymour, 2007**;** Virgin Galactic, 2007). While a high priced electric sports car may appear to address concerns about auto emissions, the problem is simply transferred from the exhaust pipe to the electricity generating station, which could be coal fired – creating carbon emissions; nuclear – creating a radioactive waste problem; or hydro – creating an environmental impact problem. Such exclusive products do little to seriously address environmental concerns but they do serve to stoke our desires and maintain our addiction-like behaviour towards consumption (de Graaf *et al*, 2001; Badke and Walker, 2008). They also bring with them their own problems. In this case, for example, no mention was made of the relatively short life or the disposal problems associated with thousands of batteries. The space tourism presentation concentrated on the ‘experience’ being offered – the excitement of acceleration, three or four minutes of weightlessness, the views of the earth and the stories to tell your grandchildren.

Such thrill rides, whether in a sports car or a space craft, have little to do with fostering meaningful notions of contentment; instead they offer a false notion of happiness based on consumption. While such aspirational products, available only to

the few, may cultivate vanity, envy and discontent, the proliferation of less expensive products creates even broader problems. For example, the recent launch of the world's cheapest car, by Indian automaker Tata, (2008) will help further transform India into a high consumption society.

These kinds of products and services exacerbate already severe environmental problems – directly through their contribution to cumulative effects and indirectly through the dissatisfaction and cravings they foster.

Philosopher Charles Taylor explains that a particular characteristic of the modern, secularised worldview is that 'meaning' is sought through self-realization, which is based in concepts of progress, reason, freedom etc. He says that unlike in previous times, where meaning was found in higher or transcendent understandings, in the modern world a sense of meaning in one's life is based in the idea that individual efforts can contribute to human progress across time. Thus, human efforts related to advancement and material progress have become central to contemporary notions of 'meaning'. Criticism of this relatively recent idea is rooted in the fear that it yields only meaninglessness, either through an unexceptional sameness, a 'levelling down' of humanity or that the denial of the transcendent results in vacuousness – the threat of an empty life, inspiring "nothing but ennui, a cosmic yawn" (Taylor, 2007, 716-717).

Between the idea
And the reality
Between the motion
And the act
Falls the Shadow

T. S. Eliot,
The Hollow Men, (1925, 91-92)

Progress, Meaning and Unsustainability

This highlights some of the most fundamental problems associated with our contemporary efforts to address sustainability. Modernity, with its ideology of progress, sought to advance human happiness, meaning and fulfilment through industrialization and the consumption of material goods. Its rationalizations led to a severe attrition in traditional sources of meaning in most of the economically developed countries of the 'west' and, as Northcott has pointed out, the imposition of this ideology on developing nations, through institutions such as the World Bank, has led to environmental and social destruction on a massive scale (2007, 175-177). Joseph Ratzinger, Pope Benedict XVI, has expressed a similar view, "The aid offered by the West to developing countries has been purely technically and materially based … It has thrust aside indigenous, religious, ethical, and social structures and filled the resulting vacuum with its technocratic mindset" (2007, 33). Moreover, it is important to recognise that there is no evidence to support the implicit assumption of modernism that technological and material advancement is accompanied by moral progress – the industrialized genocide of WWII and the consequent advance of technology for arms development belie any such claims (Armstrong, 2006, xi).

Challenges to the assumptions of the modern view gave rise to postmodernism. On the one hand, this holds the promise of a renewed sense of meaning, through its apparent tolerance of diverse forms of expression, including religious expression and the acknowledgement of meaning via the transcendent. On the other hand, it couches religion, along with other forms of expression, in relativism,

thereby denying any claims to universal truth or authority (Beattie, 2007, 132-136) and rendering them banal and ineffectual; a factor that is not unrelated to the rise of fundamentalist reaction, both religious and secular (*Ibid*, 139).

The undermining of modern assumptions about progress and the relativism of post modernity has contributed to the emergence of what Beattie calls the "voracious consumer" who constantly seeks "novelty, innovation and change" (*Ibid*, 133), but who, in lacking a sense of overall meaning and purpose, is highly vulnerable to the persuasive messages of corporate marketing where meaning is always to be found in the *next* purchase.

Having or Being

Neither modern notions of progress in general, nor technological progress in particular, can claim to have brought us closer to more sustainable ways of living; in fact, the evidence points in the opposite direction. Similarly, the multifarious and confused concerns of postmodernism mean that calls for more sustainable directions, for limiting the emissions associated with climate change, and for improvements in social equity and justice, emerge from the very same government and business leaders who simultaneously espouse the mantra of growth and free trade and who, to achieve these goals, effectively promote "voracious consumption". There are inherent contradictions in such messages, and in the perplexities created we simply continue our frenzied stripping of the planet. In the affluent countries especially, human wellbeing has become synonymous with the accumulation of products, and as people increasingly associate their sense of identity with what they own, rather than who they are, "*having* takes precedence over *being"* (Northcott, 2007, 186). When this is accompanied by a sharp rise in 'entertainment' products, as has been the case in recent times, then acquisition is combined with ever greater opportunities for distraction and atomization – further eroding a reflective sense of self within a larger, meaningful social context .

An emphasis on *having* rather than *being* and the dangers it holds for our welfare is echoed by theologians such as Williams who says, "There is something about Western modernity which really does eat away at the soul" (BBC News, 2007). Similarly, the philosopher De Botton has said, "Our minds are susceptible to the influence of external voices telling us what we require to be satisfied, voices that may drown out the faint sounds emitted by our souls and can distract us from the careful, arduous task of correctly tracing our priorities" (2004, 201). Hence, the cult of 'progress' and opportunities for distraction from reflection, self-knowing and the search for meaning have become key features of our contemporary age. Both are linked to acquisitive lifestyles and, thus, to un-sustainability.

Universities are not immune to the rhetoric of the times, indeed, as governments impose increasingly prescriptive measures on university research budgets, they have little choice but to toe the line if they are to secure research funding. Two recent university marketing strategies proclaim, *"It's not where you are, it's where you're going"* and *"It's not where you are, it's where you want to be"*[2]. Such slogans parallel commercial agendas that foster dissatisfaction with the 'now' by emphasising the potential and allure of what's coming 'next'. These are unfortunate messages to be sending out to young people about to embark on their university careers – education is promoted as a means to some other end, rather than having merit as an end in and of itself. It is marketed solely as a ticket to a good job rather than for a love of learning. Such messages implicitly denigrate the value of the present, of living fully in the here and now. They also demonstrate how insidious the

ideologies of our age have become – because if there is one institution in our society that should be examining, challenging and critiquing such assertions it is our universities. As Chesterton once put it, “It is always easy to let the age have its head; the difficult thing is to keep one’s own” (1908, 103)

Another Voice

Those who tell of a different way tend not to be politicians, business leaders, economists, or technologists, but poets, artists, philosophers, and those dedicated to more spiritual pursuits. This alternative path is represented in the Long Now project of artist and musician Brian Eno *et al* (Eno 2001; Long Now 2008); in the traditional religious understandings of the ‘eternal now’ spoken of by the Benedictine monk David Steindl-Rast (Steindl-Rast and Lebell, 1998, 7); it is alluded to in paintings such as *L’esperança del condemnat a mort 1-111* by Joan Miró (1974); and in the words of Longfellow when he writes:

> Trust no future, howe’er pleasant!
> Let the dead past bury its dead!
> Act – act in the living present!
>
> H. W. Longfellow,
> A Psalm of Life, (1981, 189)

Emphasis is placed on living fully in the reality of the *present*, rather than constantly anticipating or yearning for the *next* thing.

This suggests a rather different way of understanding sustainability - not as some future way of living we must strive towards, but as something to address now - in our attitudes, thoughts and actions as individuals; in our *being* rather than our *having*. It challenges our assumptions, our desires and our behaviours. Living fully in the ‘eternal’ present is not about momentary thrill rides or continual consumption. As such, it represents a significant change in priorities and values. Undoubtedly, without such an ‘internal’ change we will be unprepared and unwillingly to make the necessary systemic changes that are required; changes that could steer us away from our current highly consumptive and destructive behaviours. Indeed, if our contemporary modes of living are environmentally unsustainable, then sooner or later we will have no choice but to change. However, without a shift in priorities and values such enforced change will be viewed as a continuous imposition of undesirable deprivations that inexorably impede our progress towards our still-desired but increasingly elusive lifestyles.

Sustainability: Values and Localization

Sustainability does not simply represent a problem ‘out there’ to be fixed – through new technologies or legislation or policy. Without a clear sense of inner purpose and meaning such ‘external’ activities can, and do, create a host of contradictions. External change has to be accompanied and steered by inner change. As Armstrong has said, “Unless there is some kind of spiritual revolution that can keep abreast of our technological genius, it is unlikely that we will save our planet. A purely rational education will not suffice” (Armstrong, 2006, xi).

Realistically, we cannot hope to reduce environmental degradation if we are not also prepared to reduce our levels of consumption. This is only likely to occur if we can develop other ways of finding fulfilment that also provide for economic confidence and security. For such change to occur, we need to consider what it

means to prioritise *being* over *having*, and the effect this might have on our ways of living.

Such notions are anything but new. Emphasis on living fully in the present, or "being", has always been a principal teaching of the world's major philosophical and spiritual traditions. These traditions - from Lao Tsu to Thoreau and from Socrates to Gandhi – not only speak of inner development through selflessness and rejecting ego-centric desires, they also teach that concern for wealth, status and possessions hinders 'inner' growth (e.g. *Phaedo* by Plato, Tredennick and Tarrant., trans., 1954, 125). They are therefore completely consistent with contemporary sustainability concerns related to the damaging effects of consumerism. These teachings, however, could not be in starker contrast to today's corporate messages, see Table1.

Despite their wisdom and their relationship to inner development, the 'narrow path' of which these teachings speak (e.g. Mascaró, 1965, 61) has always been sidelined in the everyday busyness and business of society; striving for worldly comforts, distractions and personal gain too often take precedence. In the past, the effects of such behaviours on the planet itself were relatively minor, even though they may have been socially or personally harmful. However, this is no longer the case. The drastic rise in urban populations over the last century, accompanied by massive growth in industrialization, mass marketing and mass consumerism, have contributed to environmental impacts that in recent times have become alarming in their implications[13].

"…because the financier's sun
is not Blake's sun, there is a
word missing from the dawn chorus.

R. S. Thomas,
Mass for Hard Times, (2003, 233)

Thus, the teachings of the traditional wisdoms represent many essential considerations for sustainability: focussing on the present, rather than being preoccupied with the future and the 'next thing'; reducing acquisitiveness and consumerism, rather than constantly desiring more; being concerned for the welfare of others, rather than the self-oriented focus that is encouraged by corporate marketing. Furthermore, giving greater importance to *localization*, which is also a significant element of sustainability, ties-in well with these traditions.

Firstly, 'the local' addresses that which is proximate. Consequently, people become more directly aware of the impacts of their activities on their environment, and there are obviously individual and communal benefits in looking after one's own local environment – to ensure an attractive and healthy place to live and work.

Secondly, through direct encounter at the local level we are less inclined to objectify other people. When we fail to see and treat other people fully as people, but think of them as 'consumers' or 'labour', then we help create 'the other'. When this happens it represents a failure to empathize. Globalization would seem to exacerbate this tendency because of physical distance or differences in language, class, ethnicity, religion or skin colour. We may hear about exploitative labour practices 'over there', in countries such as China or India that manufacture goods for the affluent western nations, but the physical separation also distances us mentally and can lead to objectification and the acceptance of practices and conditions that are inequitable, unjust and that we would not be prepared to tolerate ourselves. While certainly not impossible, it is more difficult to objectify people with whom we have direct contact - our neighbours and colleagues, and the people we encounter in our

everyday lives. Therefore, in addition to efforts that seek to reduce human exploitation in developing countries, a shift towards greater localization in manufacturing would encourage direct encounters and therefore practices that conform to the sustainable principles of social equity and justice.

Thirdly, focussing on local practices, activities and solutions can rein in our tendency to consider sustainability as something to be worked towards - as something to be achieved *in the future,* where there will no longer be inequity and injustice or environmental degradation; this is Utopian and counterproductive. We are obliged to act in the present, to challenge our destructive norms and to develop practices that lead away from environmentally and socially damaging conventions. Irrespective of some future condition, each one of us, in our activities in the present, should be contributing constructively within our own sphere of impact – and with the understanding that the notion of 'the local' may vary considerably from one individual to another, depending on one's role and contribution.

A shift towards greater localization would, for the reasons outlined above, mean that the price of consumer goods would better reflect their true costs. The people making the goods would be receiving a living wage and working in decent conditions, and it would be in everyone's interest to ensure that environmental standards were upheld. Thus, it seems that a shift towards localization would encourage those attitudes and behaviours spoken of in the world's great wisdom and spiritual traditions and, in the process, would better address many social and environmental principles,

Artefact: a symbolic sustainable object

The potential difference these concepts might make in the field of product design becomes clearer if they are made more directly relevant to the design process. Therefore, this present study includes the creation of a functional object. The design and production processes and the artefact itself serve to embody and exemplify the principles being explored; the aim being to effectively encapsulate the *general* concepts and ideas discussed above within the design and creation of a *specific*, tangible object.

The practice of design is itself a form of inquiry that connects 'thinking' and 'doing' within an iterative, mutually informing process. Therefore, the creation of a physical artefact, which emerges from and contributes to the ideas, can bring an important design-centred element to our understanding of the issues.

A number of design objectives can be identified from the foregoing discussion,

- The functional benefit of the object should be consistent with or contribute towards the shift in values that have been described, including a shift from *having* to *being* and an emphasis on the present. It should contribute positively towards a reorientation in priorities – away from those that maintain a socially harmful and environmentally damaging production system, that tend to concentrate economic gains, and which encourage dissatisfaction, consumption and waste, and towards those that are in accord with the ethical and sustainable principles of socio-economic equity and justice and environmental responsibility.

- The object should be capable of being produced wholly or partly at the local level by making use of the materials and skills readily available within a place, and with a minimum use of energy resources.

- The environmental impact of the object during its creation, use and post-use should be negligible. Its concept as a thing, its materiality, its process of production, its function, its use and its disposal should all be entirely consistent with the ethos of sustainability.

Thus, the goal is not simply to achieve an object that *aims towards* sustainability by reducing its impacts compared with other similar objects but which, itself, still has a negative effect. Instead, the goal is to produce something that actually is *a sustainable object* in its very conception as a thing. This means it must be sustainable not only in its mode of creation, its function, its aesthetic and in its eventual disposal, but also in the way that its presence and use contribute to positively developing and reinforcing an attitude of sustainability.

Several other factors were considered in the development of this illustrative object:

- The place that was to yield the object had to be proximate to where I, as the designer, was living and working – i.e. it had to be local to the designer.

- The determination of what the functional object was to be, and its specific definition, would be a result of combining a familiarity and consideration of place with the factors related to purpose, materials and skills discussed above.

- An emphasis on the fitness or aptness of the object to 'purpose-and-place' overrode other factors that might be important in a contemporary design practice. Commercial viability was not a factor; the purpose of the project being to further academic inquiry and to be illustrative.

- Novelty and originality were not considered to be important and were not sought after when deciding on the type of object to be created or when designing its form. Unusual as this may seem, modern consumerism is so strongly associated with and promoted by novelty and so called innovation, that an attempt was made to eliminate such factors from this design project. There are precedents for such an approach. For example, in the creation of the icons of Eastern Orthodoxy the subject of the icon is painted (or 'written', as is conventionally said) by reference to previous depictions, and composition and style are determined by tradition rather than through individual expression (Proud, 2000, 8; Ware, 1987, 38-39).

Bearing in mind these priorities and considerations, the rural area immediately adjacent to my place of work was visited (Fig. 5). It is a place of high moors and deep fertile valleys. The main occupation is farming, and the predominant sight is dry stone walls enclosing pastures filled with different varieties of sheep. Streams and rivers cut through the moor land, with gravel beds and ancient stepping stones, and stone farmhouses and barns stand out on the horizon (Figs.6-9). Research about the area revealed a small cottage industry of rare-breed sheep rearing, together with the spinning and weaving of their wool.

Reflecting on these experiences and findings, and referring to a previous study that looked at objects used as aids for inner development and contemplation, (such as the Buddhist prayer wheel, prayer beads and the Jewish prayer shawl)

(Walker, 2006, 39-51) I was reminded of references to an ancient type of tallying device used for keeping track of meditative sayings or prayers (Schaff, 1886, 367; Schaff, 1889, Ch.32; St Paul, 2000, 24). The 'device', used since the 3rd century, consists of a simple pile of stones. To keep track of the spiritual exercises, each time a saying or mantra is completed, a stone is moved from the pile, to form another adjacent pile. Combining such a device with the local cottage industry of weaving would enable a simple, illustrative, functional object to be produced that would fulfil all the priorities set out for the project.

Revisiting the area, small stones were collected from a stream bed. These were later cleaned and dried and piled in a manner suitable for use as a tallying device. Moving the stones one by one into a second pile prescribed a comfortable 'use' area, which was then defined in terms of specific dimensions. The local weaver was visited and a piece of woven cloth was commissioned, which was to be made from the wool she had spun from the rare breed Teeswater sheep that she rears (Figs. 10, 11). Several weeks later, the cloth, woven on a small hand loom, was ready (Fig. 12). The stones were then placed on the cloth to form the simple 'tallying device', and the artefact was complete (Figs. 13-15).

A Symbolic Artefact

Clearly this object is very simple and its significance as a useful tool for a contemporary audience is marginal to say the least. However, as an artefact it fulfils all the objectives described earlier.

In terms of its function, these types of devices are used in conjunction with meditative practice – which in turn is related to a shift in priorities. Such practices have been carried out in many cultures all over the world for thousands of years. They can be based in religious tradition or they can be entirely secular. Frequently they centre on the repetition of a passage of scripture, a short phrase or even series of meaningless syllables (LeShan, 1974, 67). These practices can lead to greater attentiveness, and freedom from compulsions and cravings (Easwaran, 1978, 11) that are the kinds of behaviours associated with consumerism. Therefore, this type of object is related to the shift in priorities that seem to be needed to counter our susceptibilities to the messages of modern marketing, impulse buying etc. Hence, the conceptual nature of the artefact is consistent with sustainable principles.

In terms of its definition as a thing, its materials, and the manner by which it was produced – these are all intimately related and responsive to locale and the particulars of place. While its actual usefulness may be marginal, its relevance lies more in what it represents, in terms of its concept, its process of creation, and its materiality. It signifies a sort of sustainable ideal because, by conceiving it as an object that is related to a shift in priorities and by intentionally keeping it very simple and local:

- its use is associated with the development of values that are in accord with sustainability,
- it offers an opportunity to employ local people and locally available skills and resources,
- it takes little to create in terms of materials and energy,
- its use produces no adverse waste, and

— at the end of its useful life it can be easily re-absorbed back into the natural environment with no detrimental long-term effects.

In this sense it is symbolic. Even though this degree of sustainability may be unattainable in the creation of most other objects, it provides an example of what a fully sustainable functional object can be.

In addition, the creation of this object demonstrates the ability of the design process itself to contribute to knowledge. It exemplifies well how the experiential process of ‘designing’ can inform our understanding of the relationship between the conceptual notion of an object, its design and production, the nature of the resulting artefact and the priorities of sustainability. In this case, the consideration of aptness to place comes to the fore, which expands and deepens our understanding of 'the local' in the context of manufactured functional objects. It is not simply a case of doing things locally for instrumental benefits - to create local jobs, reduce transportation etc. The difference is also qualitative, aesthetic and cultural. The functional object is no longer an alien artefact that is imposed upon a place. Instead, it is an artefact *of* place, which emerges from a gentle rearrangement of the elements within the local environment – like the art works of Andy Goldsworthy or Richard Long, or the vernacular architecture of traditional cultures such as the adobe houses of the American Southwest, the reed houses of the Marsh Arabs, or the stone cottages of rural England. These vernacular forms, like this ‘tallying’ object, are not concerned with novelty, individual expression or ‘making a splash’. They are quiet, familiar forms based on traditions that are centuries old and processes that have been contributed to by many over time. The resulting artefacts are both refined and apposite and, in many important aspects, they ‘work’ effectively within their social and natural environments.

Thus, ‘the local’ is a critical element of design for sustainability and the nature of sustainable objects. It contributes to important extrinsic factors, such as reducing environmental impacts, and providing work and economic benefit through local employment. However, it also contributes to the intrinsic qualitative and aesthetic aspects of objects, and to the qualitative and aesthetic aspects of the culture in which the objects are produced. These intrinsic factors, so easily forgotten when discussions focus on environmental performance indicators and targets, are vitally important if we are to shift our values and priorities and develop a new kind cultural relationship with and attitude to material ‘goods’.

Table 1: Traditional Teachings and Marketing Messages

Teachings of Philosophers and Spiritual Leaders down the Centuries	Corporate Messages in the 21st Century
"There is no greater sin than desire, No greater curse than discontent" Lao Tsu, ca.500 BC, China[3]	"[The photos] never show the entire car but still arouse desire for something new." Mercedes-Benz, 21st century, Europe[8]
"…those who buy something [should live] as if it were not theirs to keep; those who use things of this world, as if not engrossed in them." St Paul, 1st century, Europe[4]	"Its yellow, white and Everose gold are timeless symbols of prestige and luxury" Rolex Ad, 21st century, Europe[9]
"Our inventions are wont to be pretty toys, which distract us from serious things." Thoreau, 19th century, USA[5]	"With an anodised alumnium and polished stainless steel enclosure and a choice of six colours, iPod nano is dressed to impress." Apple, 21st century, USA[10]
"…present -day industrial society everywhere shows this evil characteristic of incessantly stimulating greed, envy, and avarice." Schumacher, 20th century England[6]	Google's profits were up 17% to $1.21bn (£608m) for the three months to the end of December. Some analysts had been hoping for stronger profit growth and its shares fell sharply in after hours trading. BBC News, Feb. 1st 2008[11]
"Civilization, in the real sense of the term, consists not in the multiplication, but in the deliberate and voluntary reduction of wants." Gandhi, 20th century, India[7]	"Glacéau smartwater the water with all the answers." Bottled Water Ad, 21st century, USA[12]

End Notes

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Changing the Change:

A Fractal Framework for Metadesign

John Wood[1]

Abstract

If designers wish to build an ecological society they will need to participate in a profound political and economic change. Where current democracies are largely 'top-down', manipulative, and choice-based, ecological governance will also need to be 'bottom-up', holistic, imaginative, and co-creative. This paper suggests that we might go some way to achieving this by developing a new profession that it calls 'metadesign'. This is a comprehensive co-design methodology in which the metadesign team also co-designs its frame of reference. The paper's conclusions are informed by some empirical work conducted within AHRC-funded research at Goldsmiths, University of London – 'Benchmarking Synergy Levels within Metadesign' (a Designing for the 21st century Project) that produced more than 80 metadesign tools.

[1] Goldsmiths, University of London. Full professor, maxripple@gmail.com - http://attainable-utopias.org

Introduction

Inspired by the analytical logic of Aristotle, and by the mechanistic reasoning of Galileo, Newton and Descartes, some physicists (e.g. Laplace, 1819 - c.f. Rubino, 2002) believed the world to be totally predictable. And even though this was a dissipative model, it inspired the idea of a 'technologically sustainable' world – i.e. one in which the change need never change. The theory was soon discredited but it still lives on in the modern imagination. If technology can enable us to travel to the stars, we tell ourselves, we may become immortal. Perhaps this is why we have yet to embrace a smarter, more ecological mode of reasoning (Wood, 2008). Mechanistic metaphors, such as 'economies of scale', and 'law of diminishing returns' inform an industrial vision that, like the Aristotlean idea of design, is fundamentally teleological. This is not how Nature seems to work, yet he underlying vision of a prosperous future without end is inseparable from popular terms such as 'sustainable development' (e.g. Brundtland, 1987) and 'sustainable consumption' (e.g. UN, 2007). To be fair, eco-design has sought to resist the mechanistic mindset by reflecting upon lifestyle, as well as products, services and manufacture. However, the paper argues that these approaches are unlikely to work unless they are integrated within a far more holistic and situated (i.e. less Newtonian) politics of understanding. But how can designers join things together again if they continue to be educated, and employed, as profit-enhancing specialists, rather than ecologically and socially-minded generalists?

1. The Big Context of Design

As we all know, in order for our civilisation to survive, designers need to make the world 'greener'. But this also raises complex political issues, as it would include bringing a better quality of life to the world's poorest peoples. Trying to 'make poverty history' could also bring disasterous environmental consequences. At present, twenty cities now have a population of more than 10 million and more than half the people on the planet live in cities. High levels of congestion and urban poverty (around 50%) go hand-in-hand. Intensive urban farming creates health problems, largely because of food contamination and overcrowding. In poor urban communities, although inhabitants consume fewer calories, they spend 30 percent more of their incomes on food than those who live in rural areas. This is not just because of low incomes and the high cost of fuel. In many high-density cities, between 10 and 30 percent of food produce is lost or spoiled because it must be transported over long distances. The obvious way to address this issue is to grow more food in the cities themselves (Wood, 2007:1). This happens already to quite a large extent. At present 200 million urban farmers supply food to about 700 million city dwellers, i.e. one-quarter of the world's urban population. In order to re-design this dysfunctional situation we need a de-centralised system of consensual governance. Designers also need to co-create a discourse that enables everyone to understand things in a more holistic and relational way (Wood, 2007:2). If this does not happen, society's frustration will seriously threaten political stability and world peace. Unless these challenges are met by the relevant agencies, even the wealthy will pay more, albeit indirectly, for problems such as illegal immigration, narcotics, crime, wars and plagues. What has been design's contribution to these challenges, and how can we help, in the future?

2. Why Design Needs to Change

We have had more than 50 years of ecologically aware design, and the world is getting worse. If the current increases in species depletion, atmospheric carbon emissions, and pollution levels are indicators of eco-design's contribution to ecological wellbeing, then designers have

failed miserably. It would be easy to adopt a position of blame, and to argue that they have been too lazy, greedy, thoughtless or submissive to change the change. Although there is some truth in this, it would be unfair and unhelpful to blame designers for population increases and government policies. Nevertheless, this paper argues that designers can contribute a great deal more, but that this would mean asking them to work with systems that are far larger and more complex. How would we achieve this? Governments, industries and educators have yet to harness the full potential of designers as social and ecological entrepreneurs. Since 2005, in order to find ways to reduce mankind's net burden on the environment, our research has sought to expand the agenda and repertoire of design. In a 3-year, AHRC-funded research at Goldsmiths, University of London we have been exploring the idea that specialist designers can work in a higher-level, cross-disciplinary design system that, for the moment, we are calling 'metadesign'. One reason for this is that we are still trained to offer relatively narrow, specialist skills, rather than addressing deeper needs. This has alienated us from our wider economic, social and ecological potential. Many designers feel uncomfortable with ethical aspects of their predicament, but their specialist role makes them too weak to affect positive, radical change. For many designers, positive options may seem remote. Others face what seems to be a 'no-win' situation.

- *If a designer declines the chance to make cars 'greener' he, or she opts out...*
- *On the other hand, making cars 'greener' will encourage more people to drive.*
- *How did designers get into this position, and how can we change this for the better?*

3. The Narrowing of the Design Agenda

This paper calls for the creation of a more comprehensive, self-creating design system (i.e. 'metadesign'). Fifty or so years ago, in the absence of more enlightened, far-sighted policies by corporations and governments, a few eco-designers saw individual, quasi-political activism as the only way to change things. In the early 1970s, socialism was in competition with capitalism, and the idea of 'alternative lifestyles' seemed thinkable, or even feasible. Much of this work addressed the wider social questions of health, energy-production, land-use and global resources, etc. However, after the collapse of the USSR's political economy in 1989, the idea of 'alternative' anything (e. alternative lifestyes, alternative technologies etc.) became far less conceivable, politically speaking. While many saw that a global, expansionist, unified economic order might overburden the biosphere (e.g. Brundtland, 1987), it was also perceived as being too powerful a change to be changed, let alone opposed or dismantled. By the 1990s, while the term 'sustainability' warned that ecological limits would be the ultimate boundary for economic development, we were all being asked to imagine the world as a unified political, economic (and ecological) entity. As a result, virtually all socially and ecologically active designers began to work with, rather than against, the economic status quo. By helping to create the 'consumer society' as we know it, designers were persuaded to ignore the big issues such as social relations, food production and distribution. Consequently, we now know a good deal about how to 'de-materialize' products (e.g. Diani, 1992) or how to make them leaner, cleaner, slower or service-based (e.g. Manzini, 2001) rather than product-based. Nonetheless, these, and the many otherwise excellent innovations are insufficient to reduce the net environmental damage caused by globalization.

4. How Can Designers Change the Change?

How can designers work at a higher strategic level in creating beneficial change? Over the last few decades, many of the most spectacular marketing campaigns would have been impossible without a strongly visual contribution by designers. However, it is hard to imagine what design methods could challenge the stupendous forces of economic growth, unless politicians,

bankers and corporations, rather than designers, would take the primary initiative. Yet designers do enjoy a higher status and greater credibility. Ironically, this is because they have made such an important contribution to economic growth (c.f. Florida, 2002). However, politically speaking, in comparison with architects, designers are a relatively junior profession, and therefore relatively weaker. Moreover, even architects have become subservient to the growing power of capital (c.f. Chipperfield, in Dyckhoff, 2007). For example, the increasing power of property developers and the rise of cost-benefit accountancy methods, short-term efficiencies have encouraged them to focus on point-of-sale profits, rather than long-term benefits for all. At present, the current system of economic regulation and governance is managed largely by fiscal policies, legislation and political persuasion. These operate by enforcing rules and inducements that work within agreed categories and boundaries. By contrast, design works at the level of opportunities and affordances (Gibson, 1982), and how users perceive them (Norman, 1988). In this sense, what we might call call 'design thinking' (Simon, 1969) or 'designerly ways of knowing' (Cross, 1990) works more by positive persuasion, than by censure or negation. In short, unlike the negative tendencies within laws (i.e. by drawing categorical boundaries and imposing penalties) designers can transform the world by re-imagining new ways to live.

