Changing the Change
Design, Visions, Proposals and Tools
Proceedings

Edited by Carla Cipolla (Politecnico di Milano), Pier Paolo Peruccio (Politecnico di Torino)

International Conference
Thursday 10, Friday 11 and Saturday 12 July 2008
Turin, Italy

In the framework of
WORLD DESIGN CAPITAL TORINO 2008 | © ICSID An Icsid initiative of the IDA

Organizers:
Politecnico di Milano and Politecnico di Torino

Promoters:
CDD - Coordination of Italian Design Research Doctorates
CPD - Conference of Italian Design Faculty Deans and Programme Heads

Endorsements:
ICOGRADA - The International Council of Graphic Design Associations
DRS - Design Research Society
CUMULUS - Cumulus International Association of Universities and Colleges of Art, Design and Media
BEDA - The Bureau of European Design Associations
IFI - The International Federation of Interior Architects/ Designers

ISBN 978-88-422-1670-4

The Conference

Something that we know very well about the present is that the world is changing, rapidly and profoundly. The only certain thing that we know about the future is that the current change must change direction. It must find the way to sustainability.

Nobody is yet in a position to say how this can happen. However, many think that the greatest challenge we must face is this one: how to be an active, constructive part of this twofold transformation; and how to be able to interpret the way and the extent to which we are changing, recognising the opportunities that are opening up, and the forces that generate this change. We should learn to use these same forces to "change the change" and promote a social learning process that can lead us towards a society based on networking, knowledge and sustainability.

Contemporary design (seen as the community of all who operate in the design field in different ways) is deep in this turbulent process, both transforming it and being transformed by it. Given its nature it cannot but be like this. However, in this turbulence, we do not have, and cannot have, a clear vision of what is happening. What is design doing today? What could it be like in future and how will it operate in this context of ongoing transformation? What is it doing, or what could it be doing, to play a more incisive critical and constructive role in the great twofold transformation underway?

These are not new questions, but they must constantly be asked. Not only because the world is rapidly changing, but also because despite the good intentions of many, design still continues to be far more "part of the problem" than "part of the solution"; serving more to accelerate unsustainable processes rather than promoting new ways of being and doing to help individuals and communities live better, reduce their ecological footprint and regenerate the social fabric.

Aims

The Conference moves from these considerations and intends to present visions, proposals and tools that emerge from precise design research activities. If indeed design wants to be "part of the solution" it must, perhaps first and foremost, develop a new research culture and new research practices: an open research, sensitive to present contexts, that leads to a better understanding of the great changes underway and of what should be done to re-orient them towards sustainability.

In this spirit the Conference seeks to be a confrontation and discussion ground for designers and researchers operating in different cultural, economic and political contexts (in this perspective, a substantial participation from the East and South of the World has been actively encouraged).

Changing the Change is a design research conference with a strong and ambitious political goal: to focus on the design research potentialities in the transition towards a sustainable knowledge society; to show that these potentialities exist and can be found in all the design application fields (from products to communication, from interiors to services, from ITC to crafts, from medical devices to fashion) and in all the regions of the world (from the most mature industrial societies to the emerging ones). To do all that, the Conference will present and discuss visions, proposals and tools developed by design researchers dealing with various aspects of peoples lives: from food, to health, from residence to mobility, from work to tourism.

People

Coordination

Scientific Coordinator : Ezio Manzini
Conference Scientific Secretary : Carla Cipolla
International Advisory Committee Coordinator: Jorge Frascara

Organizational Coordinator: Claudio Germak
Conference Organizational Secretary: Brunella Cozzo
Head of media relations: Pier Paolo Peruccio
Art Director: Sergio Corsaro

Advisory commitees

International committee

The *International Advisory Committee* includes design research experts from different countries :

Jorge Frascara (*International advisory committee coordinator*)	University of Alberta
Roberto Bartholo	Universidade Federal do Rio de Janeiro
Luigi Bistagnino	Politecnico di Torino
Luisa Collina	Politecnico di Milano
Rachel Cooper	University of Lancaster
Nigel Cross	Open University
Victor Margolin	University of Illinois at Chicago
Stefano Marzano	Philips Design
Fumi Masuda	Tokyo Zokei University
Bill Moggridge	IDEO
Mugendi M Rithaa	Cape Peninsula University of Technology
Geetha Narayanan	Srishti School of Art, Design and Technology
Gunter Pauli	Zeri
Yrjö Sotamaa	University of Art and Design Helsinki

Lou Yongqi	Tongji University

National committee

The National Advisory Committee includes representative members of Italian design doctorates and faculties:

Alberto Seassaro	Politecnico di Milano Head of Conference of Italian Design Faculty Deans and Programme Heads
Giovanni Anceschi	Università IUAV di Venezia
Giovanni Baule	Politecnico di Milano
Arturo Bellavitis	Politecnico di Milano
Luciano Crespi	Politecnico di Milano
Massimo D Alessandro	Università degli Studi di Roma La Sapienza
Paola Gambaro	Università degli Studi di Genova
Claudio Germak	Politecnico di Torino
Vanni Pasca	Università degli Studi di Palermo
Massimo Perriccioli	Università degli Studi di Camerino
Patrizia Ranzo	Seconda Università degli Studi di Napoli
Francesco Trabucco	Politecnico di Milano

Blind peer review committee

Members of the Blind Peer Review Committee are:

Roberto Bartholo
Audrey G. Bennett
Paola Bertola
Luigi Bistagnino
Noemi Bitterman
Richard Buchanan
Peter Butenschoen
Jonathan Chapman
Martin Charter
Paolo Ciuccarelli
Luisa Collina
Nigel Cross
Alpay Er
Ken Friedman
Paola Gambaro
Claudio Germak
Elizabeth Guffey
Lorraine Justice
Robert Lederer
Soonjong Lee
Vicky Lofthouse
Stefano Maffei
Victor Margolin
Ralf Michel
Paul Micklethwaite

Table of Contents

1. Proceedings structure overview

Background documents

Changing the Change proceedings include, other than the selected papers, some background documents. These are:

1. *Presentation by organizers*: it intends to outline different aspects of the conference results and potencial directions (about future steps to be taken).

2. *DRAS – The Design Research Agenda for Sustainability. A* series of activities, called emerging issues process (a *round table,* an *international project session*, an *open discussion*) aimed to produce - in a participatory way - the final output of the conference and to make the first steps in possible post-conference initiatives. These initiatives have produced a final document in the form of a short text pinpointing emerging issues and indicating promising directions of research. It was called DRAS: *Design research agenda for sustainability* .

3. *Invited speakers papers.* International speakers have been asked to give an overview of their countries or regions in terms of design research and its contributions in changing the change. As a whole, they have outlined the state of design research for sustainability worldwide. The papers received by them have been included in this publication.

Selected papers by theme

The Conference field of interest – and the selected papers presented in these proceedings – have been divided into 6 themes and, each of them, in 4 sub-themes, generating the 24 modules in which the selected papers are presented. The 6 themes are generated splitting in two the original three ones, that were: *visions, proposals* and *tools*.

VISIONS.

These sessions present research results that lead us to imagine possible worlds, or parts of possible worlds. They include the results of activities in the field of scenario design and more general visions produced by research into specific products, communications and services. They also includes a comparative analysis of visions emerging from design history and from a comparison of different cultures.

Theme 1. Visions /Ways of living
(Scenarios/1, Scenarios/2, Ideas/1, Ideas/2)

Theme 2. Visions / Ways of producing
(Models of development/1, Models of development/2, Production systems/1, Production systems/2)

PROPOSALS.

These sessions present results of design research that give rise to concrete solutions containing elements of systemic innovation. They are also legible as concrete steps towards a new generation of sustainable products, services and systems. So, products, services and product and service systems are proposed along with the communicative artefacts that link several actors and artefacts together. It also proposes places for a new everyday life, the activities that take place within them and the new production and consumption networks that emerge from them.

Theme 3. Proposals / Daily life solutions
(Services and places/1, Services and Places/2, Products and technologies/1, Products and technologies/2)

Theme 4. Proposals / Enabling Systems
(Tourism and mapping, Energy and packaging, Networking/1, Networking/2)

TOOLS.

These sessions present the results of research that aims to redefine and develop conceptual and operational tools which enable designers to operate within change and influence its direction. Such tools enable them to participate constructively in new design networks, and deal with emerging problems. Tools may be proposed for conceptualisation and representation, for calculation and appraisal of results or for stimulation and prototype making.

Theme 5. Tools / Design Theories
(Design education/1, Design Education/2, Design culture/1, Design culture/2)

Theme 6. Tools / Design Methods
(Design thinking/1, Design thinking/2, Design process/1, Design process/2)

2. Background documents

2.1 Presentations by the conference organizers

New Design Knowledge

Introduction to the conference Changing the Change

Ezio Manzini[1] (12.7.08)

Being a designer means being an optimist. Given problems – even the most difficult problems – all we can do is to presume the possibility of solving them. This is not because we do not see difficulties. Designers must be realists. We presume that we can solve problems because we have no alternative. To be designers, we must make proposals, and we base these proposals on the opportunities we meet.

Faced with a world drifting rapidly towards catastrophe, it seems to me that we need this sense of a designer's realism and optimism more then ever. We must see the problems, and we must think that in spite of everything, it is possible to solve these problems. We must find solutions. This is why we are all here today.

A Conference as Occasion for Research

Changing the Change is a conference for designers and so the spirit of the conference is a designer's realistic optimism. It is based on two main ideas, which we can call optimistic-realistic. The first is that the change in progress towards a society that calls itself network and knowledge based, yet is still as unsustainable as what we had before, if not more so, can be re-oriented towards sustainability. The second is that the designer community can play a positive role in this necessary re-orientation and that this can be done by building new design knowledge.

Therefore, Changing the Change is a conference of designer-researchers who gather to discuss the state of the art and to consider how to create new design knowledge. We do so accepting the challenge of a transition towards a network society and a knowledge society while making the transition towards sustainability.

In organizing the conference, we have done our best to make it a serious event, properly accredited in academic terms. However, we have also done all we could to avoid a value neutral conference, a conference without values.

[1] Full professor, Politecnico di Milano (ITALY) – Conference Scientific Coordinator

More than any other kind of research, design research cannot be separated from the purpose and the social significance of its results. Today, facing grave social and environmental problems, we cannot remain neutral. Every research project we start must take a stand. Whatever the specific question, we cannot forget the need to consider our actions as a contribution to the sustainability of the systems in which we work. This involves all the systems for which we are working – environmental, social, economic and even aesthetic.

So this is the first message this conference seeks to communicate. Today, sustainability must be the meta-objective of every possible design research activity. It should not be a specialized sector along with other specialized sectors as it has been in recent years.

It is likely that no one would disagree with this statement. Who wants to design and or conduct design research in a way that leads to unsustainability? Nevertheless, we must take the term sustainability for what it effectively means – a radical change in ways of being and doing. From these words, we must move to concrete actions. If we do, things will change.

What would it really mean to bring research for sustainability into every design discipline and all areas of design research? How can we bring design research out of the straits of what green design, ecodesign, and sustainable design have been up to now?

In the face of these questions, Changing the Change is itself an occasion for research. Our call for papers was an international inquiry among researchers to see what they are working on. This enabled us to map out what we mean today when we talk about design research for sustainability. It also helped us to map what we are actually doing in the field.

The same is true of the invited speakers that we asked to critically outline the shape of these themes in their various regions.

Together these became a survey based on the opinions of a select group of privileged interlocutors.

Finally, the conference will involve an open discussion stream starting with a round table and continuing into free discussions. Our goal is to bring important issues into focus. Finally, the conference is an exercise in collaborative creation of possible lines of action that will become a Design Research Agenda for Sustainability.

Research and Design Knowledge

Much recent discussion on design research focuses on methodological aspects. I would like to focus above all on results with a simple working definition:

Design research is an activity that aims to produce knowledge useful to those who design: design knowledge that designer and non-designer (individuals, communities, institutions, companies) can use in their processes of designing and co-designing.

From here, discussion on the nature and quality of design research can move from a discussion methods where it has largely been centered until now to results. This is the issue of the knowledge design research has produced, its nature and quality, and therefore ways of getting hold of it.

In terms of content, design knowledge is a collection of different cognitive artifacts with different purposes. These include visions to stimulate and steer strategic discussion; proposals to integrate into the development of specific projects; tools to help understand the state of things and implement design ideas; along with reflections on the sense of what we are doing or could do.

However, the design knowledge we are talking about can also be described in terms of form. It must be explicit, discussable, transferable, and accumulable. It must be knowledge that can be clearly expressed by whoever produces it, discussed by anyone who is interested, applied by other designers, and it must become the starting point that allows other researchers to produce further knowledge.

Starting from the results, it is possible to outline other research methods of various kinds and methodologies that allow us to study them in comparison with one another. Research that

produces conceptual and operational tools for designing or research that helps us to understand the nature of what we are designing is research for and on design. We usually conduct this research by adopting methods proper to disciplines endowed with a consolidated research tradition, adapting them to our specific requirements. In the field of research for design, this typically includes ethnography, semiotics, ergonomics and various technological and economic disciplines. In research on design, this often means history, sociology or philosophy.

Conversely, research that produces visions and proposals usually adopts original methods, using tools and skills proper to designer culture and practice for research through design. In this case, the research modes are, and must clearly be, different from those of traditional scientific research. Research through design necessarily brings into play a level of subjectivity that would be inadmissible in scientific tradition. Nevertheless, this is not typical “artistic research,” totally guided by the subjective dimension. Design is a discipline that combines creativity and subjectivity with a dose of reflection and arguments on its own choices. The same is obviously true for research through design, with the added factor in this case that the knowledge produced cannot be implicit and integrated in the design but, as we said, it must be explicit, discussable, transferable, and accumulable.

The specific acceptable level of subjectivity in design through research is an open question. We have discussed this and we can continue to do so, but I do not believe that a precise definition of this limit is of such great interest. Going back to where we started, I believe that what is really important are to discuss the results we have achieved case by case and the contribution they can bring to solving the problems we have to face. Obviously these contributions will be solid if the methodologies we adopt are too.

A Context in Transformation

“Every project design is based on good research.” I heard this affirmation many times in the past to mean that the speaker did not understand why it was necessary to talk about specific, autonomous design research activity. I haven’t heard the phrase repeated for some time now. However, I think it is still true and it can be used to assert the necessity of autonomous design research. Indeed, if we update the terms, it would sound something like this: every good complex project requires good design research.

In order to justify this statement we must enlarge on the subject a little. I will do so very briefly by taking up the sense of the conference title.

To work as agents for sustainability, designers must take a couple of steps forward in understanding the context in which they are operating. They must understand change already in progress better than they sometimes do. This means the transition towards a network society and a knowledge society. Let’s call this Change 1. They must understand equally well the change required to re-orient the change in progress towards sustainability. Let’s call this Change 2.

This is not at all easy. Change 1 is generating system transformations that require of all social actors to use new ways of thinking and acting with totally new artifacts, organizational forms and designing networks. This includes designers. These change require designers to rethink themselves, to rethink how they operate and reshape their position in society.

This new operational situation creates the context in which Change 2 must take place. This is the change that we need to move towards sustainability. This change also concerns systems and this introduces issues that have never before been faced from commons regeneration to time ecology, from the new nature of communities to the one of places. I shall come back to these later.

The expression Changing the Change refers to a profound social, cultural and economic transformation. For this transformation to take place, we require a complex social learning process. This process in turn requires an original mix of reflection and creativity, of visionary and concrete thinking, of ability to propose and ability to listen. In short, this requires a diffused designing capability and therefore design knowledge that is able to help individuals, communities, institutions and companies to design feasible, sustainable solutions in the social and operational framework of

a network society and a knowledge society. By doing this, we can steer the future towards sustainability.

However, this last phrase is too dense and intricate, so I'd like to try to disentangle it. To do so, I wish to go back to our original question. Why do we need autonomous design knowledge and design research? In other words, why do we need knowledge and research that are independent of the specifics of any individual project?

Change 1 and Change 2

There are many transformations underway in the production and consumption system in what we have called Change 1. The problems that we face in this change tend to grow in size and complexity and the time we have to solve them tends to shrink. This means that we cannot produce the design knowledge we require each time and every time in the traditional way for each individual project. The cost is too high and few projects can shoulder all the costs of design research. Time is too short and few projects can afford a development period as long as the period we require for "good design based on good research."

It is therefore necessary to develop design knowledge that can be produced in the most appropriate time and ways, and applied rapidly, when and where needed.

In addition, another factor emerges from the nature of Change 1. In the transition towards a network society and a knowledge society, design processes tend to be increasingly distributed between numerous actors differing in culture, motivation and professional development. In these conditions, traditional design knowledge, accumulated in the implicit knowledge of professional designers, is no longer enough.

Too many subjects are involved. They are not in the same place and many are not designers at all. In this case, too, a good design requires good research. However, in this case good research must produce knowledge that we can circulate through the network. This means explicit, communicable design knowledge, transferable to different applications.

We can therefore say that Change 1 leads to a diffuse demand for new design knowledge. This claim requires two points of clarification.

The first is that the new demand is already visible. Until now, however, it has not often been explicitly stated. In my opinion however, the situation is quickly changing. The most evident signs of this change are the design research activities of recent years that have begun to develop in design agencies and in more clearly design-orientated companies.

The second clarification we need to avoid misunderstanding is that the emergence of an extensive demand for design research is not in itself a good thing. The design knowledge we require is not necessarily oriented in a direction that we can judge positively. Like all of Change 1, and like all that concerns the role of design, the design knowledge we generate through new research may be positive or negative.

The question of the transition towards sustainability that we have called Change 2 is set against this dynamic, problem-laden background. It does not require much imagination to say that this transition also gives rise to an enormous demand for design knowledge. This transition towards sustainability must see the germination and consolidation of a new idea of well being and a new production system that will make it possible to live better while reducing the weight of our activities on the environment. We must also regenerate the physical, social, and cultural quality of places, and the physical, social, and cultural quality of the planet as a whole. All this can be imagined as a great co-creation phenomenon, where different individuals and communities interact in a vast process of social learning and innovation. This process generates, and is itself regenerated by, new design knowledge.

Lessons Learned and Sustainable Quality

Nobody can really say what a sustainable society will be like -- how people will live and on what residential and production systems their existence could be based. Nevertheless, more than 20 years of discussion and experience have taught us something. Here, I would like to mention three of these lessons. These three lessons seem to me most useful in indicating directions to work along.

1. Research on eco-efficiency has been successful, but it has not improved the overall picture. Current products and services, taken one by one, use far less energy and materials than those of some decades ago. However, no indicator of aggregate consumption (residence, mobility, tourism, etc.) indicates a decrease: even in countries where research on eco-efficiency has been most successful. Overall consumption of environmental resources continues to increase. This clearly tells us that increasing improvements in the current system are not enough. The transition towards sustainability requires a systemic change. It is not a question of doing what we already do better. It is a question of doing different things in completely different ways.

There is an emerging demand for sustainable solutions. This includes product and service systems that propose different ways of being and doing from those currently dominant, lighter in environmental terms and more favorable towards new forms of socialization.

2. Recognizing the environment problem is not synonymous with more sustainable choices and behavior. The environment problem has recently come into the political policies of many governments. It appears on the front pages of many newspapers and it is evident in the sensitivity of many citizens. However, contrary to naïve expectations, we see that this leads to an explosion of new problems: international tension, financial crises, social problems, and individual fears.

In particular, when we observe the expectations and behavior of people and communities, experience teaches us that the absence of feasible, socially acceptable, and widely recognized alternatives, leads to an increase in the perception of environmental risk that – in turn – generates dangerous ideas and behavior.

There is an emerging demand for visions of sustainability. This requires scenarios that show feasible, socially acceptable, even attractive, alternatives on different scales for various aspects of people’s lives. It is possible to have food with little chemistry and without transgenic products. We can move without cars. We can feel safe without locking ourselves in gated villages. And so on.

3. The feasible alternatives found so far indicate new qualities. There are few widely recognized feasible alternatives. However, on a closer look, in every country in the world there are cases of social innovation that could be seen as significant steps towards sustainability. This includes short food chains, shared residential services, bottom-up urban improvement initiatives, and examples of sustainable territorial management.

In their diversity, these cases have a fundamental characteristic in common. Each one of them compensates for the reduction in consumption of products with an increase in other qualities. These qualities include the quality of physical and social environment with the rediscovery of commons; the quality of capability with the rediscovery of individual and community know-how; or the quality of time with the rediscovery of slowness. These aspects assume different meanings in different societies and places. Nevertheless, their presence in situations so far away from each other makes us think that they may constitute a first set of sustainable qualities. In other words, it is beginning to emerge that the quality of places, of communities, of time, of common assets in general could be the material on which to build every sustainable alternative to the current unsustainable forms of production and consumption.

A demand is emerging to investigate new qualities: design reflections, proposals, and scenarios that investigate basic questions such as the quality of places, communities, commons and time.

An Open, Collaborative Program

These are a few proposals. They are examples of a direction for our work in changing the change. A vast organized research program should be developed along lines such as these. For this reason we hope to be able to write the Design Research Agenda we mentioned at the beginning of this talk.

This program should be something of a novelty in the way it is conceived and conducted. It could develop a P2P approach, including schools, design firms, and research centers from all over the world. It could be open and collaborative, capable of self-regulation and self-management. It should be a research program with total freedom.

It is easy to think and talk about all this. Can we actually put it into practice?

We must take the positive, critically optimistic approach of the designers we started with, saying, “Yes. We can.” This conference can be a first, significant step.