- *QUESTION: how big is the carbon footprint of rain?*
- *ANSWER: too big...rain is beautiful, but it makes people drive instead of walking.*

5. The Need for a Metadesign Profession

The retrospective search for 'design activism' in the early 21st century (Julier, 2007) may remind us that design has been almost exclusively harnessed to the needs of business, rather than to the needs of society. This is unfortunate, given the tension between the quest for economic growth and the environmental damage it has caused. It may also make us question why most designers are still educated as amenable specialists, rather than enterprising generalists. Indeed, it has been by acting as mercenaries within this commercial context, that designers have created most damage. This question was one of the main motives for challenging existing models of design practice. There have been several attempts to re-design design, in a way that make it more effective, consensual, distributed, influential, or versatile. These echo what John Dewey (1939) and John Chris Jones (1998) have described as 'creative democracy'. Similar sentiments emerged in the 'Creative Commons' and 'Open Design' movements that offer new potential for social integration, and other benefits. In our research we chose the term 'metadesign' because it is already familiar. The Greek word 'meta' originally meant 'beside' or 'after' but is now also used to imply the possibility of change or transformation, including self-transformation. Although 'metadesign' may describe a preliminary activity that precedes orthodox design it can also refer to a possible design practice that re-designs itself in an ad hoc way. The idea of metadesign therefore acknowledges that future uses and problems cannot be fully anticipated at the creative moment of design. One of our aims is, therefore, to create a non-hierarchical community of designers, and other experts who can seed a new metadesign methodology and profession. Two of the key obstacles we encountered are the prevalence of ego, and the hierarchical tendencies within society.

6. The Currency of Self-identity

It is often argued that western rationality emphasises individual, rather than collective actions. The notion of 'self-awareness' seems to have emerged from a pitilessly competitive (Hellenic) culture in which self-assertion, rather than 'self-satisfaction' was seen as a public virtue. Socrates introduced a more philosophical dimension to self-knowledge when he argued that it is a pre-requisite to knowledge. Much later, where, hitherto, mankind had always believed that ideas come from God, John Locke (1689) advanced the notion that individuals were capable of

originating new thoughts. Between the 16th and 18th centuries, keywords such as a 'self conceit', 'self-confidence', and 'self pity' had emerged, and Coleridge (1772-1834) had coined the term 'self-consciousness'. These ideas also had an impact on the ideology of money. It is hard to think of ‘market forces’ without acknowledging Adam Smith’s famous idea of the ‘invisible hand’ (1776). Arguably, the modern version of this idea is that, as consumers, when we spend money to enjoy ourselves we can reassure ourselves that we are supporting the economy, thence, society as a whole. By the end of the Enlightenment, the Socratic idea of the individual had come to be understood (after Leibniz, 1898) as a self-defining and self-owning citizen. It is for these historical and cultural reasons that we now tend to see the primary duty of industry as meeting the needs of individuated consumers, rather than supporting society at large. This also suggests that the duty of the consumer is to choose the right products to make him, or her, ‘feel good’ and ‘look good’.

7. Designers Can work in New Ways

Today, design is strongly identified with the system of consumption. Today, many products and brands achieve their distinctiveness at a multi-sensory level. Sport, fashion and cosmetics frequently collide in strange ways, and terms such as ‘Hoover’ and ‘Google’ may be used as verbs, as well as nouns. Products such as the ‘Dyson’ and the ‘iPod’ represent an integration of name, form, function, and – more importantly – habit. It is surprising, therefore, that the designer’s primary contribution is predominantly visual, rather than verbal. This is so familiar to us that it may seem natural. But designers have long played a role in advertising campaigns in which words and images are persuasively combined. This combination of signs and functions will be important within the ecological design of the future. This is because neologisms are potentially transformative. Where many tabloid newspapers and business cultures tend to ‘dumb-down’ the discourse by reducing the vocabulary (cf. Orwell’s ‘1984’), advertising designers seek to enrich beliefs and, therefore, behaviours by introducing new narratives and words into the language. A non-commercial example of this method is the word ‘Genocide’, which was coined in 1943 by Polish legal scholar, Raphael Lemkin (1900–1959). For years, Lemkin had tried unsuccessfully to draw world attention to the military excesses of certain nations. Eventually, by combining the Greek word ‘genos’ (family, tribe or race) and the Latin word ‘occidere’ (to massacre) he created a new word. Only after his word was made public did the United Nations formally recognise the problem. Today, his word is enshrined in the Geneva Convention, and we all recognise genocidal behaviour where, previously, it had not even seemed to exist. This example can be reframed within the discourse of design, where similar gaps in the discourse of ecological design can be found. If conceptual gaps can be located and filled with suitable neologisms there is always a better chance of new ideas, beliefs and actions taking place.

8. Ten Characteristics of Metadesign

i) Metadesign creatively intervenes at the level of language

Arguably, designers can ‘language’ the opportunities for change by redrawing the known boundaries of what ‘is’. Therefore metadesign should also intervene at the level of language. Language informs cultural values, and these inform aesthetic norms. Aesthetics helps us to experience the world in particular ways. All of these processes guide different behaviours, habits and trends.

ii) Metadesign has tools for ‘thinking beyond the possible’

If we believe that something is possible it has far more chance than if we believe it to be impossible. In today’s rational society, many people tend to confuse the ‘unthinkable’ and the impossible’. This can be easily remedied. When we try to describe the ‘impossible’ more clearly it may become more ‘discussable’. Once we try to discuss it, it will slowly become more ‘thinkable’.

Once the 'thinkable' proliferates it will become more attainable. Once the ‘attainable' is perceived to be attractive it becomes more commonly applied (Wood, 2005; 2007:2).

iii) Metadesign is intended to deliver ‘synergies-of-synergies’

Metadesign is intended to deliver synergies-of-synergies. It takes a minimum of 2 players, or ‘agents’ (i.e. facilitating 1 possible relation) for a ‘first order synergy’ to emerge. It is what happens when two, or more agents combine to create a new outcome whose properties exceed the sum of properties of the individual agents. Subsequent ‘orders’ of synergy emerge when first order synergies are combined to create new synergies. This process may continue into successive orders, although their increase is dependent on the number of agents at level 1. Hence, for example, 2 agents cannot produce any subsequent orders of synergy. A cluster of 3 interactive agents can only produce three synergies at each subsequent order, up to infinity. With more than 3 agents, the rise in the ratio of primary agents to subsequent orders of synergy is exponential. For example, a cluster of 4 interactive agents would produce a maximum of 6 first-order synergies, which could produce 15 second-order synergies, which could produce 105 third-order synergies, etc.

iv) Metadesign tasks are too complex to be undertaken by solo practitioners

Metadesign is intended to address highly complex issues that may range beyond the expertise of individual designers. Its practice is always, therefore, expected to take place within carefully selected, and trained, teams.

v) Metadesign outcomes should surpass the individual potential of participants

Metadesign should surpass the outcomes of individual participants. Metadesign is intended to synergize the efforts of many experts, and therefore requires appropriate team-management methods. When these are effective the quality of outcomes should be higher than the best work by either/any members of the team (Van Nieuwenhuijze & Wood, 2006)

vi) Metadesign teams deliver many-layered, integrated innovations

Metadesign teams deliver many-layered, integrated innovations. Literally speaking, the term ‘entrepreneurship’ describes a ‘taking from within several sources’. By contrast, the notion of ‘entredonneurship’ (c.f. Wood, 1990) describes a ‘giving, from within several sources’. We have developed a system for facilitating a number of parallel innovations. This can satisfy the apparently incommensurate requirements of different vested interest groups. A four-fold version of this is called ‘quadratic reasoning’.

vii) Metadesign fosters, and benefits from, ‘team-consciousness’

Metadesign should foster, and benefit from, ‘team-consciousness’. It depends heavily on the development of ‘team (or ‘network’) consciousness’ for successful co-design to take place in a creative way. This needs to be mapped, but it represents a ‘field of shared knowing’ (c.f. Bert Hellinger, quoted in Hemmings, 2008) that is too complex to quantify. Controversially, Marvin Minsky has argued that consciousness is merely a ‘low-grade system for keeping records’, and that ‘machines are potentially capable of far more consciousness than we are (Minsky, 1988, p. 160). While this model is crude, it nevertheless enables metadesign teams to map salient parameters in a truly holistic way.

viii) Metadesign delivers complex outcomes that are interoperable

Metadesign delivers complex outcomes that are interoperable. Metadesign methods are effective when work achieved remains equally recognizable, amenable and usable by both, or all, collaborating participants.

ix) Metadesign's fractal structures bring unity to very large systems

Metadesign can offer fractal structures that unify very large systems. Metadesign offers a (generic, four-fold) relational model of ethical praxis whose elements are configured as a fractal structure. This means that it can be re-scaled from the smallest (e.g. individual citizen) to the largest (e.g. global society) without compromising its form. This has the advantage that it is a configuration that is shareable across very different domains, territories, cultures etc.

x) Metadesign uncovers unexpected potential for other systems

Metadesign uncovers unexpected potential for other systems. Our tools for metadesign enable outcomes from one project to be applied within other systems.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

A Taxonomy of the Changing World of Design Practice

A vision of the changing role of design in society supported by a taxonomy matrix tool

Professor Robert A. Young[1]

Abstract

Design academics have advocated the need for design to re-orient towards more sustainable outcomes and for a change in the role of design in society since the start of the millennium. Design has entered a brave new world where boundaries are crumbling and design disciplines are blurring yet the word design has become hackneyed and references often obfuscate its real impact, particularly the emerging role of designers in contemporary society. This paper presents a vision of the role of design in our lives and society in the form of a taxonomy matrix, derived by comparing literature with reflections on design practice projects undertaken between academia, industry and the public sector, which demonstrate characteristics of the changing nature of design practice.

[1] Northumbria University, Newcastle upon Tyne, UK, School of Design, Associate Dean Research and Consultancy, Director Centre for Design Research, email: robert.young@northumbria.ac.uk

1. Introduction

Design academics have been advocating the need for design to re-orient itself towards more sustainable outcomes and for a change in the role of design in society since the turn of the millennium (e.g.: Cooper, Manzini, Young), when the UK Chancellor of the Exchequer hailed design as vital to the future of British Industry in 2005 and design was cited as central to the UK economy in an influential government report (Cox), we knew that times were really changing. Design has entered a brave new world, a world where boundaries are crumbling and design disciplines are blurring. A world filled with 'T' shaped designers working side by side with scientists, engineering, computing and business professionals.

What then can we remark about design practice? Design became a hackneyed word over the last quarter-century. A conference presentation by Prof John Heskett made this point back in the early 1980s (Heskett 1987). The term is now used interchangeably with that of 'innovation' and is seen as a touchstone to denote contemporary thinking. The Design Council in the UK has been vigorous in its promotion of the link between successful innovation in business through use of design (Design Council), to such an extent that the association now has become accepted and automatic to many both in the worlds of design and business. Much less attention is given to articles which question this new orthodoxy for example James Heartfiled's criticism of; 'The Creativity Gap' in the creative industries in the UK (Heartfield 2005), which argues that whilst: "Good business may lead to more and even better design. But more and better design does not, by itself, lead to good business. To imply as much is just hyperbole. But then the design business has never been short on that." This thinking shows that despite the Design Council's claim, 'design spending is the dependent, not the independent, variable' in business practice. .

Design has long been appreciated for its style and is seen to be synonymous with fashion, modern culture and aspirational lifestyle, but these stereotypical references to design have obfuscated its real impact, particularly the emerging role of designers in contemporary society. This paper presents a vision of the emerging role of design practice on our lives and our future society in the form of a taxonomy framework or matrix. It is derived from the comparison of design process literature with reflections on a selection of collaborative design practice projects and events undertaken between academia, industry and the public sector, which demonstrate characteristics of the changing nature of design practice.

The research underpinning this paper was undertaken to address a challenge now facing design and designers to better articulate its substance. But if we are to move Design beyond its stereotypical reference, (within industry this would move it out of the studio and into the boardroom) then we need to inspire and convince people with more than our innate creativity. First we need to fully understand how design thinking and processes can and does add value to businesses, products and services in the private sector but also organizations, communities and their endeavours in the public sector. Then we need to communicate these benefits and show clearly how design can and will act as a catalyst for positive, sustainable change to the economic, political, ecological and social future of our countries and their societies – now and in the future. Developing this understanding requires an ability to reveal more of the tacit understanding that Designers bring to the contexts of their work (Polanyi). Communicating the benefits is a real challenge to designers and design academics, which typically spend their time concerned with the objects of designing rather than portraying the benefits of the design process to others not trained as designers.

Obviously Design will not achieve this change in isolation. Although it has a central role to play, it is only by working with different disciplines and partners that it will be able to deliver the holistic solutions that will drive change forward. Northumbria University, School of Design has a history of working collaboratively with companies and organisations on design practice learning projects to explore the forefront of evolving design practice. This paper and its presentation at Changing the Change intends to take its audiences through a journey of design, specifically how it has evolved within a generation. It does this from reflections on the practice of the School's work and the work of other notable projects with external collaborators and on multiple academic perspectives of the teacher, researcher and design practitioner. The journey does not dwell on the outcomes of designing but on the synthesis of reflections of its purpose and rationale.

The synthesis of the vision described in the paper is assisted by three aspects which have been recurrent throughout the author's research into and through design practice, in order to frame it. These concern design *contents, processes and contexts* (Young 2004, 2005, 2008). This frame works in conjunction with the three types of knowing referred to by Polanyi in his book; 'The Tacit Dimension'; tacit, implicit and explicit knowing (Polanyi). The frame of reference considers:

- The traditional role of the designer
- Design as a Creative Process
- The increasingly strategic use of Design and design thinking in business and society
- Why design is continuing to grow in importance and how it will affect our wellbeing and sustainability
- What are the emerging challenges and opportunities for the Designer and the Designer's influence on society?

The frame or triad of key aspects (content, process and context) is used to discuss the research reflections in the body of the paper against each of the considerations above.

The paper is based on the author's reflection on experiences within the Northumbria University School of Design, where the academic and pedagogic aims concern engagement in design practice learning. The reflections therefore represent considered views which have evolved from a research, research-led practice and academic teaching position within a School that is regarded as a leading provider of design practice learning and associated knowledge development. The paper uses a matrix (Table 1), which is progressively added to using triads of descriptive terms to assist the synthesis of thinking in relation to the bullet points of consideration above, to portray the author's reflections from design literature and selected design practice projects into ideas and insights (a vision). This is finally brought to a conclusion as an integrating vision to frame the nature of the changing state of design. The matrix therefore represents a taxonomy (or tool) which provides both narrative and artifice to understand and engage with the change as a topic of learning, research and design practice.

Table 1: Taxonomy Matrix of Triadic Descriptors

2. The Traditional Role of the Designer

Table 2: The Traditional Role of the Designer

Content

The chosen descriptor to characterize the content of traditional design practice is *Material*. This refers to the traditional role of the designer as the specialist who conceptualizes and configures the physical nature of a product or artifact design. The selector and manipulator of materials into things, products and artefacts. A superlative example of this content is the Apple I-Phone, which is described as surpassing expectations with its user interface and attention to product detail.

The concepts of beauty and order in content creation have arguably moved from the application of precise rules – prescriptive principles of beauty and order, such as the concept of entasis in the definition of the shape of a column in the context of traditional architecture – to assimilative processes of learning the art of design in design practice teaching studios. This contemporary approach concerns much of our man-made environment, and has led to the development of a tacit way of knowing and doing design.

Typical early contributory theory was based on knowledge built on concepts of historicism (e.g. the history of art and design where the emphasis was on the artifact and then the lives of the artists and designers themselves rather than the process of designing). Consequently, the branch of design history which has been perceived by practising designers as most relevant to their work was that of phenomenology for example the work of Margolin and Balcioglu T (Margolin & Balcioglu 1998).

Another important generic characteristic of design practice disciplines is the growth of importance in human centred thinking about design problems. This has naturally led to content or knowledge to support designing derived from the human sciences, specifically human factors, ergonomics and usability – being themselves not pure academic disciplines but aggregates of theory.

Process

Making is the chosen descriptor to characterize the process of traditional designing. Another keyword descriptor could be *Magic* in reference to the description of the process of designing, or lack of it, involving the creative leap that designers often dismiss as magical in fear of becoming too prescriptive about the intuitive nature of their way of working. Other characteristics of the process include:

- Learning to see – through sketching
- Seeing beyond and seeing differently, seeing from different perspectives which is the basis of the creative impetus and process
- Ways of knowing involving designing are largely tacit rather than explicit or even implicit.
- The importance of pattern matching and recognition and coalition across complex sets of data in visual, tactile ways.
- The ability to combine unrelated structures and to get out more than you put in
- Ways of communication
- Ways or learning and exploring

Craft skills were and are of utmost importance to traditional product creation and development. These enable a journey of exploration, of thinking in the round, the refinement of ideas about the configuration of form to the point of specification of surfaces, edges, patterns and relationships. Again, Apple products are an excellent example of this process of form giving, where the designer captures the zeitgeist at the point of product launch in terms of functional elegance and desirability of the product as a cultural icon.

Context

The legacy of traditional design practice is that of Modernism, however, the paradigm that drives the context of product and artefact development is *Materiality* or consumerism. Other keyword descriptors characterizing the traditional use of design in society for the purpose of this synthesis could include; *Measure and Man-Made world.*

The traditional role of design is ‘design in context’, where the context is set by business and other disciplines have a greater influence in decisions about what is designed, produced and consumed. In the face of the contemporary problems in society, rather than the traditional role of

the designer being seen as a passage to a better world, many now believe that it is generating more problems than it is solving (Thackara). Other characteristics of the context include:

- Two and three dimensions – but increasingly now the 4th dimension, brought about by the advent and development of digital technologies and the subsequent convergence of design disciplines i.e. industrial and graphic design in the context of screen-based products.
- Art and Science divided
- Types of knowledge and learning preferences, include kinaesthetic as well as aural and visual
- Developed sense of intuition
- Right brain thinking and thinking flexibly with both halves of the brain
- Design includes logical and deductive processes as well as inductive or abductive processes (Buchanan).

The context of traditional design practice also saw the emergence of Design research in the 1960s.

3. Design as a Creative Process

Table 3a: Design as a Creative Process

Content

The chosen descriptor to characterize the content of design as a creative process is *Method* . Design methods, based on the notion that design could be described as a scientific process, was the focus of early design research work in the 1960s. This work became seriously questioned by its proposers, who realised that scientific method was at odds with design method. For example, designers don't normally ask why, rather why not? Their approach is more about optimism rather than skepticism.

The outcome is that the majority of design research as a theoretical concern has not made an impact on the work of practising designers. Most of this work attempted to produce increasingly more accurate models to describe the design process. The aspects of what

designers concerned themselves with i/e/ content and the situation of its occurrence i.e. context were largely ignored (Young 2004).

Process

Meaning is the chosen descriptor to characterize design as a creative process. The School of Design at Northumbria has a strong profile and interest in developing knowledge about the creative process by observing and reflecting upon its practice. This has resulted in our work being described as Practice-based research, Practice-led research and Research-led practice into designing.

In this sense our work, indeed most of the work of design researchers in our sector could be seen as the generation of reverse engineered theory. We work in the opposite direction to most other disciplines. As Shon explained, we move from the murkiness of real world practice to eventually derive explicit theory and knowledge. Whereas, the academic norm is to move from established pure theory, to applied theory and then case study based on the experience of professional engagement (Schon 1991).

Our ways of thinking and thinking styles move over different stages of divergence and convergence. We also go round in circles in order to progressively refine our thinking about design problems and usually work both ends against the middle of a project to ensure that the best ideas are realised within a deadline. This requires qualities of discernment and holistic thinking and the capacity to zoom into granular detail and out again to conceptual schema.

But the most enigmatic aspect of our process as designers and the biggest point of intrigue for those who are not is the point of generation of creative ideas. This aspect baffled the early design research movement in the 1960s, who attempted to develop a design science method. Perhaps the most informative work that has researched into creative insight is that of Davies and Talbot – Experiencing ideas: identity, insight and the imago, published in Design Studies 20 years ago (Davies and Talbot 1987). This draws on a series of interviews they conducted with RSA Royal Designers for Industry about their moments of insight.

They produced a list of key experiences based on the analysis of interviews with the RDIs. (Table 3b) which some would say bears more relevance to religious experience than professional experience.

Having an idea & knowing it's right is based on the experience of:

- Oneness
- Transcendence of self
- Experience of paradox
- Certainty of knowledge about something being worthwhile
- Deeply felt peasant ecstatic feelings
- Defies analysis – impossible to analyse
- Sense of involvement in something that is ultimate and universal
- Sense of the sacred
- Unique sense of harmony and synthesis
- Effortlessness
- Sudden occurrence
- Obviousness

Table 3b: Key Experiences of Creative Insight

Imago refers to a state of consciousness or being in which there is experience of final perfect form. The glimpse of a higher form of consciousness. An immediate consequence of imago experience is that the person experiencing it is motivated to seek it again and again. Its reward induces an addiction, a kind of Eureka fix.

Changing states of design now means that designers have to be T shaped people (Iansiti 1991). That is people with a core discipline (the dowstroke) and the ability to communicate and work flexibly with other disciplines (the cross-stroke). “Not to be confused with a ‘Jack of all trades’ T-shaped people have a core competency, but can easily branch out. And they possess curiosity, empathy and aren't afraid to ask why” (Brown 2007).

Context

The chosen descriptors to characterize design as a creative process are *Multi-dimensional and Multi-sensorial* . Other characteristics of the context include:

- The Post industrial society
- Theory – practice divide
- Davies and Talbots’s research was also corroborated by Michlewski’s PhD in the School of Design at Northumbria concerning the affect of design culture on organisations in terms of theories, methods tools and techniques, making meaning and making things happen (Michlewski 2006)
- Embracing complexity and ambiguity, Embracing personal and social empathy and Engaging polysensorial aesthetics (Michlewski 2006)

An interesting outcome from the growth of importance of design in society is the Design Council’s interest in mapping the design process to make it more accessible to others. Whilst this might result in better recognition for the work of designers it might also be seen as too prescriptive of the design process.

4. The Increasingly Strategic Use of Design Thinking in Business and Society

Table 4: The Increasingly Strategic Use of Design Thinking in Business and Society

Content

The chosen descriptor to characterize the content of the increasingly strategic use of design and design thinking in business and society is *Modality*, Modality refers to the channels of communication and data follow and different modes of being– other keyword descriptors include; *Mannerisms*, which are an important point of study in people for strategic design.

Perhaps the most obvious sign that we need better methods of designing and planning is the existence in industrial countries, of massive unsolved problems that have been created by the use of man-made things, e.g traffic congestion, parking problems, road accidents, airport congestion, urban decay and shortages of such services as medical treatment, mass education and crime detection (Jones). Strategic design content includes Interaction design, Interface Design, Usability and User Centred Design, System operated Product Design, Experience Design and Service Design, which are all concerned to varying extents with the complex relationships between people, products, places and processes.

Here, content knowledge of human factors elements is crucial. Also, the level at which design problems are framed and decisions are taken about them (Fig. 1). The author's work to reconcile the changing states of design content with adequate processes to facilitate student learning for appropriate contexts, was initially based on a detailed review of a complex system design project. Levels of design decision making were found to reside at different levels of design content. Getting the right conditions to improve decisions about content were found to be crucial (Young 1989).

Typical contributory theory here is based on knowledge built on adaptations of social science disciplines such as anthropology and ethnography but translating data from the use of these disciplines into people-centred design opportunities.

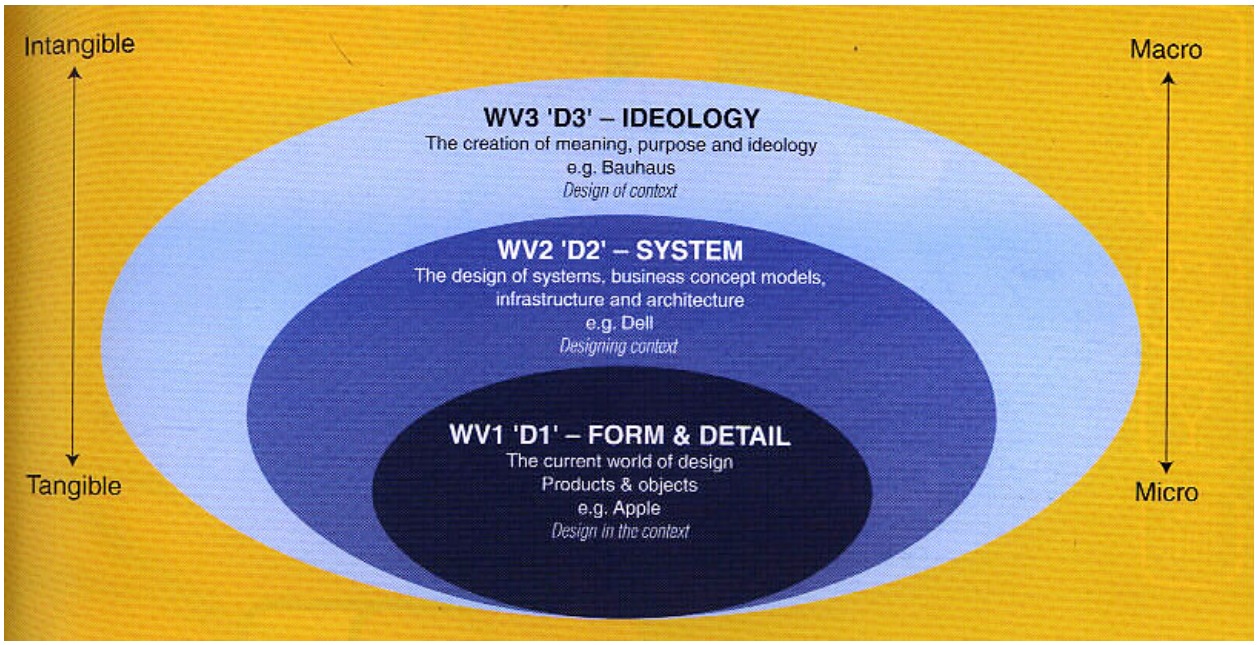

Fig. 1 Model of Levels of Design Content

Process

Mimesis is the chosen process keyword descriptor to characterize the increasingly strategic use of design and design thinking in business and society. Imitation and empathy in the design of services and systems of operation to mimic and complement the behavioural patterns of people. Other characteristics of the process include:

- Not so much learning to see as learning to listen (DASH 2007)
- Key skills are communicating across disciplines and facilitation
- Key approach of designers is using prototyping techniques to fail early to succeed sooner in interaction and interface contexts for new product development.
- Key purpose is to describe the journey – to identify the touch-points
- Main feature of service design is, that unlike our concept for traditional product design that goes in cycles of starting and finishing a new generation product and going to market, service design starts and just continues – to be refined and evolved
- Product development in the past has been infatuated with the destination – rather than the journey, with outcomes rather than the process
- This is a key learning change for the way we will have to train designers in the future, including the approach of the trainers to the learning process.
- It's lifelong and continual.

Context

eMotion is the chosen context keyword descriptor to characterize the increasingly strategic use of design and design thinking in business and society. Other keyword descriptors include:

- Movement
- The strategic role of design is 'designing context' (see Fig.1)

- The strategic role of design in respect of activities such as service design requires a very different approach to the professional dominance of ‘the designer know best’
- The context lies in the fourth dimension, where time and experience are more important than materials and physicality
- Currently the majority of industry and public sector are not familiar with the nature of service design from the user perspective
- They are unable to easily comprehend the risks involved in service delivery
- Risk assessment is at the heart of all new design projects.

In the indeterminate world of strategic design and service development where complex contexts of user needs, desires, emotions and aspirations apply, the problems of collecting and interpreting user data for the design process has a greater similarity to the nature of processing evidence in a court of law than conventional user centred product design and development. In this situation the point of interpretation can be as enigmatic as the search for truth in the face of expedient legal procedures. In a recent real-time TV drama on BBC TV; ‘The Verdict’ trailer was: ‘The truth is what we choose to hear and believe’. – Designing on this basis needs to be based on trust and integrity or a very close reference to roles and responsibilities for those addressing the design brief!

5. Design’s Growth in Importance and its Affect on our Wellbeing and Sustainability

Table 5: Design’s Growth in Importance and its Affect on our Wellbeing and Sustainability

Content

The chosen descriptor to characterize the content of design’s growth in importance and its affect on our wellbeing and sustainability is *Mutation*. We are now seeing the growth of people-centred solutions. Even our dear NHS has seen the need to move from a service based on medical resource capacity, driven by the available clinical personnel, to a patient focused service! We are moving (mutating) from industry can-do (well at least in the west) and the expansion agendas of nations to service content based on the emancipation of people in society, connected by viral communication systems and global multinational industries. Society is in awe of Innovation and creativity and all things design! Design is the new money. People, companies and public organisations see the need to be different or differentiated – to stand out!