Changing the Change:

A moment of reflection in a continuum of action

Jorge Frascara[2]

Changing the Change was a working conference. It had a clear aim: to discuss the role of design in moving society toward making human life sustainable. We, however, do not know how to do this. Discussing how to begin to meet this goal was actually the purpose of the conference. The participants' proposals and experience, their ideas and visions, have begun to flesh out the territory of possibilities for responses to the challenges we face.

The task of the conference was to allow the presentation of different visions of how a change toward a sustainable society could be articulated, and the problems we will have to solve in the process. Conference participants were invited to make an effort to understand the different positions to be heard before pronouncing themselves for or against. I proposed the conversation as a model of communication, rather than the debate. The debate is characterized by opposition, and it is centered on winning or losing. The conversation is centered on exchanging and understanding, it admits plurality of views and it ends without winners or losers, but with richer perceptions. In all process of team work, it is by far more efficient to use the conversation as a model to organize the process of working together. Each personal history brought to the table will result in a different perception of the problems we face, the priorities we perceive, and the strategies that could help in the process of changing the change. The same applies for dialogue after the event.

The papers favored different priorities: some speakers proposed that the important problem is the current understanding of design, and the way in which this understanding should change in order to move toward sustainability. Others thought that the solution must center on a change in lifestyle through a process of social innovation; others still viewed the main solution as coming through industrial or technological innovation; while others saw design education as a major place where change could be generated.

The role of the conference was not that of deciding which of these perceptions should be the top priority, but rather, how the variety of perceptions presented, these and others, could be seen as complementary, leading to a richly articulated picture of the taks we face.

The conference was organized by designers and directed at designers. We believe that designers could play a role in changing the change, in re-directing the development of our world. It

[2] Professor Emeritus, University of Alberta, Canada. Doctoral Program Advisor, University Iuav of Venice – International advisory Committee Coordinator (frascara@ualberta.ca)

is on the basis of our capacity to envision and design futures that we can affect the real world. Weren't Jules Verne as an author and Flash Gordon as a character highly instrumental in shaping the future, just because they made it visible, and therefore desirable? How can sustainability become desirable? How can it enter the equation of quality, of what designers and clients place at the top of their lists for design excellence?

There are promising initiatives: some international corporations are looking at zero waste, others have increased their allocation to research on alternative sources of energy, and on more efficient ways of generating energy. The City of New York is looking at turning all its taxicabs into hybrid cars. Too little too late? Not at all. Fifty years ago environmental conservation was totally absent from the big corporations and the large cities' agendas. Maybe these are the first steps toward sustainability.

Other interesting things that involve more paradigmatic shifts are happening at the other end of the spectrum, like in the interior of Argentina. Cooperatives are developing interesting production and distribution systems, helping the locals, recovering cultural history, and using zero environmental impact technologies.

Insights discover interstices that allow action in the most unimaginable places. Changing the Change was full of testimonies to this, showing actual, factual experiences of implementing novel design approaches that find opportunities where everybody sees only difficulties, and spaces, however narrow, that permit innovative action. The scale is irrelevant; large or small, every move in the right direction is important.

My own view is that one of the major problems we face will be to generate a value system shift in the population at large – designers and others. I could recognize three major groups in society: government, industry, and people at large. However differently expressed the wishes of each group could be, all three want benefits from whatever change they decide to support. Governments want to be helped to stay in power, industry wants to be helped to make more profit, people want to be helped to have a better life – whatever this could mean. The general question our public will ask to whatever we want to propose, is "What is there for me?" We will have to be able to formulate our moves bearing this in mind: the moral imperative of doing something "for the environment" might not work with the majorities.

The changes proposed could be paradigmatic or gradual. We need to continue to explore and discuss models of intervention.

To sum up some important questions at stake:

• How can a new direction be applied to the way things are, and change our culture into a sustainable one?

• How could design research contribute to this change?

• How could designers put sustainability as a top requirement in their design criteria, affecting the way in which products, systems, services and communications are designed?

• What are the strategies that have been successfully implemented in different contexts to make products, systems and services more sustainable?

• How could we help disseminate successful case histories, that could serve as models to be adapted and followed?

• What could be the role of all design areas in this process?

An important communicational challenge we face is that people can only understand things that relate to things they already understand. We will have to find the links that connect the large issue we face with the varied personal experiences of our public. In the case of designers, possibly the entry point would be a change in the notion of quality in design. As much as in the past design quality was centered on aesthetics and creativity, later on function, and later still on usability and innovation, sustainability should become automatically associated to design quality, moreover, it should be seen as an essential condition for design quality.

I moderated one of the sessions about Ways of living. The discussion at that meeting centered around the following eight areas:

1) Change

Change is to be radical, not gradual. It cannot depart from today's situation toward a better one, instead, it should pursue a vision of sustainable life.

Change must begin in one's back yard. Even at a small scale a change toward a sustainable lifestyle is good. Activism is indispensable.

As a civilization we have moved from myth to mechanics; now we need to consider every aspect of life in an integrated way. We need not only technological but also spiritual change.

2) Language

It is good to look at other languages to see how definitions differ. In Chinese the word for "sustainability" is "harmony," a somehow more holistic understanding of the issue. We can learn from other languages and develop a new vocabulary for design.

3) Knowledge

We have to learn how to share local knowledge. The conference uncovered strategies used by some cultures and ignored by others. We should build ways of sharing knowledge despite geographical distances and disciplinary barriers. Our design research knowledge needs to be interdisciplinary.

4) Culture

We need a better understanding of different cultures. From colonial exploitation now the world has moved to economic exploitation; maybe communication design can help different cultures engage in a mutually positive way.

5) Community

We need to learn from those who still have interconnected communities, and form those kinds of communities. Instead of telling society what to do, designers should become lifelong students of society. There is power and beauty in community development. One example was Richard Braul's presentation of a community garden. Mugendi M'Rithaa's presentation made evident how in his South African culture the sense of community is fundamental in life: the power of the individual comes from the community.

6) Meaningfulness

According to a work cited in the discussions, out of nine generally recognized human "needs" only two were really needs. We have to determine what is really necessary for a meaningful human life.

7) Quality of life

Two things were recognized: personal balance, that is, a sense of personal harmony and contentment; and a sense of community, involving communication, protection, participation, recreation, identity, freedom, and generosity. Slowness was identified as a desirable component, permitting attention to the important things in life.

8) Design

How can we make sustainability attractive? There are possibly two ways: through the development of scenarios and convivial tools, and through community generation and activation.

Changing the Change was a moment of intensity in a continuum of action. Conferences are very charming occasions: they include nice friends, exciting people, interesting presentations, new contacts, and enjoyable social events in unfamiliar friendly places. But if they do not become arrival and departure points for a continuing action, and if, in this case, a change in the current changes is not generated, the effort would not make sense.

These proceedings are a contribution to a constant flow of communication, so that like-minded designers, engaged in changing the change, could broaden their frame of reference and work more in concert. The conference contributed to the necessary drive and the indispensable tools that are needed to develop design research internationally toward a sustainable society. The effort must constantly continue, even though in a non coordinated way, but continue anyway.

As a bottom-up event, the organizers could only aim at creating favorable conditions for things to happen. The conference was not about writing a manifesto for others to implement: it was about action, reporting on action, conceiving action, and taking action. It is easy to write nice things; but it is difficult to integrate new challenges into everyone's agenda, challenges that need imaginative work, sustained effort, often politically and financially creative effort. It is easy to conceive design products in sustainable terms, but it is not easy to implement sustainable design ideas when market, political and economic imperatives come to play.

I believe the move toward a sustainable approach to designing is possible, through the exchange of actual projects, ideas, experiences, visions, and tools. All of us need all of us. The conference served to inform all there about a number of projects that offer insightful models of acting. These proceedings are a permanent source of information. Their objective is not to report on something that has happened, but to provide ideas for something that could, and should happen: changing the change toward a sustainable way of living.

Welcome to research

Role, meanings and welcoming of the Conference in the year of Design in Turin

Claudio Germak[3] (12.7.08)

The fact that Turin was nominated World Design Capital is not a prize. Turin and its regional territory were chosen by ICSID, after hosting the 20th Winter Olympic Games, as a "pilot city", with the task the investigate, implement, and promote Design.
Design as a "flexible" activity, able to generate resources, make different kinds of knowledge interact, interpret the humanistic and technological innovation, grasp the meaning of the change, anticipating it sometimes. Torino 2008 WDC, the institutions and their partners worked hard on the concept of Design "flexibility" (flexibility was the slogan for the year of design) by promoting several initiatives with different topics and audiences, involving a number of actors from the wide, by now, Design System, transferring local values to the international scenario and hosting international experiences and the debate resulting from them, in the meantime.
The scheduled activities for the third period of the year, dealing with TRAINING in Design field, focused on this objective. The Politecnico di Torino and its emerging Design area, according to its role as hosting university, but sharing this duty with other training centres, first of all, the Politecnico di Milano, took care of the organisation of some important events, accessible for the international community, whose purpose was to explore international scenarios regarding sustainability and which were developed in order to create positive results, this was the ambition…, locally and for the whole system, in terms of visions, proposals and tools.
The hint was taken by "Changing the change. Design visions, proposals and *tools"* (Turin, July 10,11,12), an International Conference on the role of Design towards sustainability that saw the lively participation of over 350 renewed researchers and speakers from 27 world countries. With its 150 scientific papers, it represented the test focus on approach attitudes and modes regarding the more and more cross-dimensional and pressing topic represented by sustainability in everyday life, production and design systems.
After this*, "Designing connected places"* (Pollenzo, July 13/29), scheduled as part of the eight main events for Torino 2008 WDC became an international summer school open to international Design students from the best Design schools in the world. Led by international experts and with the participation of Boards, Institutions and Research Centres as Local Commissioners, 250 youngsters worked for a week on extremely contemporary and internationally interesting projects, giving proper solutions (this was the brief) for the local contexts:

[3] Politecnico di Torino (ITALY) – Organizational coordinator

health and well-being, food and new food networks, urban mobility, safety and liveability in cities, new production systems, forms to represent how complex the territory and communities are. Plus, a design study in Turin to project a parametric temporary structure suggested from the connections with the problems discussed in Pollenzo.
Two events that were developed in close synergy – where the first one, the Conference, was conceived as an ideal place for *"ideas for changing the change "* and the second, the Summer School, was considered the project application for *"designing the change"*.
Two highly successful events, mainly due to word-to-mouth advertising and to the Net and the many web sites and blogs that turned it into a real topic of discussion, rather than, we must reckon, for the national press.
Anyway, these events strengthened the image of Turin, the institution which had supported them and the team composed by Torino 2008 WDC and the Polytechnics of Turin and Milan, that outlined not just their scientific contents but their structures as well, from a macro-scale to a micro-scale point of view, according to an original and conscious eco-design approach: *from the elimination of green-house gases during the designing stage (AzzeroCO2 program) to the proposed sustainable mobility; from the places were the works took place, prestigious evidence of architectural and landscape local culture (Valentino Castle, Lingotto plant, The Faculty of Biotechnologies, Pollenzo mansion) to the use of environmental-friendly equipment and materials; and finally, the catering service – a chance to educate people to consume typical products coming from short food production chain.*
Then the positive results and the basis for the future of these activities:
The *Changing the Change* Conference started up a *Design research agenda for sustainability* on its own Web site as a reference point for trends on this topic, so offering the International Design System community a virtual discussion table and real chances to meet people in order to allow the presence of a number of different opinions: if nowadays the main actor of the Conference is the academic research, tomorrow this may be the production system (the companies), the project system (designers), service design system. Seul, the next World Design Capital, is already being contacted for this reason.
The international Conference was organised according to sustainability, both in terms of eco-efficiency, for what we could do, and also talking about sharing spirit and quality of the accommodation and welfare provided.
Summing up the situation of research in terms of sustainability and acting as a structure model for discussion and international confrontation (but even for physical meetings, which is always important) about these topics: these were the two main goals of the Conference.
AzzeroCO2 – The preliminary phase of the Conference was designed taking into consideration the possibility to eliminate the green-house gases resulting from energy and materials consumption and due to transports and staff activities. This action was not solving the problem, but represented a sign to give a specific direction to our behaviours and those of the people who were organizing a conference or an event in Turin in those days. The initiative was led by AzzeroCO2, a society created in conjunction by Legambiente, Ambiente Italia and Kyoto Club. The selected "care" intervention regarded Piedmont local area: in specific, we invested on the reforestation of Po river park, thus restoring the indigenous flora and fauna that our river is gradually losing. Thanks to this intervention 35 tons of CO2 will be eliminated, as much as the CO2 consumed at the preliminary stage of the conference.
The locations – For humans, sustainability largely depends on the quality of the environment, the environmental - friendly one (zero impact) and the one related to the comfort and the cultural meaning of the space where people live. Therefore, we liked considering the Conference locations as a small stage where the city's urban transformations are taking place. We selected 3 locations telling about next present/future, recent past and ancient past of Turin.
The Institute of Biotechnologies – In the next future Turin will gradually take the aspect of a post industrial city, with activities regarding advanced technological research (seven scientific/technological parks are located in Piedmont). It will also be a city hosting high level museums, a urban setting for cinema movies and a taste workshop for food. The Institute of Biotechnologies, the place where works took place, is a prestigious technological research centre, located in a new and architecturally refined building. A sustainable building, in its own way, with hard skin (armed concrete) and tender heart (internal gardens). A compact building, protected and open towards the city at the same time: just a huge glass is separating it from the chaotic streets of this multiethnic district. I was about to forget mentioning that Turin will not just be a post-industrial

city in the future, but also a multi-ethnic one.

Valentino Castle – Location of the Conference Dinner. The people from the Turin University Design scene are bound to this place as a kid is bound to his first bed. The Faculty of Architecture has been located here for one hundred years, and the Faculty of Design research for the last ten years, by now. Before giving it back to the city that deserves this place to turn it into a museum, we just wanted to let our friends get the touching chance to spend a night in a impressive and very "savoy" place. Around the big (self-made) table shaped as an arrow as the CtC symbol, there were the 350 participants and many other institutional (but not only) guests.

It was not a gala evening but an occasion to share the pleasure of being together, with "Piedmontese jazz" and typical foods selected from the Basket of products of Turin Province, a very successful initiative testing the sustainable way of short production chain and typical food product.

Lingotto – architectural complex, symbol of modernism, first industrial FIAT automotive plant and now combining a shopping mall and a leisure and multicultural centre. Many of our guests stayed at Lingotto, precisely at its Camplus, as the university residence is now called. A university residence where you can actually breath "a sustainable air". This facility is respectful of its past and even if it was restored according to contemporary needs, this was done without upsetting the old order. Unlike the past, now it is a very bright place – the courtyards are rich in vegetation and there was a great deal of attention in preserving the old characteristics of the plant, whose main structural characteristics still recall its original function. The visible structures of armed concrete and the colours are just like they used to be: white walls and grey wainscots, including also doors and windows and rooms' furnishing. The enamel painted wainscots, purely functional in the past, is now turned into a string running through a new tale, where beds, tables, sofas come to the surface as they were peninsulas. I may think that the sustainability community noticed these aspects, which are not just simple details, secondary things. On the contrary, these signs are peculiar characteristics of the place, with a touch of novelty in comparison with the past – for instance: the orange coloured lunge, the new presence of wood and floor materials. Architect Renzo Piano, responsible for the restoration, said, when the works began (1985), he wanted to re-create in Lingotto "an original piece of the town".

Special occasions: free city transports, guided tours and 20 free bicycles for the participants to let them find out about the wonderful paths along the river Po.

A bicycle is the best means of transport to discover an unexpected Turin, a city on water, for example, with four rivers crossing it and natural parks.

As you may have understood, our will was to grant the participants a stay which was focused on sustainable design and international community: from the selected conference locations to the coordinate image of communication, mobility, sustainable food and locations themselves. Accommodation, services, and leisure time were set according to community spirit and values sharing.

Who are we?

An overview of the conference results

Carla Cipolla[4]

Numbers in Changing the Change

The conference “Changing the Change” was an invitation to build up a panorama of design research results today. Looking at the abstracts and papers after the conference, it is possible to affirm - that this invitation received a wide response. Firstly this is true , considering the geographicaldistribution of countries with approved abstracts.There were 27 - from South and North America, through Europe, Africa and Asia.

The abstracts approved were 163: 101 from the United Kingdom, Ireland, Belgium, Portugal, Germany, France, Italy, Norway, the Netherlands, Sweden, Switzerland, Finland and Denmark; 4 from Israel and Turkey; 5 from Kenya, Botswana and South Africa; 13 from China, India, Japan and South Korea; 18 from Brazil and Colombia; 13 from Canada and the United States; and 9 from Australia.

Clearly Europe, particularly Italy, sent the largest number of abstracts. This is explained by the fact that the conference took place in Turin. But if we exclude Italy, we arrive at a very balanced distribution between Europe and the other countries: 50 abstracts from the United Kingdom, Belgium, Germany, the Netherlands, Finland, France, Portugal, Denmark, Ireland, Norway, Sweden and Switzerland; and 62 from all the other countries. In synthesis, 1/3 fromItaly, 1/3 from Europe and 1/3 from the rest of the world.

It is also Interesting that a country like Brazil, which has only one PhD School in Design, had 17 abstracts approved, the total representation from Latin America (with the exception of Colombia, which sent only one abstract). After the United Kingdom, with 26 abstracts approved, Brazil was the country (still excluding Italy) with the largest participation in Changing the Change.

Other numbers: 348 documents were uploaded as papers/visualizations in the conference web platform of which, 263 were sent to 40 reviewers, resulting in 163 approved abstracts and 138 final papers.

But interest in the conference themes is not restricted to these numbers: the Changing the Change newsletter was sent to more than 1300 subscribers.

Photographing design research

As far as content is concerned, the scientific committee sorted the papers into 6 groups, around the wider conference areas of visions, proposals and tools as follows: Visions: ways of living and producing. Proposals: daily life solutions and enabling systems. Tools: design theories and methods.

On reading these papers, a still unexplored richness of possible clusters, sub themes, and even possible collaborations emerges.

In the following lines we will modestly attempt to outline one panorama of what Changing the Change hasbrought to light. This is just one possible interpretation and makes no claims to be exhaustive.Each paper could be classified in different ways and into different clusters. The intention is mainly to contribute to further discussions and facilitate potential follow up activities.

Considering that "sustainability must be the meta-objective of every possible design research activity" - as appropriately stated by the conference scientific coordinator – the clusters/themes below describe some ways in which design researchers' are *moving towards it* (or how it is coming towards them).

[Please note that all papers in these proceedings are referred to by a code: P(+number) as used in the next paragraphs.]

Cluster 01:

Local development, locally-based approaches.

It's possible to find at least 15 papers based on locally-based approaches, particularly papers from China: the majority of the papers approved from this country consider this dimension. It includes issues such as the preservation of local memory (P05, P11) or the design/architecture discipline's attempts to face up to changes in urban communities or spaces (P06, P09). But the tension between urban development and historical areas and their communities is also faced by authors in Istanbul (P08).

The question of tradition and local identity is also taken up by some European papers, also when trying to go beyond "localism" (P10), or looking at the relation between fashion and its territory (P43). A focus on landscape and urban scenery was not forgotten (P12), as well as possible ways of connecting a town (or a city) and its rural surroundings (P07).

Other papers focus on fostering or observing urban/local creativity in Europe (P4, P20), and China (P109).

This "locally based" cluster includes a knowledge based systemic approach (P22), a social network application (P88) and a new urban vision (P03) targeted to enable a "strategic" conversation between local stakeholders towards sustainable development.

Cluster 02:

Housing. Neighbourhood life.

There are at least 6 papers specifically dealing with questions relating to new visions and solutions for these two themes. New ways of living neighbourhood life (P19, P53). An intelligent management of housing resources, both enabled by technology - in a "smart home" (P66) – and by shared resources and services (P19, P54). A nomadic lifestyle was not excluded (P62), and a vision of eco-cybernetic architecture (P23) is proposed.

Cluster 03:

Consumption patterns.
User-consumers actions and behavioural changes.

A group of 11 papers focus on how to influence user-consumer behaviour in a sustainable way, i.e., how to persuade him/her to act accordingto certain criteria, or vice-versa, how design can learn from virtuous consumption attitudes (for example: P13, P15, P17, P50, P57, P59, P67, P69, P113, P129, P136).

Cluster 04:

"Emerging" countries.

At least 15 papers dealt with questions directly relating to what are usually called "emerging countries", among which 3 papers presenting visions (P1, P18, P28) and 8 proposing specific development strategies (P24, P25, P27, P31, P32, P60, P90, P93). Of the remaining 4 papers, 2 are analytical (P21, P26), another proposes a solution (P61) and the fourth one looks at design education and research (P87).

Approximately half of the papers were proposed by - or included - "outsiders", i.e., authors from the so called "developed countries" (ex. P01, P21, P24, P26, P27, P32, P61, P93).

Through the papers proposed by African authors, the focus is placed in how design can support small producers (P31) or consolidate its home-grown ideas (P90). Leapfrogging (P25) into sustainability is also considered. Brazilian authors propose three papers, particularly embedded in their cultural or environmental context (P18, P28, P60).

Cluster 05:

Product design strategies. Artisanship.

At least 11 papers deal directly with questions related to product design, divided into different strategies to achieve sustainable results on the one hand (P04, P33, P4, P68, P121), and approaches related to artisanship resources and empowerment (P41, P42, P44, P45). From the 4 artisanship approach papers, 2 come from India, the other 2 from Brazil and Italy. It is possible also to find papers facing product design issues, particularly focusing on changes in consumer behaviour (ex. P69, P129)

Cluster 06:

Production systems. Product development processes.

At least 7 papers can be classified under this cluster. Production systems are basically divided into recycling processes (P35, P36, P38), a vision of a larger cyclical production process (P33) and a systemic design approach (P40, P120). Other 3 papers propose sustainable product development processes (P39, P65).