Typical contributory theory here needs to be based on knowledge built, not only on the application of social science disciplines but also political science and arbitration skills.

Process

Mediation is the chosen process keyword descriptor which underpins the growth of design's importance. Other appropriate descriptors include; *Manoeuvre, Management, Multi-processing.*

The increasing understanding in society is that to contend with many of the social, environmental problems confronting our future sustainment we need to employ much better 'joined-up thinking'. Designers' capacity to think holistically and follow through to detailed practical solutions is becoming increasingly appreciated. Designers are happy dealing with the complexity and ambiguity that many other disciplines find intractable. Design has the ability to work in counterpoint using both deductive, analytical and rational problem solving as well as inductive, creative and intuitive processes.

Whilst the advantage of designers using prototyping techniques has already been mentioned under the strategic design consideration above, the concept; of failing early to succeed sooner in new product development, has to be questioned as to whether it is the best best strategy when you are working with people as the object of your designing! The process of 'real-world' working by people in organisations is that; anecdotes constitute their experience upon which decisions are made – design needs to be aware of this. Even in the midst of complex science issues and data, practical decisions are made this way, when scientific procedure stops.

So design can assist science to get across to lay people. It helps to translate scientific concepts in ways that people can engage. Design performs the role of mediator in complex social and technical contexts very well because it is good at seeing all points of view and honouring those that make them. It is also good at pattern matching potential solutions.

Context

Memorable is the chosen context keyword descriptor for this consideration.

Companies are curious about the level of creativity that designers can bring to bear in relation to their organisation because they are becoming increasingly aware that design is influential in changing the creative and innovative performance of businesses. Nevertheless, as GJ Galbraith famously remarked, the business of business is business (Galbraith) and businesses are naturally risk averse to the untried and tested. This is a challenge to the creative professions and for designers who wish to expand their level of influence in and through their work to the greater sphere of concern. And the proclivity of design is to have an ambitious sphere of concern. In this context of growth of design, a mantra principle of sustainment to emulate is that of Gaia! This eschews professional arrogance and requires real collaborative working.

Whilst designers have been described here as optimists, the concept of Utopia is realised as being unattainable. Designers are right brain thinkers in an increasingly right brain world. The prize for industry is that they seek after the most memorable experiences that will leave their customers and users coming back for more! But brand reinforcement cannot be the only target.

6. Emerging Challenges and Opportunties for the Designer

Table 6: Emerging Challenges and Opportunities for the Designer

Content

The chosen descriptor to characterize the content of emerging challenges and opportunities for the designer is *Multiplex*. For how do we teach the Wired Generation or the Mosaic Generation – Generation Y otherwise known as the Millenials (Sharp)?

This generation thinks differently. They are also predominantly right brain thinkers. Their drift is to study the arts and humanities rather than science and technology. Dick Buchanan of Carnegie Mellon University talks about the importance of oratory for design education (Buchanan). One of the liberal arts and sciences advocated by the Greeks and then the Romans. It forms the 'Trivium' of subjects that scholars were meant to become proficient in. His point is to underline the importance of verbal exchange of ideas and the communication of understandings between designers and clients and users. Perhaps we can go further here in support of the importance of effective storytelling in order to meet the multiplex nature of design in the future. It is not enough to produce isolated representations of design intent locked into a drawing or model or artwork or even an animation that does not communicate the full extent of a new product or service context. Designers need to become the new chattering class!

Process

Multivalent is the chosen process keyword descriptor which characterizes the content of emerging challenges and opportunities for the designer. Other characteristics of the process include:

- Emergent design is about the power of ideas
- Creative thinking without boundaries
- Naming and framing skillfully to develop sophisticated design briefs, because the bigger challenge is not designing a solution to a problem but deciding what the nature of the real problem is and how it might be addressed
- The power of stories to communicate ideas for risk assessment by boards of industry and public sector organizations
- And of course – sense making and making meaning – always!

Context

Morality is the chosen context keyword descriptor which characterizes this consideration. The emerging role of design is ‘design of context’ (see Fig. ?). Examples of this type of design have already been piloted in the School of Design with companies such as Unilever and Philips **(Unilever and Philips Slide)**. This form of design is:

- People focused
- Future facing
- Based on intrinsic creativity and modes of design thinking
- Requires high levels of craft skill and technique e.g.: film making and narrative building
- Putting creativity to work
- Making things happen
- Using design as an agent for change in society.

These are principles of Northumbria University, School of Design’s philosophy of working. They are as relevant to design at this level as they are as a guide to support design activity at the traditional/contemporary end of design principles involved in product and artefact production.

Society is infatuated with immediacy ‘right here-right now’ and global industry has to operate in this context. The problem for many industries is that this context includes a process of due diligence around the testing and validation of new products and services before they can be realised or commissioned. This squeezes much of the traditional gestation process for new design thinking out of the process of new product development. Therefore, the role of leading international University Schools of Design concerned with the development of design practice learning for real-world contexts is that of ‘slow-reactors’ in a fast reactor context! By this I mean that there is an important role for these Schools in the proliferation and development of vital ideas for consideration by industry in an off-line context.

The bigger challenge for education was alluded to in the Cox Report on Creativity in UK Business (Cox), that of building truly interdisciplinary programmes of learning to ensure the maximum capacity of industry to implement innovative business practice. This requires that students in the Schools of Design, Business and Engineering as well as other disciplines, are capable of understanding each other in the context of mutual learning. Northumbria is committed to embracing this integrated form of educational experience and is building a Design Lab (nuDIL) to pilot this type of working.

7. Conclusion - Towards an Integration

Table 7: Towards and Integration

Content

All of the derived triads or key descriptors, across the points of consideration are shown on Table 7! These show a movement from the material and physical and micro scale to the increasing concern with the evanescent and macro scale of design problems. It is not that the traditional domains of product and artefact creation are of less importance nowadays, just that the complexity of dealing with the human condition in the modern systems supporting our lives has become more prescient. This also requires a better fusion of mind, body and soul / spirit on the part of design activists to see projects through to successful completion.

Process

The problem for design is to assist the learning of tacit knowledge – (which is hidden or incapable of being described easily) in the design process to implicit knowledge (capable of being revealed through the development of skills and knowledge) to explicit forms of knowledge.

Design has evolved sophisticated ways of teaching (project-based learning) in order to help develop these different types of knowledge in its students. But the processes are still seen as largely esoteric by our colleagues in other disciplines. We need to become better at explaining the values of our processes, even though the resulting outcomes (content) usually speaks eloquently to the world.

Context

Design in society in the developed world – some would say the 'wrongly developed world' (Thackara) compares with the needs and aspirations of the emerging and developing nations. At present – 3 product groups in western society cause 70-80% of the total environmental impact in cities, i.e. Home and related energy use, mobility (air and road transport) and food (meat and dairy produce) (Thackara).

Aspects of growing concern in society that need creative and innovative solutions to help improve or alleviate them include:

- Diminishing natural resources – food, energy and water
- Terrorism and
- The increasing proportion of older people in society.

These represent real challenges for designers as part of bigger multi-disciplinary teams. We can begin to appreciate something of our current context by taking a look at previous worldviews of thinking in civilisations. This review, based on that depicted by Henryk Skolimonski, shows that the industrial era that we now live in can be referred to as 'Mechanos' (Skolimonski 1994). A view of the universe based on a clock-like metaphor, moving according to rational and deterministic scientific laws. The telling feature of Mechanos was the movement to detach thinking based on ethics and values from those of rationality, logic and science.

Following in the footsteps of Skolimonski, a bold step would be to suggest that the next paradigm should be based upon an attempt to unify the split which has previously appeared in Western civilisations as a result of Mechanos: to reconnect value and logic in our approach to the perception and design of our world. This would require a new form of education or learning to prepare the designer or 'new creative professional' for the context of their practice. Perhaps we can refer to such a new paradigm of learning and practice for the designer as 'integro'. A concept previously presented by the author at the International Congress of Societies of Industrial Design

in 2001, the thinking system upon which this paradigm is based would include human centredness & field perspective, sustainability, inclusivity and equity, holism and appreciation (Young 2001).

But before we get carried away with our aspirations here we need to remember that: very little, if anything, is completely new. It is the way in which existing elements are combined in novel and exciting arrangements and applications that determines creative opportunity, new applied knowledge and innovation. Also that the 'imago' of the designer is the elixir that drives his or her work. It is a fragment of the divine in our lives.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

360°EYE ON SUSTAINABILITY

An experimental research approach to construct an useful sustainable language

Anna Zandanel[1]

Abstract

Today's misunderstanding around sustainability prevents users from becoming aware of what the whole understanding of this concept.

Trying to divert the direction of the current misleading "changing attempts", research should be oriented to unveil, demonstrate and communicate REAL sustainability, and not its supposed or superficial aspects. It should take into consideration every important aspect, both for design and for the comprehension of the final results.

In a Foundation experience we tried to convert a complex work into a method to produce some different, maybe better approaches to the problem.

[1] IUAV Italy), Department of Design & Arti, Phd student, annazanda@hotmail.com

1. Introduction (misunderstanings around sustainability)

At the moment, the concept of sustainability is mistaken because of a kind of confused approach, mainly connected to disinformation and to the tendency to label objects as “sustainable” also when they are not, in line with a sort of trend that denigrates the concept and falls short of the connected expectations.

I will speak about sustainability from a design and product point of view, strictly oriented to the final user's needs. With “sustainability” I will mean the dimension of the design, applications and communication possibilities that regards the user itself.

I think, in fact, that the main aims in this fields are the conscious design and the good information.

Disinformation is an huge problem. Also the European Commission underlines the problem in the Green Book on the Energy Efficiency, on 2005, speaking about “information and education as two underused tools”. They tell, in fact, that Europe needs a great sensibility campaign. They tried to do it form 2005, because the problems are “lacks in public information and education”, and not only about the energy question! (European Commission, 2005, pp.20-21)

Often, it happens that the eco-friendly aspect is announced with emphasis, but badly explained or studied. The user, instead, should be involved at 360°, not only pushed to the purchase by the illusory idea of using-cost savings.

If the product is analysed through every discipline involved in human wellbeing, we would surely get to the concept of real sustainability, and we would achieve greater success. To do this we not only need to consider the current attempts (even if adequate) at achieving sustainable design, but also the psychological and social impacts, and the user's approach to them. Interdisciplinary approaches to sustainability are necessary because even when it is very good, just a designer’s knowledge can not be exhaustive in every field.

2. Aims (trying to work in a different way)

When I speak about “real planning sustainability” I refer to the attitude that should be the kernel of the process of design, production, use and divestment.

I refer to a kind of approach typical of “good design” that requires each of these aspects to work simultaneously and entirely, not individually.

In order to reach a sustainable result from all points of view, a really good design should take into consideration, in parallel, all these elements and give each of them the same relevance.

The main aims should be:

- **to associate sustainability with planning, society and consumption,**
- **to always take users in consideration**
- **to work together** with all the disciplines able to help the achievement of the goals.

So, to achieve our aims we have to consider human being at the center of research and development. It is, in fact, just starting from people's needs, from each person's needs, that we can get and develop innovative, concrete and effective solutions and ideas.

It is really difficult that just following the market trends something will ever go against the tide and fight against the negative aspects of present economy. Current economy is, in fact, just devoted to profit and it has no interest for the future. Thus it detaches itself from Burtland‘s statements which, in 1987, defined sustainable development as: “meeting the needs of the present, without compromising the ability of future generations to meet their own needs”, and also from the definition of the following World Business Council for Sustainable Development (in 1992)

that considered sustainable development as a tool to “ensure a better quality of life, for now and for generations to come”.

Having lost sight of the real and effective aims, we gave life to a generation of consumer products hardly connected with the concept of sustainability.

In the last few years, acts and laws have been passed to push companies and societies into a more responsible behaviour and, as a consequence, a lot of new objects have appeared, and they have been labeled with an absurd variety of terms and prefixes, underlying their (supposed) belonging to the world of eco-design. Suffice it to mention terms as eco-materials, eco-paints, eco-solutions, eco-efficiency, or the frantic use of the term “sustainability”.

In that way, it has been created a “tendency” or even worse a “fashionable trend” that made the concept of sustainability a stylistic trend (not always well attended) more than a basic value, independent from any aesthetic or production decision. As a consequence, wrong expectations and misleading currents of thought have been generated, giving the idea of sustainability as an added value that increases the economical aspect of an object making it more expensive and elitist.

At present, what is offered to the user is, in most cases, a contest rich in perfunctory and very expensive sustainability.

Even if, at the moment, sustainability can be truly considered as an added value (and this because it is not considered as an essential condition for design procedures), it does not mean that it implies more onerousness.

It is because of the amount of things that are sold as “eco” even when they are not that the user does often not consider this prefix as synonymous of positive quality. The user expects to find a low-quality or inferior product that, in addition, costs more.

Here comes the paradox: actually, what should be an advantage turns semi-automatically into something less valuable, both for its performance and its aesthetics. The message delivered is therefore: more money and lower quality. Lots of literature has dealt with this huge and risky problem. To provide an example, Daniel Williams states that:

“Sustainable design creates solutions that solve economic, social, environmental challenges of the project simultaneously, and these solutions are powered by sustainable energies. [..] Endurance and beauty are central to sustainable thinking.” (Williams, 2007 p.12)

and more:

“As architects we are taught to work on a project until it is done, then move on to the next one. But design, like sustainability is a dynamic and living process. Sustainability is not a point that when reached all is fine. Sustainability is better thought as a continuum [...] A design is sustainable, or it is not. If it is not sustainable, changes can be made to make it sustainable. If it is sustainable, by necessity it will be changing and evolving. “ (Williams, 2007 p.17)

In his famous book on ecodesign, Alastair Fuad Luke tells:

“In his 1971 book, Design for the real World, Victor Papanek confronts the design profession head on, demanding that they face their social responsibilities instead of selling out to commercial interests. [...] By the 1980s three factors, improved environmental legislation, grater public awareness of environmental issues and private-sector competition, ensured that “green consumers” become a visible force. [...]designers and manufacturers applied themselves to the task of making their products “environmentally friendly”, not always with genuine zeal or success. Unsubstantiated claims on product labels soon disillusioned an already skeptical public and green design got buried in an avalanche of market- driven, environmentally unfriendly products from the emerging capitalist- driven “global economy”. (Luke, 2006 p.11)

The main problem is now represented by the confusion that makes users unable to comprehend what could follow the understanding of the real concept of sustainability. A whole understanding would enhance necessary changes for the preservation of our planet and of future

generations, and it will bring positive “side-effects” connected to the improvement of the environment and of people’s quality of life.

In this respect, in Italy, Serena Omodeo Salè, talking about ecology, stated that the term sustainability has lost its fascination because it has been abused. She adds:

“[..] c’è bisogno di una migliore economia che diventa benessere e assenza di aggressività (all’ambiente). [...] qualunque approccio ambientale non piò che essere globale.[...]”(Salè,1996. p.8)[2]

The problem is really deep. At the moment there are still different issues linked to sustainable products:

“la comunicazione pubblicitaria, che introduce confusione nella percezione e nella valutazione dei prodotti [...], l’impossibilità di creare attualmente un prodotto che non presenti impatti sull’ambiente [..], (il fatto che) pochi progetti siano frutto di un re design interno, attento a materiali e a caratteristiche ambientali [..]

Sarà quindi necessario strutturare progetti Più APPROFONDITI [..] e progetti COMPLETI,[...] stimolando la collaborazione tra settori diversi. [..] (perchè) bisogna passare da una produzione lineare a una circolare [...”[3] (Salè, 2005, p.52)

This is the reason why diverting the current (not properly productive) idea of “trying to change” means that research will be oriented to unveil, demonstrate and communicate the concept of “more sustainable sustainability”, that will not focus anymore on a supposed, partial or just superficial notion, and that would give greater importance both to design and to the appreciation of the final result.

On the contrary, what is often commercialised results in a very subtle attempt to sell as eco-compatible things that have just little in common with the safeguard of environment and society.

Think, for example, of the pieces of furniture made of natural materials mixed with toxic paints that are passed off as “eco-design”. Moreover, there are creations made of recycled or recyclable materials, selected just because economically cheaper. None of them gives the rightful importance to the needs and wellbeing of users, environment and society.

In this respect, Vezzoli has stated:

“Una questione collegata alla precedente, che ha invece sollevato diverse ambiguità, è la **naturalità** dei materiali. L’ambiguità, che all’origine è squisitamente terminologica e che ha trovato e trova ancora credito, nasce dall'asserire che un materiale naturale è un materiale che non ha un impatto ambientale o ha un impatto necessariamente inferiore a un materiale di sintesi. Questo, come si è compreso, è falso per due ragioni. La prima: la natura è piena di sostanze tossiche e nocive [...]. La seconda: praticamente tutti i materiali *naturali* subiscono un serie di processi per essere disponibili per la produzione; e questi processi hanno un impatto ambientale. Oggi è comunque chiaro [..] quali siano i vantaggi ambientali dei cosiddetti *materiali naturali*: sono solitamente più rinnovabili di quelli di sintesi e sono generalmente più biodegradabili [...][4] (Vezzoli, 2005, pp.3)

---

2 “Definitely, there is a need for a newer and better economy that is to be translated as environmental wellbeing and non-aggressiveness. [...] every environmental approach must be global..[...] “

3 “Advertisement, which generates confusion in the perception and evaluation of the products [...], the current impossibility of creating a product that has no impact on the environment [..], (the fact that) just few projects are the result of an interior design that gives importance to materials and environmental characteristics […]

It would be therefore necessary to make use of thorough and exhaustive projects and to stimulate the co-operation among different areas […] (because) it is necessary to switch from a linear to a circular production […]”

4 “A question connected to the preceding is the naturalness of materials. The ambiguity, that at the beginning is perfectly terminological and that found and still finds relevance, is generated by the idea that a natural material is a material that does not cause environmental impact or that causes a lower impact if compared to synthetic ones. This is, as understood, false for two reasons.

For all the reasons herein listed, when I was given the possibility to work as representative for eco-design in the Rino Snaidero Scientific Foundation, whose aim is the research for the quality of life at home, I preferred not to think about sustainability as a research criteria, but as a reference value, following the concept that considers real sustainability as the necessary base for quality of life and for ensuring wellbeing at home and out.

One of the requirements was the implementation of a state of the art, aimed at life at home and at the house itself.

The Foundation needed a cataloguing of products, ideas, currents of thought and laws useful not just to define the nature of the products, but also to be discussed and interpreted in the light of an analysis oriented to the identification of critical or strength points, and to be used for a new and more conscious attitude towards planning.

The team, called “creative group”, consisted of different members, representing different fields of knowledge (sociology, statistics, demography, design, eco-design, architecture, biomedicine engineering, economy, ergonomics, color, interaction, micro-finance, etc.)

All of us were between 24 and 35 years old.

The Foundation looks for people who had not been in the job market for long time, to avoid their previous experiences limit the huge possibilities, the ideas or attempts that could be developed in its environment.

However, the main obstacle was exactly represented by the heterogeneity of the team, which, at the same time, was its strength point.

After the beginning of the job, in fact, all the different specializations showed immediately to be extremely rooted, and to have their own “language”, precise and full of meanings.

This was the reason for dedicating the first months to the comprehension and the sharing of terms that change their meaning according to different contexts of use (for instance “sustainability” for some people means just “care for the environment”, while design is for some others an “irrational process”...)

The sharing of in-depth concepts has been very motivating, and it has enabled the research and the development of a more conscious vocabulary.

The sociological point of view about sustainability, the influence that demographic changes can have on it, the planning that should deal with it, the misunderstandings which from time to time have led to discussions and debates, have contributed to create a common team language.

In this way, if at the beginning, while trying to delineate priorities for the research process each of us showed his or her own beliefs about rules and relations among the different disciplines, at the end the ideas about such rules have changed. They have merged together and have developed thanks to cultural exchanges and to a final agreement on the meaning of each term, which has explained itself in its context of use, and particularly thanks to debates, every time preferred to a silent assent.

Once we created a common base for dialogue, the next step was even more important: to reach the state of the art. The bibliographies used as reference were scientific and not, and they were used to establish the values on which we based the cataloguing.

Now, what do we mean by “values”?

The investigation on quality of life at home made it necessary to individuate some requirements for the analysis of the state of the art.

The first: nature is full of toxic and negatives substances [...] The second: practically all natural materials are subject to a series of processes in order to get ready to be produced, and such processes have an environmental impact. Today [...] biodegradable materials bring some advantages: they are commonly more renewable and biodegradable than synthetics.”

So, through bibliography we have been able to underline some gol@h parameters or, in other words, those values that can surely be useful for improving the quality of life at home.

All the representatives for each discipline proposed and discussed the most peculiar references for their fields of specialization, giving life to a list subjected to a constant updating, and used to file all the documents. Some parameters examples are: Genuiness, Accessibility, Energy saving, Aesthetics...

In this way, everything we filed was immediately provided with a reference and with clear reasons explaining why the team had chosen it.

These parameters were born from the in-depth reading of authors that have dealt with the investigated main themes (these analysed by team members) and that openly, or between the lines, affirmed that a particular point could or could not be important for the improvement of quality of life at home.

In other words, once selected an architectural solution, for instance, it was connected with values relevant for the quality of life that the architect associated to the project. Thus, if the source was mentioned together with the pertinent comments about the object that could be found in the same source (or sources), the genuine existence (or the absence) of these parameters could be verified.

In addition to this, in the original edition, the author (in this case the same architect) had to add her personal observation, explaining why she had chosen that architectural creation and which were in his opinion the best qualities, or the worst faults related to the field he was analysing.

We focused our attention also on the **user profile**, connecting it to his **way of living**, and it leads us to the analysis of different targets and to the filing of every object according to its connection with a specific kind of user instead of another (i.e. children, disabled, etc.).

Demography and statistics analysed this parameter in detail and provided us with certified data both to explain people's characteristics and to underline their needs. Their studies brought to light relevant data that pointed out the shortcomings of design in respect to the needs of a certain kind of user.

The **actions** parameter was created in order to better detect the target of our research in relation to the different places they live in. Avoiding the nineteenth century's subdivision of the house into rooms and areas and having in mind the current tendency of merging together all the rooms (i.e. disappearance of the kitchen replaced by the kitchenette), the **actions** parameter gave us the opportunity to classify the objects with more awareness, considering them not just as physical spaces, but connecting them to activities (i.e. sleeping, cooking, eating etc.).

Lastly, to complete the cataloguing of the analysed elements, each time we added the **name of the discipline** that planned and monitored the research.

All the data, from a graphic point of view, were collected in folders, and then gathered to create a database (in constant updating).

The co-operation of different members of the group enabled a closer examination of filed concepts. Once we reached a sufficient number of folders/sheets to analyse, we moved to the following step: data sharing.

The realization of a common base for communication, at that point, was the ace up on our sleeves to convert the team from multi-disciplinary into interdisciplinary.

Thus, sustainability found an extremely fertile land, and many ideas came to life, which were useful for theories, discussions and surveys and which are still to be analysed better.

At this stage, the members of the group were getting along very well and this helped the initial terms misunderstanding disappearance. As a consequence, commonly accepted definitions were ready to be enriched in their meanings. Once unveiled "sociological" or marketing reverses,

doubts and questions (considered also from the point of view of classic subjects, such as ergonomics or product), sustainability, from both the architectonic and the product point of view, showed itself from different perspectives that maybe have never lived together in a so vivid environment before.

Every researcher proposed to the group some topics chosen from his/ her field of knowledge and filed according to technology parameter.

In this way, specialists in various disciplines commented on the data produced by other authors, therefore providing different opinions and comprehensive interpretations.

Then, what about sustainability?

Not only it was studied according to different sciences or points of view, but sustainability itself studied other *formae mentis,* connecting a new deep meaning to what already was or would be, or maybe had already been into the market, discrediting the superficial definitions that reflect only perfunctorily its characteristics.

Sustainability analysed sociological beliefs and it was fundamental to comment on design, architecture and all these appearances that just superficially represent products, ideas and theories in every fields.

Let us give an example: from the sociological field it was proposed an Automated Custom Manufacturing, that is a process with which an user can draw its own object online, and receive it at home, manufactured, in 10 days.

On the website you can either upload a digital design for a product or select another user's design, and within five to ten days, the company has manufactured the components of the product and is ready to ship them back. Customers can also design objects without building them, leaving their designs on file for others to use; the website has a "showroom" where customers can browse through a catalogue that lists pictures and prices of designs and products created by other users.

Sociologist said:

“This is an example of *mass individualisation*. With services like that we will be able to design and manufacture our own furniture. It is the same process that involved television and the whole media industry: from the 1-MANY approach to the MANY-MANY one!.

Eco-designer commented:

“This method deletes many steps from production to user, and it's positive to avoid waste, money and pollution for each step. But I would know how it works exactly, just to understand if user has to know deeply how design the piece of furniture, how use the specific software (in this case it would be not for all) or not (in this case it would be positive have someone that controls that the design is really well done, to avoid waste of materials, energy consumption and so on).

Another point: transports. For the moment it would be difficult for many receive a product by them, for the few locations they are in. “

Sustainability developed in the different fields analysed, and it was sustainability itself to give the user prominence, trying to provide him with the best solutions, avoiding, for the same reason the ostensible ones.

For instance, an aluminum chair (fully recyclable material) was described as “superficially sustainable” not only because it was planned by a famous designer (who did not choose the material), but also because the company selected it just for economic reasons. Moreover, the brand name made the product very expensive, oriented only to an elite generating a social selection. What’s more, it lacked in ergonomics and it was not intentionally recyclable.

On the contrary, a seat from Droog Design was considered as fully sustainable. It was expensive as far as single production was concerned, but more or less easily reproducible and

from a statistical and economic point of view it was within reach of every culture and every purse. It was made of racked grass, was biodegradable and it could be endlessly produced

At the moment, I do not intend to comment on the debate about luxury design, which has got great relevance in the world of design, and which is at the center of many different schools of thought.

What we tried to do was generating useful opinions for the improvement of quality of life at home, being understood that quality of life depends on life itself.

This is the reason why at first sustainability had been considered a planning and environmental value and then it grew empirically, following always more the criteria of other connected fields of knowledge, and appropriated them .

In this way the ergonomic valuation of a chair was conducted not just through ergonomics, but also through “sustainable ergonomics”, as well as sociological events were looked also from a sustainable point of view, and so on.

Once the database was created, we selected the most used values.

We tried to understand which values were used more and why and which missing criteria could be indicative of new or different needs.

In this way, when we moved to the design step, overall research activity, knowledge-sharing and common language represented the starting point.

We began from different vocabularies and, at the end, with lot of efforts and mistakes we were able to create a new common language. We enriched the meaning of the topics we dealt with, and we enlarged the meaning of each word.

Above all we designers, gave up the feeling of “omniscience” that our job requires to be carried on in the best of the ways. Opening the doors to specialists in different fields of research, and above all in planning, we followed the idea that the user has to be studied in the round.

If quality of life at home needs the user as the point of reference, each of the science we represented worked together to meet such need. Sustainability became, for everybody, a basic value and it raised the consciousness that to reach quality of life at home it is necessary to work firstly on the quality of life, and to avoid any kind of mistakes in production, management, use and consumption. And also in society and development.

The research phase was followed by the planning stage that was really brief and concise for contractual reasons. The proposed projects, about which I can not tell more at this time, was conceived trying to follow all the previous (not at all simple) guidelines.

To sum up, I can say that I am not sure of having found the solution for the huge problems that sustainability is trying to hold back. What I can say is that I feel enriched by this experience that, even with its significant limits, had all the same shown how the combined work of different disciplines can only improve the course towards sustainable solutions.

If “sustainability” really has to be a value of reference, an improvement for the user wellbeing and a solution for the future, we need to carry on an interdisciplinary, combined study, that normally is less or quite never used and that should be the starting point for every sustainable project.

I do not know if our team’s projects will be manufactured or not, and if so, how they will be made, if they will fulfill our aims or not, if in the manufacturing stage they will meet more or less problems than other objects. However, I am enthusiastic about the attempt to learn a different approach and, of course, about having enriched my personal idea of sustainable design, and having found other issues to work on and having developed with my colleagues the consciousness that every discipline can produce values for sustainability.

Finally, I am really happy of having tried instruments, immediately when they were created, maybe different from the others, but surly inspiring and worth being used to reach our ambitious goal.

DESIGN VISIONS PROPOSALS AND TOOLS

Rubbings

Preserving the industrial memories amid change

Xian Zhang[1], Ming Cao[2]

Abstract

Based on the investigation of an old mill in Wuxi, the birthplace of China's national industry, the project seeks to continue and expand the life of the industrial culture through the approach 'Rubbings', whose role is regarded as a communicator connecting the past and the present. We not only reveal the long history of the mill, the cool scenes with the special aesthetics, but the workers' everyday subtle life.

The project narrates the past, present, upcoming and imaginable stories through different media expressing the emotions such as recalling, commemorating, reviving, hoping etc., thus the industrial memory, its own value as a culture would get more attention and right preservation finally.

1. Introduction

Everything seems temporary and easy to be torn down in today's fast changing China. Wuxi, one of "China's Ten Cities with the Most Economic Vitality", is the birthplace of China's national industry, who boasts over half century's accumulation of industrial heritage. However, in recent years, the city's appearance is reshaped so quickly that some historical industrial sites have disappeared in a hurry. Although the recognized industrial heritages have been renovated and reused as bars, galleries, restaurants, museums, and shops etc., their original culture wasn't paid attention to carefully, therefore the past stories have lost to a large extent.