Cluster 07:

Food.

3 papers can be found under this cluster, facing sustainable food communities (P46), how to have a fast "good" food (P47) and novel forms of intermediation and communication (P48).

Cluster 08:

Mobility.

3 papers are directly related to this issue, two of them are mobility system (P49, P51) and the other one is specifically related to attitudes and behavioural changes in users (P50).

Cluster 09:

Energy.

The 3 papers classified under this cluster are based also on a reflection about the role of design. One in creating a new paradigm for new solar heat and power systems (P75) and the other in making industrial energy needs more sustainable (P76). The third one does not deal only with energy questions, but it has been included as a model for responsible design practice (P77).

Cluster 10:

Packaging.

2 papers can be classified under this cluster: one describes the challenges for design in the Australian packaging industry (P78) and the other indicates how a sustainable packaging solution does not reduce the industry's efficiency (P79).

Cluster 11:

Tourism.

2 papers concern tourism activities. One introduces an existing community based tourism initiative, proposing a reflection on the role of design in promoting and sustaining such initiatives (P70). The other one proposes a solution to avoid the "harmful" effects of tourism, enabling tourists to visit places and communities that do not have the facilities of urban contexts (P71).

Cluster 12:

Social innovations.

Social-based approaches. At least 10 papers explicitly enounced the word "social", *in its different connotations.* Seven papers show how design can empower social innovation processes (P01, P52, P56, P70, P97, P89, P81). The design role in promoting social business (P80), the definition of what is called "social design" (P105) and design research approaches applied to complex humanitarian issues (P117)are also considered.

Cluster 13:

ICT based solutions.

Al least 8 papers can be classified under this cluster. It includes mobile communication tools (P56), but the main focus is on web tools: for design activities (P82, P86); for didactic purposes (P98, P99); for empowering social innovation (P89) and a SocialDesignSite (P105). A social network application for local development (P88) is also proposed.

Cluster 14:

Networks.

7 papers focus on networking activities: design networks (P27, P82, P86, P98, P105), a social network application (P88) and a virtual institute (P89).

Cluster 15:

Specific technology-based approaches and solutions.

At least 2 papers can be found. One using RFID as a platform (P120) and other using ETC to promote sustainable mobility (P51).

Cluster 16:

Mapping.

4 papers can be classified under this cluster: cartographies (P72), diagrams and complex systems (P73, P74) and a design research map (P85).

Cluster 17:

Design per se.

A large number of papers are concerned with what here we are calling “design per se”, i.e., designers and design researchers reflecting on their own practices, developing specific tools and elaborating theories. It includes as examples:

- enabling tools for design practices (P55, P83, P84, P91, P111, P112, P114, P135);
- specific approaches to design practices (P104, P106, P107, P109, P133, P132, P134), including inter-transdisciplinary ones (P116, P118, P119, P127);
- design networks (mentioned before in the paragraph “networks”);
- design education/education through design (P87, P92, P94, P95, P96, P97, P98, P99, P100, P102, P103)

What’s next?

The conference organizers have always considered the Changing the Change conference not as the "final result" of a process but as a starting point. Therefore, we hope that these "proceedings", the conference results and the DRAS – Design Research Agenda for Sustainabiliy can also be considered as work material, favouring fruitful post-conference activities and contacts.

Debates

Some issues emerged on the Changing the Change newsletters

Pier Paolo Peruccio[5]

Sustainability has to be the meta-objective of all design research. Every complex project needs to be based on a solid design study, i.e. an activity that produces responsible transferable knowledge for the purpose of achieving tangible sustainable results. This was the clear and universal message of the three-day conference in Turin. In-depth discussions were held on the role of designers in contemporary society, with special attention given to the possibility of designers becoming the "curators" of the transition toward a society of networks, information and sustainability.

"Changing the Change" positioned itself at the crossroads of two vast disciplines (design and sustainability): to explore the role and potentialities of design research as it changes its orientation towards sustainability, reawakening the interest in a scientific community that has gone beyond the 'secured' turf of design. Certain crucial issues emerged regarding the prospects of sustainability, from the local potentialities of South America and Africa as well as China and India – without mentioning, for obvious reasons, the countries that have traditionally dealt with, and continue to deal with, design *latu sensu*. These potentialities can converge into design research in the next few years.

Among the participants invited to ponder the issues addressed by the conference, the names of John Thackara and Bill Moggridge (the CEO of IDEO) stand out, as did Josephine Green of Philips Design who represented the business community. Ideas about design theory and research were voiced by Victor Margolin and Nigel Cross.

The task of current-day designers discussed at the conference is to be found somewhere between design and social issues, and it includes, among many other things, intelligent mobility, output and input of industrial systems, food that is *Good, Clean and Right* (the title of the book written by the founder of Slow Food, Carlo Petrini), self-organization and new ways of living on and taking from the earth in sustainable terms.

This approach to design looks at people and geographic settings, tradition and the circulation of information, the use and enjoyment of goods as more vital than the possession of goods, social factors as more essential than economic or aesthetic ones, relationships as a priority over products, collectivity and cultural growth over individuals and analyzing the GDP, *social design* over industrial design.

[5] Politecnico di Torino (ITALY) – Head of Media Relations. Co-editor: Conference Proceedings. pierpaolo.peruccio@polito.it

Social design was the focus of the conference, starting with a discussion about its meaning in the newsletters of CtC which preceded the event. The definition of social design given by Victor Margolin is "*Design aimed specifically at improving the quality of life. It is accountable to social results and not simply successful market exchange*" (***Social design/debate/1 newsletter)***. According to Josephine Green: "*Design on its own is too broad and can be too easily co-opted by the old. Industrial Design reflects the past not the future. By putting social before design, things change, things open up. Social Design offers vistas of social change and transformation and emphasizes its relevancy and meaningfulness for the 21st century. Put simply, a broader meaning to social innovation/sustainability equals and is complemented by the broader meaning of social design. A design for the next era*" (***Social design/debate/2 newsletter***). In the opinion of Ezio Manzini "*One of them is a design with an explicit social agenda: a new design field where some designers specialize in collaborating with social workers to solve specific, acute social problems. The other one is more general and refers to the whole design community. In the latter, all designers, whatever their specialization happens to be, must redefine their aims and re-orient them towards new emerging social demands. Though both these actions are important, for me, the biggest challenge today involves the latter definition of design: to develop knowledge that is needed to improve the welfare of the whole society, as we move towards sustainability*"(***Social design/debate/3 newsletter***).

Sustainability is available to everyone because it already exists in many places in the form of extensive planning.

All of us together are the designers and stewards of our future. Sustainability is earned in daily life by making changes, even to the small things in our way of living and partaking of the earth, using energy resources more efficiently without necessarily jettisoning them, moving away from systems that devour energy and starting to use the potentialities offered by the information society more efficaciously.

In the new Italian edition of his book *In the Bubble*, Thackara writes "Sustainability is about a world based on less stuff, and more people. Sustainability therefore means putting people back into control of situations rather than replacing them with technology."[6] The United Nations demographers tell us that the world population, now standing at 6.6 billion, will reach 8 billion in 2025, and 9.2 billion in 2050.[7] This increase, generally described with great alarm in contemporary literature which focuses on the relationship between development and the environment, is in Thackara's view a form of "social capital", as Jane Jacobs would say.

Perhaps we are at a turning point: the vast tangle of planning networks that make up our society is more insistently calling out for an expert professional figure who can guide the transformation processes toward sustainability. Many virtuous cycles are already under way. We are seeing actions being made to overcome various entrenched local customs. These creative and entrepreneurial energies can be networked and shared with the entire community, whether they are proposals, sometimes even naïve ones, for an alternative mobility in villages with few inhabitants, or other actions having a thunderous media impact like the bottom-up distribution system suggested by Jeremy Rifkin, the so-called "Third Industrial Revolution" in which each citizen produces for them self their own renewable energy and shares it through "intelligent networks", much like the Internet.

It is a well known fact that every day designers design products, services and communication. They can really affect the behaviors of people, no longer just "in their own small way", regarding everything in the sphere of using and consuming material and immaterial assets. Sometimes this has minimal effects (positive or negative), but other times it has a domino effect on social systems. From Shanghai to Belo Horizonte, came one of the certainties offered by the conference, where many schools of design have become promoters of specialized training to prepare professionals who can give use expert advice and orient this change in the right direction.

Visualizations to Change the Change

Emerging issues from Visualizations Exhibition

Walter Mattana[8], Francesca Piredda[9]

Design research is looking for its own ways of communicating. This was one of the main purposes of Changing the Change Conference, looking for new models for building relationships and engaging conversations. Visualizations Exhibition gave some evidence of that and its proper results: interesting creative solutions and also criticalities in terms of languages and formulas available for communicating.

Starting from this kind of experience, the paper will go back along the work made for the Exhibition, telling the backstage and the main characteristics emerged from the show (Visualizations overview). The Exhibition itself will be analysed as a way of communicating and socializing design research results: did it work? How can we improve it? Which are the issues emerging from this kind of experience? How does communication design deal with and how can it contribute to the Design Research Agenda for Sustainability emerged from the Changing the Change Conference? This paper would like to promote the dialogue about the role of communication design *in* and *about* design research.

[8] Politecnico di Milano (ITALY) – Faculty of Design. Lecturer, walter.mattana@polimi.it
[9] Politecnico di Milano (ITALY) – INDACO department. Contract researcher, Visualizations exhibition art direction, francesca.piredda@polimi.it

1. Introduction: purposes

How does Design Research communicate itself? We think that design research has the responsibility to spread knowledge and make it diffuse, as popular as it can. Communicating means telling stories, sharing knowledge, building new aesthetics for complexity and making theoretical issues tangible and comprehensible problems.

Visualizations Exhibition wants to offer the opportunity to look at design research as a communicative process with different audiences: users, peers, companies and institutions. Changing the Change keeps on looking for new ways of expression and dialogue.

We started from the scientific community and asked ourselves: how can we talk each other? The Exhibition at Changing the Change Conference was intended as a step towards the building of a peer to peer communication strategy. We collected desgin research material as visualizations and we showed it as a parallel event during the conference, in order to start a discussion about possible ways for shaping design knowledge.

The aim is to promote the idea that design research should also be a process leading to high communicative results. Looking at the final Visualizations, we can say that in many cases it can effectively be. It represents an urgent challenge to face, in order to widespread design knowledge and its culture for a sustainable innovation.

In the era of bottom-up contents and diffuse creativity the ability of image production is widespread. Is there a designerly way of communicating? Could we identify a common ground? Are there different genres for different kind of design research?

2. What we did

Visualizations Exhibition at Changing the Change Conference was a loop of video projections showing participants' research results. We asked authors highly communicative artifacts as animated storyboards (animatic) or short sequences of images and pictures (slideshow).

We think that video (even a slideshow) can help to represent complexity. Is that true for design research?

As we said in the submission guidelines, Visualizations should not be traditional scientific posters or diagrams: we asked to send us short sequences of images (each of them should not exceed 35 secs) conceived as a self standing presentation of visions, proposals and tools.

We received 30 Visualizations of the selected papers. 18 where video files, 12 were folders of images that we edited in a sequence, in order to uniform all the material. Some of them exceeded the requested duration. Others have been extended during the editing in order to have enough time to read the texts in the slides and to make contents much clearer.

We think that the brief format requested (35 secs) is an useful exercise of communication, eventhough that means sacrificing depth for clarity and effectiveness.

Preparing the Exhibit at Changing the Change, on one hand, we applied the same clusters of the papers: visions of possible worlds, research results as solutions proposals, or tools to enhance them. Visions, proposals and tools are the main themes of final Visualizations. Most of Visualizations are proposals and visions. We dedicated one monitor to each theme, in order to better appreciate the contents and the different styles for communicating them.

We didn't give authors any guidelines about the design of Visualizations: layouts, graphic elements or norms, and so on. In fact, in respect of contents, we preferred giving them the freedom of making sense producing a sequence of pictures, choosing their own layout and contents organization.

Let’s briefly analyze final Visualizations. We’ll do that without referring to contents. In fact, contents quality was the focus of the papers selection by the blind peer review committee. Our point of view looks at presentation methods and cognitive styles.

We can identify different genres and languages for communicating design research, different styles of Visualizations that mostly reflect some typical processes of design research: ethnographic documentation, photo and collage, info-graphics and maps, Power Point style. Of course, we can also find hybrid rhetoric and languages.

Typographic style also emerges as an interesting language for building relations between nodes of contents. 3D interfaces, finally, is a metaphor for the space of the community and the content sharing.

3. Visualizations at Changing the Change Conference: an overview

Communicating a project or a research is never an easy task, even if it must be made through an audiovisual presentation. In this case, in fact, tools and skills that we usually use (texts, photographies, illustrations, diagrams, maps) must be translated and recombined into a new linguistic dimension. What’s more, it is a very complex dimension, even more complex than we can imagine: space and time assume particular values; the language of images is regulated by a specific grammar; rhetorics are constructed by metaphors and metonymies.

Whenever an illustration, a photography or a diagram are inserted into a film they immediately forgive their autonomy and change matter. In other words, they are no more simply photographies or diagrams, but they become shots (or part of a shot): narrative and temporal units that live according to the relations that they set up with the other shots in the sequence. In the same way, when text takes part of an audiovisual artifact, it necessarily splits in two separated forms: the one which is exclusively oral (voice over and dialogues), and the sign (titles, captions, intertitles).

Producing an audiovisual artifact - and it is always true, from films to visualizations - means that you should be able to manage simultaneously a series of heterogenous elements (fixed and animated images, sounds, words, time and space) through a narrative process made by continuous selections and combinations. This kind of process is not always easy to assimilate, just because it is very different, by nature and history, from the traditional models of scientific communication.

Fellow researchers, as well as students, often ask us whether there is a sort of linguistic formula for producing an audiovisual artifact, or a conceivable model that applies universally. The answer is no. The audiovisual code is more similar to the open structure of a *langage* rather the closed, conventional an hierarchical structure of a real *langue*, as Christian Metz (1968) noted in his semiological studies on films. Please note that, in order to avoid misunderstandings, we keep in French the words *langage* and *langue*, according to the distinction made by Ferdinand de Saussure. In structuralist linguistic *langage* is a system of signs, non-verbal too, that combines a concept (*signification*) to an acoustic image (*signifier*), for example: the language of flowers. While *langue* is a conventional and abstract code with a grammatical structure, for example: the English language. In the audiovisual forms, as far as *language* is concerned, the connection between content and its expression is very high, they are inseparable, and they always determine each other. Moreover, from a linguistic point of view, a shot is not comparable to a word. It is not the minimal unit of a code, which exists independently from the use that you can make of it, but it is a complex proposition that must be “written” again and again. Unlike a word, a shot is a *unicum* made with a specific purposewithin a wide communicative context (film, video, commercial, etc.).

Quoting P. P. Pasolini (1972), the word "tree" (the abstraction of a tree) does not exist in a film. In a film there is the image of a real tree (a sign of the reality).

Of course, audiovisual syntax exists, but it can not be contained within rigidly coded convention or formula. Its plastic and polymorphic structure does not allow that, because it contains a virtually infinite number of joints and combinations.

Filmic grammars establish general rules for a correct management of the sequence and the editing; studies on narratology and storytelling teach to organize a story or a plot; technical standards define exactly which are the useful operating parameters.

All this kind of knowledge and skills are necessary, but they can solve just one part of the entire problem. The final outcome, its clarity and incisiveness, is a matter of author's expressive and creative skills. His ability to build his own personal visual syntax. Besides, the lack of a syntax is exactly the element that separates professional and disciplinary practices from non-professional ones, as emerging from the studies on home movies by Roger Odin (1995). In fact, home movies have different and more limited communication purposes. An amateur movie does not pose the purpose of getting a specific style of language. It comes from a personal and affective need and it is addressed to a small and known public. In contrast, visualizations must present a defined and expressive language that can enter into relationship with a wider and varied audience.

In these terms the best way to get and improve knowledge of the visual language is observing and inquiring directly the audiovisual texts around us in order to understand the mechanisms that regulate them; without marking the bounds of our proper discipline, but expanding it and looking at all the visual world that is talking to us since the last century, telling stories at several levels about the complexity of the contemporary age. We believe that this could be a good way for us, as designers and researchers, for writing *by* images and not just writing *through* images.

From this point of view visualizations at Changing the Change Conference represented an useful test ground for verifying how does scientific community spread research results, both the positive and the critical aspects.

First of all, as we already pointed out in the second paragraph, we can identify five main styles of visualizations: ethnographic documentation, photography, illustration, info-graphic, Power Point style.

These categories and their several hybrid solutions supply a key for our analysis. We can find each style in all the thematic areas (Visions, Proposals and Tools), but we can say that the Power Point approach is the most dominant. For a detailed comment on this specific topic, please refer to the next paragraph.

We can also find two examples which deal much more with the typographical and the 3D world. The first one is the one by Scagnetti (*Integration through communication tools*): she proposed a video made by the typographical processing, where framing, rhythm and assembly spring from the dynamic composition of texts and key words. The second one is by Walden (*Medium Mash-Up Tool*): the use of three-dimensional graphic is the distinguishing mark of his visualization (even if it wasn't the only case of 3D).

Another example is the one by Xinxin Ma (*The Twig and the Wall*): it's a sequence of photographies that creates a time lapse effect. It is a language, metaphorical rather than narrative, that closely refers to videoart.

Only one visualization used a real video take. Lynda Grose (*Fashion That Helps Us Flourish*) proposed a single long shot of a girl knitting; an image that in some way strikes for the strongly amateur character that bring it near to the etnographic approach. All the other authors are faithful to more customary visual forms like photography, drawing or graphics, and this is probably the effect of an insufficient familiarity, or at least of inhibition, with video and editing techniques.

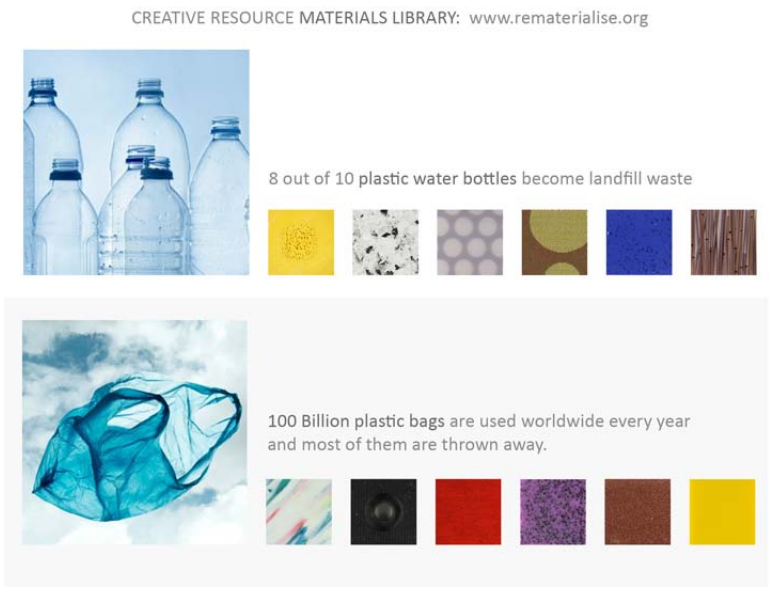

Fig. 1: Jakki Dehn, *Supporting Communities: Design led collaborations exploring the creative and economic potential of materials made from waste*, Visions – Ways of producing.

Fig. 2: Lara Penin and Francois Jegou, *Creative Communities Sustainable Lifestyles*, Visions - Ways of living.

Info-graphics characterize the works by Arquilla (*Dac Link*), Castelli (*Design Directory Italia*) and Quaggiotto (*Knowledge Cartographies*). The cartographies of the last one are not metaphors but examples of real semantic and relational maps. The others are characterized by a quite similar graphical style, speed and dynamism. On one hand *Dac Link* arranges different types of animation mainly based on diagrams and typographical compositions; on the other hand, *Directory Design Italia* entrustes the representation to the metaphor of the map explored by a mobile point of view, identifying the attraction elements of the Italian design research.

The use of photography and illustrations is referable to two big trends. The first one is the slideshow treatment, which is a sequence of images according to a logical or narrative order with key words, titles or voice over.

For example, this kind of visualization belongs to the works by Mendoza (*UFOs Unidentified Future Object*), Lutz Barbosa (*Technoforest*), Morra/Vitolo (*A Narrative Metaphor*), Gamman (*Less is More - Design Against Crime*), Brass Bowden (*HiRise Garden*), Stairs (*Designers without a Border*).

The second one refers to a different treatment of photographic image or illustration. In some cases it belongs to the etnographic genre. In particular, visualizations by Franqueira (*What a wonderful world*) and Ferri/Conditi (*Italian co-housing experience*) use collage technique and photographic overlap for showing and emphasizing the possible renewal of a habitat and the new relations that can be established. We can find the overlap of images, drawings and shapes in other works too and it identifies a visual common style, useful for inserting objects and products into different contexts.

The three visualizations edited by François Jégou (also dealing with the etnographic group) stand out not just for the treatment of the images, but also for the attempt at building brief narrations based on the experience of real people.

At last, according to the critical elements emerged from the visualizations, we can identify three main issues to face: narration, the management of space and the management of time. Those elements occurred, at different levels, in all the visualizations presented at Changing the Change.

The first topic is probably the most difficult to face. Most of visualizations have a narrative structure that is not detached from the tipical presentation practices. Some of them, not many in all truth, entrusted to the logic of metaphor, therefore the topic of narration is still perceived as a specific issue of some disciplines or fields like literature and cinema, instead of a way of improving the comunicative potentialities of a project or a research.

Talking about the other two topics, the management of space and time, authors mostly have difficult adapting the elements of the research or the project into the bonds proposed for the audiovisual artifacts: the PAL format (720 x 576 pixels) and the duration limit (35 seconds).