The process of the worldwide recognition of the value of industrial heritage only spanned 30 years, while the large-scale practice of industrial heritage's protection happened in British Iron Gorge in the late 1980s and Ruhr industrial area in Germany in the end of the 1990s. Unlike before, the huge and ugly plants and machinery in these two sites were not removed totally as burdens, but as something valuable to the industrial heritage's protection, rehabilitation and re-use. As a result, the strong industrial culture, unique industrial heritage landscapes attracted investors and tourists from around the world. The old industrial areas revived and now they have been listed as the world cultural heritage. The practice of the new way of protection developed into the international protection campaign of industrial heritage in 2003. Thus " The Nizhny Tagil Charter" was issued and formally approved by the UNESCO as a programmatic document of industrial heritage protection and use. (Yu. 2007, Preface)

According to The Nizhny Tagil Charter,

'Industrial heritage consists of the remains of industrial culture, which are of historical, technological, social, architectural or scientific value. These remains consist of buildings and machinery, workshops, mills and factories, mines and sites for processing and refining, warehouses and stores, places where energy is generated, transmitted and used, transport and all its infrastructure, as well as places used for social activities related to industry such as housing, religious worship or education.'

The Charter also indicates the value of industrial heritage:

I. The industrial heritage is the evidence of activities which had and continue to have profound historical consequences. The motives for protecting the industrial heritage are based on the universal value of this evidence, rather than on the singularity of unique sites.

II. The industrial heritage is of social value as part of the record of the lives of ordinary men and women, and as such it provides an important sense of identity. It is of technological and scientific value in the history of manufacturing, engineering, construction, and it may have considerable aesthetic value for the quality of its architecture, design or planning.

III. These values are intrinsic to the site itself, its fabric, components, machinery and setting, in the industrial landscape, in written documentation, and also in the intangible records of industry contained in human memories and customs.

IV. Rarity, in terms of the survival of particular processes, site typologies or landscapes, adds particular value and should be carefully assessed. Early or pioneering examples are of especial value. (TICCIH, The International Committee for the Conservation of the Industrial Heritage)

However in China till mid-2006, the State Administration of Culture Heritage issued the "Notice on strengthening the preservation of industrial heritage", pointing out that "China's preservation of industrial heritage is a new topic in the cause of the protection of cultural heritage and is of importance and urgency." Then some cities gradually began to recognize the significance of the protection of industrial heritage. (State Administration of Culture Heritage)

This paper focuses on the industrial heritage's 'social value as part of the record of the lives of ordinary men and women', aiming to map out the history and current change of the industrial

heritage in Wuxi, elaborate our view on the industrial memories and exploit industrial design's potential to give conceptual proposals.

We, two young lecturers in the School of Design of Jiangnan University firstly involved into the research of industrial heritage and introduced this to a junior students' course and 3-group senior students' graduation projects. Teachers and students from the Department of Industrial Design have been working together for nearly five months.

The project proposes an approach that uses the conceptual design as a vehicle reflecting bits of the industrial memories, thus continuing the culture's life. It touches the domain of industrial heritage trying to broaden the boundary of industrial design, looking beyond the objects' preservation to the aesthetic possibilities with the local culture.

Rubbings mainly consists of two main parts: the first part discussing the industrial heritage in Wuxi, our understanding of the industrial memories, and the second part presenting several conceptual design proposals expressed as videos, images and objects.

2. Industrial heritage in Wuxi

Wuxi is situated in the lower reaches of the Yangtze River, whose name, literarily meaning "no tin ", was given due to the extinguishing resource of tin in the Tin Hill. During Ming and Qing Dynasties, Wuxi was known as the "rice market", "cloth dock" and "silk market" all around China. In 1895, Yeqin Cotton Mill, founded by two brothers, Yang Zonglian and Yang Zonghan, signified the beginning of the early industrial production. Wuxi became the cradle of China's national industry and commerce by virtue of its wisdom and diligence. Till 1948, there had been over 628 enterprises of 20 types of business covering cotton yarn, filature, flour, printing and dyeing, rice grinding, tile and papermaking etc.

The unique history left Wuxi over half century's accumulation of industrial heritage, such as Yongtai Silk Mill, Maoxin Flour Mill, Qingfeng Cotton Mill, Dingchang Silk Mill, Shenxin The Third Textile Mill, Lixin Textile and Dying Mill, Xiexin Feather Textile Mill and Kaiyuan Machine Tools Mill etc., most of which are located along the 2500-year-old Grand Canal[3]. The industrial buildings scattered by water have an impact on the city's structure and layout, thus gifting Wuxi the distinct characteristics. These buildings, reflecting the early principles of location and operating features, are of great research value as they provide the important evidence for people to explore the history of China's national industry and the plant layout of the early industrial enterprises. With the passage of time, these outstanding industrial buildings will be even more valuable. (Xu, Zhang, and Xin 2007)

Nevertheless, the urban development in Wuxi is undergoing extensive and profound changes. On account of the shift of the urban structure and function, more and more new mills gradually expanded to the suburb resulting in the old industrial zone close to the center city falling out of use. On the other hand, due to the introduction of the modern technologies, traditional industries declined slowly; some enterprises even had to be shut down, ceased production, merged into other enterprises or switch manufacture. The urban reconstruction has been advanced so quickly that quite a few of significant industrial sites disappeared in a hurry. (The Graduate School of Landscape Architecture.)

Fortunately, Wuxi municipal government has been aware of the significance of the industrial heritage and set the target for the urban development as establishing a famous city of history and culture with humanities. In terms of the 'Notice on the Development of the Industrial Heritage and Protection of the Census Work' issued by the Municipal Government Office in April 2006, the government presented the basic idea of the industrial heritage's preservation, namely 'protecting

[3] The Grand Canal, the world's longest man-made waterway linking Hangzhou with Beijing, once played a vital role in transporting goods and even helping to hold the empire together for centuries. Today it is still very busy although other means of transport are widely available.

its appearance and casting its soul', aiming to highlight the comprehensive historical and cultural connotations of Wuxi. The government planned to conduct five important projects: to build a unique protection zone of industrial heritage, so that dozens of various types of industrial Remains beside the Grand Canal could receive the comprehensive protection; to construct four museums of the 'four major terminals' separately, which actually means four types of the pillar industries, once enjoying their reputation in the history of Wuxi industrial and commercial development in the beginning of the last century, namely the Rice Market Museum, the Textile Museum, the Silk Museum and the Museum of Money; to carry out the industrial restructuring focusing on the functional transformation, the establishment of Art and Design Park, the Industrial Design Park and the Cultural Industry Park etc. (Wuxi Government Gazette)

A Forum on Industrial Heritage Conservation jointly sponsored by ICOMOS China, the Chinese State Administration of Cultural Heritage and Jiangsu Provincial Administration of Cultural Heritage was held on April 18th 2006 in Wuxi. In this forum, 'Suggestions on the Reservation of China's Industrial Heritage' was produced, which is the first time at home to put forwards the definition of industrial heritage, the present threats industrial heritage faces and the approaches of its protection.

Still, problems exist in the practice of the industrial heritage's protection in Wuxi. The typical example is Beicangmen Culture and Art Center.

Beicangmen, located beside the Grand Canal, built in 1938, was the largest Silk Warehouse around Jiangsu, Zhejiang and Anhui province. Two brother and sister Zheng Haoming and Zheng Haohua who returned home from abroad, found this idle silk warehouse. They tried their best to protect it from dismantling and invested in building an art center, quite similar as the foundation of Shanghai art studios beside Suzhou Creek[4]. In Shanghai, most old factories and warehouses along Suzhou Creek were originally set be demolished in favour of the construction of modern high-rise buildings, aiming at a social and economic regeneration of the Suzhou Creek area. However, following initiatives of artists in the late 1990s the riverside has been designated as a protected heritage zone and many warehouses have been conserved, now providing quarters for Shanghai's flourishing art scene. (Wikipedia)

In Sept. 2005, the rebirth of the old mill, the so-called 'Beicangmen Phenomenon', shocked the city who had been busy working on the economic development purely for many years. Painting exhibition space, cafes, and bars with the post-modern style in the center were full of the nostalgic atmosphere.

However the center's sustainable development lives in difficult circumstances, and it can even hardly maintain. Unlike Shanghai, Wuxi's innovative industry is in the embryonic stage and the market hasn't been exploited yet. What's more, Beicangmen's Shanghai style is a little bit far from Wuxi ordinary people's life and far beyond their reality. The public haven't prepared very well to accept or realize this change's value. (Wang. 2007, 297-298)

It is worth noting that, the present Beicangmen Culture and Art Center has partly lost its characteristics as a silk warehouse except the architecture itself. The similar story happened in '798' Art Zone[5] as well. 798's spontaneous rise promoted the practice of the industrial heritage's preservation in Beijing. However, what is "798" lacking in? Wang Chuncheng, the director of Heritage assembly of the Capital Museum gave his answer-the workers' and industrial memory associated with the original context. (Lifeweek)

To sum up, we believe one of the urgent things we should do now is to educate or remind people of the value of the disappearing industrial memory in a more local and diversified way and industrial design could be a bridge filling the gap. For example, the commodity design with the traces of the special local industrial memory, which will enter people's life little by little and arouse

[4] Suzhou Creek (whose original name was Wusong River) is considered as Shanghai's mother river, which nourished Shanghai's prosperity in the early years of the last century.

[5] '798' Art Zone is a part of Dashanzi in the Chaoyang District in Beijing that houses a thriving artist community, among 50-year old decommissioned military factory buildings of unique architectural style.

their sympathy. The way paying close attention to people's everyday life may generate the unimaginable power for the industrial culture's preservation and communication. In the mean time, in regard of the topics of sustainable design and localization design, industrial memory is undoubtedly the priceless treasure inspiring designers or artists with passion for innovation.

3. Warm Realism

Our project started with Wuxi Kaiyuan Machine Tools Mill in November last year.

Wuxi Kaiyuan Machine Tools Mill, today's Wuxi Kaiyuan Machine Tools Group Co., LTD, a large-sized backbone enterprise of the machinery industry in China, was founded by a famous industrialist Mr. Rong Desheng in 1948. Rong's family had been one of the most influential business groups in China since the beginning of the last century and Rong Desheng was one of China's richest persons and well-known entrepreneurs.

The businessmen like Rong's family in the times are regarded as the representatives of Confucian Traders. Confucianism traders mean have high artistic appreciation relatively, have the Confucianists moral concept and value orientation, have and make unremitting efforts to improve oneself and dare the entrepreneur of the initiative spirit. The more modern by" trader of Confucianism spirit" is profit "must at society, use in by society". (Chinese Confucius Institute)

In history, Confucian Traders looked upon the market as a hub, as an opportunity to integrate resources to seek for the common ground and internal relations between the nation, people's livelihood, markets and enterprises and shape brands relying on their unique commercial spirits and value systems. Moreover, it is more attractive that Confucian Traders advocate Confucianism and Taoism culture in pursuit of the strong sentiments of the humanities. (The State Council Research Center of The State-owned Assets Supervision and Administration Commission) The culture of the Confucian Traders influenced the industrial culture deeply. A very small detail can embody this culture's imprint: the sign 'Happily go to work, return home safely' can be found easily in the factories in China which actually suggests the close relationship between home and factory, whereas as a unique virtue ethics, Confucian ethics firstly started with the family. (Fig. 1)

Sixty years have passed. The mill experienced rise and fall but still in good condition and in operation. However, change will take place one year later at last. In line with the relevant policy, the old factories are set be demolished and moved to the industrial park located in the suburb in favour of the urban development. Most of the land of the mill has been sold to a real estate company giving way to a modern apartment complex. We feel anxious the objects and scenes with the traces of the common workers' everyday life that moved us deeply will lose inevitably to a large extent even though Wuxi municipal government has planned to keep the earliest workshop buildings through functional transformation and later reusing. Our aim of this project is to use the medium of design to keep the stories of the workers and the mill's original culture from disappearing. The project focusing on the subtle life may extend personal works to stimulate people's imagination. It introduces new ideas to deal with old problems, quite different from the customary architectural or literal preservation.

Besides the mill, the investigation also involves in visiting some old workers' houses, finding out their life at home and listening to their telling stories. Factory workers are the people whose fate has changed the most drastically of anyone in China in the past decades, whereas most of them usually serve for one enterprise loyally in their whole career lives and have plain and profound feelings with her. Industrial culture affected the life of the countless workers and their family, even other fields such as literature, art etc. in different times.

'Warm Realism' is quoted from an interview with a Chinese director Jia Zhangke, whose film '24 City' tells a story about three women in the 50s, the 70s, and the present day, as society makes the transition from collectivism to individualism. We choose it as the interpretation of the industrial memories since the memory of the past life in old factories always brings people back to a warm dream. Realism in the visual arts and literature is the depiction of subjects as they

appear in everyday life, without embellishment or interpretation, which is the starting point of our design innovation.

4. Rubbings

There is no civilization that has relied as much as the Chinese on carving inscriptions into stone as a way of preserving the memory of its history and culture. By the beginning of the seventh century, or perhaps much earlier, the Chinese had found a method of making multiple copies of old inscribed records, using paper and ink. A rubbing, by accurately reproducing every line of the inscription in a white impression on black ground, provides a sharper and more readable image than the original inscription or a photograph of the original. Rubbings (also known as inked squeezes) in effect “print” the inscription, making precise copies that can be carried away and distributed in considerable numbers. (East Asian Library, University of California, Berkeley)

We assimilate or analogize the value of rubbings. From our point of view, a rubbing is a communicator connecting the past and the present, a vehicle for showing the past culture and a new form of life with the past traces. So we pile up the first-hand materials, exploit new ways to narrate the past, present, upcoming and imaginable stories through experimental videos and design works, expressing the emotions such as recalling, commemorating, reviving, and hoping etc. and sharing with more other people. The project not only reveals the long history of the factory, the cool scenes with the special aesthetics, but the insignificant reflecting workers’ life, and consequently the memories could be continued and revived through different media.

Rubbings could be a transdisciplinary platform on which designers can tell their stories through images, videos, products, installations or other graphic works etc. Below is a summary of several possible elements for us to develop diverse ideas.

A. Fiber, dry wall, awning, broken windows…
B. Natural sunlight & electric lamps
   These elements are related to architecture. The fiber features the introduction of natural light, while at night the workshops are cast a pale yellow and warm color because of the electric lamps.
C. Greasy dirt, dust, rust, chipping, welding marks…
   These all are different textures, the footprint of time.
D. Industrial color & everyday life color
   The color of the Industrial culture is exceptional: the relatively high saturate degree and a strong contrast, which affects the color of the workers’ articles of everyday use in workshops.
E. Machine Tools, old moulds, parts…
F. Furniture: Stools, chairs, tables, and lamps…
G. Articles of everyday use: Thermoses, mugs, fanners, glasses, shoes and clothes…(Fig. 2)
   You would have a very special feeling, especially these things were found in a different state of existence in workshops. (Fig. 3)
H. Grass, trees…
   Nature is always a faithful witness of history.

Except the elements related to the buildings, such as fiber, dry wall etc., or trees, commemorative equipments, many of elements the above mentioned can hardly be seen again once the old workshops are rehabilitated, especially broken windows which will be repaired; greasy dirt, dust, rust and chipping which will be wiped off or painted again; stools, chairs, tables, and lamps which will be replaced. Surely nothing will be left if the buildings are demolished.

Whereas it is the insignificant, often being overlooked, that triggers our passion. We regard them as a huge source of inspiration. The conceptual design proposals below have something in common: small stories mirroring the broad background and deep reflection . Each proposal is a process of investigation, an interface between the industrial culture and far-ranging people.

A. ‘Renrenyouze’

Three students, Yushan Wang, Yanfei Xu and Yupeng Gao’s video narrates the story of a little mouse ‘visiting’ the mill. Thus most of the frames are recorded from the upward angle of view, representing the mill’s state during her final period of time with a joyful fast-moving camera.

Another group, including four junior students Yimai Guan, Xianyin Li, Xingyu Zhang and Mingnan Wen focuses on the characters, scrawls or graffiti which can be found everywhere in the workshops, especially the slogan ‘Renrenyouze’ which means everyone has a share of responsibility, reflecting the far-reaching cultural and historical context. Both groups’ works contain the true details and scenes, their own emotions and imaginations as well.

B. A branch on the wall

Nature witnesses the change of the mill silently. A senior student Ma Xinxin noticed a branch propped against a wall of a plant building, and the almost disconnected twig drew a circle back and forth like a swinging pendulum, leaving the imprint on the wall. She recorded the twig’s move from winter through to spring and the process of its growing leaves gradually. The story is the base of her creation. She made a video and a set of products including a table, a clock and a diary. Her works all connect with time and suggest vicissitudes of life.

C. Rubbings

In addition to the videos, postcard or bookmark design is another easy way to show things familiar to the workers, however probably strange to other people.

During the investigation, we were surprised to find the different handmade furniture in a small-sized hardware machining workshop. It was the intelligent workers who made use of wood and steel in the mill making tables, chairs and stools, some of which are elegant, some are simple, and others are clever even full of humor. Time left wrinkles in wood chairs and lacquer flakes on steel stools. Our concept is very simple: magnifying these beautiful wrinkles and flakes in order to trigger people’s imagination to the past. This proposal developed from our desire to create the beauty of the insignificant.

Concerning the materials of the postcard or bookmark, we plan to choose the rice paper, whose character is strong and wearable enough. Furthermore, the traditional paper, integrating the modern printing technology, suggests the culture of the Chinese Confucian Traders and echoes the theme ‘Rubbings’ as well.

5. Conclusion

History has always been shaped not by reality alone but by imagination. The title *Rubbings* on the one hand suggests we respect reality, on the other, a rubbing is another form of relatively independent art with warm memories and dreams.

This project set out to develop a design approach for producing conceptual works that encourage meaningful reflection on the preservation of the industrial memories in Wuxi, a city of rapid change and advancement. This approach provides a multidisciplinary platform for designers and artists to show their respect for history, innovative capability for promoting people’s everyday life and the imagination for the future. We hope our research can achieve the goal, which is communicating the industrial heritage culture to the public and integrating sustainable design with localization design.

Industrial heritage is a special language of a city as well as a kind of special historic memory. We may not be able to preserve everything but what we can do is to raise awareness, introduce new ideas and ensure that the culture they represent survives into the future. Not only as a matter of respect for the memories of the older generation, but also as part of our debt to history and the historical record for generations to come. (Huang 2007, 157-165)

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

“DEMOLISH” AND “CONSTRUCTION”

A Research on transition of urban communities and sustainable lifestyle in China

Xiaojiang Zhou[1] and Xing Liu [2]

Abstract

In the last 20 years, China has been in the radical change of urbanization. The cities have been growing fast through continual construction and demolition.

This research focuses on the development of several cities in Southern Yangtze of China to investigate the change of the residents in their lifestyle, living attitude during the “demolition’’ and ‘construction’ in the perspective of urban plan and environmental design. Through the experiments of design projects in urban plan and environmental design, solutions would be found for those disharmony problems occurred during the transition process of ‘demolition’ and ‘construction’. The proposals, from both the tangible and intangible points of view, would be developed for the development of the cities and regroup of residents, as well as the reconstruction of new communities with extension of traditional customs.

Keyword: Demolition, Construction, Urban Environment, Community, Lifestyle, Living attitude, Sustainability

[1] School of art and design, China Jiliang University, Hangzhou, China, zhxiao5960@sina.com

[2] Facolta del design, Politecnico di Milano, Milan, Italy, xingstar555@hotmail.com

Since the late 1970s, China implemented the open policy and the introduction of private economy, the Chinese economy has entered a sustained, rapid period of development, and this period is also the most rapid process of China's urbanization. At present, China's urbanization level has reached more than 35%. The demand of economic development, the rapid expansion of the urban population, the change of transportation mode, the implementation of engineering project for people etc. led to the rapid expansion of Chinese cities through continuous “demolition" and "reconstruction". The old community "are not suited" to the needs of the development and are removed and replaced with wide roads, modernized squares, high-level residential or commercial facilities. It seems simple in appearance but this process is a city member change through which the original residents have to move to the extension part of the city while the new gentry and immigrants come to occupy the center of the cities.

“Demolish” and “Construction” in the cities

One city changes after another, such changes also bring about a risk of the break of the original historical context of the cities. During the process of transformation of old urban areas, a lot of cities has adopted the approach of demolition in large scale and re-build the whole land without division of ‘good’ or ‘bad’ in their detailed work. The so-called "one year a kind, three years a big transformation" is a typical motto for the reconstruction work of many cities in the 1990s construction. Then there came out some examples of destructive construction for the economic interests or the need to highlight political achievements for local government.

Taking an example of the coast of Wulinmen canal, the original city is constructed along the bank of the river, with streets for land traffic in front of the buildings and the canal for water traffic behind the buildings. The living environment manifests the characteristics of south Yangtze River culture. Canals are a main transport and rivers are essential in life. People's daily life and production activities are all around the canal. But now along the coast of the canal, we could never find the original community construction. The canal has degraded as a decoration of the environment and original constructions are replaced by high buildings. Speedboat has eliminated those wood boats. Modernization has put the history far behind. Although the urban constructors want to preserve some historical marks, these symbols have already been squeezed in the flow of the city development. (Figure1) There was a hot time that the whole nation was fond of building new Modern Square in front of the municipal government gate. For the ancient city of Shaoxing in the "Square hot" period, all the old lanes, aged streets and residents of the center of the city are demolished totally. In stead, all around, tall building stands in great numbers. It’s difficult to find the trail of graceful historical culture.

However, due to historical, social, economic, technological, and other comprehensive factors and the impact of constraints, the old cities left by different times are not suited in some degree for people’s current life needs. The original functions and personalities are declining in some old cities. In some old residential areas there exist serious problems of backward facilities, poor environment, economic depression, increasing social problems etc., such a phenomenon tends to give people an error in the understanding of the old city: They thought that ‘the old community’ was a “mess” left by the past, and was a “burden” of the city and a representative of "dirty, disorder and poor conditions,”. In order to change this impression, by the promotion of the powerful commercial interests and the need for the development, updating, renovation and construction of a city's image will certainly become a main subject of the development.

“Demolish” and “Construction” and the changes of the lifestyle and life concept of the urban residents

The urban changes of “demolition” and “reconstruction” occurred not only in the urban landscape, the culture contest and the characteristics. More importantly, this ‘demolition’ and ‘reconstruction’ has brought tremendous changes to the lifestyle and life concept of the residents

who moved to the periphery of the city. This change reflects in the changes of living conditions, of the reorganization of the community residents, changes in the material conditions of life, and of the distance between city centre and traffic changes, and so on.

The living environment changes

These changes can be seen after the changes of living environment. In the past, the relatively traditional and compact living space brings inconvenience in life; however, it brings also the convenience for family communication. In the past traditional residential, a big family usually live together. We can see or feel the other members' activities or we fulfill one commission by division and coordination. Living in such community, it's convenient to communicate with other families. Original community is relatively open between families and the living environment and space provides opportunity for exchange between them. In this atmosphere, a single family can easily integrate into the community. Now the new residential are mostly high-rise buildings. The family inner space has increased greatly. We can say it's a big improvement in the respect of comfort. However, it could result in less communication between family members and some families have to be divided into several small families. At the same time, because of the division of independent unit and the lack of public activity space, the communication between families has been reduced. Even if one family member is keen on community activities, it'll be rare to see a whole family participation.

Changes of reorganization of the community residents

This change is also reflected in the reorganization of community residents. People living in the original same community have common understanding and know each other's habits because of a long period of coexistence. Therefore, they have a lot in common in their life style and are able to find better way of living together. The relocation of community residents will inevitably bring about the restructuring of residents. Large number of indigenous people moved out, (often retained original household affiliation), which destroyed the original social network, disintegration of community awareness, and led to the confusion of social order and disorder of individual behavior.

Although the reorganized communities have property management agencies and neighborhood committees, in China these organizations or institutions only play a role of coordination and regulation in the disputes or vote on those affaires related to the whole community residents. In other words, their role is passive; so far very few of these organizations can actively work for the community integration and the construction of community culture. It's because of the rapid development of China's new communities and the result of the fact that the society has given the preparatory work to the real estate developers in recent years. At present, the mutual communication in the community has followed the traditional way – people get to understand each other in their daily life. On the one hand, this way cannot be developed after new residential style; On the other hand, this kind of mutual understanding could only be achieved after a long time, which will bring about lots of problems for initial community construction, such as issues of assistance, disturbance, the feeling of belonging and sense of honor etc. (Figure2)

The effect of improvement of material conditions

These changes are also reflected in the improvement of material conditions. In order to implement smoothly the urban construction, the government gives economic or material compensation to the residents who have to move to the urban periphery. Such compensation with people's material wealth by the economic development lead to changes in the concept of happy life which in the past it was usually a wealthy life. While enjoying the material wealth, people come to pursue other things such as 'quality of life', 'happy connotation' etc. New communities may have some facilities, but in general not perfect enough or just facilities without services because of the immature market. Compared with the original residential in the city center, this economic improvement hasn't brought the improvement of 'quality of life' for moved people.

Changes of the distance from the city center and traffic changes

Changes are also reflected in the transport inconvenience caused by the big distance between residential and center of the city. Accustomed to living in the city center, the residents feel some loss once relocated. This is not only because of inadequate facilities matched for the new community far away from the city center, but also because these residents will have the feeling of being bordered by changes of inhabited area and they will think that they have become marginalized people of the city. It is the result of differences between urban and rural areas as well as the dominant position of the urban area. In order to compensate for this difference, some people purchase cars to reduce the distance from the city center, but, more and more automobiles has caused traffic problems and it starts a vicious cycle.

The sustainable development of urban community

"Demolition'' is the development need and it has broken the original balanced system; while "construction" is to establish one kind of new balanced system. During this process, 'construction', 'adaptation' and 'new balance' have constituted a new melody for China's current urbanization. On this circumstance, "demolition" is inevitable, then how to "reconstruct" is a current priority.

As a social organism, cities have to face a process of the metabolism, sustained changes. The key is a progressive improvement of living environment and maintaining the quality of vitality of old and new community alternation. At the same time, they have to "maintain the neighborhoods structure", "keep the traditional characteristics", "protect the diversity of urban life ","coordinate overall of urban space "and other sustainable development goals. A city's 'demolition' and 'reconstruction' development should be considered in two aspects: on one hand it's the issue of culture continuity and life style evolution by 'demolition' of original buildings and communities; on the other hand, how the construction of new community could keep their original lifestyle and life concept while adapting new development demands become important.

Thoughts of reconstruction of the original 'demolition' areas

The first problem is related to reservation or eliminations of urban culture renewal and urban characteristics. It's more likely considered on the form. As mentioned earlier, most of the new residents are those new gentry and elites from the outside of the city and they do not have deep understanding about the city connotation. It's not possible for them able to take the responsibility to prolong the city culture. To some extent, they have already become masters of the city and they will construct a new city connotation by their own mode. If they can retain some symbols of the original city (even on the surface), it's already a good result. (Perhaps there exist some strong utilitarian purposes.)

A relatively successful example in the urban transformation is the project of the Nanjing Confucian Temple area. Since the Eastern Jin Dynasty, the "Confucian Temple" has been the center of cultural exchanges, and a center of the merchants movement, known as" ten mile of Qin Huai ", which is the birthplace and the historical testimony of ancient capital of Nanjing. Time brings great changes to the world. Before liberation, the "ten miles Qin Huai" was once dilapidated and in deserted depression. Since 1984, Nanjing restored the "Confucian Temple", rehabilitated the East and West market, the learning Palace, examination hall and other ancient buildings. Although there are differences with the original construction, the rehabilitation was done in the absence of protection of ancient sites. The cultural advantages of Confucius Temple, examination hall, the scenery of Qinhuai River and of the traditional Lantern Festival characteristics have restored the traditional features pattern and the vitality of old community. It has effectively promoted the development of the city's historical, cultural continuity and the revitalization of the local economy, so that the old community areas have obtained the sustainable development.

From these words, we can clearly feel the proud and the sense of achievement of the city dominant. They are proud of their own "masterpiece" and at the same time, have forgotten the fundamental reason for the rise, forgotten the psychological feelings of those indigenous residents who were moved to different places. If we compare the transformed Confucian Temple

and the original "Ten mile Qin Huai", we can discover their purpose for quick success - all around the commercial development, the so-called culture is only a layer of "skin", an object which controlled by the dominants. Therefore, I'll not discuss too much here.