In fact, generally all graphic (diagrams, maps, illustrations) and textual objects (titles, key words) are designed for a larger size with a higher resolution, but when we take them inside the video format they usually become very small, therefore difficult to read, especially if the scheme is too much detailed. What's more, we have to pay attention to the duration of the images, that means the temporal component of a shot.

Every picture needs a time for reading, a time that is proportional to the scale and to the composition of the image itself. Too complex illustrations or diagrams, showing too many data or very extensive captions, require long observation to get clear and complete information. For this reasons, visualizations, just like all short formats of communication, found their effectiveness on syntesis, on the economy of signs. It doesn't mean sacrificing contents, but knowing how proportioning and distributing their value.

This double problem can be solved in many ways. From a graphic point of view you can make diagrams and drawings, as well as texts, looking more simple than the original ones. If it is not possible, you can show them in detail or scrolling over them according to the definition of a reading path. From a temporal point of view we cannot apply to definitive rules from the editing practice: rhythm and readability remain fundamental problems for communication design. In other words, we have to make a selection of the materials available in the research, in order to include the most significant and important, without claiming to be totally exhaustive.

Visualizations don't have the task of replacing the traditional form of scientific communication, but are valuable tools for complementing and amplifying its spreading, enriching it with a new dimension.

4. What happened: how did the Exhibition work

Visions, proposals and tools are the main themes of final Visualizations. We dedicated one monitor to each theme, in order to better appreciate the contents and the different styles for

communicating them. The Exhibit allowed getting a wide and complete look at the themes presented, stimulating the dialogue on urgent issues.

We edited the sequences by the genre of Visualizations, trying to underline the variedness and to improve the rhythm of their order.

The big monitor was dedicated to a sort of “The Best of” projection. We selected 8 Visualizations according to two main criteria: the ones which are much more understandable telling research processes and results and the most effective ones from the communication’s point of view.

Some Visualizations have the author’s voice over images, so that we provided earphones for listening. The music theme by Mattia Amadori filled the exhibit area and the space beyond, calling for people to go there and have a look.

5. Visualising Design Research Results

We can say that many authors chose a Power Point presentation method. Maybe, it is the standard method for making a presentation, even within the design research community. Anyway, we are a scientific community of researchers, let's say an academic community, talking each other by a list of points organized into slides. Many design researchers are not designers. What's more, they are not communication designers. Even though designers can manage complex systems and artifacts, in many cases theyr're not used to broadcasting their knowledge, to making it comprehensible to a wider public or translating it into different communication languages and formats.

Visual and audiovisual communication has a target of reference, it always knows who is talking to and it always has a format for doing it. We, as researchers, are very good presenters as speechmakers. Needless to say, images have a different grammar, language and rhetoric for making sense.

A famous essay by Edward Tufte (2006) attacks the cognitive style of Power Point, a monopolistic "bureaucracy infected throughout by the pitch culture". Power Point style is a given. It immobilizes presenter's variability and his style is pre-determined.

How can we make visual productions with a more personal and communicative style? How can we produce visions and visualize imaginative worlds for "changing the change"? Looking at final Visualizations, the most emotional and effective are the ones with characters, showing actions; the ones with metaphoric objects building a narrative path or graphically building a space for the community presented. Key words can help the comprehension of images, not long paragraphs of text. What's more, introducing the idea of sequence into a presentation makes it more effective.

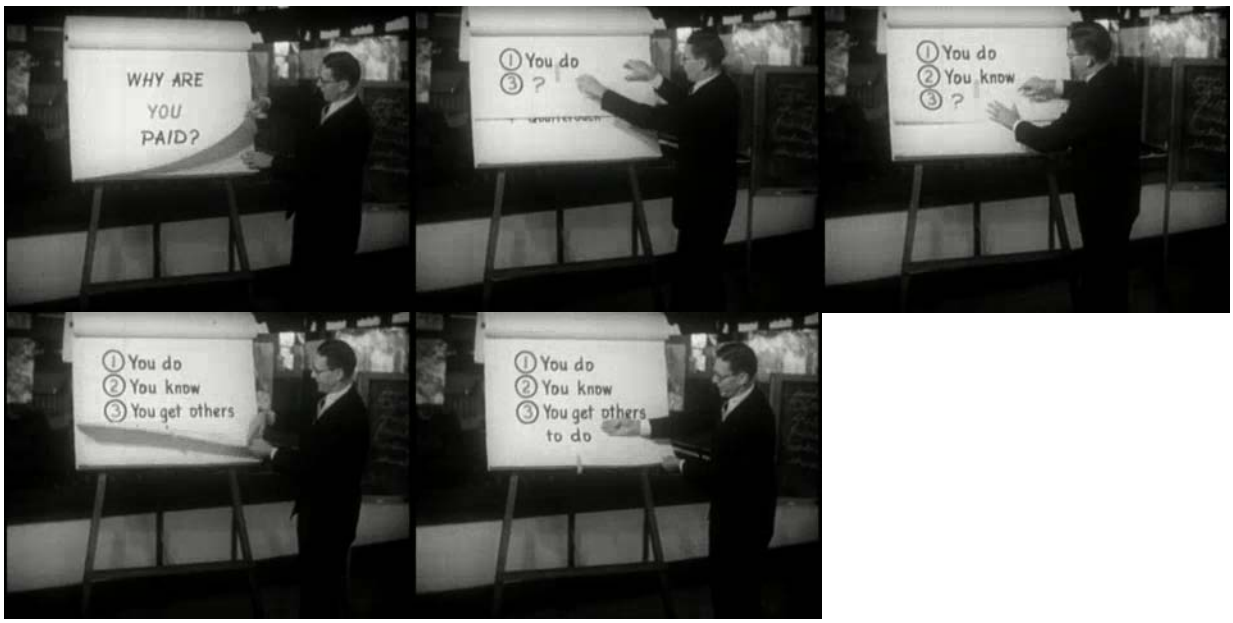

Fig. 4: *Industry on parade: Sylacauga Saga* (Public Domain), part 3: "Seminar For Executives", 7'14", http://www.archive.org/details/sylacauga_saga

Donald Norman (1993) argued that Technology is not neutral. Each technology poses a mind-set that soon informs the way we organize our thoughts and our cognitive patterns for representation. The more successful and widespread the technology is (just think about Power Point!) the greater its impact upon the society.

That's why, even though we asked authors to produce a sequence of pictures and images or a video presentation, most of them didn't refer to the audiovisual language, making sense by the editing of a sequence, but made a sort of Power Point timed presentation. Asking for a slideshow, we intended slides as pictures or frames of imaginative worlds, possibly introducing a third dimension, different layers for representing complexity. The idea of depth of field in photography and cinematography is a good example. We didn't mean bullet points or legends.

On one hand, many of us are familiar with Power Point as a tool for presentations; on the other hand some of us use photography or ethnographic documentation, photographic or illustrated storyboards, mapping and info-graphics as methods for design research practice. Focusing their energy on writing the papers, authors made Visualizations with the same languages of their research practice. Visualizations effectively can be considered as presentations of different approaches to design research, more than communication artifacts of the design research results. We would like to promote the communication of visions of possible worlds.

6. What shall we do next? An Agenda for Communicating Design Knowledge

Which are the next steps to change the direction of change towards a sustainable knowledge society? We have to face two main levels of action: the one that keeps on and bring forward the work we started at Changing the Change Conference; the other one dealing with the possible contribution of communication design for the development and the implementation of the Design Research Agenda for Sustainability.

First of all, we are going to upload Visualizations videos in a dedicated section of the Changing the Change website. In fact, we want to make the material we collected accessible, building a network of visions for communicating international design research.

To achieve this end, according to the policy of sharing knowledge, we encouraged the liberalisation of certain rights, as advocated by the Creative Commons licenses (www.creativecommons.org). Most of the authors accepted this conditions submitting their final

visualizations. Nothing will ever impair or restrict the author's moral rights, but we as organizers of Changing the Change Conference and Exhibit guarantee the attribution of each work and we are now legitimated to distribute and share Visualizations. Works will be accessible to peers and to the extended community of design, as it is a key principle underpinning social interaction.

On the other hand, in order to support the Design Research Agenda for Sustainability, we can define a sort of agenda for communicating design research and knowledge: assuming visions, proposals and tools as a shared framework for design activities, both academic and professional, skilled or not, we can say that processes, methods and outcomes need to be illustrated, exemplified and widespreaded. Of course, we have to refer to the transformation of design within the new paradigm of economic and social processes and, quoting Simone Bertolino (2008) and the Italian Consorzio AASTER (2006), we can identify three typical ideal types of design practices: *communicative work*, *productive work* and *survival work*. We can therefore have a design of communication, linked to the object itself, but also to the symbolic dimension whom the object refers and the process through which it is conceived, conveyed, sold and consumed. A design still focused on the manufacture and finally a design that springs out of marginal situations, both from the society and the market point of view. As many visualizations show, it deals with communities inserting symbolic contents in artifacts that express through semi-artisan design their own common identity. Professional design and design research have to face the challenge of promoting and communicating those different types of design and knowledge coming from different contexts and experiences. It means building scenarios for a sustainable wellbeing in a distributed knowledge economy, but we think that scenarios should integrate *imagery*.

We can hardly give a definition of the term *imagery*, because common language refers to "symbolic", "imagery" and "imagination" without distinction, locating those terms within an unspecified semantic area. In spite of that, it is maybe the most recurrent term in the history of media studies. In this paper we leave out the meaning of *imagery* as opposite of *reality*. On the contrary, we refer to the set of pictures and symbols lying in people's mind, a sort of cultural or trans-cultural archive that we can stimulate and refer to, in order to produce a visionary communication. *Imagery* informs our daily life and puts real facts, figures and objects into a cultural framework and a cognitive pattern for interpreting the world and change it. It should be intended as a cultural tool for political action. Design should translate and shape this rich matter for communicating, both in terms of design knowledge and design education. In fact, it is to be desired that design research learn communication languages in order to understand that an advanced use of storyboarding can be very useful, for example, both as research and negotiation tool. Images are conventional expressions of a particular set of techniques, science and social order in a specific historical moment. The representation of the world by images is a matter of visual and audiovisual rethoric, which is a discipline that examines the expressive power of images in relation or instead of verbal communication. When *imagery* is intended as a social common, communication design has to feed it towards a sustainable knowledge society.

As we already said, the Exhibition offered an opportunity for facing the state of the art: how does design research communicate itself? Visualizations offered a good bent for scenario building, but also showed a lack of *imagery* communication. Now we have to face a new challenge: the integration of *imagery* and *scenario* for new visualizations that can enrich the emerging issues "ways of designing", "ways of living" and "ways of producing". This hypothesis is now orienting our research activities and collaboration to the Design Research Agenda for Sustainability.

Acknowledgments

This paper is a result of a collective work process of discussion, analysis and elaboration, but the writing of the different paragraphs of the text could be attributed to: **Walter Mattana** (paragraph n. 3); **Francesca Piredda** (paragraphs n. 1, 2, 4, 5 and 6).

We would like to thank **Elisa Bertolotti** (Politecnico di Milano, INDACO Dep.) for her help to collect and edit final Visualizations for the Exhibition; **Mauro Zambetta** (associazione culturale Planalto), for his help to edit videos and for the dvds authoring for the Exhibition; **Mattia Amadori** (olo creative farm) for the music theme of Visualizations Exhibition.

2.2 DRAS
Design Research Agenda for Sustainability

DRAS
Design Research Agenda for Sustainability

An open and collaborative program

/ *Draft 1* – 12.7.08

Proposal

This *Design Research Agenda* presents some statements, some emerging issues and some promising design research fields and directions for sustainability.

It has two main goals: (1) to outline and progressively consolidate a shared framework for a multiplicity of research activities on design research for sustainability. (2) To trigger new autonomous research programs that will enlarge and or re-orient the present framework in order to give more coherent programs and more effective results.

Design researchers who agree with this proposal should orient their on-going activities, or start new ones, in such a way that they can enrich these emerging issues with visions, proposals, tools and reflections.

Doing so, they will participate in the development of an open and collaborative design research program and, most importantly, in the realization of an articulated but convergent set of visions and proposals (and of the ideas and tools necessary to better understand and implement them).

This document

The process where this document comes from started with the organization of the Changing the Change Conference (and the debates that took place between several involved researchers to prepare it) and continued in the discussions and the co-creation activities that took place during the this same conference.

Its possible future evolution will depend, first of all, on the commitment of the conference participants who will agree with its spirit and its present proposals, and moving from here, to all the other design researchers who will also agree with them.

In conclusion, *this document is a draft, and it will remain a draft*: an open artifact to be integrated by the free collaboration of whoever will accept its spirit and the simple rule it proposes.

Structure. The document is organized in 4 sections:

- *Background statements.* These are some general ideas to be shared by those who intend to participate in this co-creation process.

- *Emerging issues*. These are research themes that, at this stage of the process, appear to be potentially relevant to orient a variety of existing or future research programs.

- *Basic concepts.* This introduces some working definitions, needed to start a conversation within the community. In the future, these working definitions could be up-graded and new concepts could be added.

Background statements

Background statements are some general ideas to be shared by those who intend to participate in this program co-creation process.

Sustainability must be the meta-objective of every possible design research activity.

Sustainability is here intended as a systemic change to be promoted at the local and global scale. It will be obtained through a wide social learning process, re-orienting the present unsustainable transformations towards a sustainable knowledge society.

Design research has to feed the social learning process towards sustainability with the needed design knowledge, that is, with visions, proposals, tools and reflections to enable different actors to collaborate and to move concrete steps towards a sustainable knowledge society.

Emerging Issues

Emerging issues are research themes that, at this stage of the process, appear to be potentially relevant to orient a variety of existing or future design research programs

The following ones are the results of the "Emerging issues" exercise that took place during the Changing the Change conference (10th-12th July 2008). Each one of the six proposed research lines integrates several topics proposed during the first two days of the same conference and has been discussed in one of its dedicated sessions the last day. The specific topics indicated for each one of these research lines is an open list that in the future will be implemented and, if necessary, re-oriented.

1. Ways of living

How to generate radical changes in everyday life, orienting them to visions of sustainable life styles? How to promote sustainable qualities, sharing knowledge across geographical distances, cultural differences and disciplinary barriers? How to develop scenarios and convivial tools, through community generation and activation?

1.1 Physical and social commons and sustainable qualities.

Understanding the "*commons*": from the physical ones (such as air, water, landscape), to the social ones (such as lively neighbourhood, public spaces, sense of community, perception of safety, social knowledge), to the new ones (such as internet and open knowledge). What makes them exist (what is their "glue")? The people and community recognition of the commons in the definition of a sustainable wellbeing; what media and design can do. How to design solutions capable of generating or re-generating the commons?

1.2 Active and collaborative behaviours and the ecology of time.

Understanding "sustainable wellbeing": individual *vs.* collaborative; passive *vs.* active. Sharing different local knowledge. The sense of personal balance as harmony and contentment. The sense of community as communication, protection, participation, recreation, identity, freedom and generosity. A new sense of time, with the re-discovery of *slowness* as a desirable component, permitting attention to the important things in life.

2. Ways of producing

How to promote models of production and consumption based on a sustainable use of physical and social local resources? How craftsmanship, traditional productions and advanced technologies can merge and collaborate in the perspective of a sustainable, distributed knowledge economy?

2.1 Distributed economies and symbiotic production.

Understanding *"distributed systems":* from computing to power generation, from manufacturing to the whole economy. Distributed systems and system resilience. Distributed systems, democracy and power shift. Connecting people, places and things: distributed systems and the convergence with the p2p and open source movements.

2.2 Local development in the global society.

Understanding *"the local":* local identities and cosmopolitan culture; local economies in an interdependent world. How to design the collective local wisdom. Craftsmanship validatation and regeneration. Sustainable tourism ad community-based tourism. Local and seasonal food and new food networks. The "Slow food model" and its applicability in other fields. The design role in local and regional development.

3. Ways of designing

How can designers become agents for sustainability in a society where more and more people have to take design decisions? What are design's conceptual and practical tools in an interconnected world where different (i.e. non-western) narratives are emerging? What is the role of schools and universities in this new context?

3.1 Designing networks and forming new professional designers.

Understanding the new *designer role:* designers as connectors and facilitators, as quality producers, as visualisers and visionaries, as future builders (or co-producers). Designers as promoters of new business models. Designers as catalysers of change.

3.2 Design knowledge and design education.

Understanding the new *design nature* and developing a new *cultural background:* from products to services and systems, from individual activity to collaboration. New designing networks and new learning networks. Changes in the education priorities and methods. Challenge the barriers to Design for sustainability in design schools.. Increase the transfer of knowledge between projects and develop new educational resources. Integrate global and local knowledge.

Working definitions

What follows is a first list of working definitions needed to facilitate the conversation among the researchers involved in this program's co-creation process.

***Sustainable society**:* a society where all the people and the communities have the same possibilities to live well (that is, to be what they want to be and do what they want to do) in a sustainable way. That is, maintaining their environmental footprint in the limits of the ecosystems resilience, and regenerating the quality of the physical and social commons.

Design for sustainability: everything design can do to facilitate the social learning process towards a sustainable society. That is, to sustain promising social and technological innovations and to re-orient existing drivers of change towards sustainability.

Design research: an activity aiming at producing knowledge useful to those who design: *design knowledge* that designer and non-designer (individuals, communities, institutions, companies) can use in their processes of designing and co-designing.

***Design knowledge**:* a set of *visions*, *proposals*, *tools* and *reflections:* to stimulate and steer strategic discussions, to be applied in a variety of specific projects, to help understand what we are doing or could do. This knowledge has to be *explicit* (to be clearly expressed by whoever produces it), *discussable* (to permit the exchange of opinions among many interested interlocutors), *transferrable* (to be applicable by other designers) and possible to *accumulate* (to form a reservoir of design knowledge that could be the starting point for producing further knowledge by other researchers).

2. Background documents

2.3 Invited speakers

Ovierview on invited speakers participation

International speakers have been asked to give an overview of their countries or regions, in terms of design research and its contributions in changing the change. As a whole, they outline the state of design research for sustainability worldwide. These presentations will take place each day, in late morning plenary sessions.

Bill Moggridige, IDEO
USA

It's getting so complicated! Design research methods to change the vector of change in an increasingly complex world.

Complex problems are messy! They make your head hurt! They are difficult to understand and challenging to solve, but they are often the ones that make a difference to the sustainability of our society and planet. If designers are to change the vector of change, we will need clarity about the directions that we choose as well as our methods.
The paper describes the design research methods that he has seen employed in the USA, as well as elsewhere in his travels, both in general and for sustainability. It examines the design research methods that are used as part of the design process, as well as the research about design itself, illustrating his findings with examples.

Geetha Narayanan, Srishti School of Art, Design and Technology INDIA

The Taste of India. India as Design or Designing India.

Beginning with the local and with an India set in the early 50s and 60s the paper juxtaposes the development of the culture and the business of food and food related products and services in India against the rapid panoramic change that the country has seen in the last two decades.
Using real voices of designers, the paper intersperses commentary with dialogue enabling an understanding of the complexity embedded in the field of design, design research and practice in India today.
What emerges from this is a set of conundrums that highlight design-related concerns for the future.

Luisa Collina, Politecnico di Milano
ITALY

In which way in EUROPE design is, or is not, an agent for sustainability?

In Europe, several PhD programs in design have been established. Some of them started research lines on design for sustainability or, more precisely, on the different possible intersections between design and the emerging environmental and social problems. Complementary to these academic institutions, other organisations have developed, and are developing, interesting initiatives. For instance: some EU funded projects, some independent programs (as the Sustainable Everyday Project, Doors of Perception or Multiplicity), some entrepreneurial activities (as the ones promoted by Philips Design or Design Continuum).
The paper will move from the map of these initiatives and research lines, to discuss their cultural and social background and perspectives. The paper main aim is to present the potentiality of the European design to the worldwide demand of design research for changing the change.

Mugendi M Rithaa, Cape Peninsula University of Technology
SOUTH AFRICA

Engaging Change. African Universities' Response to Design for Sustainability.

Africa has a predominantly youthful demographic- it makes sense to engage the youth at a time when societies can indeed change the change. This paper presents an overview of design education in a number of African universities. The information covered includes their student profiles and details of design programmes with a specific slant on sustainability. Of particular interest (and relevance to CtC) is the question of how flexible the curricula is in response to the needs of local communities and societies in a formal (or informal) sense.
It is heartening to note, that in spite of pervasive financial limitations, a vision of a sustainable future is still possible. To realize this vision requires a proactive and creative response. Some of the institutions presented in this paper have embraced the ideals of design for sustainability and are actively equipping future designers with requisite skills for bringing about positive social transformation.

Aguinaldo dos Santos, Federal University of Paraná
BRAZIL

Design research and locally-based social initiatives.

In South America, due to poverty, a large portion of its society has learnt to live with fewer resources, paradoxically surrounded by an abundance of resources. On such environment entrepreneurship, flexibility with cultural diversity and easiness to deal with uncertainty is required from people on a daily basis in order to guarantee survival. Such environment aligned with an increase on the education levels, political awareness and information access, has induced a widespread of locally-based social initiatives that in many cases represent truly innovative social changes towards sustainability. Hence, based on this context, this article presents emblematic case studies gathered mostly in Brazil, trying to understand their underlying strategies to radically change current patterns of consumption and production.

CHINA

Calling for “She Ji”: Rethinking and Changing the Changes in China.