The sustainable life style of the indigenous residents

The main body of the second aspect is the indigenous inhabitants. They have special feelings for the city they lived. The changes of the city affect not only their life style but also their life concept. They are the real successors of the original city's connotation. However, they have to face these changes and to adapt to these changes, they're trying to retain their own existing way of life and life concept, and at the same they're adjusting themselves as well. So in addition to the help with the basic system and major infrastructure construction, we should do research in the following aspects:

1, In the design and construction of new community, what should be taken into account is that the real needs of inhabitants' original way of life, so that their original lifestyle could be extended. This kind of needs include basic need for living, health need, education need, exchange need, entertainment need and ceremonies need etc. This requires a deep investigation on the new residents who have the plan to move into the new community and thus carry on the integration. As showed in the picture, the Hangzhou government is establishing a file of a new community of relocated residents. The first floor is to be stilted to the bottom of the upper floor, which provides the public active space for the residents, especially practical for traditional family ceremony such as traditional family wedding banquet, traditional memorial ceremony etc. at the same time, there'll be an open style activity room on the first floor, just like the "courtyard" of the original residential, to provide a space for people's gathering. The children who come home after school can be taken care of for free if their parents are not off work. More importantly, this space will become the core of the building. Through this "courtyard", many families are able to carry out the activities which they can not do in their own house. The conflict of the original life style and the modern life style may obtain a buffer a in the residential house can not carried out by the "yard" the original way of life and lifestyle of the modern conflict can be a buffer. (Figure3)

2, To establish a platform of communication, so that the residents of new community can be integrated into a new environment as soon as possible. As the new community has transformed from the plane housing to the three-dimensional housing, which has brought certain limit for the face-to-face communication. Community platform can be direct, and it can also be a virtual network platform by modern technology. Direct exchange platform can give more mutual communication chances to the community residents through the themed activities. Based on the needs of original way of life, the platform can provide a free space for the residents' communication. In short, the direct exchange platform enables the residents to go out of their honeycomb-like housing, to return to the residential community. The virtual exchange platform can be established by network. Through the virtual platform people can be overcome the awkward and the psychological closer problem to be able to communicate with the unfamiliar neighbors. Modern technology and material conditions can provide reliable protection for the realization of virtual platform. This kind of work is being carried out. The key is how the network service could be accepted by ordinary residents. On the one hand, it can be achieved by development of products easy to be operated; on the other hand, it can be promoted by topic activities about the review of original life style.

3, Promotion of community service system, to create a sense of belonging to the new community residents. The original community has formed relatively perfect service system along with the time accumulation. Whether on the emotion or from the habit, the newly moved-in residents from the original community will have no doubt some feeling of not adapted at the beginning. This feeling is manifested in the memory of the original living environment, and the complaints for the new environment. A more human design with the help of the original service system is required to provide the residents a sense of "home", to help them find their own feeling of belonging.

Ideal model of community

Therefore, we can conceive this kind of community: in such a community, when people moved in from the old community, along with their complaints and confusion, they will be surprised to find that in this community, they can clearly identify their original community shadow, although there’re some changes in the form, this doesn’t change too much their habits. They can find the appropriate facilities to their needs, and even better than before. Living in the new community, people find some new faces in neighbors, and there’re some differences in their living habits. However, they discover that they have similar experiences in many aspects through the themed activities. Then gradually, the neighborhood relationship becomes intimate. At leisure, they could also try to know new neighbors through the community platform. Through constant exchanges and communication, they become friends and this promotes also exchanges and communication between the family members. When somebody needs help, they could offer their help. When coordination is needed, they can gather as quickly as possible. They are no longer isolated and helpless, and they began to integrate into the new organism. Community support and services are not worse than their original community. Although it’s far from the city centre, they can have everything they want. They began to approve this living environment, and also enjoy fun of a new life. The new community makes them no longer have the original feeling of "the allocation". More importantly, as a result of the improvement of material conditions and habitable space, they begin to have more experience and strength to engage in things that they wanted to do initially but haven’t realized. They feel that their dreams are not far from them, and they feel real happiness.

China’s development and changes of cities have brought unprecedented impact on the life style and life concept which have continued for thousands of years. This kind of impact has urged us to find a way suited for our development while changing our original way of life. Change is inevitable, and the key point is to maintain our own characteristics during the changes.

Urban Memory Responds to the Change[1]

Improvement and Revitalization of Public Spaces in Macao's Historical Corridor

ZHU Rong[1], Francisco Vizeu Pinheiro[2]

Abstract

Each city has memory elements. However, some deep changes in the city, a consequence of modernization in the global scale, are negative because they erase layers of history and tradition.

Taking Macao's Historical Corridor as a case study, this paper investigates the historical context of the city and makes a SWOT analysis of key parts of Macao's Historical Center. This method of revitalization addresses issues like public transportation, historical preservation, commercial viability, and cultural tourism.

The conclusion respects the historical character and contributes to reinforcing the traditional meaning and sense of the place. This paper also presents strategies and principles to improve and revitalize public spaces located in dilapidated or misused historical centres that contribute in a holistic way to retrieving the unity and ambience that were lost, thus promoting heritage sustainability. Finally, the new systematic approaches for preserving the continuity and cultural identity of the city are especially highlighted by means of a multi-disciplinary participation in the urban planning process.

Key words: Urban memory, Public Space, Historical Corridor, Macao's Heritage

1. Introduction

As an important human mental activity in psychology, memory appears to be a dynamic and interactive "art"[2], located between the internal virtual consciousness and the external real world. In a broader aspect of social and cultural contexts, the collective memory contributes to the formation and maintenance of cultural identity and collective coherence in a group or community.[3]

Each city has memory elements. Urban memory helps to maintain urban continuity and integrity, to construct urban spirit and soul. As the mnemonic codes to recall history, place and architecture always have a close relationship with urban memory. Memory is one of the crucial factors influencing the creation of architecture and city places. Simultaneously, it is the existence of urban memory that restricts the evolution of urban structures and social culture. City structures such as urban fabrics, streets and monuments contribute to inscribing and preserving historical events, linking social life to spatial structures for recollections and references of latter ages. They not only provide the living spaces, but also allow habitants for direct living experience and value conception. According to Ruskin, the important role of urban architecture in the psychological and sociological aspect could be that, "We may live without [Architecture], and worship without her, but we cannot remember without her."[4]

2. Urban memory in the change

In the recent decades, most Chinese cities have witnessed the huge process of change caused by urbanization and globalization trends. Unprecedented prosperity and opportunities were anticipated in the field of economic growth and urban development.

However, in the urban renewal, considerable risks and pressures brought about by these big changes could not be neglected. The high speed of new urban constructions and the prevalent influence of market-oriented developers in the city planning are erasing layers of history, disrupting the traditional urban continuity and unity. The fragmentation trend of the old city fabric seems unavoidable. Individual historical buildings are more and more separated and surrounded by many modern high-rise buildings. Some historical public spaces had abandoned their traditional functions, and degenerated into uncharacteristic spaces or adapted as parking lots that serve only practical logistic functions. But while, one of the problems which come up with more intensity is the issue of the "social amnesia". The changeable urban physical form destroys the familiar narrative circumstances for residents, threats and distorts urban memory. Urban memory is on the brink of extinction, resulting in cultural homogeneity and identity crisis. Therefore, how to protect culture, continue urban history and sustain social identity in the change have come to be the urgent tasks and research objects of urban sustainable development nowadays.

As the core part of urban fabric, urban public spaces in the urban historical center take unique historical and social roles in recording history, preserving collective memory and cultural identity. Although never visually presented to be in existence as physical structures, they are still regarded as the aggregation of relationship between material carrier and spatial form. Furthermore, urban public spaces are the connection ties and media to continue and regenerate historical memory in the urban historical areas. Therefore, they could be the most effective objects to control the holistic ambience and character of one place in the preservation of urban history and culture.

3. Research experience applied to Macao's historical corridor

3.1 Urban context

L. Mumford, the famous town-planning historian had mention that “the city lives because it has a memory. Thanks to its buildings and to its institutional structures, and thanks to the even more lasting symbolic forms of literature and of art, the city combines the past with present and with the future. Within its historical walls time clashes with time and defies it, because its structures survive the functions and the purposes which determined their creation is the locus of the collective memory”[5]. Macao is that kind of city which has considerable historical depth as an urban environment. Several layers of time overlapped to reveal how history, present, the future fused into this city. As the melting pot of Chinese and Western cultures, Macao city owns the special historical background and culture character. Its particularity and distinction are especially represented in the Historical Center of Macao (HCM), which was enlisted by the United Nations Educational, Scientific and Cultural Organization (UNESCO) as part of World Heritage on 15 July 2005. Whereas, as a consequence of the rapid growth in estate development, population and tourism economy, some areas still inevitably confronted with tremendous pressures. For the HCM’s survival, scholars have established the concept of defining a thin and long Historical Corridor, starting in the riverside Chinese temple of A-Ma to the Hills of the Portuguese Monte Fort, linking many Portuguese and Chinese monuments and historical spaces of the city.

Aim to make improvement and revitalization for dilapidated and uncharacterized public spaces located in the historical center and to retrieve its unity and continuity, in the last two years selected squares and streets in two sites of the HCM were investigated and researched by the Department of Architecture and Environmental Design, School of Design, Jiangnan University in collaboration with the Civic and Municipal affaires Bureau (IACM), the Institute For Tourism Studies (IFT), University of Macao (UMAC), and Inter University Institute of Macao (IIUM).

3.2. Case studies from two MHC’s sites analysis

Strongly contrasting with the commercial feature, “sustainability’ of (northern part) corridor linking the Senate Square to S. Paul Ruins (approximately one kilometer long), is the ambience in the second half (Senate to Ama temple Square) where most of buildings in the circuit are contemporary ones of uncharacteristic qualities originated by poor design. Some old buildings are very dilapidated. A few bright spots like St Augustine, Lilau and Ama Squares are the exception. The stretch linking Senate Square by way of Calcada do Tronco is very steep, polluted, and narrow, surrounded by un-descriptive ugly modern buildings. Two sites in the MHC were chosen for analysis.

3. 2. 1. Site 1-- Area linking Senate and St. Augustine Squares

The approach to the revitalization of the 2-kilometer long stretch of MHC’s was made step-by-step, in this case stretch-by-stretch. Two areas were chosen; the first is the one linking the Senate to St. Augustine Squares. In this short zone exist several green spaces and historical buildings such as Senate Square, Sir Robert Ho Tong Library, Dom Pedro V Theatre, St. Joseph Church & Seminary, and St. Augustine Church. The access to this site is problematic because of the steep and polluted road without place for shelter or refreshment.

3.2.2. Site 2-- Lilau Square

The second site corresponds to the area near the Lilau Square. It is one of the more traditional Portuguese spaces, very near a large Chinese mansion and a popular site knows as the old Lady fountain in Chinese.

Other major problem of this place is the large of empty buildings that received the nickname of “Ghost houses”, a title not very conducive to World Heritage status. These empty houses form more than 80% of the square facades. Until now renovation actions were painting the walls,

changing the pavement in the square and building square flower bases for the old trees. Only the large mandarin house, property of the government, is being fully remodeled. The historical Chinese and Western buildings and the real Lilau fountain site live divorced from each other. The mandarin mansion building is being restored and will open to the public before 2010. At the western end of this mansion, there is a road bottleneck without space for sidewalks but only dimension for one car passing, constituting a dangerous situation for tourists.

The Name of the place comes from the old Lilau fountain. However, the memory of this fountain is nearly lost when in 1995 was built a new one with a minimalist approach design. Geometry and minimalist are often in the opposite spectrum of a design based on memory, local culture and tradition. The “minimalist fountain” that looks like a wall and often wets the square ground, is disliked by local population and visitors, which often uses its back site as a toilet. The real fountain, the one that generated the legend of “The one who drinks from Lilau will return to Macau” is abandoned and forgotten in a nearby place.

3. 2. 3. Main problems of the sites in the southern corridor

Through SWOT analysis, the main issues of this southern corridor were found to be as follows: **1) Heavy traffic and noise pollution.** This route is occupied by heavy traffic of motors and cars, which cause terrible noise and pollution; **2) Poor accessibility and safety for pedestrians**. The narrowness and the ups and downs of the streets are very hard for pedestrians to traverse. In areas like the one near Chang Mandarin, the corridor is so narrow that either cars or persons can pass at one time; **3) Uncharacteristic public spaces and streetscapes.** Abundance of uncharacteristic contemporary constructions, mostly residence or commercial buildings are very poor and lack character, hiding in a forest of cement destroying the heritage value, ambience and spirit of this historical street; **4) Lack of shelters** for protection of the often-inclement local wheatear in raining seasons; **5) Lack of support services** necessary in the long corridor, like places for resting, tourism information sites, coffeehouse, toilets, etc. Considering that this stretch is 1 Km long, this is a serious hindrance, a bad experience for tourists; **6) Confusion and difficulty to navigate in the historical corridor**. Due to the lack of historical and visual contact references, tourists are often lost in this area; **7) Non-placeness.** Due to the limited information of site history and social stories, some famous historical buildings such as Dak Seng Pawnshop, or lanes such as the Happiness Street are less known. Contrasted with the site from Senate Square to S. Paul Ruins, social, commercial and tourism activities for the neighborhood are not so prosperous; **8) Lack of proper urban furniture and lighting**. Urban furniture is lacking or designed to be the inappropriate one in historical places, like large trashcan containers in historical squares or near historical buildings. Parts of this corridor are not well light. For example, the Ama Temple Square is dark by night.

4. Propose rehabilitation strategies

4.1. Strategies for site 1--Senate to St. Augustine Square

In meeting challenges of improvement and revitalization of these research areas, the initial focus is on improvement and revitalization centered on urban memory and culture identity for residents and tourists. It was avoided to solve urban problems by applying contemporary geometric compositions and materials that are not linked with the history, vernacular, and classic tradition of the place. Therefore, the solutions present a practical approach that are applied for solving issues of historic preservation, urban transportation, commercial viability, and cultural tourism. Based on the analysis of physical and social issues, four strategies were suggested by way of a sustainable, phased re-development. The proposed strategies are: **1) Pedestrianization of the district.** The existing main road should be adapted for pedestrian use

after routing major traffic around the whole district instead of going through its narrow roads. Public and private transportation should be restricted to a minimum, helping to create a less polluted environment. Electric buses could be used for shuttle services in the historic corridor. The car-free environment helps to conserve and enhance the more traditional and distinctive streets that link up existing monuments forming a heritage trail. The pedestrian circuit should not be limited to one linear experience but enriched by several options providing a more compressive understanding of the urban fabric and local architecture. Through interviews of various groups, the other alternative route is put forward from Senate Square to St. Augustine Church; **2) Promotion of urban memory by a balanced urban development.** Construction guidelines are necessary for creating a balanced urban development so as to maintain urban memory and culture identity as a major place for citizens and tourists. This approach includes revitalizing Happiness Street[6] by emphasizing spatial nodes, public facilities, protection roof, facade element (Fig.1); reconnecting the corridor with more cultural attractions such as the Tak Seng On Pawnshop[7]; attracting tourists from the north part of the Corridor (Senate Square-S. Paul Ruins) to the south part (Senate Square-Ama Temple). At the same time, commercial vitality and cultural tourism could be enhanced with the reintroduction of the traditional custom and hand-making snacks and foods; **3) Adaptive reuse of dilapidated buildings**. Selectively rebuilding some buildings for cultural and historic use will highlight the "memory venue" in circulation. In site 1, several buildings are dilapidated and empty; others are even collapsed in this part of the historical city. To bring back life to this area, some of the un-characteristics buildings could be adapted as for supporting cultural and heritage activities as well for improving the streetscape of this "unclassified" area that is nevertheless an important link between the Chinatown and the western St. Augustine Square. A new museum (Fig. 2) will help to create a local landmark in this district, contributing for memory preservation and cultural identity reinforcement in this area. It can also hold civic cultural activities and provide information to visitors and tourists from the region. The design of this new museum is based on the decorative vernacular patterns of the buildings in the neighborhood, apparent in the hexagonal windows shutters framework supporting mother-of-pearl screens, timber hinged door panels and sliding gates, roof gable, blue bricks plastered in different color layers, etc; **4) Revitalization of residual void open spaces.** To collect and fill in residual voids of this district, revitalize them into temporary and changeable open spaces which could be used by local residences and tourists. These open spaces are expected to be multifunctional and involve exhibition, entertainment, relaxation. They not only serve as supporting facilities and services, but also play an important role of flexible and motivating elements in promoting diversity of everyday activities, and fostering local community sense of place.

4.2. Strategies for site 2--Lilau Square and surroundings

Historical research and a survey to the local community precede the rehabilitation project of this area. Previous surveys in this area by the workshop and IFT research teams focus on the past memories, present use (of the dilapidated areas) and expectations for the future in terms of quality and preservation of the cultural identity. Other Heritage stakeholders like site owner and government managers of public spaces were included in the survey. There are many possible layout solutions for the reuse design of this site. However, the chosen ones should be elaborated in a way respectful of the memory and spirit of the place that is linked with vernacular practices in architecture, urbanism and social and cultural traditions. The strategies proposed to apply on the second site are: **1) Re-adaptation for reuse of the dilapidated buildings** in Lilau Square. The dilapidated yellow mansion could be reused as a boutique hotel. With the cooperation of building owner, a study of hotel adaptation was elaborated by IFT[8] students after a survey to local residents. An automatic parking system could be built behind the house. The boutique hotel can meet a local need for quality spaces or for youth travelers who like to stay near heritage sites; **2)**

New interior layout for dilapidated houses to bridge different external spaces. The white small houses in the square are supposed to be adapted as a hotel. Respecting the existing layout and considering the memory of the place, one practical solution is suggested to link the houses and adapt them to be a restaurant/café serving Macao's typical foods (and complementing the boutique hotel functions) and as a library/bookshop with souvenir/museum where memories related with the Chinese and Portuguese history of this place are easily accessible. In the pavement of these houses, a water path is expected to be created (Fig.3.), providing the link between the real Lilau water source and the fountain in the square; **3) Remove the minimalist wall fountain** (number 3 in fig 3) for a new one, in a better located and less dominant position; **4) Create more shelters and the green areas** by planting trees, for example in the corner area near the fountain wall; **5) Dismantle the illegal metal structures** in the open space near the real Lilau water source and landscape this area; **6) Improve the connections between all present isolated historical buildings** like the Mandarin house, landscape areas and squares, making them an important nucleus of the southern part of MHC's.

5. Conclusion

"City is the locus of the collective memory"[9]. Cities have to provide their habitants with not only a better physical environment that is livable for all, but also a real "spiritual home" that possess memory, belonging and identity.

Urban memory can contribute to regaining lost unity ambience in urban sites. They are venues where the spirit of that place is anchored, containing the cultural identity that is deeply rooted in the community and is stored in the memory of individuals. Urban memory can help to positively change the negative effects brought about by globalization and, although subject to some degree of abstraction, it is an important tool in retrieving and preserving urban traditions, in this way keeping local culture alive.

Using the concept of urban memory, this paper gives the psychological and sociological points of view to find the historical value, practical effect, future destiny of public spaces in the historical center and ultimately tries to explore the improvement principles and revitalization methods for public space located in historical centers that contribute, in a holistic way, to retrieving the historical continuity and promoting heritage sustainability. More particularly, facing with challenges in the globalization changes, this and other examples seem to suggest that urban structures and spaces should be put into a value system closely related with man, society, historical culture, and new systematic approaches for preserving the city continuity and cultural identity. New systematic approaches for keeping urban memory responsive to the change should be expanded by way of integration of more disciplines in the urban planning process.

Fig. 1: Revitalization of Happiness Street by emphasizing spatial nodes and adding awing roof as well urban furniture elaborated from local design patterns

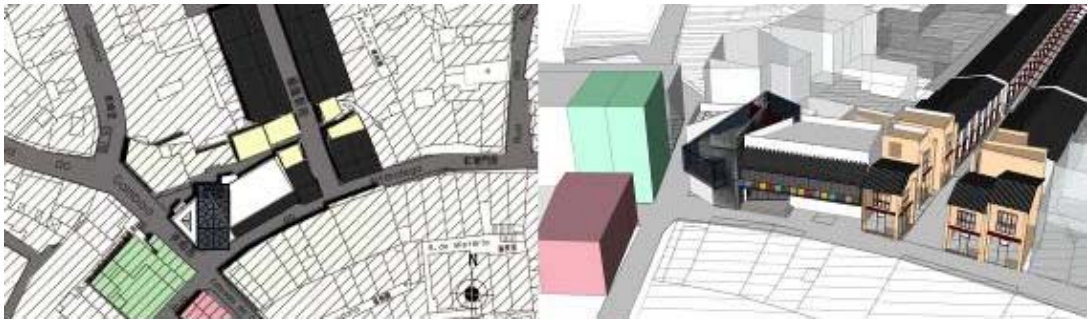

Fig. 2: Selectively rebuilding some buildings for cultural and historic use. A new museum will help to create a local landmark in this district, contributing for memory preservation and cultural identity reinforcement.

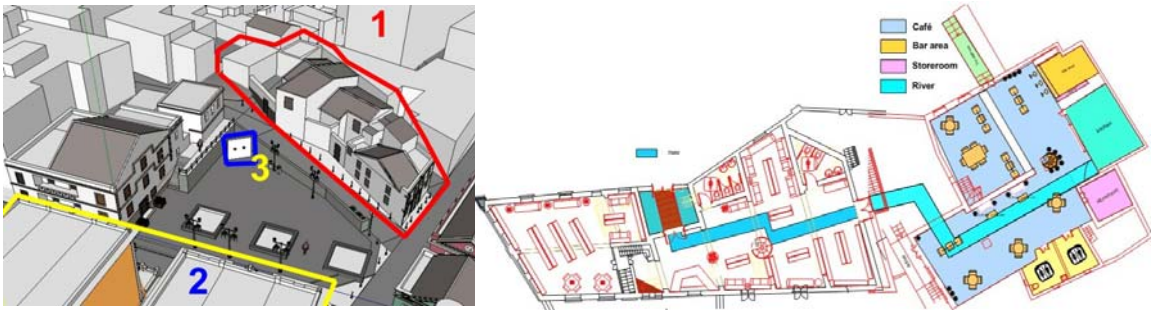

Fig. 3: White houses are proposed to be adapted as a library and café, supporting activities in the square as well complementing the yellow houses (2). The Layout of the white houses (1), with inside water stream linking the real Lilau source with the square.

[6] Happiness Street is part of large Chinese quarters of Macau facing the inner Harbour. It is one of the best-preserved lanes that survived intact until our times. This street represents the old gambling center; the entertainment area and the red district that were built by the end of the 19th century. This street is paved with granite slabs revealing the wealth of these quarters. The architecture follows the traditional Qing dynasty practices in the South China region; using brick structural walls for support of the roof and the upper wooden floors. The ground floors were used for commercial purposes and the above level for residence. In this area most of the houses follow the same style, making it difficult to distinguish a shop from a residence. The differences were in the character signs at the gates and in the detailed elaboration of painted frescos over plastered walls. A decorative frieze on the gable walls or written characters on non-structural parts like the crafted timber doors added meaning and intended to attract “luck” and prosperity to the space. Mother-of-pearl is used in windows panels. Gilded crafted screen partitions protected the houses from sunrays and rain.

[7] Established in 1917, the Tak Seng On Pawnshop consists of a pawnshop and a storehouse. Its architectural design and layout, interior decor and equipment would have been very similar to pawnshops in Mainland China at the time. Listed in the Macao Heritage, it is at present the best-preserved pawnshop building in Macau. After its adaptive reuse, the Heritage Exhibition of a Traditional Pawnshop Business was opened in the building, with the Cultural Club next to it.

[8] The study of the yellow and white houses adaptation was done by IFT (Macao’s Institute For Tourism studies)3rd year hotel students under the surveillance of Dr. Penny Wan and Architect Francisco Vizeu Pinheiro.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Eco-Cybernetic Architecture

Jon Goodbun[1]

Abstract

In this paper I will try to weave together some of the intellectual ideas and practices that contribute to an eco-cybernetic conception of architecture, and will then show some examples of trying to apply this thinking to my own teaching and design research practice. I will conclude by evaluating these examples, discussing what has worked as teaching and design practice, and what problems can be identified. I will generally consider how this research might contribute to the expanded conception of design as the primary agent of socio-political and enviro-economic change.

[1] University of Westminster (UK) - School of Architecture and the Built Environment, Senior Lecturer and University of Greenwich (UK) - School of Architecture, Senior Lecturer , WAG: Working Architecture Group, **moss**: holistic systems consultants, jon@wag-architecture.co.uk

Introduction

In this short paper I will try to outline and reflect upon the design research that has emerged from and cross informed the three strands in my practice: as a teacher of architectural design, a working designer, and an academic winger somewhere near to finishing a PhD.

The core material comes from thinking about architecture as a fundamentally cybernetic practice and discipline. By architecture I mean the stuff that surrounds us. Physical stuff certainly, but physical stuff which is constantly emitting messages, in many different ways. By cybernetics I mean the study of systems, and more specifically the study of communications and control within systems, or between an observer (read inhabitant, user, co-designer...) and a system (Weiner (1948) etc). Typically today, any discussion about cybernetics and architecture tends to focus upon interactive environments, or upon other technologies embedded within the built environment that enable buildings to self regulate in some way, such as opening windows, managing the internal climate etc. These are certainly legitimate uses of the term cybernetic architecture, and indeed I will discuss many examples of these kinds of technological environments. However, I want to argue that architecture, as a field of communication and control, is a fundamentally cybernetic practice in a much more basic sense as well. Architecture is an extended mind-field, or consciousness ecology, constructed out of organised objects, media, signs, technology and people in space. An architecturally, or environmentally expanded theory of cybernetics, combines communications theory with morphology, pattern, archetype and demographics, and is profoundly ecological, in the fullest sense of the word. Architectural objects are cultural artefacts that work as a series of systems embedded within other systems. These systems are grounded in the experiencing body of the inhabitant. This body is partly natural, but it also extends out into the world, projecting itself into, or empathising with (Lipps (1935), (Schmarsow (1994), Vischer (1994)), or feeling alienated from (Marx (1959)), other fields, networks and systems (Castells (1996)), whether social, emotional, spiritual, economic, environmental, and technological (McLuhan (1964)). These extensions are primarily cognitive, but are also physical in important ways. They are formed and reformed by the clothes we wear, the buildings and environments we inhabit, the cities and regions that we live in, and the objects and technologies that we use and interact with (McCullough (2005)).

So this, in condensed form, is the ‘academic’ background to all my practice, which I have given the rather clumsy working title of an eco-cybernetic conception of architecture. The point is, is that it is not a question of *can* architecture and design be ecological - they *always already are* fundamentally ecological. Architecture and design are always already as much to do with processes and feedbacks, as they are objects. The question rather is of how *well* do architecture and design *perform* ecologically, and how *consciously*, in relation to other bigger planetary and social systems. The question is how can we find ways of conceiving of architecture and design in such a way as to be sensitive to these feedback loops, between ourselves, the objects that we make, and the world that they are a part of.

In this paper I will try to weave together some of the intellectual ideas and practices that contribute to an eco-cybernetic conception of architecture, and will then show some examples of trying to apply this thinking to my own teaching and design research practice. I will conclude by evaluating these examples, discussing what has worked as teaching and design practice, and what problems can be identified. I will generally consider how this research might contribute to the expanded conception of design as the primary agent of socio-political and enviro-economic change.

Steps to an ecology of (extended) mind

I really like this quote that I collaged together from Gregory Bateson. It is actually spread over a few pages, but I am sure that he would not mind.

"the elementary cybernetic system with its messages in circuit is, in fact, the simplest unit of mind; more complicated systems are perhaps more worthy to be called mental systems, but essentially this is what we are talking about… the individual mind is immanent but not only in the body. It is immanent also in the pathways and messages outside of the body; and there is a larger mind of which the individual mind is only a subsystem. This larger mind… is still immanent in the total interconnected social system and planetary ecology… when you separate mind from the structure in which it is immanent, such as a human relationship, human society, or the ecosystem, you thereby embark, I believe, on a fundamental error, which in the end will surely hurt you…. You decide that that you want to get rid of the by-products of human life and that Lake Erie will be a good place to put them. You forget that the eco-mental system called Lake Erie is a part of your wider eco-mental system - and that if Lake Erie is driven insane, its insanity is incorporated in the larger system of your thought and experience"

Gregory Bateson, Steps to an Ecology of Mind (1972)

In this piece of thinking the cybernetician (or anthropologist, ethnographer, biologist..) Bateson suggests that any organised system or ecology is in some sense a *mind*. This kind of thinking of course has a history - often a rather mystical one. However, it re-emerged with some force around Bateson and a number of related thinkers in the second half of the last century, and it continues to animate the thinking of many evolutionary scientists and philosophers today. In its most properly holistic form, this kind of thinking suggests that all matter, from the most elementary quantum particles and fields, up through atoms, molecules and so on up to planetary biospheres (often referred to as Gaia), should be thought of, in so far as they are organised systems, as minds. In the quote above, Bateson goes on to suggest that that the social systems that we construct should also be thought of as larger minds, and that both these, together with the planetary ecosystem, are in fact extensions to our own minds. Furthermore, he suggests that our minds are ultimately inextricable from these larger environmental minds - if they go mad, we go mad. In this piece of writing Bateson anticipated much of the research that has been produced in recent decades in cognitive science and biology, which for simplicity here I will group together under the name Extended Mind.

Extended Mind thinking emphasises the structural co-evoloution of an organism with its environment, to the point where it is difficult to define the boundary of the organism. It describes a fundamentally cybernetic and ecological conception of being in the world. The core argument of this thesis is that human consciousness cannot in any simple way be reduced and localised to the physical brain, but rather requires an understanding of what Bateson above refers to as "ecologies of mind". These ecologies are co-evolutionary, that is to say historical and environmental, temporal and spatial, and require thinking that goes beyond the cognitive sciences (Clark and Chalmers (1998), drawing in ideas from evolutionary biology (Sheldrake (1981,1991), Lovelock (1979), Harding (2007)) evolutionary psychology (Fodor (1983), Gardner (1983)), Cosmides and Tooby (2005)), anthropology and archeology (Wynn (1996), Mithen (1996), Lewis-Williams (2002)), and indeed architecture.

The basic 'Extended Mind' proposition was put forward by David Chalmers and Andy Clark (1998), in a paper of that name, and is essentially the idea that cognitive processes are not simply located in the brain, but extend out into the world. The term describes an "active externalism", or " the active role of the environment in driving cognitive processes". The classic example (first given by David Kirsh and Paul Maglio (1994)) is that of the scrabble player reorganising letters to help to find new letter-word combinations, as an example of the kind of structurally epistemic relationship that is set up in cognitive processes that are initiated in the brain, but are extended and completed in the world. They argue that the scrabble player is not

simply reorganising letters as representations of processes that are taking place in the mind, but rather is thinking by moving the physical letters.
The scrabble player is a particularly clear example of the kind of structurally epistemic relationship that sets up cognitive processes that are initiated in the brain, but are extended and completed in the world. However, the point I make is that architectural environments, are one of a number of ways by which we have socially extended our minds beyond the 'confines' of our physical brains, in the same way.

This work by Clark and Chalmers was in many ways a restatement, and development of, ideas that had been articulated in evolutionary biology in the previous decade. Closely related, and at time identical concepts, the Embodied or Embedded Mind, considers consciousness to be extended into and throughout the body, both literally, in terms of the extended nervous system, but also in a phenomenological sense, arguing that it is meaningless to talk about conscious experience without the structurally formative sensuous body. These ideas were developed in particular by Maturana and Varela (1987), who developed an innovative rethinking of the way in which organisms exist in the world. For Maturana and Varela, the organism must be thought of as coupled to its environment, and co-evolving with it, as a body and mind. They give as one example the movement of fish through water. Biologists had been puzzled for some time about the speed and agility that some fish in particular have in moving through water. It seemed that they were generally faster than would have been expected through an analysis of the strength and size of their bodies etc. However,it became clear that the fish cannot be understood by analysing their bodies in isolation. It is necessary to understand their movements as part of a system. They are highly sensitive to the flows and eddies that surround them, constantly using minor variations to gain advantage, momentum etc. They cannot be understood removed from their environment.

Clearly, whilst we humans do not exist in quite the same fully immersive fluid substance as fish, it is nonetheless meaningful and productive to ask: how have we co-evolved with our environments? The environments that we primarily co-evolved with were the natural ecological systems within which our bodies developed. According to recent critical archeological work by Steven Mithin, the kind of time frames that we need to consider here are firstly 2 million years ago, when our ancestor homo habilis started making tools, and secondly 100 thousand years ago, when our species, homo sapien sapien first emerged. However our species is unique in that it has learnt to manipulate its external environment to such an extent, that we can consciously intervene in the 'co evolution' that we share with our environments. By actively externalising much of our cognitive activity into shared mind-objects like cities, and mind-systems like language, we have been able to consciously act upon and effectively intervene in the evolution of our extended mind - ie the planet - for better and worse.

Cybernetics, sharpened through extended mind theory, can provide the epistemological and phenomenological structures that might allow us to both describe the existing, and design the future 'interactive architectural ecologies' which couple our embodied minds out into society and the physical environment. By interactive, I do not necessarily mean anything digital or mechanical, but I do mean technological - in the sense that the physical morphology which organises individual and social bodies in space is technological. Steps and platforms that one can sit on or lie down on, basic changes in level, frames and physical enclosure - these archetypal spaces, occupied and required by the most basic human activities, are the most fundamental way that architecture acts as a technology, an interface or prosthesis, and as extensions of the body. When morphology organises human bodies socially, it can be said to have archetypal architectural effects. Just as when driving a car our cognitive map of our body expands to envelope the machine as a prosthesis, so too when occupying architecture, we can project ourselves out, into and over the spatial interface. These interactive architectural ecologies are the basic structures with which we have co-evolved - our most immediate and fundamental interfaces with our environments and each other. Understanding how these various interfaces and feedback loops are mediated by architecture is what I mean by environmental cybernetics.

As the sociologist Georg Simmel intuited, there are correspondences between the forms of experience, the forms of society and the forms we make (Simmel (1903)). If traditionally, the knowledge contained within our social building practices was able to mediate stable mental relationships with the other minds of the biosphere with which we co-evolved, today we find ourselves in a very different condition. In a positive way, we have increasingly intervened in our evolution, and extended ever further our minds out into an environment now composed of a superposition of our first and second natures (Lukács (1971)), which in its modern global metropolitan network form I argue can be thought of as our shared, social, mind.

The geographer and sociologist Manuel Castells has argued that our contemporary condition can be described as a “bipolar opposition between the net and the self”, and he has suggested that if we are to take control of our futures, and the futures of our cities, then we need to build what he calls “bridges” (or we might say ’spatial interfaces’) between what he calls “the space of flows” (ie global information and capital networks) and the “space of places” (ie the real, local world and its specific geographies and environments).

If Bateson is right, we need to think about our emerging ecological crisis as a spatio-mental illness- for which we need to design spatio-mental therapy. Perhaps the ‘bridges’ that Castells calls for are part of the design solution.

Global metropolis, network architecture, ecology diagrams and patterns

This section starts by outlining a history or discourse around spatial networks that can be found and worked with, as new 'bridges', within our collective socio-spatial unconscious. In particular I focus on images of networks that combine our first and second natures... images that explore and develop a new social vocabulary, based on collages and assemblages of people, cities, food production, nature and technology. These include slides showing, in approximate chronological order, work by Antonio Gaudi, Bruno Taut, Frank Lloyd Wright, Buckminster Fuller, Paolo Soleri, Archigram, Superstudio, Cedric Price, Ken Yeang, CPULs, AOC, WAG, Jason Bruges, Usman Haque, Ruairi Glynn and others

This work charts a consistent engagement of modern architecture with questions of network. In some cases the projects should be interpreted literally, as design proposals. In other cases the work should be understood more discursively, as contributions to a discourse, using architectural projection as a means thinking philosophically about networks. All of these projects demonstrate an interest in thinking about how architecture as physical morphology creates contexts and scenarios in which new social engagements with other media can be facilitated (Shepard and Greenfield (2007)). In many cases these scenarios also posit social relationships to ‘the natural world’. Some of these relationships are highly progressive, others are dynamic, but in need of ‘reorientation’. Frequently this discourse has been weakest in thinking about the interconnected questions of procurement, ownership and co-design. There are other traditions within architecture that to some extent deal with progressively with these issues, such as work done by some housing association or co-housing groups. However, these in turn have tended to be weak on ‘bridging’ real archetypal place, to the ‘space of flows’. However, when considered together these projects describe visions of an Eco-Cybernetic renewal of our existing urban-global fabric.

These general visions are developed and explored in more detail through two new ongoing pieces of design research:

1. ‘Hackney Central Ecologies’ is a new sustainable masterplan for Hackney Central in East London. Co-ordinated by local architects WAG and working with students from a local university, this project is generated out of a new kind of drawing: the ecology diagram. Ecology Diagrams aim to capture in one drawing-diagram the various natural, technological and social flows of energy, matter and people, which define the spaces and times of any given site, in such a way as to facilitate an understanding of feedbacks between different system-ecologies. The local traditions of allotment food growing are expanded across a replanned town centre, and reconnected to local markets, co-ordinated through a new local information network, the Democratic Billboard.

2. The ‘Extended Ecologies’ project is a installation, to be realised later this year in London. It is structured around a scaffolding network that contains multiple levels, platforms and connections across and through the space that can be occupied by humans and other organisms and systems, both natural and artificial. The artificial organisms are largely composed of readymade robots and responsive installation pieces contributed by various artists. The proposal is to design an environment that they can ‘co-evolve’ with. Together these structures and organisms will form an experimental new cybernetic ecology.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Rethinking the smart home:

An environmental perspective

Daria Loi[1] and Jay Melican[2]

Abstract

In this paper, we propose a vision of the "smart home" that diverges from current trends in home automation and home-as-machine paradigms, where lights are dimmed and music is tuned on to suit one's mood or where one can set the Jacuzzi's temperature from the car while driving home.

In the future that we hope for, the "smart home" is about intelligent management of resources – for personal cost savings and for the benefit of the environment.

The notion of a "smart home" must change to match people's day-to-day realities, and technology companies must shift their understanding of the relationships between people, technology, and the environment, to identify solutions that enhance everyday life with minimized impact to our planet.

[2] Intel Corporation (USA), User Experience Group, Design Researcher, jay.melican@intel.com

1. Introduction

Over the past few years the severity of the issues that this planet is facing has become not only noticeable but something to be addressed promptly and cautiously – from global warming to environmental degradation and the depletion of natural resources. Growing concerns have pushed governments, NGOs, corporations, regulatory entities and individuals to take action. Among these groups, technology developers and the broad HCI community have a great responsibility.

As Blevis (2007, 511) reports, in the USA 567 million (1/3 of worldwide sales) new Windows-based computers have been purchased since 1981 and nearly half of them have been purchased in the last 5 years, meaning that "the number of computers purchased new in the US in the last 5 years is equal to nearly 90% of the number of people who actually live in the US". Clearly, this is not sustainable from an environmental perspective. However, if we look at the matter from a different perspective, the HCI community and technology developers can balance their responsibilities by playing lead roles.

Blevis (2007, 313) highlights a link between interactive technologies and the use of resources, stressing how "interactive technologies can be used to promote more sustainable behaviours" and how "sustainability can be applied as a critical lens to the design of interactive systems". Recent work by Jain & Wullert (2002), Wash et al (2005), Gustafsson and Gyllenswärd (2005), Bång, M., et al (2006), Stringer et al. (2007), Mankoff et al (2007), and Blevis (2007) demonstrate how technology can be adopted to motivate and enable people to have a more sustainable behaviour, by using social networks as motivational tools, reducing ride sharing's coordination costs, promoting awareness around energy consumption, or focussing on the impacts of interactive or pervasive technologies from a use, development and disposal perspective.

As part of the User Experience Group at Intel Corporation, we typically concentrate our efforts around the home environment and, when looking at domestic technologies, we believe that the concept of "smart home" needs to shift: from a place of seamless automation to one of empowerment. The User Experience Group at Intel uses a blend of ethnographic, human factor and design research skills to develop user-centric consumer electronics products and technology solutions that can genuinely support people's values and practices. Our user experience design enables Intel's Digital Home to start with people to then define the experiences that they want and enable platform designers to create more compelling solutions for a richer user experience.

In this paper, starting from a brief analysis of how the concept of "smart home" evolved through time, we put forward four key principles and metaphors that provide a philosophical foundation for what we believe a smart home should really be about:

- The "smart home" is about using technology to empower people to control and maintain waste and resources in their own domestic landscape;
- The "smart home" has to be a communicative entity – capable of equipping people with a clear and solid understanding of what is going on around them, in their own homes;
- The "smart home" must be accessible, transparent and easy to "read", mirroring how people live (versus how developers, technologists, designers and engineers believe people live); and
- The "smart home" means different things to different people, requiring personalizable, customisable, local practices aware, socio-culturally relevant, open and networked technologies.

The paper is divided into five sections. In the first part we introduce the paper themes while in the second we offer selected historical examples demonstrating the evolution of the ideas

behind the “smart home” as they have led to today’s notions of home automation that caters to an unscaleable and unsustainable lifestyle for the privileged. In the third section, we outline underlining principles and metaphors that should be taken into account when designing the so-called “home of the future”. In the fourth part of the paper, we discuss how companies like Intel can actively support and promote sustainable lifestyle changes by driving alternative visions of the smart home. In particular, we discuss current Digital Home prototyping efforts and the benefits of “smart homes” that enable intelligent resource management. In the final section of the paper, we offer a number of concluding remarks and an overview of next steps to be addressed.

2. A Brief History of the “Smart Home”

We can trace the concept of “smart home” to the early 1980s and that, more generally, of a technologically-enhanced “home of the future” much farther back in time. Alongside the evolution of these idealistic domestic visions, our understandings of ourselves as inhabitants of such futuristic, “smart” homes – and of technology’s role in our lives – has changed over time as well.

Hardyment (1988, 1) points out how the industrial revolution has “turned the home from a productive unit into a consuming maw, and from a nest and refuge to a ‘physical service station’, a battery of bought conveniences from which individuals recharge themselves with food and sleep”. Homes today appear to be more like *shop window*s, rather than a place for baking, brewing and making clothes (Hardyment 1988, 2) – shop windows that are the products of relatively fast paced changes brought about by technologies and how we conceptualized them over time.

In the next sessions we briefly overview some of these changes, to show how the notion of “smart home” developed over time and to support the view that today’s notion of home automation caters to an unscaleable and unsustainable lifestyle for the privileged.

Forty (1992) discusses the impacts of the 1920s labour shortage, related to the introduction of electrically powered machines in the home – machines that could enable one person alone to manage an entire household and still enjoy left over leisure time. Opposed to this idealistic view of technology, Vanek (1974) argues how time spent in housework has hardly changed since 1926, regardless of domestic appliances’ introduction. Vanek’s view has been challenged by many, including Gershuny and Robinson (1988) and their argument that between 1965 and 1985 domestic technology has considerably reduced women’s routine housework. Although the argument around these opposing perspectives appears to be still unresolved, Cowan (1983) and Hardyment (1988) noted how in the 1940s an emphasis on consumption and the introduction of more domestic technologies implied an increase in time spent on housework, paralleled by an increase in standards.

During this first part of the 20th century domestic technologies increasingly populated people’s homes and did so at a fast rate: as a symbol of freedom from everyday chores and the promise of newly discovered leisure time. Even if the notion of “smart home” per se did not exist as we understand it today, the escalating inclusion of new (smart?) technologies in everyday life dramatically changed the notion of home and people’s relationships with time and space. Interestingly however, during this first of part of the century many thinkers, architects, artists and inventors were exploring the relationships between home and technology, challenging the notion of modernity, exploring the benefits of new technologies or investigating future opportunities. Examples include Fuller’s *Dymaxion Dwelling Machine* (1927) and *Aluminaire House* (1932) and William and George Keck’s House of Tomorrow for the Chicago World Fair of 1932.

With the Second World War things evolved again and the depiction of women as technically competent figures capable of freeing men from work outside the home contributed to the post war uptake of domestic technologies. Many women liked outside-the-home roles and needed to be free from domestic chores (Harper 2003): technology was there to address such a need. However, as men started to return from the war, women started to be encouraged to go back in

the home through propaganda depicting ideal images such as waving wives on the doorstep, smiling at their husband about to go to work – just before immersing themselves into daily domestic chores. The below extract from a 1950 article in *The Atlantic Monthly* describes the kind of social sentiment that was at stake:

> Instead of apologizing for being a mere housewife, as many women do, women should make society realize that upon the housewife now fall the combined tasks of economist, nutrition expert, sociologist, psychiatrist, and educator. Then society would confer upon the status of housewife the honor, recognition, and acclaim it deserves. Today, however, the duties of the homemaker have become so depreciated that many women feel impelled to work outside the home in order to retain the respect of the community (Agnes E. Meyer in Plante 1995, 283).

During this time modern technology increasingly supported new ways of living, considerably changing home design: new kitchen styles emerged to accommodate refrigerators and washing machines and television lounges were introduced alongside a substantial increase in TV sales (Aldrich 2003). In brief, the latest home technologies functioned to demonstrate prosperity – as props for the perfect housewife in her display of domestic prowess. During this time the reality of domestic technologies as tools to enable new lifestyle were paralleled by a vast array of visionary and critical explorations of the home and its future.

Mon Uncle, a 1958 movie by Jacques Tati, ironically explores ultra-modernistic notions of the home, where everything is automated and gadget-like, including a candy-coloured space age home complete with neurotic houseboat and automated dogwalker. In Robin Boyd's *House of Tomorrow* (1949) – a two-storied home which included a lounge-room, a study, a dining room with kitchen and a bedroom – technology and the notion of *good taste* were mixed to illustrate modernist aesthetic ideals as well as a new and contemporary way of life. In this modernist proposal of the future, technology played a pivotal role and not only from a structural perspective. A good example was a mocked-up television which anticipated its introduction in 1956 (Serle 1996, 96).

As the 60s and 70s approached, new belief systems related to the role of women in society overturned the 50s ideals: more women had out-of-home occupations and technology was consequently needed to save time and effort within the household. During this time a vast array of domestic technologies emerged, from automated kitchen utensils (e.g. food processors) to personal care (e.g. electric razors) and cleaning devices (e.g. vacuum cleaners). The *house of the future* came to mean something more than simply a collection of futuristic looking technologies collected under one roof. During those decades our imaginary future homes edged ever closer to a vision of the home itself as a machine, capable of precise automation in the service of our human wants and demands for uninterrupted comfort.

During this time of socio-cultural shifts and positive appreciation of the future, new materials and technologies offered the opportunity to explore new options and, importantly: freedom. Consequently, many architects and designers explored the notion of the future home, exploring materials, new structural possibilities and futuristic technologies. Famous examples include Disneyland's Monsanto's *House of the Future* (1967), made almost entirely from the latest plastic technologies, and Matti Suuronen's *Futuro* (1968), a prefabricated space-age home made of fiberglass-reinforced polyester plastic that summarized the typical utopian architecture of the era: mobility, leisure and new materials. An increased interest in wiring homes to augment their functionality started during this time. America's Independent Electric Light and Power Companies for instance promoted during that time a home of the future where "electrically operated climate-conditioned extensions will permit *summer terraces* all at will by your electricity" (in Heimann 2005).

In the 1970s and 1980s colour TV set dramatically penetrated the market, together with video cassette recorders, compact disc players, microwave ovens and personal computers – these technologies considerably changed the home landscape as it was known. In many ways the two previous decades can be seen as preparatory for the 1980s trend toward "smart homes,"

where advanced control systems automate the domestic space in seamless ways that isolate inhabitants from the realities of their environment.

Following the *Cooperative Research and Development Act* passed in 1984 by the U.S. Congress, the National Association of Home Builders (NAHB) in Washington, D.C. formed the SMART HOUSE Limited Partnership with the aim of providing integrated wiring for all current home services and provisions for home automation technology. NAHB's vision was that of a computer-controlled home: a house, condominium, or apartment where people can spend more time pursuing life's rewards and less time performing routine household tasks (Howard and Wagoner 1991). The concept of the smart home was officially born.

Within this context people started integrating new technologies in their homes in different ways and similar technologies implied a variety of social changes in different parts of the world.

Ironmonger et al (2000) for instance describe how different types of Australian households adopted new technology at different rates, with higher technology adoption in households with children and slower in one-adult households. Trend analyses revealed that color television, cable television and the videocassette recorder collectively played a major role in expanding the share of disposable personal income devoted to mass media in Belgium between 1970 and 1991 (Dupagne 1997). In the US 95% of the households had a TV in 1972 (half of them in color), HBO opened its doors in 1975 and by 1987 half of U.S. TV households (about 55 million) subscribed to basic cable. Finally, the introduction of personal computing in the home opened up new opportunities for work, play, connecting, learning, and doing business, significantly impacting everyday life, from spatial, time and speed perspectives. Aldrich (2003, 20) highlights how through time different forms of domestic technologies have been adopted at different rates and how such a trend might have implications for how smart home technologies might be adopted in the future, reiterating Bowden and Offer (1994) a distinction between "time saving" goods (such as washing machines) and "time-using" goods (such as the television).

Since the 1990s the concept of smart home has permeated popular culture (Aldrich 2003, 22): from publications in popular magazines such as Vanity Fair to television programs such as BBC's *Dream House,* the idea of inhabiting a smart home has become of public domain, together with related fears, uncertainties, concerns and dreams.

The uptake of home automation and control technologies has however been slower than predicted; many of the ideas behind these homes of the future and the associated promises of housework-free living do not match people's day-to-day reality. Gann et al (1999 in Aldrich 2003, 22-3) suggest a number of reasons for such a slow uptake, including: relationship between the required high initial investment and the its benefits; the costs associated with "retrofitting" old homes versus wiring new homes; a lack of common protocols and the consequent focus on on/off switching systems for single applications; suppliers narrow "technology push" approach and lack of users' needs; and little usability evaluation by suppliers.

Nonetheless, the dream of a technology-enhanced home of the future continues to permeate current thinking around smart homes and domotics. Technology companies are equally caught up in this dream, which isolates them as well from the realities of domestic living and from the impact that their home technologies have on people's aspirations and expectations and, in the end, on the environment.

At the 2008 Consumer Electronics Show (CES) Bill Gates described a home of the future in which computing power will be available in every room, through embedded-in-furniture touchscreens. To have a clearer understanding of such view of the future home one can refer to what is called *Microsoft Home*, modeled on Bill Gates' own Seattle mansion.

Microsoft Home, powered by four PCs running Windows XP, features dozens of networked monitors, Xboxes, appliances, and consumer electronics devices scattered everywhere: security and entry to the future home is enabled through an electronic kiosk with a touchscreen, a biometric scanner, and a smartcard reader; as one enters lights and heat automatically fine-tune to one's preference and a screen on the wall reads emails aloud; in the kitchen one can run a pot

beneath the barcode reader on the microwave and automatically set time and temperature or get help with cooking by scanning RFID tags on specific ingredients; digital media is everywhere and accessible from any room, on every device, thanks to a central media server which supplies entertainment throughout, seamlessly streaming content where is needed (O'Brien 2003).

Microsoft does not stand alone, of course, as the source of our collective vision of a future smart home. It is precisely this type of vision of embodies in our view the type of future home that should be re-considered: it represents a concept of home automation that caters to an unscaleable and unsustainable lifestyle for the privileged. In the following sections, we propose alternatives to this lifestyle and discuss how companies like Intel can actively support and promote sustainable lifestyle changes by driving alternative visions of the smart home.

3. Smart homes for the rest of us

Blevis (2007, 503-4) overviews five principles that set sustainability as the focus in the context of interaction design: linking invention & disposal; promoting renewal & reuse; promoting quality & equality; de-coupling ownership & identity; and using natural models & reflection.

Gann and Barlow (1998, 13) discuss how the smart home industry must "motivate consumers to buy its products" and therefore develop "solutions that satisfy real user needs" – solutions that have to "operate as (1) *generic technologies*, providing the basic, standard compatible building blocks for (2) *context-specific systems*, adaptable to a wide variety of dwelling types, and (3) *personalised systems*, tailored to specific individual and household requirements". The authors (Gann and Barlow 1998, 13) also highlight how smart home solutions must satisfy a number of conditions:

- Functionality – the equipment/system must have clear and unambiguous functions;
- Ease of use – clear and simple user interfaces, interactivity and connectivity;
- Affordability – for individuals and housing providers;
- Reliability and maintainability;
- Flexibility, adaptability and upgradability – systems need to develop as user needs change; and
- Replicability and ease of installation – systems need to be available as a standard, reproducible product.

While we agree with Blevis' and Gann & Barlow's views, we would like to add a set of nested underlying principles and metaphors that provide a philosophical foundation for what we believe the smart home should be.

First of all, we believe that on a conceptual level the notion of "smart home" has little to do with that of automation, where technologies in the home can predict one's mood and reconcile one's preferences, seamlessly and automatically. We indeed believe that the "smart home" needs to be about using technology to *empower people to control and maintain waste and resources in their own domestic landscape*. To do this it is crucial we conceptualize the home as an ecosystem that generates waste and consumes resources. In such a paradigm, "smart" means capable of helping people manage their resources and waste.

An ethnographic study conducted by colleagues at Intel in 2006 and 2007 (Woodruff et al. 2008) reported how for participants the notion of living in a "green home" meant "constant activity to keep it in tune with nature's changing state and rhythms", to minimize energy use and maximize comfort "by constantly reconfiguring windows, doors, skylights, solar panels, etc". The metaphor of *living on a ship* was often used by participants to refer to this ongoing configuration and maintenance, embedded in their experiences of living in a "green home". This "living on a ship" metaphor comes directly from everyday practices around the use of technologies to live in a

“greener home” and it mirrors our proposition that a “smart home” is about the capacity of controlling and maintaining waste and resources, instead of spectable and the seamless automation of multiple “intelligent devices”.

Within this paradigm, we secondly propose that the “smart home” needs to be about information, not spectacle. We believe that the smart home has to be a *communicative entity* – capable of equipping people with a clear and solid understanding of what is going on around them, in their own homes. Within this paradigm, “smart” means practical, everyday, accessible, and, more importantly, in touch with the relationships between house and household – place and inhabitants.

If we accept the above notion of the mart home as a communicative entity, it is clear that today’s smart homes often do not allow people to be smart. Today the home is indeed un-transparent about what it does, when and why. This generates a situation where its inhabitants cannot clearly and easily see what is occurring and what would enable them to make smart decisions. We consequently propose that a home is smart when it is *accessible, transparent and easy to “read”*.

These features align themselves with the conditions proposed by Gann and Barlow (1998, 13) overviewed at the start of this section. This notion of accessible, transparent and easy to “read” smart home is fundamentally about developing technologies that mirror how people live, versus how developers, technologists, designers and engineers believe people live. To gain such deep understandings and embed them into the design of new home technologies, developers must ensure ethnography and design research efforts are natural components of the development cycle and that such insights are truly embedded in it – from its start to the end.

Only by gaining a rich understanding of what, how and why people use the world around them the way they do, we can find ways to design accessible, transparent and easy to “read” smart home technologies.

Finally, while for some (like Bill Gates) “smart” means one thing with one solution, we believe that for the rest of us *smart home means several things*, as the home is a complex, multi-layered and multi-faced entity where new technologies increase complexity, generate possibilities and potentially create unnecessary and un-transparent layers. Different geographical location and socio-cultural environments call for technology solutions that take such differences into account and that stay away for *one-size-fits-all*. Personalization, customization, local practice awareness, socio-cultural relevance, open platforms and local networks all play a crucial role in the development of home technologies we believe can make our homes smart.

To summarize, we propose that a paradigm shift must occur and that we must reconceptualise the idea of “smart home” as a *communicative entity* that employs *accessible, transparent and easy to “read”* technology which empower people to *control and maintain waste and resources* in their own domestic landscape in a manner that is *personalizable, customisable, local practices aware, socio-culturally relevant, open and networked*.

4. Changing the Change from Within: a Corporate Credo

The perspective we represent in this paper, and to this community of researchers, is squarely rooted in the authors’ collective backgrounds as design academics and, now, as corporate practitioners of design research. We are not so naïve as to believe that corporations might altruistically lead the charge toward a sustainable future – not until there is clear evidence of profit in that direction. On the other hand, we know that large corporations can instigate widespread change: their weight may make steering them an unwieldy operation, but, when they decide where they are going to land, their impact can be mighty powerful. And it is ultimately the individuals working within corporations who set the company’s direction and decide its goals.

In this section of the paper, we discuss how companies like Intel can actively support and promote sustainable lifestyle changes by driving alternative visions of the smart home. In particular, we discuss current research and prototyping efforts within Intel's Digital Home Group, and, in as much as we feel we have achieved some success in shifting the corporate conversation at Intel in a positive direction, we offer these thoughts on what we might have done well when we were most successful. Every organization will be different, of course. Accordingly, we submit the following principles as our own credo, in which others may find helpful guidance when it comes to rethinking their visions of a sustainable, technological future from within a corporation.

Change the conversation. That would have to be the first principle and the cornerstone of our approach as outlined in this paper. As designers working in the high-tech industry, we are responsible for communicating back to the company – and eventually back to the many other companies we work with, and to the end consumers of their products – a coherent vision of the integration of the industry's technological advancements in people's everyday lives. We do not work alone in that endeavor: we would not get very far if we tried. But by joining our voices with those of like-minded individuals throughout the company – in corporate strategic planning, in public relations, in sales and marketing – a growing group of committed individuals has been successful in shifting internal conversations about Intel's sustainability initiatives: away from a singular focus on producing ever more energy efficient products and toward a broader conversation that encompasses not only the corporation's responsibility to maintain greener office buildings and production facilities, but increasingly to one that highlights new business opportunities in enabling eco-technologies[3].

We could consider the glut of electronic gadgets to which we contribute simply part of the world's problem, or we could rethink our products and the services they enable in ways that will best support sustainable end-user practices (by promoting telecommuting over air travel, to give an obvious example). In Intel's Digital Home Group, we have begun to talk more frequently about home electronics not only as devices that draw power in order to provide us with entertainment, but also as devices with which we may outfit homes of the future so as to empower their inhabitants to intelligently manage home systems and the consumption of non-renewable resources. Our challenge to ourselves has become: "How can we leverage the 2% of overall household energy typically used to power the home PC, to significantly curtail the remain 98% of residential energy consumption?" (US DoE, 2001).

These conversations have been heavily – if second-handedly – influenced by the rhetoric and ideas of *bright green environmentalism*, championed at Intel by our colleague Jay Hasbrouck (Hasbrouck and Woodruff, 2008)[4]. "[B]right green environmentalism," according to writer Ross Robertson, "is less about the problems and limitations we need to overcome than the 'tools, models, and ideas' that already exist for overcoming them. It forgoes the bleakness of protest and dissent for the energizing confidence of constructive solutions" (Robertson, 2007). Its proponents tend to look optimistically toward human innovation, smart design, and new technologies to provide answers to the human-made problems of our environment (Wikipedia, 2008).

As such, it can be an extremely empowering force in a culture of solution-driven engineers. Nonetheless, that change in the corporate conversation has not happened quickly. Convergence on the talking points that have now begun to take hold has been the hard-won product of many conversations and much repetition. And it has been aided by the rhetorical value of prototyping and simple mock-ups – by our ability to show our colleagues what it might look like to provide end-users with the capability to measure and then to model their homes' inner workings, to set rules for heating, cooling, and appliance use that respond to real-time fluctuations in energy costs,

[3] We should note that Intel has a long history of working with the U.S. Environmental Protection Agency on a range of environmental initiatives, including Climate Savers (http://www.climatesaverscomputing.org), and is consistently recognized for its efforts to improve sustainability of its operations (http://www.intel.com/intel/environment).