This paper gives special attention to China’s traditional “She Ji (design)” system which almost been replaced by western oriented modern design disciplines for century. The advantages of "She Ji" notion have become increasingly obvious according to the criteria of sustainability. The considering of sustainable develop provide a pause for rethink, revaluate, and redesign many phases and changes in China. This paper tries to outline a vision that the dual-structure of “She Ji (design)” system can offer new philosophies and methodologies for Chinese design, design education and design research. The ways in which design can play important roles in culturally conscious and be an agent for sustainability in China is also explored together with some cases.

Fumi Masuda, Designer, Tokyo Zokei University
JAPAN

Asian view of sustainable future.

In order to explain possibilities and evidences of “Changing the Change”, the paper will start from the historical background of Japanese craftsmanship and will arrive to outline the on-going tendencies in eco-design, and in the emerging consciuness that eco-design is not just to improve products, but is the actualization of sustainable society.
As conclusion, the paper will propose the idea that, although Asian societies certainly are going through a radical change, there are also unchanging cultural aspects. One of this is flexibility in change. Historically, both natural and cultural sustainability had been secured through this flexibility and hopefully this system will be able to work out for the future to come.

Chris Ryan, Melbourne University
AUSTRALIA

An rapid re-focusing on sustainability.

Two issues explain the connection between design and sustainability in Australia. The election a decade ago of a national government that viewed 'climate change' as a threat to its (fossil fuel) business power base, and the visibility of climate change because of drought (cities are rationed and agriculture and national river systems are threatened). Concern about water and climate change was instrumental in the defeat of the national government last year. In the practice of design, as in other areas of business, there is a rapid re-focusing on sustainability. However, the orientation is again towards 'eco-re-design' not design for systems change. In recent large scale government programs to 'promote' design, there is still a real disconnect between design promotion and eco-innovation.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

It's getting so complicated!

Design research methods to change the vector of change in an increasingly complex world.

Bill Moggridge[1]

Abstract

Complex problems are messy! They make your head hurt! They are difficult to understand and challenging to solve, but they are often the ones that make a difference to the sustainability of our society and planet. If designers are to change the vector of change, we will need clarity about the directions that we choose as well as our methods.

Bill describes the design research methods that he has seen employed in the USA, as well as elsewhere in his travels, both in general and for sustainability. He examines the design research methods that are used as part of the design process, as well as the research about design itself, illustrating his findings with examples.

Contents

1. It's getting so complicated

I studied Industrial design at the Central School in London in the sixties. The course was very practical, with a small studio of twelve students learning through a series of design projects. We were taught lots of skills of drawing and model making, which were exercised in the design of a series of products over a period of three years. The assumption in the curriculum was that we would spend our whole careers designing everyday things for work or life, that our employers or clients would be British companies, and that the leaders in the companies and organizations would decide what products we should design. This situation only lasted five years after I graduated.

It's true that the first consumer product that I designed that went into production was an electric toaster for the UK branch of Hoover, and my first design award was won for a Microscope for a British company, but after that things changed fast! It was like a preview of globalization. Britain announced the decision to join the EEC (European Economic Community) in 1967, becoming part of an economically united Europe. This caused a competitive shakeout, with best companies gaining a continent-wide market and the less strong ones vanishing surprisingly quickly. Britain was strong in service industries like banking and insurance, but weak in most of the manufacturing industries, so that by the time I started my design firm in 1969, most of the clients were in other European countries instead of on home ground. This resulted in my working in ten countries during the seventies, getting used to travel and to the idea that the world is large and diverse. There was an answering machine in Italy, a computer in Spain, a marine radio in Sweden and telephones in six countries, but not in Britain.

Next came the invasion of digital technology. Electronic chips were turning up everywhere, so that more and more products included hardware and software. If we were to design things for people, we had to design the electronic behaviors as well as the physical objects, or we would only solve part of the problem. This led to starting a second office in California's Silicon Valley, developing the practice of interaction design, and forming teams of designers with varying backgrounds, including industrial design, interaction design, human factors, cognitive psychology, mechanical engineering, as well as hardware and software engineering. The design context was too complicated for even the most renaissance individual designer to be effective.

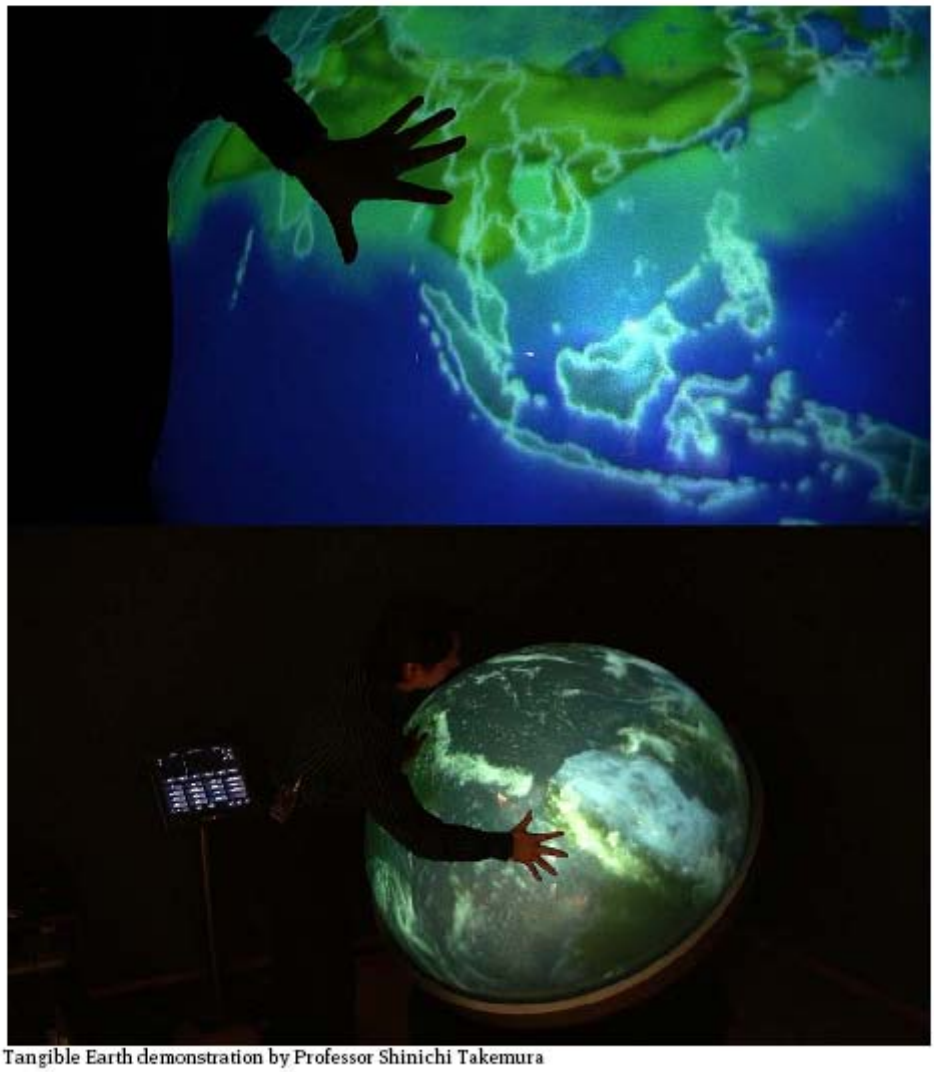
When the internet surged in scale, becoming ubiquitous and accessible, the world suddenly got smaller, as everyone with online access could be connected to anywhere. Globalization was enabled. We could employ resources across national and continental boundaries in real time. Design contexts took another leap of complexity, as now connected technologies were being employed to create complete experiences. We designed websites, connectivity tools, and services that included elements of physical and digital design. We also found ourselves needing to design online solutions to systemic problems in a global context.

Can we design for social innovation towards a sustainable world?

Now we are facing a future where the design context needs to be the whole planet, as we face climate change and realize that human behavior has an increasing impact on everything. Complex problems are messy! They make your head hurt! They are difficult to understand and challenging to solve, but they are often the ones that make a difference to the sustainability of our society and planet.

People may change if they are more aware of the situation. More than a generation ago, the grass roots movement towards sustainability in Germany and Scandinavia changed habits about recycling. This social innovation came from the awareness of the general populace and enabled the implementation of sophisticated recycling systems and the development of new materials.

The public in the USA seemed to be ignoring the dangers of climate change and to be unwilling to take any action towards sustainability until the last few years, but at last there is a surge of awareness, triggered by the Iraq war, energy crisis and perception that climate change is an emergency. The traditional media is at last full of the concerns, helped by the visibility of Al Gore and the popularity of his Academy Award-winning documentary *An Inconvenient Truth*.



Tangible Earth demonstration by Professor Shinichi Takemura

Professor Shin-ichi Takemura is a Japanese cultural anthropologist, teacher and social media designer. He has created a representation of the world called *Tangible Earth* that connects us very intimately to the condition of our planet. Here is a wonderful example of a design that takes advantage of digital technology and the connectedness offered by the internet, to help us feel directly and emotionally the condition of our planet.

(http://www.tangible-earth.com/)

The *Tangible Earth* is an interactive luminous world. A transparent hemisphere of 2.8 meters diameter contains a projector with a fish-eye-lens at its center, casting an image of the globe onto the inner surface of the hemisphere. Force sensors recognize the direction of your thrust as you push on the surface, allowing you to spin the globe in any direction and speed that you want. The computers connected to the projector are powerful enough to respond in real time, so that you can see the world move under your hands, giving an emotional sense of what is happening. You feel like an astronaut in space with the means to fly in any direction.

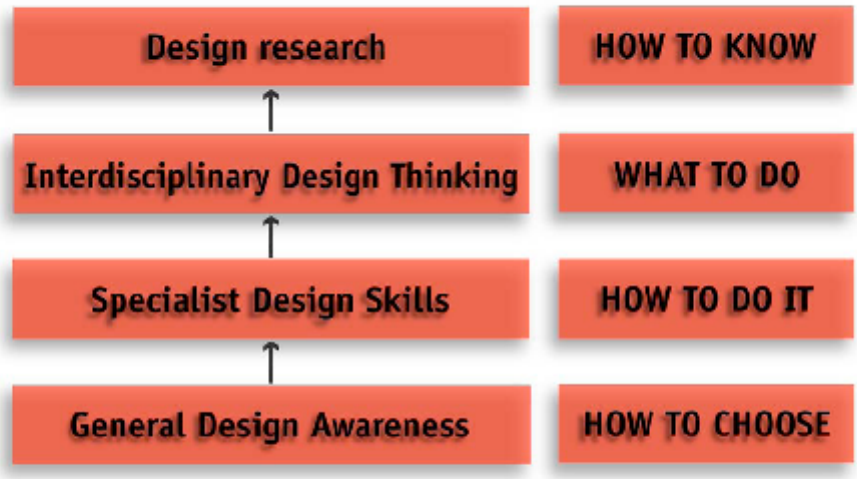
It's not just the satellite view. Takemura and his team have been collecting data for years to allow different representations. The closest to real time is the weather systems of the past four days, played back as a loop of a few seconds, so that you can see typhoons forming or sunny skies approaching. You can see air pollution, ocean currents, bird migrations, earthquakes, temperature changes predicted for the oceans, and global warming projected out to 2050. All of the data is painstakingly gathered from the international scientific community and rendered from the computers to the real time projections. Takemura says:

"I was looking for a way to visualize the reality of what's going on on this planet. It's a matter of information environment. If we design the social signal system so that you can get information in real time, you can make changes by voluntary action. What we need is to design the social use of informational infrastructure. This is what I call social sense-ware to make us more conscious of what is going on in the world. It will become a dynamic self-portrait of our planet, a sensory infrastructure, a public sensory platform for the global age. What we need is the design of media to feel the context of the daily life of the people all over the world to each other."

So far there are several installations of the *Tangible Earth* and Takemura is planning to connect them to each other in real time, as well as allowing access online.

2. Learning How to Know

You can think of design in four levels, forming a simple hierarchy. At the simplest level, people make choices about the design of their clothes or the environments that they live in, based on their awareness of design qualities and issues. Greater sophistication is achieved by people when they learn specialist design skills; they become designers, knowing how to design with greater fluency and expertise; they become adept at the craft of designing, but they usually rely on other people to decide what to design, to define the brief. It is becoming more widely recognized that design processes can also advantageously be used to decide what to do, employing interdisciplinary design teams in processes that harness the powers of intuition, where the shared mind is more productive and creative than the sum of the individual minds. At the highest level, design research can give access to knowledge; both research for a particular project and also research into methods and processes. Let's look at the items in this hierarchy more closely, starting from the bottom.



General Design Awareness

In the Epilog to his book *Emotional Design,* Don Norman says,

"We are all designers. We manipulate the environment, the better to serve our needs. We select what items to own, which to have around us. We build, buy, arrange, and restructure: all this is a form of design. When consciously, deliberately rearranging objects on our desks, the furniture in our living rooms, and the things we keep in our cars, we are designing."

When someone chooses what to wear, how to decorate their home or layout their garden, they are exercising skills of general design awareness. These skills are most visible in countries like Italy or Japan that have a strong aesthetic culture and tradition, but are improving fast in countries such as Britain where design is a subject offered as a major option in schools, so that teenagers can choose design as a mainstream subject and qualification before the go on to university.

Specialist Design Skills

Professional designers know how to create new solutions, based on a synthesis of all the relevant constrains. They have mastered specialist design skills, making them expert at deciding how a design can be formed, and how to create a elegant solution to the problem posed by the constraints, but they expect the context that they operate in to be decided by someone else, normally the boss or the client. This expectation limits the economic value the contribution made by designers. Most current design education is still focused on teaching these specialist design skills, whether the design discipline is industrial design, interaction design, architecture, graphic design, web design, or more craft based disciplines like ceramic or jewelry design.

Interdisciplinary Design Thinking

Interdisciplinary design thinking is especially valuable for deciding what to do in the first place, so that the power of intuitive creative processes can be harnessed to stimulate innovation, solve any type of problem, and develop new opportunities. Design thinking can help with the messy and challenging

problems posed by the complexity of design contexts in the world of digital technology, global connectivity and the need for social innovation. Complex design problems, such as systems or services, will be better tackled by a team of people from varied backgrounds, harnessing intuitive processes, but collaborating so that the output from the *shared mind* is more productive than the sum of individual contributions.

The range of design disciplines from which an interdisciplinary team is formed for a *Social Innovation* project at IDEO normally includes the human design disciplines, such as ergonomics, psychology, anthropology, industrial design, interaction design and graphic design. It includes people from the technical design disciplines, such as computer science, materials science, mechanical and manufacturing engineering. People from non-design disciplines also contribute to the projects, typically those with business and brand backgrounds, as well as writers, storytellers and prototype developers, for physical, digital and video prototypes.

For example, in the USA a lot of people are fat. Obesity has reached record-breaking levels, especially among children and teens. According to the Center for Disease Control (CDC), an estimated 17% of children and adolescents aged 2-19 are overweight. Resulting from an imbalance in the number of calories consumed and those expended, this epidemic involves genetic, behavioral, and environmental factors that could lead to serious health problems later in life. The problem is growing fast. In 1990 there were no states with a proportion of obese adults as high as 15%, but in 2006 there were 24 states above 20% and 21 states above 25%.

(CDC Behavioral Risk Factor Surveillance System)

The CDC, a sentinel for global health and wellness, strives to provide people with reliable health information and the benefits of strong public and private partnerships. Recognizing the growing obesity epidemic, the CDC and the Academy for Educational Development engaged IDEO to conduct a workshop relating to research done around lower-income women and exercise. The brief workshop led the CDC and IDEO to another project for social impact, looking at fruit and vegetable consumption among tweens.

In this current project, IDEO and the CDC are examining ways to change the habits of an entire generation of tweens, a group susceptible to changing attitudes and behaviors about health before they become life-long issues. To date, IDEO has begun observations with a number of stakeholders and change agents. While still in the early phases of development, and with final deliverables still undefined, the team is looking at communication, product, or service design possibilities to promote wide-scale change and prevention in the battle against youth obesity, and the promotion of fruit and vegetable consumption.

You can think about design research in two main categories; research as part of the design process and research about design. When part of the design process, research methods can be included in conjunction with *specialist design skills* as well as *interdisciplinary design thinking* and therefore should not be separated at a higher level on a hierarchy. Research about design is more definitely an enquiry about *how to know*, and deserves the location at the top of the list. Let's look at the two types separately.

3. Design Research *in* Design

If your goal is social innovation through design, your product, service, or organizational structure has not even been thought of, so by definition it cannot be explained to research participants. This is where mindsets and methods for design research are needed to discover latent needs and desires that will help the members of the design team define potential opportunities.

Design research is most valuable when it is fully integrated into the process. Jane Fulton Suri, Chief Creative Officer at IDEO, describes the way in which design research methods can inform the collective intuition of a design team.

(Fulton Suri 2008)

"To inform intuition, it is important to have team members actively interpret the richness of evidence and discoveries as they emerge. Research that brings rich information will provide not just facts, but insights and possible reasons behind the facts. Even seemingly bad news – that we have been considering something that seems to be a fruitless opportunity or a concept with serious flaws – can serve as inspiration for new and better ideas, instead of signaling a depressing failure. With richly understood bad news, we can adjust our assumptions and perhaps see a new opportunity to move in a more fruitful direction. A huge opportunity for learning is missed when research phases are simply tacked on to a program as 'safeguarding' or when research activities are outsourced to a separate team.

To be effective, decisions informed by design research demand a much higher level of personal commitment and engagement at all levels within an organization than do judgments based purely upon hard facts and objective data. Design research often means changing the way work gets done. It means getting out of the office, being where customers are, becoming aware of and sensitive to social trends and the broad ecology of stakeholders, rolling up our sleeves to try out unfamiliar things first hand.

The largely qualitative and interpretive nature of design research is its strength, but this also makes it potentially vulnerable to invalid or ill-founded conclusions. In order to be done well, design research demands that everyone involved be prepared to grapple diligently with ambiguity and nuance. It asks us to bring creative energy to the synthesis of confusing and conflicting information, to be willing to challenge and adapt our own and our colleagues' interpretations, and to stress-test these interpretations both with other points of view and in the harsh light of relevant evidence, even if such evidence is not statistically-proven fact.

This degree of direct involvement often brings another advantage to the design and innovation process – that of creating common ground and shared perspectives among people representing multiple functions within an organization, in ways that have seemed previously unachievable. Enabling teams to share raw evidence and create meaningful frameworks, principles, goals, criteria, and priorities together energizes movement forward with much more enthusiastically supported ideas and greater confidence. In this way, successful design research first requires, then perpetuates, forms of cultural transformation in organizations that enable radical innovation to thrive."

Jane categorizes design research in three types:

- Generative: gaining insights and opportunities – research that provides human-centered insight, revealing new ways of framing opportunities and inspiring new ideas.
- Evaluative or Formative: learning and refining – research that provides continual learning throughout the process to determine the what, how, and to whom of the offering.
- Predictive: estimating potential – research that helps to estimate the scale and potential of an opportunity even when most variables are unknown.

1. Generative design research

Generative research involves looking for emergent patterns, challenges, and opportunities. The intent is that ideas about new possibilities are informed and inspired by understanding people's aspirations, emotions, perceptions, and motivations within their social, cultural, and technology context. Crucially, it is about interpreting this understanding to inspire new perspectives that disrupt current conventions and ways of seeing things.

For example, after a series of workshops examining various world issues, the Acumen Fund and IDEO decided to pursue the issue of clean water usage in the developing world. The Acumen fund tackles some of the world's most challenging needs for social innovation by combining venture capital with philanthropic business practices.

Currently, 1.2 billion people worldwide are drinking unsafe water. Despite efforts to provide clean and treated water, supplies often become contaminated through improper transport and storage. The approach to design research has been immersive, with IDEO's team spending time in Africa and India in the communities where an absence of clean drinking water is prevalent. We hope to have working prototypes of products, services, and business models that can be implemented by developing world entrepreneurs in 2008.

2. Evaluative or formative design research

Evaluative or formative design research is where design research and prototyping overlap. As soon as ideas emerge that are worth trying, they can be given form, whether as sketches, models, stories, videos or other kinds of prototypes, allowing an iterative series of 'learning loops.' In design research, ideas don't stay intangible or ambiguous for long. In this context, a prototype is simply a visible or tangible representation of an idea, to be thought of as a probe or thought-experiment; it is not a full-fledged pilot or a preproduction version of the real thing.

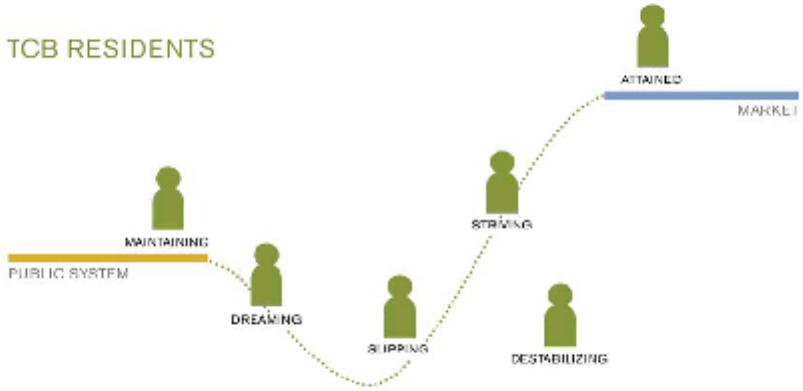
Evaluative design research is about building confidence by addressing questions and uncertainties *as they arise*. Frameworks, ideas, and concepts are shared in various ways as prototypes from very early (even in insight-gathering phases) to late in the process in order to learn from other people's reactions, and to check, revise, and refine assumptions.

For example, when working with the American Red Cross (ARC) to increase the national blood donor base, spurred by conversations with existing and potential donors, IDEO looked at ways the ARC could refocus its emphasis on the donor as the most valuable asset and gain greater emotional relevance with potential donors. Ideas emerged and IDEO designed and prototyped full-scale spatial layouts, furniture components, service tools and protocols for use in evaluative research around the United States.

3. Predictive design research

Predictive research tries to look ahead to estimate the potential of future opportunities and ideas, primarily from the perspective of their business or organizational viability. How confidently can we really predict whether a radical innovation will be a success? If it were easy, venture capital would no longer be needed and everyone would be an entrepreneur. This type of research is much less well-charted territory

for design, as the unintended consequences of design decisions often surprise, particularly at the level of social innovation. Designers need to be more creative in finding good ways to work through these business and organizational questions, both in helping to define potential opportunities and in determining the viability of ideas.



In-situ experimenting seems to offer great potential to social innovation in enabling accessible, rapid, and considerably lower-risk and lower-cost learning than would a full-fledged launch. For example, The Community Builders, Inc., (TCB), an organization dedicated to developing low-income housing communities in the USA, approached IDEO to examine its approach for helping residents and communities realize their full potential. After team members spent time as guests of low income residents in communities around the country, tangible outcomes were developed as a suite of tools named "Ways and Means." These are aimed at transforming TCB's properties from places of residence to arenas of value creation by reorienting offerings from service-based programs to demand-driven opportunities. The tools kits are being tried out in more than 200 situations currently, and will help to evolve the next level of solution.

A similar approach is exploited on an even larger scale by Google, through Google Labs, which has multiple experimental projects running at once and takes full advantage of the nature of hosted software to allow early launches – frequently updated in response to what is learned from users – of what effectively become eternal beta versions of their offering.

In summary at the end of her article, Jane Fulton Suri says;

"Both a personal and an organizational mind-shift are required to get comfortable with the emphasis that design research places on informing our intuition. Like many people in our culture, my formal education placed higher value upon received knowledge than upon personal discovery. But the longer I practice design and innovation, the more I am convinced that true learning comes not only from ready-processed data, but also from concrete sensory evidence and direct subjective experiences that have the power to capture our imaginations and achieve new understanding."

4. Design Research *About* Design

Research about design is not very mature as yet. Most practicing designers *Just Do It*, to quote the Nike slogan, relying on the intuitive nature of their process to yield results. Designers don't worry about underlying principles or postulate theories about methodology. Compare design to the fine arts or poetry. There are plenty of people earning doctorates in the history and theory of fine art and poetry, but nobody expects them to be the same people as those who create excellent art or write beautiful poems.

Korea

Perhaps design is growing up, as interest in design research expands. A methodology for the quantitative assessment of the sustainability management of firms may be the most challenging goal for design research about design, but that is just what Professor Cho, Dong Sung, of the College of Business Administration at Seoul National University, is proposing. The 6th International Design Culture Conference in May was sponsored by the *Korean Design Research Institute* and a *Korean Society of Design Science*. Professor Cho presented a keynote titled *Sustainable Management through Design Creation*.

(Cho 2008)

In his presentation Professor Cho addressed two issues:

- Redesigning the Design Theory for Application to Management.
- Designing a Guideline for Sustainability Management Reporting.

He discussed the objectives of companies and organizations pointing out that there are marked differences between the philosophies applied in different countries. For example:

- In America, the objective is to maximize shareholder value.
- In Europe, the objective is to maximize stakeholder value.
- In Japan, the objective is to maximize employee value.
- In Korea, the objective is to maximize major shareholder (i.e. owner) value.

He gave a critical analysis of existing guidelines for sustainability reporting, pointing out that they are investment driven rather than performance driven, that they impose high hurdles and that they have no auditing. He enlisted the efforts of the BEST (Business Ethics is the Source of Top Performance) Forum, a group of Korean firms inaugurated in 2003, which proposed a sustainability report guideline that was adopted by the Korean government. He explained concepts for the quantification of performance criteria, an auditing system, and the design for a dual reporting system.

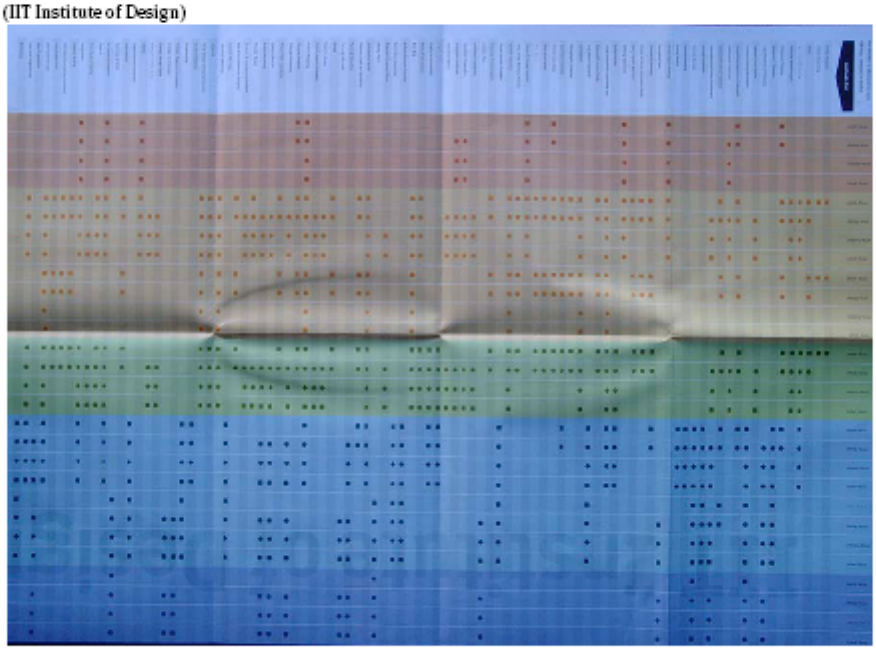
The characteristics of the BEST Guideline embrace subjective criteria such as harmony, balance, unity and rhythm, as well as objective characteristics such as reporting systems, standards, compatibility with other guidelines and report auditing. Professor Cho expects that his new approach will be adopted soon by the Korean government, so perhaps leadership about design research for social innovation and sustainability will come from this initiative.

USA

Most design education in the USA is still very pragmatic, but there are some respected centers of design research. IIT ID in Chicago, where the strongest tradition of Design Research in the USA resides, has published a poster containing over 90 design research methods taught at the school, analyzing them

by mode, so that one can see at a glance where each method can be used, and whether it is focused on users, offerings, company or market.

(IIT Institute of Design)



CMU (Carnegie Mellon University) is another interesting center for ideas about design research. Richard Buchanan, Professor of Design, leads an eclectic and international team of contributors to *Design Issues*, a journal of history, theory and criticism about design, published by The MIT Press.

(Design Issues)

At IDEO, our contribution to design research about design has been to publish team our methods whenever they are evolved to a cohesive level. We have achieved this with our *Methods Cards* describing fifty-one methods for design research. These are all about discovering what people might want and need, revealing opportunities for innovation and inspiring fresh ways of thinking about new possibilities.

(IDEO Methods Cards)

We added ergonomists and psychologists to our staff in the eighties and by the nineties their contribution had proved so valuable that we decided that every project should include their input. As time went by, they evolved a substantial portfolio of tools and techniques. When the number of methods was approaching fifty, one of the team suggested that they represent them as a deck of cards.

The idea of the methods cards is to make a large number of different techniques accessible to all members of a design team and to encourage a creative approach to the search for information and insights as their projects evolve. The intention is to provide a tool that can be used flexibly to sort, browse, search, spread out, or pin up. One can use the cards after a project briefing meeting, working through the pack as if in a game of patience and selecting the most useful set for that particular project in its various phases.

Each of the fifty-one cards contains explanatory text about how and when the method can be used and a brief example of its application to a real design project, with an illustrative and sometimes whimsical image on the other side. The cards are divided into four categories, ranging from the objective to more subjective—Learn, Look, Ask, and Try: "Learn" from the facts you gather," Look" at what users do, "Ask" them to help, and "Try" it for yourself.

It is generally most valuable to apply, or sometimes modify, a range of different methods for any given project. The most useful set will depend on whether the purpose is primarily a generative one of defining design opportunities for particular kinds of users or a domain of activity, or an evaluative one of refining specific design ideas as they develop. In an evolutionary project, where the new design will be closely related to something that exists, techniques that yield explicit information about a particular context and usage may be valuable. If the project is revolutionary—the design will set a new precedent—methods that help the designer understand a broader domain of activity and related latent needs may be more appropriate.

5. The Designers Accord

The Designers Accord is a global coalition of designers, educators, researchers, engineers, and corporate leaders, working together to create positive environmental and social impact. Adopting the Designers Accord provides access to a community of peers who share methodologies, resources, and experiences around environmental and social issues in design. Any designer, consultancy, or organization creating consequence at scale should join.

(http://www.designersaccord.org)

Valerie Casey is now at IDEO, but she was working with *frog Design* when she instigated this endeavor. Here is how she describes the initiative:

"This proposal began as a personal project, and has grown with the support of a loosely connected and passionate group of people

The inception of the initiative was rather simple. My revelation - or, the "spear through the heart" moment, as one of my green friends calls it - happened as I was sitting on a 50-seater jet, crossing the country for the third time in a month. I had just pitched a packaging project for one of the world's largest delivery services. Earlier in the week, I had discussed new diaper design with one of the world's largest paper product manufacturers.

I was acutely aware of each company's middling environmental record, but I was ill equipped to engage in a productive conversation with either of them about their environmental impact or propose sustainable alternatives. In addition, I was vaguely anxious about bringing up this sensitive issue and possibly losing their business. The negative rhetoric about the cost of green alternatives and accusations of greenwashing has made many companies bristle before a meaningful conversation can even begin.

That was the winter of 2007. At that time, I undertook a program to educate myself and my design teams about green design so that none of us would be in that position again. Throughout my fifteen years of design experience, I have been able to learn about technology, market trends, and organizational behavior, and speak about them with credibility and confidence. I believed I could do that again, with the most critical issue to date. I wrote a "Kyoto Treaty" of Design on that plane trip. Now, with the support of many experienced designers, activists, and thinkers, I feel it is the right time to bring a more developed version of the Treaty - now called The Designers Accord - to the broader design community. I hope you agree.

Thanks, Valerie Casey"

The goal of the Designers Accord is to create positive impact for social innovation and sustainability. There are three ways to join:

- Adopter (design firms, corporations, educational institutions) An organized group within the creative community who pledge to work through the guidelines.
- Supporter (artists, freelance designers, students) An individual who is making the guidelines relevant to their personal practice. Like adopters, we expect supporters to evangelize the movement within their communities.
- Endorser (organizations) Organization that adds awareness to the cause, and can provide infrastructure for education and outreach programs (like AIGA and IDSA).

All adopters, supporters, and endorsers follow a basic code of conduct: do no harm; communicate and collaborate; keep learning, keep teaching; instigate meaningful change; make theory action.

When Valerie started The designers Accord in July of 2007, she managed to enroll 450 people in three countries and covering four design disciplines. Now (June 2008) there are over 100,000 members in 100 countries covering all the design disciplines. This dramatic expansion shows that we are hungry to make a difference by working together for social innovation and sustainability.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Engaging Change

an African perspective on designing for sustainability

Mugendi M'Rithaa[10]

Abstract

Africa has a predominantly youthful demographic- it makes sense to engage the youth at a time when societies can indeed change the change. This paper presents personal reflections on design education at tertiary level in a number of African contexts. Though their specific responses vary in degree (and direction), there appears to be a deliberate attempt at addressing sustainability from uniquely local perspectives.

Notwithstanding pervasive infrastructural and financial limitations, a vision of a sustainable future is progressively emerging. To fully realize this vision requires a proactive and creative response. Some of the institutions presented in this paper have embraced the ideals of design for sustainability and are actively equipping future designers with requisite skills for bringing about positive social transformation.

1. An African Perspective

Africa is not homogenous, but a vast and diverse continent with a richness that is ill-appreciated. There are 53 independent states under the umbrella body of the Africa Union. The continent has a combined population of 840 million people- the vast majority of whom are youth. This burgeoning population is projected to reach a billion in less than a decade form now. “Africa bashing” as described by Frederick Cooper (1997, 189 cited in Ibhawoh and Dibua 2003, 61), “sometimes sounds like the ‘resurrection of the myth of a backward Africa of an older era’”. Pascal Eze calls this *PIDIC*- an acronym he coined to describe the asymmetrical fixation and reporting on *poverty, instability, disease, illiteracy* and *corruption* (Jere-Malanda 2008, 1). When one looks beyond this form of glorified pessimism, a picture of a vibrant engaging and resilient people begins to crystallise.

Africans are beginning to redefine their own destiny in terms amenable to their own aspirations. To this end, South Africa has emerged as the champion of a rejuvenated and increasingly confident people. From its origins in South Africa, the much touted African Renaissance has captured the imagination of the continents’ denizens. Eddy Maloka (2001) quotes the African National Congress’ “Developing Strategic Perspective on South African Foreign Policy” discussion document of 1997, in identifying the following as the key elements of the “African Renaissance”:

1. The recovery of the African continent as a whole
2. The establishment of political democracy on the continent
3. The need to break neo-colonial relations between Africa and the world’s economic power
4. The mobilization of the people of Africa to take their destiny into their hands thus preventing the continent [from] being seen as a place for the attainment of the geo-political and strategic interests of the world’s most powerful countries; and
5. The need for fast development of people-driven and people-centered economic growth and development aimed at meeting the basic needs of the people.

The African Renaissance is a stirring metaphor, but must must however move beyond the “triumphalist syndrome” that afflicts many emerging states (Maloka 2001). The continent can only achieve its fullest socio-economic potential if the anticipated action builds upon participatory grassroots ideals. To facilitate the achievement of such goals, the New Partnership for Africa’s Development (NEPAD) was adopted by the Africa Union in 2001. The stated long-term objective of NEPAD “is to eradicate poverty in Africa and to place African countries, both individually and collectively, on the path of sustainable growth and development and thus halt the marginalisation of Africa in the globalisation arena” (Ezeoha and Uche 2005, 6). A peer review mechanism has been formulated to enable NEPAD members to hold each other accountable on a wide range of socio-economic and political issues.

Further, the ancient and time-honoured anthropocentric philosophy of *ubuntu* is being evoked to rally up support for this call. Mfuniselwa Bhengu (1996, 5) describes *ubuntu* as “a way of life that contributes positively towards the well-being of a people, community or society”. Richard Tambulasi and Happy Kayuni (2005, 158) however caution that *ubuntu* alone cannot resolve Africa’s woes and must be embraced “in harmony with democratic and good governance principles”. The strength of *ubuntu* is in its pervasiveness and inclusiveness. In sub-Saharan Africa, it is the relational bond that holds entire communities together through an expanded view of kinship. It is a vital force in a continent that has such a diverse range of cultures, colonial histories, and geo-political realities.

South Africa is undisputedly the pivotal state on the continent currently the largest foreign direct investor in the African continent (Ezeoha and Uche 2005). According to David Fick (2006, 166) this economic powerhouse accounted for 38% of the entire sub-Saharan Africa’s gross domestic product (GDP) in 2004. Other economic successes include its neighbour Botswana, as well as Mauritius and Tunisia (Jere-Malanda 2008, 5). The principle reason for Botswana’s

economic “miracle” is attributed to what Abel Ezeoha and Chibuike Uche (2007, 24) call “honest competent leadership”. Other countries worth emulating for their consolidation of democratic practices include Namibia and Ghana. Africa has the fastest growing market for information and communication technology (including mobile telephony), whilst the economic growth forecast for the continent is a promising 6.7%.

2. Changing Landscape

Agricultural activities account for between seventy and eighty percent of the employment opportunities in Africa. Increasingly greater numbers of the continent’s labour force is exploring alternative livelihoods in the provision of goods and service in the informal sector. To illustrate this trend, the promising evolution of the informal sector in eastern Africa is interogated.

The informal sector is popularly known as the *jua kali* sector in East Africa. This unique phenomenon emerged in Kenya in the 1980s and spread to neighbouring countries in a viral manner. Bani Orwa (2007, 3) identifies the Kamukunji Jua Kali Association as the pioneer of the *jua kali* movement in Kenya having been formed in February 1986. The association received special recognition from the Kenyan government for its contribution to national economic growth and development. *Jua kali* means literally *“(under) the hot sun”*- a term that aptly describes the often harsh conditions under which *jua kali* micro-entrepreneurs and their employees eke out their livelihoods. The *jua kali* sector originally was almost exclusively restricted to artisans converting scrap metal into usable goods. The sector now includes a diverse range of professions, with the scale and scope of the participating businesses becoming the definitive factor. Orwa (2007, 1) emphasizes the sector’s significant contribution of 18.4% of Kenya’s GDP, and the fact that it “provides goods and services, promotes creativity and innovation, and enhances entrepreneurial culture”. According to Sarah Macharia (2006), “every official document defines the *jua kali* sector as micro and small enterprises (MSEs)” or Small, Medium and Micro Enterprises (SMMEs). These enterprises typically employ 1-49 people and are legally exempted from registration with the Registrar of Companies.

The *jua kali* sector is massive in coverage- almost every Kenyan is linked to the sector. It is estimated that 76.5% (5.9 million) of Kenya’s labour force works in this sector (Macharia 2006). Indeed it is the norm for most people employed in the formal sector to run a number of *jua kali* businesses. To put the job creation potential of *jua kali* in perspective, a staggering 95% (450,000) of all new jobs created in 2005-2006 were in the informal sector whilst the remaining 24,000 were in the formal sector (Macharia 2006). Orwa (2007, 6) reports of promising developments such as the recent registration of National Informal Sector Coalition (NISCO), a multi-sectoral body that brings together all *jua kali* associations in the country.

Only 29% of those engaged in formal employment are women whereas in the *jua kali* sector, women constitute the overwhelming majority (62%) (Macharia 2006). This situation is consistent with that found in other countries on the continent. In South Africa for example, rural and peri-urban women form *stokvels* (co-operative societies) for their mutual support and benefit. In Botswana such practices as *molaletsa* (collective labour sharing systems) and *motshelo* (group credit unions) serve an important socio-economic function and are consequently actively encouraged (Ebewo 2005, 96). Indeed, a number of *stokvels* have organised themselves to buy large tracts of land for their members’ benefit. Various grassroots initiatives exist where members channel voluntary revolving funds to their membership. This is particularly important as credit options are limited to people operating in this sector of the economy. Isobel Frye (2006), Andries du Toit and David Neves (2007) note that this “survivalist” informal sector is known as the “second economy” in South Africa- one that is structurally removed from the activities of the mainstream formal economy. Du Toit *et al* (2007) and Macharia (2006) highlight the adverse influence on gender roles on women’s entrepreneurial options. Subsequently there is a proliferation of “me too businesses” characterised by low innovation and even lower technology adoption among the participants Du Toit *et al* (*ibid*). The importance of women as key participants in micro-enterprises cannot be over-emphasized and progressive strategies must take cognisance of this fact- this would in effect translate into more sustainable communities.

In reviewing the prevailing climates for micro-enterprise development in Kenya and South Africa, two distinct realities emerge. Whereas the informal sector receives official recognition and support in the former, the same cannot be said in South Africa where corporate businesses are so dominant that micro-entrepreneurs are virtually denied any opportunities for sustainable livelihoods. In this latter context, the so-called 'second' economy is seen as being retrogressive and a drain on the resources of the formal economy (Frye 2006, Du Toit *et al* 2007). As du Toit *et al* (2007, 32) argue:

> *"Rather than aim at "eliminating" the second economy or hoping that it can somehow be transfigured into the first, policymakers would do better to look carefully at measures that can ameliorate existing power imbalances and reduce inequality. Looking at "what is found there" by a less pathologising, less normative gaze, abandoning the naïve belief that "integration" on its own will confer the benefits of modernity on those who unaccountably remain outside, and looking at the exclusionary implications of mainstream corporate practice in South Africa may help crafting policies that are better at addressing the adverse nature of some of the power relations between poor South Africans and the larger economic formations to which they are connected; policies which value and support the fragile survival strategies that take shape on this hostile and difficult terrain".* Du Toit *et al* (2007, 32)

3. Sustainable Design Responses

The Network of Africa Designers (NAD) is the brainchild of Adrienne Viljoen, the Manager of the SABS Design Institute in Pretoria, South Africa. This loose network was inaugurated in April 1999 and encourages designers from across the continent to network and exchange experiences and information on a regular basis. The now annual Africa Design Day provides an ideal platform for dialogue on design. NAD has membership in nine countries on the continent and this number is growing steadily every year. The bulk of NAD's membership is composed of design educators in tertiary institutions.

The following section is a sampling of some of the unique challenges facing universities on the continent. Further, there is a brief discussion on specific responses towards achieving their respective visions. A summary (Table 1) is provided at the end of the discussion and covers an additional sample of institutions represented by members of NAD.

3.1 University of Botswana, BOTSWANA

The Industrial Design & Technology Department (IDTD) of the University of Botswana was established around 1982. It was initially known as the Technology and Education Studies Department as part of the erstwhile Botswana Polytechnic which became the Faculty of Engineering and Technology of the University of Botswana around 1995. From an initial focus on training Design and Technology teachers, the IDTD began offering an additional programme in Industrial Design to cater for the relatively young but promising manufacturing industry. The first cohort of this programme successfully completed their fifth (and final) year in May 2008.

From the outset, the focus of the Industrial Design programme has been on producing graduates equipped with professional and entrepreneurial skills to aid in the diversification of the national economy. Botswana is the world's largest producer of gem diamonds by volume and has historically relied almost exclusively on the export of the mineral. Further, IDTD sought to compliment national efforts towards value–addition (via jewellery design and related activities), as opposed to the previous practice of exporting raw diamonds to be processed elsewhere.