[4] The term "bright green" was first coined by American blogger and author Alex Steffen in 2003 to characterize an emerging, more technology-friendly school of environmentalism, in contrast to the traditional, "dark green" environmentalism which, to over-simplify, advocates the return to simpler ways of living and radical political change as the path to a sustainable future (Wikipedia, 2008).

and to monitor real-time feedback on their energy consumption from the computing and display devices distributed throughout their homes.

Change the metaphor. In short, this is the single, simple point we would like to make with this paper. The biggest roadblock we have encountered in introducing design concepts for computer-supported sustainable living has not been our colleagues' resistance to acknowledge that human impact on the environment is indeed a real problem, nor has it been failure to recognize a potential business opportunity in home automation and control: it has been fatigue. Any mention of "smart homes" within the organization is likely to draw a familiar, frustrated response from our well-seasoned technologists: "We've been down that path before". It is this frustration and disillusionment with the technological dreams of the past which has made it so important for us to redefine what it might mean for homes to be "smart".

Our "smart home" is a response to a new set of technological and social circumstances: a widespread and growing base of installed home networks that allow for the piecemeal introduction of networked devices and distributed sensors on the one hand, and the rise in consumers' awareness of the impact of their aggregate personal actions at a global level on the other. The "smart home" for us is now inextricably linked to both a negative (the old, unrealistic vision of a domicile designed to pamper its inhabitants while minimizing the need for human effort or imput) and a positive (the "smart home for the rest of us" described in this paper).

Persist in taking on the tough, small problems. While it can be helpful to sketch "the big picture" in explaining our particular ideas to others, it is often necessary that we tackle big problems from many fronts simultaneously. That means taking on small, but very tough, design challenges. Here we offer a concrete example in the user-interface problems associated with home energy management devices. Early in our explorations for smart homes equipped with whole-home energy management solutions, design team members installed in their own homes devices currently available on the market for monitoring and controlling home energy consumption. The results of those studies remain unpublished, as we are unable to put ourselves in the position of critiquing other companies' products, but we can report that there are many shortcomings associated with the available consumer solutions (this is a product category that would benefit greatly from the attention of a few concerned interaction and experience designers). Home energy monitoring devices were found to be difficult to install and set-up, often requiring the assistance of a professional electrician and labelled to warn consumers of the potential for death in the case of mishandling at instsallation (not generally considered the hallmark of a user-friendly product). While all the devices our collegues tested provided them with data, none but the most elaborate systems currently available (and generally installed only in newly constructed homes) provide information that suggest to users actions they might take to improve their current energy comsuption patterns. Providing actional information on the operation of home systems has become one of our driving objectives.

Even more discouraging were the findings of scientists who have determined that programmable thermostats – perhaps the simplest and certainly the most widely adopted of efficiency-oriented smart home appliances – may actually decrease the energy efficiency of home heating and cooling systems. In 2005, Energy Star endorsed a number of commercially available programmable thermostats, but by 2006 was forced to rescind that endorsement in the face of mounting evidence that homes equipped with programmable thermostats were not more efficient and were, in some cases in fact, less energy efficient than the same size homes using standard mechanical thermostats (Meier, 2007)[5]. The empirical findings at first seem implausible. How could a programmable thermostat, which is "smart" enough to automatically adjust the temperature in my home to optimal levels for every hour of the day, regardless of whether or not I remember it, be less efficient than the old-fashioned human-operated switch? Most of the blame has fallen on the user interface. Many users, it turns out, never properly learned to program their thermostats. Others used theirs just as they would use a mechanical thermostat – as a switch to

[5] Energy Star is the US Government program that promotes energy efficiency products and practices, in part by setting standard, energy-efficient performance requirements and endorsing products that achieve those standards (http://www.energystar.gov).

turn up the heat or cooling fans, regularly over-riding the programmed climate controls (Meier, 2007).

The simple residential programmable thermostat may be the example that best demonstrates the shift in metaphorical thinking proposed here in this paper; given a bit more thought up front, we may even have predicted such an outcome. Thermostats, for most of us in the US anyway, generally include a single temperature sensor integrated (and located together) with a wall-mounted control unit. The programmable thermostat adds to that configuration the ability to set rules for high and low temperatures and, often, accommodates alternate schedules for weekends and weekdays. We might have predicted that, as humans, we are unfortunately unskilled when it comes to predicting exactly how warm or cold we might be on any given Sunday or Monday of the year; whether we are likely to appreciate a warmed home when we return, on schedule, at 7:00 each evening, or if we might not have thought to turn the heat until several hours later when temperatures outside had reached much more uncomfortable lows. It might just be that "comfort" is more difficult than we had expected to peg to a specific measure of Celsius or Fahrenheit. Today's programmable thermostats may be too "smart" for their own good. Then we must account for the thermostat's singularity of placement. It may be a minor inconvenience that at the moment I recognize my slight discomfort of having just barely over-heated (or over-cooled) my home, I am not in the same room as my thermostat control. It may add only a few minutes to the time it takes me to adjust that control (probably the next time I happen to pass by the thermostat). But cumulatively, each of those hesitations might be just enough to make a big difference in my energy bill. Add all those factors to the simple usability problems of most commercially available programmable thermostats, and the findings which led to Energy Star's retraction of its original endorsement seen much less a puzzle, and much more a hairy UI design problem. At Intel, it has signaled the opening of an opportunity to employ some of the company's research in distributed sensor technologies and to establish a guiding vision of how mobile and embedded displays that have spread throughout our homes might be thought of as useful components in a system of home controls which empowers people to be smart about their own home energy use.

Demonstrate viability by demonstrating resonance. We rest assured that we will eventually be called upon to answer the question: "but how big is the market?". In many ways a focus on "green" solutions can make it too easy for executives to dismiss sustainability-minded initiatives as catering to a niche – a negligibly small group of left-over hippies who have taken up residence in the American Pacific Northwest. Executives need to see the numbers that affirm a concept's viability by confirming the size of the available market. In early 2008, we had an opportunity to conduct a six-country, 2400-person survey with the Nielsen Company. Our aim was to evaluate the appeal of some of our smart home product concepts and, more broadly, to understand people's (consumers') level of commitment to, and motivations for, engaging in sustainable practices at home. Much of the existing research in this area is limited to a specific market or region of the world, so we were very fortunate to have this opportunity to survey a large, international sample. While it is beyond the scope of this paper to report the results of that survey here, we can report that we were surprised – perhaps because of our own cultural prejudices – by our survey respondents' consistent sensitivity to the impact of personal choices on global conditions, and by the willingness, even eagerness, to invest personal energy – time, and even money – in smarter solutions and individual actions that might reduce their environmental impact. Across the six countries surveyed (US, Australia, Germany, Italy, China, and South Korea) we found the most enthusiasm from our Chinese respondents, 66% of whom said they would be willing to spend both more time and more money if it meant being environmentally responsible[6]. It is in research findings like these that we find the data we need to respond to critics who continue to believe that people are unwilling to participate in the intelligent management of their own resource consumption, and to win the continued support of the companies we work in our pursuit of smart home solutions for the rest of us.

[6] Findings of a survey conducted by the Nielsen Company for Intel Corporation, March 2008.

5. Conclusions

In this paper we briefly reviewed how the notion of “smart home” evolved till today’s concept of smart home as a place of seamless automation: a concept that in our perspective caters to an unscaleable and unsustainable lifestyle for the privileged. We then counter-proposed alternatives to this lifestyle by overviewing a set of four nested underlining principles and metaphors that provide a philosophical foundation for what we believe the smart home should be about. We finally discussed how companies like Intel can actively support and promote sustainable lifestyle changes by driving alternative visions of the smart home, offering insights on the principles that we adopted as our own corporate credo.

Within the paradigm we just offered, the future “smart home” that we hope for is related more closely to the intelligent management of resources – for personal cost savings and for the benefit of the environment. To achieve this result, the notion of a “smart home” must change to better match people’s day-to-day realities – technology companies must shift their understanding of the relationships between people, technology, and the environment in order to identify solutions that enhance everyday life with minimized impact to the planet on which we live.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Fashion that helps us flourish

Kate Fletcher[1], Lynda Grose[2]

Abstract

Designing and making fashion clothes that *help us flourish* would transform the fashion industrial system at root. Not only would it change what we design and produce, it would also influence consumption. It makes a distinction between a culture defined by its material consumption and one that is catalysed by using material and non-material satisfiers to help us engage, connect and better understand each other, our world and ourselves. This paper explores these ideas, introducing this unconventional agenda and examining what format fashion could take if designed to help us flourish.

1. Introduction

It is an obvious truth that the relationship between fashion and high volume consumption conflicts with sustainability goals. In the UK we are now buying one third more clothes than four years ago and nearly 40kg of clothing and textile waste is discarded per person per year (Allwood et al. 2006, 4). The negative sustainability implications of this high volume consumption is still a taboo subject for global brands and high street retailers who depend on a high throughput of product for financial success. Indeed, high product throughput has come to characterize everyday living in the West, where shopping and spending are the leisure activities of choice. Fashion is at the forefront of the consumerist lifestyle, where we meet our desire for pleasure, new experiences, status, and identity formation through buying goods – many of them clothes. And because we have an inexhaustible supply of desires, consumption - particularly of new items – continues to grow because we see the purchase of each new item as providing us with novel experiences that we have not so far encountered (Campbell 2006, 284). In the first decade of the twenty first century we shop for clothes addictively, frequently with money we don't have and are trapped by record levels of credit card debt. The pressure to constantly reformulate identity in the light of changing fashion trends helps feed psychological insecurity and rising levels of mental illness. Not only is fashion consumption a sustainability problem, but so is fashion production: manufacturing garments exploits workers, fuels resource use, increases environmental impact and generates waste.

Thus it would seem that the fashion industry is a near-perfect case study in all that is pejorative and reprehensible in the arena of production and consumption. And that fashion, rather than helping us flourish, i.e. helping us engage, connect and better understand ourselves, each other and our world (as is suggested by the title of this paper), is, for the most part, obstructing and actively undermining this process. Indeed there is little dispute that fashion is part of the sustainability problem. For some people the best way to 'fix' this problem is to subject fashion and its creators to controls and constraints and legislate against its ill effects. But cutting back, limiting and stipulating what we can't do or can't have is ultimately a negative view of sustainability and fails to recognize the importance of fashion to human culture. It stops short of showing us what *is* possible. Fashion can, and indeed must, be cast in a different role: as an integral part of a range of sustainability solutions. This paper explores one approach to designing fashion that helps us identify the causes of sustainability problems and cultivate new aspirations.

2. Value-free fashion

For many people the tension and apparent paradox between the competing values and objectives of both sustainability and fashion are almost too great to resolve. These values and objectives seem to call upon disparate parts of knowledge, experience, society and almost even different parts of our brains. Sustainability is concerned with the long term, with material restraint, natural integrity and promoting human well-being. Fashion in contrast, is communication, display, the production of symbols and 'the perfect investiture of the now'. For some people, fashion is the epitome of value-free expression and equips us to appear in a world that has little or nothing to do with the earth, the health of its soil or its people but is instead a world of ideas (Farrell 2008, unpaginated). Indeed, in this world of absent connections between fashion and the social and ecological systems that support it, almost anything is possible; there are few limits.

For critics of fashion, it is this free-floating limitlessness that feeds many symptoms of unsustainability including: consumerism, insecurity, peer pressure and homogeneity. This degradation is further fuelled by the globalization of fashion, described as 'McFashion' (Lee 2003) where the same garment and same shopping experience is available in the New York, Tokyo and London retail outlets of a global brand. Also implicated are serious medical conditions such as anorexia and bulimia, tragically common among young women and men, and high levels of stress linked to the need to constantly reformulate our identity each season. Not only can fashion damage individuals and escalate consumption and disposal (consumerism is as much about individuals disposing of goods as about buying them) but fashion trends themselves have confused sustainability issues and promoted misconceptions. Here passive consumers 'follow' the trends prescribed by industry and choose between pre-fabricated, largely homogenous goods. These products boost the elitist myths that have built up around some brands and designers. They allow the fashion system to mystify, control and 'professionalize' the practice of designing and making clothes and further dictate how we consume them. The result is disenfranchised and dissatisfied individuals, who feel both unrepresented by the fashion system and unable to do anything about it.

3. The cultural value of fashion

It is fairly easy to frame fashion as the villain of the piece with regards to sustainability. Most of us are already familiar with the serious labour abuses, high resource use and pollution impacts associated with making fashion clothes, let alone the numerous issues associated with (over) consuming them. But how do we go about moving from analysis of what is wrong with fashion to imagining and creating something that is right? For many people (including some policy makers, industry executives and environmental campaigners) what is 'right' is the same as reducing the impact of what is 'wrong' and a great deal of effort is expended on implementing changes that slow down the process of environmental degradation and social injustice. Indeed these approaches are valuable and bring some benefit particularly in the short term. Yet there is no getting away from the fact that such approaches are borne out of negative starting points: they frame things in terms of what we cannot have and what we cannot be, rather than showing us what *is* possible. So for example, such changes suggest that we filter wastewater from a dye house. But while this cuts down on river pollution downstream, it does not show us alternative ways to colour fabric. Likewise, substituting organic cotton for conventional fibre in a garment is recommended. But while this reduces chemical use in the field, improves the health of workers and reduces soil toxicity, it does not present us with a way to design garments that are loved and cherished for many years. Similarly they suggest that we choose second hand clothes. But while this saves water and energy in production, it doesn't show us what form conscientious and sustainable buying habits will take.

In short, many of these popular approaches attempt to navigate us to a place we want to be (sustainability) by extrapolating from a place we don't want to be. But this is an impossible journey. Industrial ecologist John Ehrenfeld (2004, 4) states: 'creating sustainability is not the same as reducing unsustainability'. He continues, 'They are categorically different. Unsustainability is measurable; it can be managed and incrementally reduced. But sustainability – the possibility of flourishing in the future – is aspirational'. Yet it seems that, in the fashion sector at least, we have been very slow on the uptake of recognising the imperative of creating a sustainable future that is not just an extension of how we do things today; that is something that flows from different ways of thinking and acting to those we have used in the past. This is perhaps all the more astonishing given the centrality of fashion clothes to human culture. Fashion clothes are important to our relationships, aesthetic desires and identity. Throughout history clothes have been at the centre of how human interaction; they are an expression of gender,

sexuality, age and ethnicity. Yet bizarrely when it comes to exploring new and different solutions to sustainability questions in fashion, this very cultural value tends to be diminished, rather than celebrated. Emphasis is placed on constraining the actions of designers and manufacturers, rather than attempting to cultivate synergies that flow from bringing these players together to address common concerns. We argue that it is in the action of celebrating the individual, societal and cultural value of our clothes that new opportunities emerge for us to create sustainability and help ourselves and our world to flourish.

4. Fashion and needs

Central to this vision of fashion is an understanding of needs. Not all clothes meet needs in quite the same way. For example, fashion clothes and non-fashion clothes are different entities and meet different needs. While the ostensible function of non-fashion clothing is material – to protect our modesty and keep us warm, this function changes for fashion clothes. Fashion clothes are used to signal who and what we are, to attract (or repel) others and to put us in a particular frame of mind. These emotional needs are complex, subtle and inexhaustible and where we try to meet them through our clothes, leads to an escalation in how and what we buy. It follows therefore that understanding more about the relationship between fashion and sustainability is contingent on a greater understanding of needs. If we want to avoid depriving people of their need for identity and participation, we can't just forget about fashion and scrap everything other than the wardrobe basics. In other words, we can't radically cut consumption of clothing until we begin to understand its significance as a satisfier of human needs.

Humans possess specific, identifiable needs that are the same, regardless of nation, religion or culture. Manfred Max-Neef (1992) has identified these as subsistence, protection, affection, understanding, participation, creation, recreation, identity and freedom and they fall into two broad categories: physical (material) needs and psychological (non-material) needs. Crucially while these needs stay the same, what changes with time and between individuals, is how we go about meeting or satisfying these needs. Some of us may, for example, satisfy our need for identity with fashion while others may meet this need with religion, language, work etc. Each way of satisfying needs has different environmental and social impacts. Where these satisfiers are products or services (though they can also be social practices, forms of organization, political models and values), they are the traditional - if unconscious - focus of design.

We consume materials to put a roof over our heads, keep us warm and well fed. Increasingly – as is the case with fashion - we also use them to help meet our non-material or psychological and emotional needs. Here lies a paradox: psychological needs are not easily satisfied, and in some cases are even inhibited, by consuming materials alone. Thus consuming material goods doesn't stem our desire for more material goods if we are buying them to meet psychological needs. Many of us will, for example, be familiar with the feeling of a new want or desire surfacing no sooner than the first one is satisfied. Put simply, consuming materials gives us a false sense of satisfying our psychological needs - a fact long recognized by many religious communities as seen in their guidelines for living materially-simple but active and spiritually-rich lives. This point is further reinforced by a number of studies that suggest we are no happier now than in the 1950s, even though we own far more material possessions. Max-Neef stresses that needs are met by a combination of internal and external means, yet in our society, as Ann Thorpe (2007, 118) points out, most satisfiers come from sources outside of ourselves (like garments), with very little attention placed on internal means such as personal growth. The pursuit of commercial opportunity has drawn psychological needs into the market place and replaced internal means of meeting needs with products. Marketing techniques have been perfected that

link products like fashion clothes to non-material needs and where the consumption of fashion is a way to signal wealth, identity and social status and experience new things.

Understanding needs helps us understand why fashion is important to us. According to Max-Neef, any fundamental need that is not adequately satisfied reveals a poverty. Just as people are poor when they have insufficient food and shelter to meet their need for subsistence, poverties can also be experienced in relation to other needs. We are poor if we experience bad health care, domestic violence, etc. (a poverty of protection); and poor if we cannot for reasons of widely dispersed family groups, oppression, etc. meet our need for affection. We are also poor if we can't satisfy our need for identity, participation and creation – three needs which can (at least in part) be met by fashion. Yet fashion clothes as we experience them today are also the cause of multiple poverties; impairing the possibility of garment workers to meet needs of subsistence, protection and freedom due to low wages, forced overtime, sexual harassment etc; damaging our collective rights to enjoy a safe and convivial natural environment through toxic pesticide use and chemical pollution; and inhibiting our need to participate, understand and be creative by being sold 'closed' ready-made products with little opportunity for self-expression.

Our real design challenge is to build a new vision for fashion that satisfies needs and minimizes poverties. To do this we must first understand what represses or stimulates opportunities for meeting needs. Then we must apply this understanding so that we minimize negative effects and maximize positive ones. To minimize the negative effects, we can begin by making simple changes such as switching to fair trade and organically-grown materials. To maximize positive ones we can establish decentralized local production facilities and promote participative design between user and maker. This changes the emphasis of our practice away from producing goods that undermine us and the health of our environment and society and onto those that nurture our well-being. Max-Neef (1992, 202) describes this as a shift from a system where 'life is placed at the service of artefacts (artefacts are the focus)… to (one where) artefacts at the service of life (quality of life).' This simple shift changes the goal of the industrial system. It is a distinction between a culture defined by its material consumption and one that is catalysed by using material and non-material satisfiers to help us engage, connect and better understand about each other, our world and ourselves. John Ehrenfeld has described this as *flourishing*: 'our artefacts need to be designed to support conscious choice and reflective competence rather than blind consumption. They should produce long-lasting human satisfaction… We will be able to flourish simply by living life as we encounter it' (Ehrenfeld 2004, 7).

Designing and making fashion clothes that help us flourish would transform the textile industrial system at root. Not only would it change what we design and produce, it also influences consumption. Max-Neef suggests that if we promote a broad understanding of needs that recognises the importance of internal as well as external means of meeting them, then we can start a process of transformation that draws us out of a narrow focus on material wealth (what we do or don't have) and instead motivates and mobilises people to use their own skills and ideas to satisfy their needs.

Designing fashion to help us flourish is extremely challenging. One project that specifically worked with Max-Neef's ideas of needs was Super Satisfiers, part of the 5 Ways project (Fletcher and Earley, 2002/3). Super Satisfier's aim was to develop a concept piece that explored the way we meet needs by converting subtle and unconscious uses of clothing into a design brief. The hope was that this would imbue a garment with meaning to try to break the cycle of consumption and dissatisfaction and in doing so make our hidden needs more obvious so that we can connect more with ourselves. The project focused on the need for affection and developed the 'caress dress' (see Figure 1); one designer's highly personal take on how she attracts attention from

others through garments. The designer noticed how she attracted more attention when she wore tactile fabrics and enjoyed the feeling of friends touching her garments. The dress uses slits and subtle cut-aways to reveal hints of bare skin at the shoulder, the waist and the small of the back. Its purpose is to invite friends to touch and embrace her and for the wearer to feel the warmth of others affection for her.

Needs and satisfiers are both complex and extremely personal. Each of our psychological needs is met in different ways and what is nurturing for one of us is frustrating for another. So if we pursue a needs-based approach to promoting sustainability, then we have to build an industry that respects - and actually finds business opportunity in meeting - our diverse, individual needs. To do this effectively, we need to recognize that products only play a partial role in meeting needs and that the majority of human well-being lies entirely outside the product world. This does not mean that products and the industrial sectors that produce them aren't part of a needs-based approach; only that they aren't all of it. There is also a key role in needs-centred design for the public sector, community groups and by fostering different types of social practices and forms of organization.

4. A new fashion ethic

What will fashion that helps us flourish be like? As hinted at above, it will have to be responsive to our diverse, individual needs. Diverse products do far more than just showcase lots of different materials, they can also sustain a sense of ourselves as human beings by being more likely to recognize a wide range of symbolic and material needs. Smaller makers with flexible and nimble production systems can produce products that are personal and specific and that are 'just right' for us. They reject homogenization and autonomy in favour of expressiveness and difference. This necessitates a different production system, one where industry is made up of 'millions of markets of dozens' (a plethora of small volume products), rather than our present day set up of 'dozens of markets of millions' (a limited number of large volume products). This more needs-friendly approach to production happens to also chime with predictions for the future of business more generally, which make use of new media and tools like the Internet to match consumer needs with specific products. This is the complete opposite of the Fordist way of doing business so dominant in the twentieth century, where a few generic products were marketed to all people.

The success of this diverse, flourishing fashion ethic will also be secured in the relationships it fosters. We will see beauty and greatness in garments that value process, participation and social integration, in pieces that advance relationships between people and the environment. The activity of friends knitting together is joyful, compostable garments are joyful, supporting a disadvantaged community with careful purchasing is joyful. Relationships can be fostered by designing garments that encourage us to ask deep questions about our sense of place in the natural world. Such garments could accomplish this by supporting our desire to ride a bike not take the car or by being sharable between friends. Sustainable fashion is about a strong and nurturing relationship between consumer and producer. It is about producing garments that start a debate, invoke a deep sense of meaning or require the user to 'finish' them with skill, imagination or flair. It is about designing confidence- and capability-inducing pieces that encourage versatility, inventiveness, personalization and individual participation.

This unorthodox agenda is a call to get 'back to roots' and in essence describes a future for sustainable fashion that *reconnects us with nature* and *with each other*. It works at many

different levels: individual and industry, emotional and material, fashion and fibre. Sustainable fashion must encourage our sense of ourselves as human beings and revitalise our relationships with others, including those who make our clothes, and so will work to counter our lack of awareness of poor working conditions, poverty wages and poor environmental standards. It will emancipate us from a submissive dependence on fashion by instead giving us the skills to creatively participate with and rework our clothes. We have to become activists, skilful producers and consumers of garments, our actions exploding some of the mystique, exclusivity and power structures of the fashion system breaking the link between fashion and material consumption and allow alternative visions of fashion's future to emerge.

To this end the work of Israeli designer Elisheva Cohen-Fried (2007) begins to show us the form that fashion designed to help us flourish can take. Her work engages the end user and embraces family participation and starts by simply asking the question: 'what makes us happy?' The responses to this question varied from: work, love, music, family, and companionship to learning new skills, putting effort into something and helping others. The work that emerges from Cohen-Fried's compassionate dialogue with users sees the role of designer devolved so that the user finishes and adapts a piece with imagination and originality. Her short jacket (see Figure 2) is designed with finger knitted extensions that the user adds to after buying the garment. Loops on the garment are strategically placed to capture the lengthening knitted pieces, and creativity is enabled through the simplest of craft techniques: finger knitting. The jacket invites the wearer to be more than a consumer of commercial products, engages them as a co-designer, adding craft and personality and gaining making skills in the process. Moreover, this creative contribution can be easily accomplished without specialized tools and even in our fast paced modern lifestyles: on the move, commuting on public transport, on a bus, a train, in a taxi…

Exploring these ideas in a different format, Cohen-Fried also developed the layered capelet (see Figure 3). Here the designer's focus was on enabling the end wearer to contribute to the continuing design of the garment with family participation. The capelet is designed to be manipulated by the simplest of craft skills possible by a small child; cutting with scissors. Made from non-fraying fabric, the top layer is constructed to allow easy access and to be cut away to show the colored fabric below. The more the fabric is cut into, the greater the visual reward, as flashes of bright colored under-layer are revealed. Joyful and easily accomplished, this garment nurtures shared creativity between parent and child and captures the memory of playing and crafting together. When worn, the pleasure of co-creation, accomplishment is experienced over and again, deepening the joy of making and encouraging story telling of the experience. Imbued with deep and personal meaning these garments reject the manufactured commercialized illusions of status and self worth. Instead, they celebrate unique, authentic self-expression and open up possibilities for nurturing us, our families, our communities and our world.

These garments show that needs-centred design challenges the rhythms of fashion as well as fashion processes and finished products. Indeed it is these economic, strategic and business rhythms that are perhaps the greatest barrier to more sustainable change. They are also the area where designers have, historically in any case, least interest in working. Yet in order for 'flourishing' to be a genuine alternative to the addictive and destructive fashion industry, it is vital that wide-ranging economic and business questions are addressed. Our next step – and a huge challenge for all of us – is to move out of the 'safe' sustainability territory of small makers and 'slow' production and begin to explore what needs might mean for the large-scale rapid fashion rhythms of the high street. Yet for development practitioner Nabeel Hamdi (2004, xix), 'going to scale' with these ideas requires, paradoxically, that we start small: 'in order to do something big… one starts with something small and one starts with where it counts'. Therefore in the best tradition of Hamdi, giving form to flourishing in a fashion context requires that we design small, simple, local elements. Yet we do so with an awareness of the larger framework

constantly alert to the ‘emergent’ or ‘multiplication’ potential of these small changes. Our task is to design for, and notice when, one plus one adds up to more than two.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The Melbourne 2032 project:

Design-visions as a mechanism for (sustainable) paradigm change.

Chris Ryan[1]

Abstract

Climate change presents a truly challenging task for government: to decide how best to stimulate and manage restructuring, to change the trajectory of development, without loosing political support.

This is the context of a new research and visioning project in Australia known as the Victorian Eco-Innovation Lab (VEIL). Eco-innovation is taken as encompassing technology, lifestyles, infrastructure and the organisation of systems of production and consumption. The project enlists an extensive network of designers, researchers, government policy advisors and hundreds of design students in four universities. One focus is the re-envisaging of Melbourne in 2032.

VEIL is a 'vision-agent' for change, describing possible new trajectories and configurations systems of production and consumption for a sustainable Melbourne.

[1] Professor and Director Victorian Eco-Innovation Lab, ACSIS, University of Melbourne, Australia 3010. cyran@unimelb.edu.au

Changing the world as we used to know it.

We stand at a unique point in human history, when the compelling need for radical social and technical change for a sustainable future is placing new demands on design, transforming and expanding its role from the *(re)construction* of the world, to its *(re)invention*.

The 'reality' of climate change – the scientific data, media attention and the community response – has altered the political dynamic for action to reduce greenhouse gas production. This changed dynamic is exquisitely clear when viewed from Australia because it has been instrumental in the defeat, late last year, of a conservative national government. That government, for almost a decade, had portrayed climate change as either a sinister fraud or diabolical choice that faced Australians: take action on climate change ***or*** continue to have a thriving economy. Behind such fear campaigns lay the harsh economic reality of a country that has been – literally – structured around plentiful and cheap supplies of fossil fuels, significant in their own right as exports, but also as an essential subsidy for the export of other raw materials and produce. However, in spite of that entrenched power and the years of dismissive rhetoric from Federal government leaders, climate change became one of the top three issues in the election. The new government proclaimed the ratification of the Kyoto agreement, named a minister for climate change and sent a large delegation, including the new prime minister, to the Bali Climate Change convention, all within its first weeks of office.

In Australia, as across much of the industrialised world, there are policies and programs which aim to 'carbon-down' economies. Over 200 cities and towns have committed to a program of targeted reductions in greenhouse gases[2]. Most governments at all levels (local, state and federal) have departments of climate change and sustainability; for many climate change is now a 'whole of government' program. It seems that every day there are new announcements of companies going 'carbon-neutral'; there is even a sporting alliance of elite athletes committed to making sport carbon-neutral. Reality TV programs focus on transforming the lives of average families and celebrities by getting them to live (for a period) within a strict carbon quotient. Major business consultancy firms are recruiting to build up sustainability and carbon-auditing capabilities. Governments have set long term (2050) targets for greenhouse gas reduction. There are serious and extensive exercises to model scenarios for changes in energy production, transport, buildings and so on, to meet future targets; studies originating from governments, industry , academic researchers and community organisations.

In spite of this flurry of action, it is becoming clear that climate change presents democratic governments with a truly monumental task: *to decide how best to stimulate and manage economic restructuring, to change the trajectory of development without loosing political support.* Community concern and demands for action are one thing; channelling this concern into an agreed program of response is quite another. The great social challenge we face is not just 'how to change direction', but how garner sufficient agreement on what that direction might be.