IDTD offers three modules dedicated to the pressing issue of sustainability, namely; *Design for Sustainable Development*; *Environmental Factors in Design*; and *Eco-Product Design.* These are offered to students specialising in Design Education well as those in Industrial Design.

The staff and students of IDTD have also participated in a number of sustainable design-specific projects with various private and public sector organisations. Additionally, links through

NAD have provided staff and students opportunities to tour design practices, academic institutions, and manufacturers in neighbouring countries. This is significant in view of the relatively nascent design-supporting industry in Botswana. Designers in the country are presently in the process of formalising a design association to facilitate a forum for negotiating their contribution with key stakeholders in the country.

3.2 University of Nairobi, KENYA

The School of the Arts and Design (StAD) of the University of Nairobi, Kenya was arguably the first tertiary institution to train designers in Kenya. Previously all art education was acquired at the pioneering Margaret Trowell College in Makerere University, Uganda. StAD has the widest range of design programmes from undergraduate to doctorate level. These include Graphics, Textiles and Fashion, Interior, Illustration and Product design specializations. Further, StAD is the longest running provider of tertiary level design training, having been established as the Department of Design in 1967. Increased competition (especially over the last five years) from new schools offering specialized courses has led to a recurriculation and repositioning of StAD as a key actor within the regional design landscape.

Design for sustainability is not offered as a dedicated module/course, it is however covered under Materials and Processes, and Product Design. In response to local community and societal needs, StAD collaborates with Non-Governmental Organizations (NGOs), other universities, and organisations that are engaged in development and action research. For example, proactive partnership with NGOs has equipped many crafters/artisans and *jua kali* informal sector operators with requisite design, management and entrepreneurial skills.

StAD intends to roll out a newer curriculum that is more responsive to socio-economic and industrial needs of the country. Further, the School has made specific input in the national development strategy of a vision of Kenya as an industrial state by the year 2030. Other strategies include:

- Building capacity to transform into a centre of design excellence in the East African region
- Strengthening linkages with industry for the benefit of all
- Developing the fields of fine and applied arts, visual communication and design, and performance design and technology by 2011
- Providing incententives (such as awards and scholarships) to enhance competitiveness and innovation among design students

A recent phenomenon in the training sector in Kenya is “training for production”, which perhaps could be more aptly described as “product-based training”. Essentially it refers to an interesting mix of skills development and product development: small producers receive, usually short-term, skills training that is entirely focused on the production of a new or improved product.

3.3 **Federal University of Technology, Akure, NIGERIA**

The Federal University of Technology, Akure is one of the five universities of technology established by the Federal Government of Nigeria in 1982. Industrial design emerged in 1977 when it was carved out of the Fine and Applied Arts of Ahmadu Bello University, Zaria. The programme initially had an art and craft focus and essentially concerned itself with the aesthetic appearance of hand-made products. With the establishment of Universities of Technology, the minimum admission requirements were revised to include chemistry, physics and mathematics. The National University Commission provided the curriculum which was subsequently described as disjointed and lacking in focus by design teachers. The Department of Industrial Design (DID) was established during the 1992/93 academic year and began to formally admit candidates two years later. The design programme sought to provide professional education that focused on the following:

- producing designers capable of understanding and solving complex problems in the field
- to acquaint students with appropriate knowledge and skill necessary to solve design problems
- develop students' understanding and awareness of the social, cultural, physical, technical and economic activities of the Nigerian society;
- develop students' ability to understand elements and principles of design as well as design methods and synthesize appropriate information to produce effective design and prototypes
- develop students' ability to provide appropriate solutions to technological, economic and aesthetic problems of the society.

The Nigerian universities offer Textile Design, Graphics, Ceramics, Glass Technology, Jewellery, and Interior Design. The duration of the programme in the conventional (or traditional) universities is 4 years whilst the Universities of Technology qualification takes an additional year- this adversely impacts on prospective students choosing to study in the latter institutions as they have to delay joining the workforce by a year. Compounding this reality is the inadequate (official) recognition of Industrial Design as a profession in Nigeria. Graduates also contend with the consumers' preference for imported products over locally designed and produced ones.

DID is reaching out to the community and local secondary schools to promote design. The Department has a consultancy unit which is working with the state government in its poverty eradication programmes. The Department has been participating in the sericulture and cottage industries projects in the state for a while with positive results. There are concerted effort is targeting the government and the general public to educate them on the importance of design to the local economy. This is fuelled by the realisation that design education can only make meaningful contributions to sustainable national development when adequate attention is given to art, design and technology at the primary and secondary school levels. Further, design education at the tertiary level must be properly funded with appropriate infrastructure. It is anticipated that these activities will help promote a more positive perception of design in the country.

3.4 Cape Peninsula University of Technology, SOUTH AFRICA

The Cape Peninsula University of Technology (CPUT) came about in January 2005 as a result of a government directive that merged the former Cape Technikon with the Peninsula Technikon. The Department of Industrial Design first began admitting students in 1988 and is presently one of two departments/institutions offering the said course in South Africa. From the humble beginnings where the first cohort of four students qualified with the National Diploma Industrial Design in 1990, the Department now services on average between 160-170 students from undergraduate level through to doctoral studies.

The initial focus of the Department was to produce individuals with the ability to grow the design industry. The fact that there was no locally established market meant that graduates had to be equiped with above-average self-reliance and resourcefulness in addition to the traditional technical competence. The Department's belief that the entry level to the Industrial Design porfession should be a Masters degree – a vision shared with numerous institutions internationally - has allowed it to branch out in fields of study such as Interaction Design, Universal Design, Design for Development, Design for Sustainability, and Participatory Design.

Through its active participation in ICSID-endorsed InterDesign workshops around Design-for-Development themes such as Water and Sustainable Rural Transport, the Department has been particularly instrumental in taking the workshops' concepts through to experimental prototype stage for field testing. Although started in 2005 this process is still ongoing and attracts an increasing amount of provincial government funding based on its proven successes.

It's staff members have been involved in and are part of the executive committee of the Design Education Forum of Southern Africa (DEFSA), a professional organisation of design

educators based in South Africa but with its eye on international cooperation within the Sub-Saharan region. The yearly DEFSA conferences have generated a strong network between tertiary institutions offering design courses which has influenced a number of national political issues related to design education. The DEFSA network has been inspirational and its members have contributed to the growing Network of African Designers some of whose members have made valuable input in this paper.

Ultimately, through it's international contacts and exchange programmes in Africa, Europe, North America and Asia the Department is positioning itself strategically to be at the cutting-edge of technological and theoretical design knowledge and to channel the resultant flow into the African reality. This effectively supports the long-term vision od accelerated appropriate and sustainable development on the continent.

The following table (1) summarizes eight instutional perspectives from a sample of corresponding universities on the continent.

Table 1: Summary of selected institutional perpectives

INSTITUTION	CHALLENGES	COURSES	RESPONSES	VISION
University of Botswana; *Botswana*	narrow economic base: over-reliance on diamonds	design education; industrial design	projects with industry, parastatals and NGOs	diversification of the economy
Kwame Nkurumah University of Science & Technology (KNUST); *Ghana*	negative effects of imported products on local production	Industrial and fine arts (including graphic design)	infusion of indigenous (*adinkira*) symbols in graphic design	mainstreaming appreciation of indigenous knowledge systems
University of Nairobi; Kenya	contribution to newly industrialised status of the country	graphic; illustration; interior; textile & fashion; product design	training of people working in the informal sector	to be a centre of excellence in the region
Federal University of Technology, Akure; *Nigeria*	lack of recognition of the design profession	textile; graphics; ceramics; glass technology; jewellery; and interior design	participation in project of social significance	recognition of design in socio-economic development
Kigali Institute of Science & Technology (KIST); *Rwanda*	reducing dependency on expensive imported products	electrical and mechanical engineering (no design courses offered as yet).	assistance to graduates in prototyping products	promoting self-reliance and entrepreneurship
Cape Peninsula University of Technology (CPUT); *South Africa*	engaging with new geo-political dispensation and technological opportunities	industrial; graphic; surface/fashion; interior; jewellery;	participation in and driving of sustainable design for development initiatives	enhancing peoples quality of life through design; applying new digital technology to accelerate development
Makerere University; *Uganda*	need to support SMMEs	industrial and fine arts (including textile design)	integration of entrepreneurial skills to graduates	sustainable entrepreneurial environment
Zimbabwe Institute of Vigital Arts (ZIVA); *Zimbabwe*	designing in a constantly changing and volatile environment	visual communication (including advertising and graphic design)	working with the resources available to designers	sustainable context-responsive design solutions

4. Building on Local Values

Traditional African societies have always relied on a system of collective responsibility for self-reliance, and mutual assistance known by various names such as *bataka kwegaita* (communal solidarity) among the Banyakore people of Uganda, *boipelogo* (self-reliance) in Botswana, *harambee* (pulling together) in Kenya, and *ujamaa* (familyhood) in Tanzania. Bonny Ibhawoh and Dibua (2003, 62) state that the philosophy of *Ujamaa* "was rooted in traditional African values and had at its core the emphasis on familyhood and communalism of traditional African societies". Indeed, all the traditional value systems discussed here are underpinned by the ideology of *ubuntu*, wherein the (extended) family has acted as the custodian of all that is good and noble within such societies. Despite the massive movement of peoples within and beyond the continent, these values are still cherished and in abundant evidence in the mutually supportive relationships between individuals and their communities.

A number of related concepts further enrich communal life in Africa. With respect to Botswana, Ebewo (2005, 92) discusses the value of *Laedza Batanani*- a form of theatre for development practice (TDP) as "an empowering approach to poverty reduction and community development" in rural areas and urban villages. The focus of TDPs on enhancing a form of functional (as opposed to formal) adult literacy (Ebewo (2005, 93). Kidds (1984, 264) states that TDP:

> *"is used as means of bringing people together, building confidence and solidarity, stimulating discussion, exploring alternative options for action, and building a collective commitment to change; starting with people's urgent concerns and issues, it encourages reflections on these issues and possible strategies for change"* (Kidds 1984, 264 cited in Ebewo, 2005, 94).

This is an excellent way of mobilizing communities for change in low-literacy contexts as the participation is community-based and context-specific and building on Africa's rich oral tradition and indigenous knowledge. Previous top-down approaches such as the Bretton Woods institutions (International Monetary Fund and World Bank) prescribed structural adjustment programmes exacerbated poverty as the programmes did not invite communal participation (Ibhawoh *et al* 2003, 77; Ezeoha *et al* 2005, 8). On the other hand, bottom-up examples encourage participation and ownership (such as the *jua kali* phenomenon discussed previously) thus resulting in promising and sustainable socio-economic development.

5. Conclusion

African societies have proven to have very resilient and sustainable traditional systems that were in harmony with the environments they flourished in long before Western colonisation. Although an abundance of non-African technology has been integrated into the African way of life today, huge opportunities still exist to advance the continent based on its own naturally developed cultural values. To quote Mazrui (1986):

> *"the African family is the most authentic social institution in the post-colonial era. In a continent steeped in artificiality, the African family is more real than many of our countries which are colonially made…more real than our economies most of which are mere shadows.… You see, the family in Africa is vibrant in its emotions, compelling in its loyalties. It is alive and well, living right across the continent"* Mazrui (1986 cited in Takyi and Oheneba-Sakyi 2006, 273).

The continental programme of action known as NEPAD has a coordination mechanism based in Johannesburg, South Africa that could compliment economic strategies across member states of the African Union. NEPAD relies on peer-support and peer-review through loose networks of stakeholders to function. Provided it can muster the necessary political will, NEPAD is the ideal vehicle for mobilising the continent's creative potential and help Africa 'leapfrog' into a truly sustainable future (Manzini 2007).

Du Toit *et al* (2007: 32) challenge the conventional wisdom of attempting to eliminate the informal economy or even absorbing it into the mainstream economy. Instead, an effective policy should focus on "measures that can ameliorate existing power imbalances and reduce inequality" *(ibid).* It would be wiser to remove structural obstacles to the naturally available creativity and

promote government programmes that stimulate the growth of spontaneous economic seedlings through education and appropriate design input. To this end, lessons learnt from the thriving *jua kali* sector are instructive and would provide motivation and inspiration to policy makers grappling with the challenge of harnessing their respective peoples' entrepreneurial potential.

The number of institutions and the variety of their appraoches to design education illustrates the value of diversity. Diversity should be embraced without disjuncture from the common goals and aspirations of the continent. The establishment and expansion of existing networks such as NAD will provide a dynamic platform for sharing knowledge and experiences in the teaching and practice of the design profession in its various disciplines with a tuniquely African perspective.

This vision is message best personified through the example of Kimani Ng'ang'a Maruge who entered the Guinness Book of Records in 2004 for being the world's oldest primary school pupil to enroll for grade one at the ripe old age of 84 (BBC News 2005). He represents the resilience and optimism of a people hungry for opportunity who are willing to learn new and exciting things – a people willing to engage with change. This is the vision that Africa would want the world to share...

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Strategies of Change Towards Sustainability

The South American Experience

Santos, Aguinaldo dos[11]

Abstract

In South America, due to poverty, a large portion of its society has learnt to live with fewer resources, paradoxically surrounded by an abundance of resources. On such environment entrepreneurship, flexibility with cultural diversity and easiness to deal with uncertainty, is required from people on a daily basis in order to guarantee survival. Such environment aligned with an increase on the education levels, political awareness and information access, has induced a widespread of locally-based social initiatives that in many cases represent truly innovative social changes towards sustainable consumption and production. Hence, based on this context, this article presents emblematic case studies gathered in Brazil, trying to understand their underlying strategies to change current patterns of consumption and production. It also presents a general picture of the design research community in Brazil with a focus on sustainable design.

[11] Federal University of Paraná, Brazil, Professor, asantos@ufpr.br

1. Introduction

Most of the undergoing actions in Brazil on the field of sustainable design do not come from scientific research. Design Research itself is relatively recent when compared to other fields of knowledge. Whilst fifteen years ago there was no postgraduate course on the field, today the country has 10 postgraduate programs, including the only PhD course at PUC-Rio. Furthermore, the interest of the Brazilian design research community on the topic of sustainability is divided with a number of other research themes that are far more consolidated such as ergonomics or semiotics. Indeed, next figure shows sustainability as the focus of only 15% of the papers submitted to the 7th Brazilian Conference on Design Research & Development (2006), the largest event on the field of Design in Brazil.

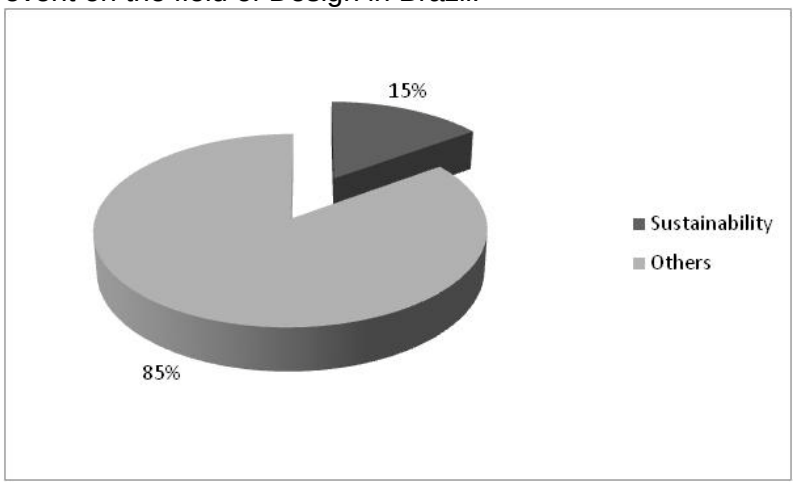

Figure 1 – Amount of Papers Submitted to the 7th P&D on the Field of Sustainability

Developing and disseminating sustainable design knowledge faces the challenge of expanding the amount of research groups as well as improving its geographical distribution. Nowadays there is a concentration of the few research groups with a focus on “sustainable design” around the states of Rio de Janeiro, São Paulo, Paraná and Santa Catarina. As result vast areas of the country present a total absence of sustainable design research even in those areas where there are private or public projects to change current patterns of consumption and production.

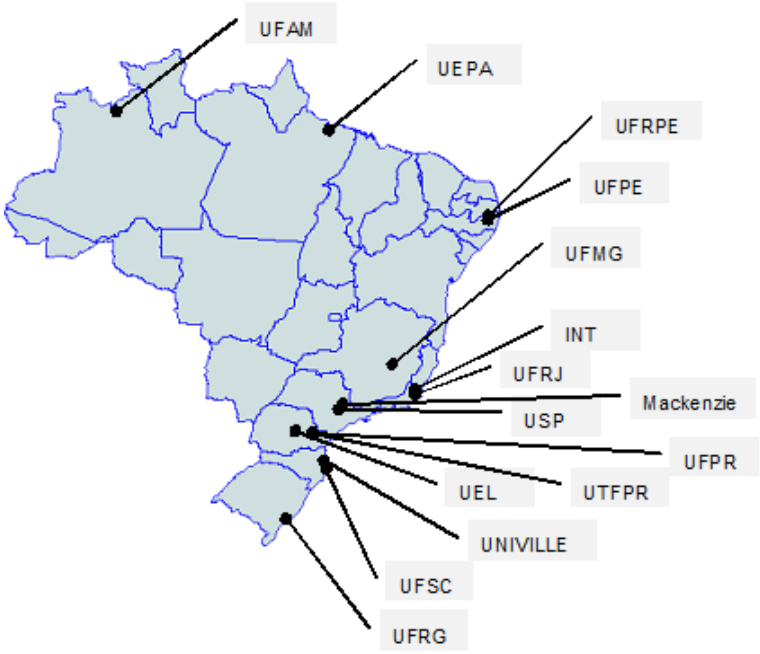

Figure 2 – Location of Research Groups on the Field of Sustainable Design in Brazil

The main challenge for radically change the current patterns of consumption and production is radically increase the number of designers with expertise on sustainable design. A research carried out by this author on the database of CAPES (Brazilian agency in charge of evaluating postgraduate programs) using the keywords “sustainable design”, “eco-design” and “social design” showed a set of only six PhD thesis carried out in this area in the country until May 2008. Also, within the same database and with the same keywords the research has showed a total of 34 MSc dissertations carried out since the year 2000. Taking into consideration that the country has around 300 design schools this number falls far behind the demand for lecturers on sustainable design, let alone the growing demand of the market for design professionals with expertise on this field. With one take the position that every lecturer on design should have basic knowledge on sustainability the target for training could be estimated to around 6.000 lecturers.

In 2007, the I International Symposium on Sustainable design has resulted on the establishment of the **Brazilian Network on Sustainable Design Research**, with the mission of contributing to speed up the amount and depth of design research through an increase in the synergy among research groups, including design offices working on this field. The Network invites designers from around the world to contribute with ideas and actions.

The case studies on the following sections show that the end result on the social dimension of sustainability is already clear (social equity and cohesion, promotion of principles and rules of democracy, promotion of human rights and freedom, achievement of peace and security; access to information, training, employment; respect for cultural diversity, regional identity, etc). The cases present various directions of change towards sustainability where Design Research can play a key role.

2. From Individual Change to Systemic Change Towards Sustainability

2.1 Individual Change

2.1.1 Definition

Change towards sustainability here has two known approaches: the Behaviourist and the Gestalt-Field psychologists. The Behaviourist psychologists would see behaviour modification towards sustainability as the manipulation of stimuli so as to reward a desired activity connected to a sustainable scenario. According to Burnes (1996) the strategy here is to reward immediately all instances presenting the desired behaviour, ignoring all instances presenting an undesired behaviour.

Gestalt-Field psychologists, on the other hand, would understand that individual behaviour towards sustainability as not just a product of external stimuli. Individual behaviour arises from how the individual uses reason to interpret the stimuli. Consequently, according to Burnes (1996) Gestalt-Field proponents seek to help people to change their understanding of themselves in any situation in question, which, in turn should lead to changes in behaviour.

2.1.2 Case Study on Behaviorist Approach: “Ecological Supermarket Check-out” in Curitiba

This is a design led project developed in the city of Curitiba, Brazil, by Albach et al. (2007) as part of a program to reduce urban solid waste, intending to instigate consumer involvement in environmental initiatives and, also, to assess people’s acceptance concerning habit change. Supermarket clients are invited to participate in the initiative by means of two actions: a) bringing their own bags to place some of their purchases on the lookout for the reduction of plastic-bag residues; and b) discarding – in appropriate containers at the side of the Ecological checkout, and according to the consumers’ free-will – packages that do not have to be necessarily brought home.

The “ecological check-out” offers also green plastic bags, which distinguishes the customers’ participation from the other check-outs (ALBACH et al., 2007).

Figure 3 – Packaging disposal besides the ecological check-out

Once the customer has finished his/her purchase, the number of plastic and paper packages left at the check-out is visualized by the customer at the point of sale along with the name of the charity institution that will benefit from the amount of packing collected. The first benefited institution was the school supported by the Paraná State Rehabilitation Association, which assists approximately 200 children and young adults free of charge (ALBACH et al., 2007).

According to Albach et al. (2007) employees from different sectors (check-out operation, supervision, wrapping up, security, data processing, bakery, fruits and vegetables, reception, among others) were trained to fully understand the meaning of the initiative. The intention was that all employees, whether directly working in the project or not, knew and provided information about the Ecological check-out to customers who could approach with doubts. In those trainings, the employees got information on the environmental problems of our society, focusing the generation and discard of packing residues (ALBACH et al., 2007).

2.1.3 Case Study on Gestalt: EEHouse Project

This case study shows an example of actions led by designers (Battaiola et al., 2006) that supported the education of people regarding the use of energy, allowing them to make more judicious decisions. It came from the realization that university courses can (and do) include topics about this subject but the society in general has little access to this knowledge. Thus, it was understood as necessary to implement mechanisms to disseminate energy efficient concepts to the general public.