It is in this context that a new role for design is emerging as a powerful tool for public visioning and for generating a dynamic for change. The Eco-Innovation Lab (VEIL), a government funded[3] program in Melbourne Australia, is a particular case of a more general phenomenon of

[2] Led by the International Council on Local Environmental Initiatives (www.iclei.org)
[3] By the Victorian Sustainability Fund.

using design to re-envisage the future. In its first phase VEIL is developing 'a projection' of Melbourne in 2032 (25 years from the start of the project) as a way to 'open up' public expectations about future directions for development.

There is no eco-efficiency path to a sustainable future.

What emerges from most future low-carbon scenarios (e.g. Pacala and Socolow 2004; ZeroCarbonBritain 2007) is that to achieve a serious reduction in greenhouse gas production will require restructuring systems of production and consumption, including technology, business, infrastructure and life-styles. Continuous, incremental, technological improvements (in the eco-efficiency of the existing economy) will not get us 'there'; we need *systemic change in socio-technical systems*[4].

As if finally recognising the scale of change represented by a zero/low carbon future, there is increasing rhetoric in Australia (and elsewhere) that we are heading into the *next industrial revolution*. On one hand this reflects a policy shift to 'decarbonisation' as a driver for innovation and the future economy. On the other hand, this also seems to be a comforting, but flawed, allusion for government and business, often developed from the success of the last industrial revolution - information and communications technology and the internet (ICTI). That revolution brought about a fundamental restructuring of social and technical systems - the organisation of systems of production and consumption, infrastructure and technical capacity, life-styles, behaviours and social and cultural formation. We now have an economy and a social system that would all but cease to function if ICTI were to suddenly disappear. The ICTI revolution wrought its change very quickly (compared to past industrial changes) and with little of the great social dislocation or disruption that was often predicted. So, the thinking goes, perhaps the zero/low carbon revolution will be just as easy?

There are two problems with the ICTI revolution analogy. Firstly, whilst there is strong evidence that ICTI has contributed substantially to the continued reduction in the energy intensity of the economy in industrialised countries, [for a review see Ryan 2003, Chp 7] this reduction is small compared to what we now understand as the scale necessary to avoid serious climate change. In other words, in spite of its extensive and pervasive influence, the ICTI revolution has not significantly altered the fundamental underlying structure of society and the economy derived from more than a century and a half of development based on 'inexhaustible' and 'cheap' fossil fuels. It is this *deep structure* that is now being challenged.

The second problem is about the dynamic of change; in this sense the zero/low-carbon revolution is *not* like the ICTI revolution (or any past industrial revolution). Industrial revolutions in the past have proceeded from the active development (research, innovation, investment, ownership) of a new technology (or as in the case of ICTI, a collection of technologies to *act* on information. Castells M. 2002). In those revolutions, the development and diffusion of the new technology enabled a progressive reshaping of the economy and a new future *unfolded* as a result. *In this case it is the future which is defined* (in terms of greenhouse gas targets) and technology, business, life-styles have to *unfold* in such a way as to arrive at where we need to be.

[4] Throughout modelling exercises still a predilection for technology based change. But in 'wedges analysis' (auch as that of Pacala and Socolow 2004), solutions show the need for a balance between behaviour and life-style change (reducing car usage by half, for example) and technology shifts (doubling car fuel efficiency for example).

So the challenge for government (and business and the community) is how to initiate and guide a socio-technical (industrial) revolution that will bring us to a future defined by abstract modelling of environmental conditions, in order to avoid impacts which could be truly calamitous, but which are largely still predictions from abstract scientific data.

Nothing like this has confronted human society before; it demands a level of collective intelligence, foresight and purpose and a social commitment to experimentation and change that is truly unprecedented. Agreement on direction in these circumstances is difficult enough for democracies, but the time scale for action makes this so much more of a challenge.

Climate change is closer than we think.

The economic arguments to overcome 'the greatest market failure in human history' [Sterne 2007] suggest that immediate action on reducing greenhouse gases is essential if we are to avoid the escalating costs of waiting to respond; new market mechanisms need to be in place, nationally and internationally, within a decade. Yet, even the climate science on which those estimations are made is changing rapidly and there is real concern that the time horizon for serious global impacts may be decades rather than centuries. Over the last year the concerns of climate scientists about the pace (and impact) of global warming have become more public, shifting the political and community debate in some unpredictable ways. The 'first period' of doubt about the proof of human induced climate change now seems well passed[5]. Now uncertainty and concern is focused on the significance and timing of various 'tipping point' effects, positive feedback loops within the Earth's atmospheric system, which could presage the triggering of irreversible, runaway warming. This places great doubt around the estimations of acceptable (average) temperature rise. There is recent evidence that the modelling of some critical changes in the weather system[6] has been way to 'conservative', with the observed effect sometimes decades in advance of predictions. At the same time the concentrations of greenhouse gases in the atmosphere are rising faster than had been expected.

Many governments, like many businesses, are aware of this shortening of the available response time. This just makes the shaping of a program of action all the more strategically contentious. Planning for fundamental structural change in 15-20 years challenges most established systems of management and governance. When it comes, in particular, to making decisions about new long term infrastructure, and the shape of the economy, and social organisation, this challenge can be disturbingly evident. The cultural and economic heritage of past development (investment, institutions, knowledge, cultural and social expectations, as well the physical form of the built environment) can shape patterns of responses in ways that are counterproductive or dysfunctional in the new context.

'Unlocking' the expectations of the conceptual market.

[5] if the science is not beyond all reasonable doubt then it is at least a doubt so small, with implications so significant, that no rational agency can any longer argue that we must wait for more data before acting

[6] Such as the thawing of the artic ice

The *Victorian Eco-Innovation Lab (VEIL)* is a novel experiment in changing commitments to past patterns of development, providing a mechanism for advancing social and technical innovation as a response to climate change (both mitigation and adaptation). In its mission, VEIL aims to change the 'landscape of expectations' about the future. The premise of the project is that significant and rapid change in the direction of social and technical innovation (of the scale needed to counter climate change) is difficult because it has to 'unlock' a shared commitment to an opposing market trajectory that extends beyond the present and well into the future. This landscape of expectations, in which people live out their daily lives in developed economies (and also, increasingly, in developing economies because of global communications and global business), exists as a mental 'terrain of the future' which is already laid out, if not in detail then at least as *a field of future consumption possibilities*. These possibilities exist as an ever expanding set of seductive future-products or services, projected to consumers as sophisticated *future-real* design concepts, from producers who recognise that 'exhibiting the future' has become an integral and essential part of their business strategy. This reflects a strategic shift in the locus of competition, from the here-and-now, to the *conceptual market* of the shape of things to come. As the VP for global marketing of Philips, Geert van Kuyck, says this of their ventures into the conceptual market: *"By being able to see, touch, feel, smell the future in the present - if only for a moment – our people see the world through a new set of eyes"* [Next Simplicy2007]. The 'our people' he is talking about includes both their customer base and their company designers and engineers. By focusing design on the task of bringing the future into the present - making ideas and scenarios for potential future products visible and tangible - a producer's reputation and brand identity can be enhanced, company strategy can be reinforced and the risk of market failure reduced. [Ryan 2002].

Producers and consumers have their future expectations moulded by this field of future possibilities. The conceptual power of this 'future in the present' points to an inertia in the economy which may be a significant retarding force against rapid change. It is this force that is the target of the VEIL project. From the very way that future possibilities come into being as part of the business strategies of existing companies, they are unlikely to embody aspects of radical, or systemic, change in patterns of production and consumption which would challenge the deep structure of our existing carbon based development[7]. VEIL sets out to explore the potential to intervene in the conceptual market, using the same sets of skills and techniques as that of the producers of consumer products, but from 'outside' the existing economy. The idea is to open-up 'new space for eco-innovation' (social and technical innovation directed to sustainable outcomes) by using the agency of design to create seductive, intriguing visions of future possibilities that are based on significant structural change, that embody paradigm shifts in systems of production, consumption, infrastructure and life-styles. These new future consumption possibilities emerge from 'outside' the principal social institutions of production and consumption, through a collaborative structure that encompasses a number of university design schools, bringing design academics and a large cohort of later year students into a public 'laboratory'.

Speaking of the Philips approach, Stefano Mazzano, as Chief Creative Director, refers to their use of human sciences experts as 'sensors' for new consumer demands, to provide understanding or interpretation of people's motivations. [Mazzano 2005:] VEIL is structured to approach the task or re-invention of the future in an analogous way to Philips but without the

7 Developing the VEIL project involved an extensive survey of future products from a wide range of production sectors – automobiles, white goods, domestic appliances, information technology, communications, home entertainment. Those emanating from large established – leading – producers were, predominantly, restricted to design improvements along existing and well established trajectories of innovation. In so far as they addressed the challenge of climate change and fossil fuel usage they were essentially restricted to (incremental) improvements in resource efficiency, largely staying within existing product typologies. There were new businesses and would-be entrepreneurs proposing radical alternatives, hoping to establish a new market niche with a disruptive technology or product. At the time of that investigation (2005), these alternative concepts would probably not have reached a mainstream public audience, they would have been barely visible in the field of future possibilities.

accumulated social and technical capital and commitments of a corporation; social and scientific experts come from university and government research groups as well as community organisations and NGO's. Industry is not sidelined in this process, its enormous power to bring about change is recognised; links with people within companies have been established (as they have been for government) and are expected to grow. But the aim is to engage in the conceptual market from an independent position to produce 'oriented radical innovation' [Manzini 2003] through *the co-production of an alternative future* and eventually affect strategic investment decisions in ways that may never be possible given the organisational commitments that constrain government[8] and business decisions.[9]

The project also has some funding to extend its work into the realm of professional design consultancies by acting as an 'public-interest' client for the development of sophisticated and well resolved future concepts that have been generated by VEIL[10].

The creative power of a twenty-five year perspective

It is not only the independence from dominant social and economic structures that gives the VEIL project some power to change expectations, it is also its conceptual horizon. After reviewing research on established methodologies and experience in the areas of scenario setting, foresight, social planning, technology assessment and so on, VEIL has set its initial focus on a 25 year future[11]. There are logical reasons for adopting this target, and work to date has exposed another, possibly more critical, advantage for this future time-line.

There is a climate change logic: the critical period for an organised response to climate change (mitigation and adaptation) is covered by this timescale. There is a 'realistic' logic: a 25 year horizon is far enough into the future that some significant infrastructural change is possible but it is not so far that it moves into the realm of 'invented' technology (or social movements). (Any new technology or innovation that will be significant in 25 years time will exist, at least as a working concept, in today's laboratories[12].) It is thus possible to use a network of researchers to identify emerging or incipient technology (and social trends) and to speculate on its value in 25yrs time[13]. But experience has shown there is also a logic of engagement: VEIL depends on the co-production of sustainable future visions, bringing 'design' to the centre of a process to engage students, academics researchers, government, industry, and the community in a visioning activity.

8 The most significant of these in the Australian setting is the short political – election – cycle

9 Both internal and external. E.g. : brand, history, competitive position, established partnerships, distribution networks, existing markets shareholders.

10 In retrospect not nearly enough such funding; work has proceeded to date on the basis of reduced fees for designers from design practices that see the process as a part of their own investment in socially responsible work and as a way to build knowledge in a critical arena.

11 Hence Melbourne 2032, 25 years from the launch of the project.

12 It is assumed that the same argument applies to social movements as well, although this was not formally investigated in the establishment of VEIL.

13 These arguments for the value of a 25 year perspective have been well explored in programs such as the UK DTI foresight program (http://www.foresight.gov.uk).

However, these futures intentionally challenge both 'business as usual' and 'incremental eco-efficiency' scenarios for future development, so it was unclear, when the project commenced, just how easy it would be to gain the active participation of business and government. It seems in practice that a 25 yr horizon provides a safe future space for (relatively) unfettered participation, a 'disarming' period that encourages people to 'play' without concern for their current positions and commitments. For governments, 25 years is way beyond the time-frame of most current policy commitments; for business, 25 years is outside of most current intellectual property considerations. Engagement has been easy and for the most part enthusiastic.

Ultimately, for the project, the value of a 25 yr perspective will rest on the ability to 'back-cast' from the visions of the future to identify productive new directions for shorter-term eco-innovation. This has led to the development and elaboration of aspects of the project, referred to as *revealing the present*[14], *vision driven research and innovation* and *trajectories of development*. These concepts will be examined later in this paper.

The paradigm shift to distributed systems.

Setting future horizons and overall 'sustainability targets' provides some structure for a process of future-visioning but the VEIL project revolves around the critical question posed earlier: how can one break out of current paradigmatic thinking and expectations? There is a need to ground design projections in an 'alternative logic for the process of development, to change the trajectory of how things could 'unfold'. For the VEIL project, this alternative logic revolves around the concept of *distributed systems* of production and consumption. The conceptual power of this alternative framework for future development derives from a number of interrelated factors. It is an alternative model that challenges the dominant underlying logic of economic and social development since the first industrial revolution. That past logic asserts that increasing the scale of production (and distribution) of goods is the only viable route to overcoming scarcity, to increasing human productivity, security and well-being. In that logic the spatial location of any area of production is determined only by relevant economic factors, most typically the cost of labour. Distributed systems, in the sense that it is used in this context, presents an alternative model for the economy and well-being, based on *networked small(er) scale systems of production and consumption* that are *re-localised*, so that they utilise regional resources, increase diversity of productive cultures and goods and services, strengthen communities and increase socio-technical innovation[15]. Distributed systems, in this sense, are part of a rich intellectual history of ideas in political economy (often couched in terms such as *self-sufficiency*, *decentralisation*, *local self management* and so on), from the anarchist and utopian socialist movements to its more recent incarnation in the early 1970's in the response to 'Limits to Growth' [Meadows et al 1972] and 'Small is Beautiful' [Schumacher, E.F 1973; 1999]. However, whilst that history provides a rich territory of ideas to explore, the dominant social perspective today is that the weight of historical development and the formation of global capital

[14] A term developed by one of the VEIL researchers, Ferne Edwards, when talking of the Melbourne 2008 Food (production) Map which is part of the project's research.

[15] This echoes the arguments of the Distributed Economy Labs in Sweden that a distributed systems approach will 'open up new possibilities for innovations, increased regional entrepreneurship and viable solutions for sustainable development' [www.DELabs.org].

has largely rendered such ideas obsolete[16]. This makes engagement with the alternative model quite difficult.

There are countervailing factors, however, that make the concept easier to consider. There is the technological success of the ICTI revolution which has established an infrastructure based on a model of decentralised, networked, production, distribution and consumption of information. The internet thus provides a recognisable and well understood alternative structure for the organisation of systems of production and consumption. So it becomes a reasonable proposition to ask whether that model has wider applicability than the field of information. This is not such a difficult question because there is another critical area of technological change where distributed systems are delivering increased efficiency, lower greenhouse gas production and economic success: *renewable energy*. The idea of distributed energy production from wind, solar, geothermal, combined heat and power, and so on, connected to 'the grid' is well understood. Such a system is almost technologically determined because of the distributed nature of the energy resources being tapped. But it is often more efficient, reducing losses in distribution because production and consumption is (on average) more localised. In such a system the grid can be thought of as a 'load-sharing' network, providing for any shortfall in local production and distributing excess where local conditions provide for it.

In Australia the distributed systems case is made easier because it is also observable in the provision of water as the country adjusts to almost a decade of drought[17]. The 'old' paradigm of large scale rainwater collection systems based on river catchments and dams is being replaced by what could be termed Water Sensitive Systems Design (WSSD). WSSD involves retaining rainwater where it falls and connecting it to appropriate local use. This incorporates a change in the relationship to the 'grid connected' supply from catchments; freshwater consumption is reduced by use of retained rainwater and the treatment of waste water at various local scales. The old engineering classification of water into separate 'classes' with separate engineering systems[18] is giving way to a more complex eco-systems approach where appropriate supply (quality and quantity) is matched to appropriate use, with the least movement of water. The most successful large scale project derived from the WSSD approach and VEIL workshops on distributed water systems for Melbourne 2032, is a Melbourne City Council project called 'Melbourne as Catchment' which aims at a dramatic reduction in the city's demands for reticulated water by the utilisation of all rainfall and waste water streams available to the city.

Resilience as a focus for eco-innovation.

The distributed model for water and renewable energy is a response to climate change, bringing together both dimensions of 'response': 'mitigation' and 'adaptation'; this is central to the VEIL scenario for Melbourne 2032. Action to reduce greenhouse gasses will need to be accompanied by other action to protect society against the impacts of climate change which will clearly be manifest for a very long time, regardless of the global success in decarbonising economies. WSSD is an example of such an adaptive response because drought is considered to be a product of climate change; modelling suggests that there is a very high likelihood that

[16] In spite of all the social and cultural dissatisfaction and opposition that attach to the 'forces of globalisation' and the products of homogeneous multi-national markets.

[17] Exacerbated by patterns of water use which have essentially been outstripping sustainable supply for a long time

[18] These used to be: *fresh* (potable) water from 'nature' (rivers and dams) – with reticulation systems; *storm* water (rain running off urban structures) – with drainage systems; *waste* water (potable water contaminated by human and industrial use) – with sewerage systems. [See Ryan 2007]

rainfall patterns of the past will never return [CSIRO 2008]. However a change in average rainfall is not the only outcome of such models, they also predict an increase in 'heavy' rainfall days. Extreme weather events are predicted to increase – heat, cold, fire, drought, flood, storms. Each year there are significant examples of such events that challenge the security of old patterns of infrastructure. The VEIL positioning document – "Melbourne 2032; Looking back" [19] – says this about the dynamics of current conditions:

> *The persistent and devastating drought in the first decade of the century increased the community's sense of vulnerability as past investment in water-hungry systems proved to be a barrier to adapting to changed conditions. This problem was evident in so many critical areas of life, from agriculture and food, to parks and home gardens, building systems, bathrooms, kitchens, laundry and sewage. Big engineering solutions such as desalination plants introduced new dependencies and vulnerabilities when supplies were disrupted through technical and other failures. Large systems created large vulnerabilities.*

Melbourne has suffered disruption of electricity supply and blackouts when unusually hot summer weather increased the load from high air-conditioning usage at the same time as a severe shortage of (cooling) water reduced the capacity of (coal-fired) power stations. National electricity supply has been disrupted by severe forest fires raging in the vicinity of the main national transmission lines. When effects such as these coincide then disruption can be significant and painful for the population. Floods are causing immense damage to residential and farming communities[20]. Reducing such vulnerabilities is becoming a focus for planning and design.

The VEIL approach to future visioning sets *resilience*[21] as a high priority, proposing distributed systems and diversity as a model for increasing the resilience of urban life. The structure of the internet was a response to concerns about securing information against deliberate attack. Water and energy, even more fundamental for human existence than information, require delivery systems resilient against all forms of disruption, including changing climatic conditions and events. Networked, localised and diverse systems of production and consumption becomes a conceptual framework for designing resilient systems in a structural sense, but also in a social sense, offering a way to strengthen community connection and diversity without increasing insularity or inequality (often a criticism of regional or local self-sufficiency). In the VEIL work up to now this resilience-design approach has brought into to focus another dimension of resource provision: *food*.

A retrospective history of the next 25 years.

[19] Available from www.ecoinnovationlab.com/library

[20] Other impacts have been felt as well. A banana drought was caused by a cyclone in the banana growing area where storms had not before been part of the weather pattern. Bananas were almost absent from the market for several years.

[21] in its simplest terms, the ability of a system to recover from shock.

The VEIL project commenced in February 2007 with a one week-long workshop for around 45 people. The task was to draw a wide group of people into the process of re-inventing and (re)visioning the future, around the distributed systems paradigm. A literary device was developed to assist the workshop participants (re)think about the form of the future. Through this device, the VEIL program writes the history of change from the position of the future. The positioning document "Melbourne 2032 –looking back over the last 25 years[22]" introduced participants to a specially framed set of 'drivers' of change which were depicted as shaping the unfolding future from 2007-2032. Although drivers of change are described in the document in some detail, the resulting shift or transformation of the fabric of Melbourne is not described; it deliberately leaves 'open' the resultant physical and organisational outcomes of the forces described. Visioning is then a creative task of exploring (many) possible configurations of daily life ('possible worlds' in the terms of Manzini and Jegou 2003) that could have resulted from such forces. The task asked for descriptions of people lives and also of the world in which those lives were lived. More importantly the 'drivers of change' carefully avoided introducing events that would stretch the readers own sense of plausibility; although the future might be open to invention, the forces of change were carefully not invented but relied on the plausible future evolution of dynamics of change (technology, resource costs, weather patterns, social and behavioural interests and actions) that are observable in some emerging form today. In the process used for the workshop, ideas and discussions recorded over a day were taken as the vision-field for designers who then turned them, over a five day atelier, into visible and plausible images and life-narratives[23] that give 'glimpses' of the future. These were presented back to the whole workshop group for another day of discussion and elaboration.

This idea of *testable plausibility* has been critical to selecting glimpses of the future and what we call *trajectories of development* (which describe the way the envisaged future might have taken shape). *Food* was the catalyst for these ideas.

Distributed food production and consumption

Food, energy and water are the fundamental resources for all living systems. In human society the production of food depends, directly and indirectly, on the organisation of energy and water systems. Any change in the latter will impact on the systems for producing the former; the 'embodied' energy and water of foodstuff will cause the cost of food to rise as the price of energy and water rises due to carbon taxes and supply shortages. Extreme weather events threaten the security of food supply particularly if the concentration of agriculture into large monocultures continues[24] and the biodiversity of food species continues to reduce. Changes in energy supply could disrupt food distribution, processing and storage[25]. There is already evidence of social unease about the food system from a range of new 'consumer movements' which challenge established patterns of consumption: farmers markets, local consumption and distribution (low 'food miles') systems, organic food, fair trade, community assisted agriculture, and so on. All

[22] A constantly developing document - subtitled: "the dynamics of change and the impacts of various policy approaches; learning from the revolution of the last 25 years".

[23] A term developed by one of the VEIL team, Dianne Moy, to describe a range of communication devices through which the lives of individuals and communities, including their interactions with the systems and infrastructure that make those lives possible, are conveyed to the observer.

[24] A recent VEIL report for government documents all the threats to the security of the food system from environmental change: See Larsen, K., Ryan C., Ambrahams, A 2008.

[25] For a range of foodstuff the energy inputs are concentrated in transport, processing and preservation, i.e. are post farm, for others, resource use is principally pre farm-gate, particularly due fertiliser inputs.

these developments that could effect the trajectory of future food systems were brought out in the first VEIL workshop which developed a strong interest in the idea of urban food production: if water and energy systems become distributed, so too would food systems. As Appendix 2A of the M2032 Looking Back report expresses it:

> *'Any analysis of the change to the city of greater Melbourne over the last 25 years would have to place the (re)emergence of urban agriculture, and the contribution to the city's total food consumption that derives from urban sources, as amongst the most significant features worthy of attention.'*

As a new metric for the city, by 2032, more than 40% of the food that Melbourne citizens consume will come from within the urban boundary. The M2032 Appendix 2A notes:

> *"The change … reflects a significant shift in private and public investment, as well as concerted community action, … it has been a serious and purposeful pattern of development. Food as part of the urban fabric is now well entrenched, enshrined in planning regulations, supported by (and supporting) new institutions and services…a use of public and private space and a vital part of the economy. It is universally accepted as necessary for the security of life in greater Melbourne."*

Trajectories of development – visualising the evolution of new systems.

The notion of urban food production is a radical and challenging idea for a city such as Melbourne, but by 2032:

> "Urban food production has grown to be a complementary part of all residential development; it is supported by (and supports) new institutions and services; it is high on the indices of 'liveability' for the city; land vacated by declining industries and unused infrastructure is first considered for its potential for food production. Local food specialisations and community food 'brands' form a culturally significant part of the diet of most Melbournians."

In 'back-casting' from that future condition to the present, the project has been able to develop visions of intermediary steps in the dynamic of change. These steps are not derived from modelling in the usual sense; they start from considering actors that will be caught up in the response to climate change as it relates to food and developing plausible responses by those actors. The actors and their roles are described in M2023 Appendix 2A along with their trajectories of development.

Individuals and communities.

Engagement in growing food increased as a product of various factors: rising food costs; an aging society and leisure (people like gardening as pastime); a response to concern over food

quality; concern about ‘food miles’; desire for more seasonal diets; ethnic populations and cultures growing ‘traditional’ herbs and spices and other regional foods; a desire to act on issues of climate change. Food growing increased in residential gardens and in communal allotments on sites made available by public authorities.

Schools

School ‘kitchen’ gardens were being established in primary schools in Melbourne in the early part of the century as part of a movement to address health and education about nutrition. Children grew food which they then consumed as part of healthy lunch-time meals. The idea spread rapidly with some funding from government and industry sponsorship until it became a norm for most schools. The school garden started to *diffuse out* into the community beyond the school. First teachers took on the role of producing seedlings at home. School garden space was often limited and children and teachers, and then parents, sought to identify additional garden opportunities. In suburban areas gardens were established near schools by using ‘nature-strips’[26] and the edges of parks. Children recruited their parents and additional plots were soon appearing in their home gardens, tended by children and their families. Fresh food was often taken from home to school in the mornings. Soon school classes took on a coordination role, tracking what was growing where using internet based systems, planning lunches around the available items and, on weekends, running small markets to sell/exchange excess foodstuff.

Local government.

Local councils respond quickly to concerns and desires of their communities. Food became a new arena for their activities and services. Programs were developed which responded to the need to deal with:

- calls for assistance to establish local ‘farmers market’s and similar food events,
- access to waste or unused land for allotment gardens and school gardens,
- advice to residents on food preservation and safety as well as horticulture.
- changing planning rules to support urban agriculture.

Addressing the issue of rising food prices led to policies and activities directed to the idea of “Free-food”. Productive landscapes of fruit and nut trees became a new organising principle for the refurbishment of parks and gardens and street plantings. Social services that revolved around food provision (meals for the elderly etc) became more targeted at supporting local food production and at the possibilities for deeper social and community engagement in food preparation. Councils became partners with commercial entities (see below) in local food depots dealing with the preservation of excess crops.

Commercial activity

Entrepreneurial small businesses moved into this new market and a number of prominent public / community activities evolved into commercial enterprises growing and processing food. Of the three commercial case studies envisioned for this process, one was a franchise service known as *Jims Urban Farming*. The ‘Jims’ service grew to prominence in the nineties with the development of a local lawn mowing service as a national franchise – Jims Mowing. In the early part of the century many residents across Melbourne found that they need to realise some of the

[26] The wide verge between the footpath and the street usually planted with lawn.

asset tied up in their homes. “Downsizing” was one option (moving to smaller units) but in most cases that required leaving established social networks as housing types in most communities were fairly homogeneous. For those living in suburban dwellings Jims Urban Farming offered an attractive alternative. It offered to lease back gardens, paying an annual fee to households to allow that space to be re-used as market gardens. Householders got increased income if they persuaded neighbours to join the system so that there was adjoining land for larger farming plots. Homeowners got an annual income but still had the visual amenity of a productive agricultural landscape. Jims only used organic practices so there was no concern about chemical use. Residents like the security of ‘farmers’ present during the day. The system evolved to incorporate options for residents to have access to the gardens, including paid work at critical production times.

Revealing the present.

Future visions which define new trajectories for development provide a ‘window’ through which to (re)view the present, to expose hitherto ‘under-recognised’ activity which is consistent with the future change. For food production and consumption a small research project and a student team[27] has been mapping existing sites of food production in urban Melbourne finding over two hundred such sites covering community gardens, small scale commercial allotments, school gardens and so on. An interactive ‘food map’ showing these sites and facilitating the collection of additional data from the community will soon be launched. Various sites around Melbourne that are well recognised take on a new purpose when viewed through this window. One such site is the community environment park known as CERES (www.ceres.org.au) which is now developing a small closed-cycle system for fish farming built by design students from RMIT University, one of the VEIL partners.

Vision driven research and innovation.

In the VEIL project the future visions are approached not as forecasting but as goals which can stimulate research and innovation projects which are vision driven. One example of such a development is a combined heat, power and water system, known as the Blue Box. In this system a gas-powered CHP unit provides around 25 kilowatts of electricity into the grid. The heat however is used to distil available waste water for uses that demand higher quality clean water. This unit uses existing technologies modified for the purpose. The business plan is for many units able to be located where waste water and gas are available, with all units connected to a central maintenance system using sensors in each Blue Box to monitor performance in real time.

Some of the vision driven research and innovation is being considered as *pre-emptive industry building*, with a focus beyond a particular product to a wider concept of the transformation, or creation of a sustainable product or service *industry*. One area being explored derives from the idea of the ‘Re-Designer’, operating in a local/regional economy, producing limited-run (differentiated) products incorporating mass-produced ‘used as-new’ components (traded internationally) with some locally produced components or sub-assemblies. Initially this

[27] Involving RMIT University landscape and industrial design students, lead by VEIL sustainable Melbourne researcher, Ferne Edwards - see ww.sustainablemelbourne.com/food

future vision for a new global-local industrial system focused on the availability of 'orphaned' components from products taken back from users, at the end of their life, under extended producer responsibility regulations. The scenario has since been extended to a more detailed projection of global-local manufacturing in 25 years time, broadly aiming for a 75% reduction of material flows in the economy. Such an idea relates to the concept of mass-customisation but transforms the way that such systems are usually conceived[28].