According to Battaiola (2006) attempts to increase energy efficiency awareness through public campaigns are too expensive and have resulted on limited effects because it is typically difficult for the public to focus solely on one topic (e.g., energy efficiency) over a long time period.. A computer game, accessed through the internet, can provide interactive tools (“edutainment”) to transmit energy efficient concepts to professionals as well as to the public.

EEHouse is a game intended to teach energy efficient concepts to the general public. It was led by designers in cooperation with researchers from Computer Science and Architectural Departments at the Federal University of Paraná and Intelligent CAD and Games Lab of the Pontifical Catholic University of Rio de Janeiro (PUC-Rio).

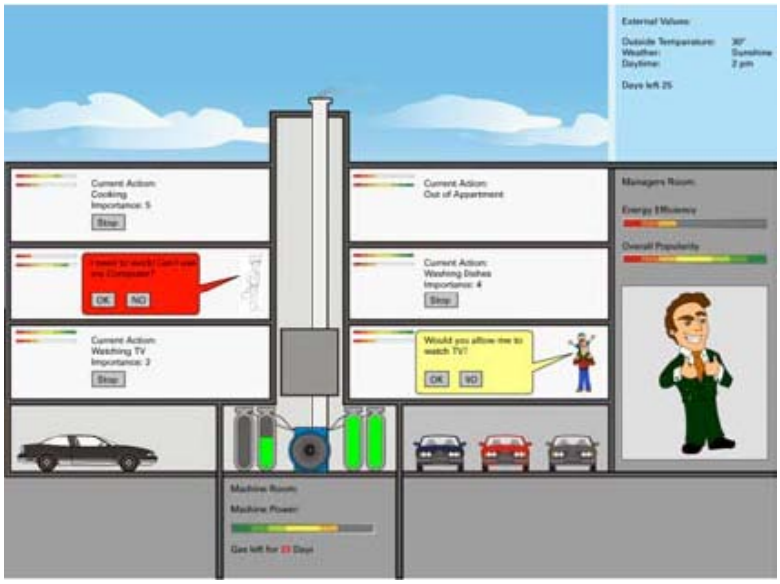

Figure 4 – A View of EEHOUSE Game First Version

In this game, as described by Battaiola (2006) the user assumes the obligations and role of the syndic and must organize the life of the residents in a way that it is possible to consume energy in an efficient manner so that it doesn't result in unnecessary discomfort in the occupants' lives. If the personal discomfort is significant, the syndic loses points in the satisfaction factor/category. If this factor value decreases below a minimum limit, the syndic is fired.The game's first version allows playability only through the syndic. He decides if a resident can use energy to execute a specific activity based upon a priority activity list. The list is dynamic; it can change in function with varying external factors, such as weather, length of day, profession of the residents, as well as health and emotional conditions (BATTAIOLA et al. 2006).

2.2 Group Change

2.2.1 Definition

The paradigm of "group change" understand that, since people work within groups, individual behaviour must be seen, modified or changed according to a group most prevailing practices and norms. The group changes the individual and the individual changes the group in a continuous process of mutual adaptation. Therefore, according to the supporters of this point of view it is useless to concentrate on changing the behaviour of individuals. The focus of change should be on the group level and concentrated on its norms, roles and values (Burnes, 1996).

2.2.2 Case on Group Change: A School for Carpenters in the Amazon Region

In this case study the challenge set for designers was an urgent need to increase the value added by local people in Xapuri, Acre, on wood-based products aiming the local community. EMEC – School of Carpenters, based in Xapuri is an NGO connected to *Cooperazione Italiana* and its main mission is to contribute to the sustainable development of the High Acre through integrated multi-sector projects. This particular project was carried out by Oficina Nomade (Design Firm) in partnership with the NGO Friends of Earth and EMEC. An important innovation here was the fact that every group of students received support to implement a company or cooperative with their classmates (average of 7 students per year) at the end of their learning period at EMEC. Design in this case was strategic to bring more competitiveness to these incubated companies.

This project brought external knowledge but, at the same time, tried to use most of the already existing knowledge among the locals in order to avoid dependence from designer consultants.

Most of the design problems identified during the diagnosis were related to the poor quality of ergonomics and, also, with the excessive amount of time to manufacture these products. Also, very importantly, the design solutions had to consider the possibility of maintenance carried out by the user itself or, alternatively, carpenters with a reduced set of tools.

Figure 5 – The Xapuri Carpenter´s School Shop

Along with the benefit of helping the local economy, enabling local people to have better quality of life, the project brought a severe reduction on the environmental impact of this economical activity. The artisans began to use only wood from managed forests, including waste from FSC - SW COC 1026 certified wood. They use certified wood that did not reach the dimensional standards required for export markets and, due to that, have reduced economical value. CooperFloresta, a wood management cooperative run by a local community (68 families) in Rio Branco, Acre, supplied the wood for this project.

2.3 Systemic Change

2.3.1 Definition

Advocates of this type of change strategy see society as composed of a number of inter-connected sub-systems. The central idea on this strategy is that any change to one part of the system will have an impact on other parts of the system, and, in turn, on its overall performance. This approach for change is based on a method of describing and evaluating sub-systems in a meaningful way for any individual, in order to determine the best pathway to conduct the change so as to improve the overall performance (Broome, 1990; Burnes, 1996; Vollmann, 1996).

2.3.2 Case Study on Systemic Change: BOP at Masisa

This case study reports the use of the Base-of-Pyramid (BOP) business approach at Masisa. This is a vertically integrated forestry company with pine and eucalyptus plantations in Chile, Argentina, Brazil and Venezuela. This company produces wood products for a variety of uses: wood boards, solid wood products such as doors and mouldings, as well as timber, for which it maintains industrial operations in Chile, Argentina, Brazil, Venezuela, Mexico and the United States.

The BOP projects within Masisa comes under its vision of being recognized as a leading industrial group in Latin America , operating in a framework of ethics, eco - efficiency, and social responsibility, that generates economic value and improves our neighbors' and our regions' quality of life. Based on this vision Terranova has established an ambitious goal: by 2010, 12% of its sales will come from "socially inclusive business", by which the company seek to offer its customers opportunities to break the vicious cycle of poverty. To this end, Masisa has created partnerships with more than 300 of its retail outlets (PlacasCentro) licensed in Latin America so as to train

carpenters in producing improved furniture that meets the needs of the poor. Also, in order to create a new sales force for these products it is contracting and training women from low-income segments of society. It is also helping carpenters, with the collaboration of other civil society organizations, to become micro-entrepreneurs and thus participate in the formal economy (Grupo Nueva, 2003).

However, despite such initiatives a critical analysis of the conventional process for designing, producing and distributing furniture on the low-income market has shown that, in order to achieve its BOP goals, Masisa had to enable more equity among all stakeholders throughout the supply chain. The conventional business process generates income and employment quite distant from the areas where low-income people live (see left diagram on the next Figure). Therefore, one of the strategies to implement a socially inclusive business process would require bringing the employment and revenue generation closer to the low-income community that actually buys the furniture (see right diagram on the next Figure).

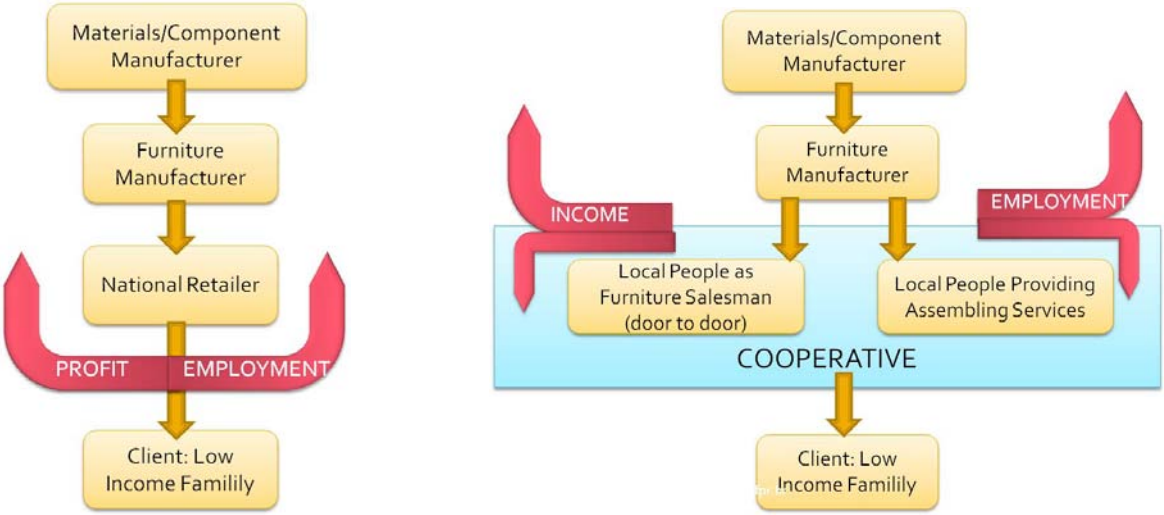

Figure 6 – Conventional business process x New Business Process Under BOP

With the idea of enabling a change in the business process, the present project has aimed the development of products that could be produced, distributed and maintained within the low-income community itself within Masisa BOP strategy. Next figure shows one of these products which fulfills a gap on the furniture market for low income people: a furniture to divide spaces between bedroom and living room or between the kitchen and living room. The product illustrated here is shelf that can be assembled like a Lego and enables its usage on both faces and, very importantly, acoustic insulation.

Figure 7 – The Location of the Product and Some of the Alternatives

The product has been designed in a way that even local producers, using widely available wood processing technologies, would be able to produce and maintain it, thus providing income generation closer to where the low-income families actually live. The scenario for producing and distributing this furniture has considered an undergoing BOP project within Masisa that attempts to

train local people as furniture salesman (door-to-door), emulating other similar marketing approaches such as the one adopted by Avon for its sales force. All wood-based material specified for this furniture follows FSC standards and it was selected within Masisa´s range of products. The product allows the use of accessories to increase its functions and appearance. The current phase of the project includes the analysis of local cooperatives of craftsman in order to include their work as alternative strategies to provide textures and accessories for the product, thus stimulating the local economy. These two channels of product development together with the already existing range of color/textures possibilities offered by MASISA enables a more customized product for each low-income family.

3. From Emergent Change to Planned Change

3.1 Emergent Change

3.1.1 Definition

The emergent approach of change towards sustainability sees change as a continuous, open-ended and unpredictable process of aligning and realigning an organisation to its changing environment. Advocates of emergent change tend to adopt a contingency perspective. For them, it is the environment's uncertainty that makes planned change inappropriate and emergent change more pertinent. Environmental change is so rapid and complex that the initiation and implementation of change in the emergent approach tends to be "bottom-up" rather than "top-down". Supporters of the emergent approach stress four features that either promote or obstruct change, in the case of organizations:

- Organizational or community structure: this can be an important lever for achieving change, but its effectiveness will depend upon the recognition of its informal, as well as its formal, aspects (Burnes, 1996);
- culture: it is important to understand the culture of any organisation or community that is to be changed in order to avoid contradictions and to plan the build up of change (Burnes, 1996);
- Learning channel: involving people in change has the effect of enabling them to challenge existing norms and question established practices that result in commitment towards the change themselves. Organisational or community learning can be precipitated by making impending crises real to everyone in the organisation or encouraging dissatisfaction with the current systems and procedures (Leonard-Barton, 1992; Senge, 1990:150; Argyris, 1993);
- Designer behaviour: designers are expected to operate as facilitators and coaches that bring together and motivate teams and groups to identify the need for change, and the implementation of change. It is necessary to create a shared vision about the future.

The role of designers becomes one of ensuring that the satisfaction of the end user is obtained through the products/systems and that structures, resources and the necessary skills and motivation are in place to initiate, support or consolidate changes towards sustainability.

3.1.2 Case Study on the Emergent Approach: a Jewerly Workshop on a Women´s Prison

This case study shows an initiative that brought work into a women´s jail. On the workshop organized within the jail by a local entrepreneur the women produces collars, earrings and all sorts of jewelry using natural components. With the money they make on this job they are able to help their families outside the jail and, at the same time, increase their employability after their jail time.

Figure 8 – Bringing Employment into Women´s Prison

Important benefits of the Project is elevating the self esteem of the women, reducing stress and helping them to cope with the distance from their children and family. Furthermore, for each three days of work their sentence reduces in one day. Some of the former jailed women now work on shops and workshops outside the prison, with all their employment rights fully respected.

3.1.3 Case Study on an Emergent Approach: The ReciclaJeans Project

Recicla Jeans Project is a good example of an emergent new pattern of designing and producing that supports fundamental social changes. It is project run by Florescer (NGO) where waste from jeans donated by people and companies turn into fashionable new costumes (see photo below). This business went so well that it has now franchising in São Paulo and Belo Horizonte and partnerships with brands such as Eugênia Flori e MOB. In the beginning the project used to sell these recycled jeans solely in Paraisópolis, the second largest chantey town in São Paulo, where it was produced.

The NGO's workshop, built in partnership with the São Paulo city hall and the United Nations Educational, Scientific and Cultural Organization (UNESCO), produces around 1,000 items a month (trousers, jerseys, jackets, skirts, handbags, belts, etc). A conquest of the project was the donation of a space in the shopping mall Shopping D, where the NGO has a shop and the implementation of a shop in Vila Madalena neighborhood, both in the city of São Paulo, where it sells clothes and accessories. The project worked out so well that the products produced by the seamstresses and embroiderers from Paraisópolis have already even been exported to USA, Lebanon, Portugal, Spain and Italy.

Figure 9 – Costume Produced by Recicla Jeans (source: Martins & Castro, 2007)

In 2003 Recicla Jeans began the activity of training craftsman to work on the process of recycling. Thus, it opened the opportunity for increasing the employability of local people and stimulating their entrepreneurship. Currently Recicla Jeans is responsible for generating income to a dozen of families, enabling the NGO to provide health and educational assistance to 75 thousand inhabitants on the chantey town. The project clothes have labels with the "Recicla Jeans"

trademark. Behind the labels is an explanation about the work of the NGO.

3.1.4 Case Study on an Emergent Approach: the Brastemp PSS

This is the case of Brastemp, a brand of Whirlpool. They now are selling “filtered water’ instead of “water-filters”. This could be understood as a PSS since they now manage the life cycle of the product, including changing spare parts, changing filters or recycling the entire product at the end of its life cycle. The company has designed the product to enable the provision of services, including the substitution of parts and other general maintenance activities. Their certification on IECQ – QC 080000 HSPM (management of toxic substances), ISO 9001, ISO 14001 e OHSAS 18001 has helped the implementation of this PSS.

Figure 10 – Moving from Filters of Water to the Service of Water Filtered at Whirlpool

The company has faced the challenge of changing current consumption patterns in Brazil where most people want to be the actual owners of the product. The strategy of selling the PSS to companies, where the burden of changing filters and the opportunity of sharing the service with large amounts of people presents direct economical benefits, appears to be a strategy in use by the company to attract the consumer´s attention to this new consumption model.

An interesting initiative run by this company is the project “Brastemp Independente”: a group of solutions to provide more independence to people with earring, eye or physical disabilities on the use of everyday utilities produced by the company. It consists of a kit with stickers for Braille language and a CD with audio explanation of the product operation and installation, including information aimed to people in wheelchair. The company also provides a special after-sell phone service for their users with earring disabilities.

3.2 Planned Change

3.2.1 Definition

The planned approach views change as essentially a process of moving from one fixed state to another through a series of predictable and pre-planned steps. There are a number of models and techniques for planned management that have been developed within the Organisational Development field. However, the most well known planned change processes emerged from the pioneering work of Kurt Lewin (Lewin, 1958 apud Burnes, 1996) and includes:

- The Action Research model: it usually comprises a senior manager, people from the area where the change is to take place, and a change agent (e.g. design consultant). Diagnosis and redefinition of the situation and of the problem under consideration is carried out interactively by a team after careful consideration of the entire system. The role of the change agent in this team will vary from being the generator of a crisis, in order to drive change, to simply helping fine-tuning existing changes (Burnes, 1996; Vollmann, 1996). It

maybe necessary to build multiple scenarios when establishing the desired changes of any situation;

- The Three-Step model: this method provides a general framework for understanding the process of change. Other writers have expanded the number of steps or phases in this model, but the essence remains the same (Leonard-Barton, 1992; Senge, 1990:150; Argyris, 1993). In general terms, it involves the following steps (Burnes, 1996):
- Unfreezing the present level: this usually involves reducing those forces that maintain the present behaviour (e.g. confrontation meeting). The essence of this step is to enable those concerned to become convinced of the need for change;
- Moving to the new level: having analysed the present situation, identified alternatives and selected the most appropriate, action is then necessary to achieve the desirable state;
- Re-freezing the new level: this phase seeks to stabilise consumption at a new state of equilibrium in order to ensure that the new ways of consumption are relatively safe from regression. Supporting mechanisms that positively reinforce the new ways of consuming are the usual ways for achieving objectives.

3.2.2 Case on Planned Change – Pernambuco Imaginary Project

In the Northeast of Brazil a large percentage of the population as the only option for income the exercise of manual and/or arts and crafts activities. According to Cavalcanti et al. (2007) this background has been aggravated by the ineffectiveness of specific public policies towards the production of handicrafts (arts and crafts, and popular art) and by the total lack of liaison between communities producing such material, and seed money agencies and entities (whether governmental or non-governmental). Brazilian arts and crafts remain culturally marginalized, allied to obsolete models of productive organization, contributing to large number of enormously talented and potently creative craftspeople and folk artists being shackled to severe poverty. Many of them have been obliged to abandon their activities to seek alternative sources of income in more developed regions, and thus they form a population of rural migrant workers who do not even manage to build other opportunities for a decent life in the large cities (CAVALCANTI et al., 2007).

It was with the aim of changing such situation that, starting in 2003, this project was carried out within the municipality of Cabo de Santo Agostinho, situated on the South coast of Pernambuco, Brazil. This was called Pernambuco Imaginary Project and it was led by researchers from the Pernambuco Federal University. Craftwork in ceramics in Cabo dates back to the time of the sugar-cane plantations, a period at which the production of bricks and tiles was only targeted on consumption by the factory itself and on homes for its workers. With the passage of time and in each succeeding generation, these potteries, where ceramics were produced, became independent in order to produce and sell utilitarian artifacts such as pots, pans and drinking water containers to the population in the vicinity. Such a tradition was passed down from grandparents to parents, and from them to their children (CAVALCANTI et al., 2007).

The Pernambuco Imaginary Project carried out its initial activities with a group of potters. In the municipality there are around 25 productive units but the current position is that only ten individual producers in the area known as Mauriti make a living exclusively from this activity. A full diagnosis, assembled from observations of the technicians and craftspeople involved, has permitted a better understanding of the relationship between the flow of production, the management of the space, the development of the products (see next Figure), the use of the natural resources and the commercialization of the pieces. The project involved training and the strengthening of groups, by encouraging the construction of collective agreements and the quest for autonomy. Action favored the recognition and training of community leaders, improvement of self-esteem by raising the awareness of the men and women craftspeople to the value of their work (CAVALCANTI et al., 2007).

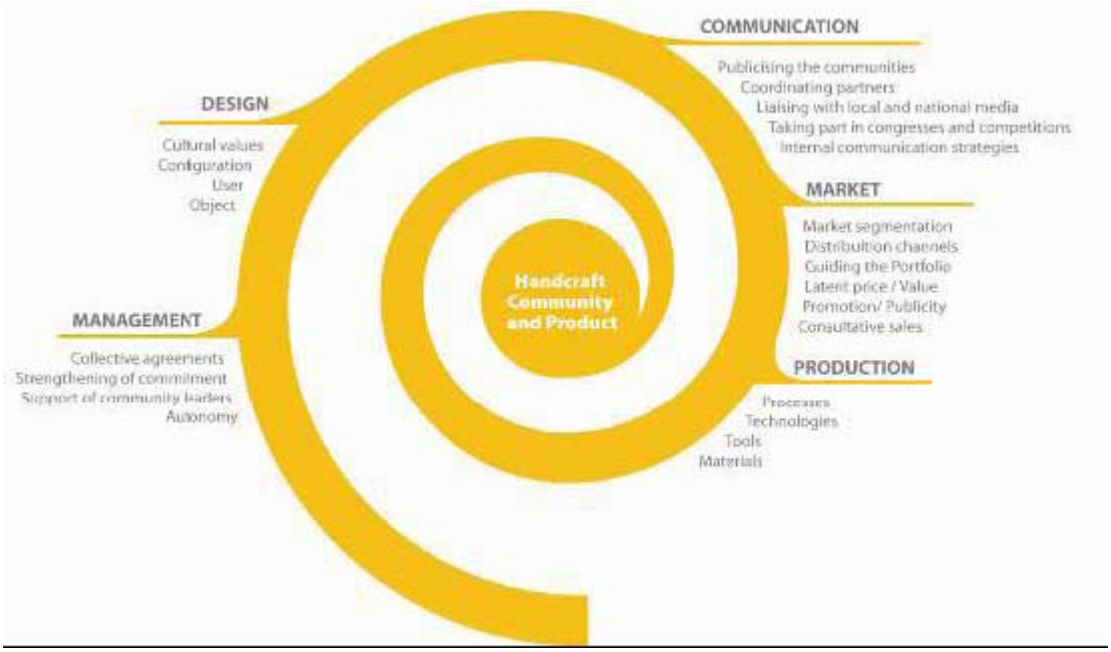

Figure 11 – Overall View of the Methodology at the Pernambuco Imaginary Project

Based on the existing modes of production and respecting the communities' rhythm of life, the Pernambuco Imaginary sought to optimize productive processes, improving working conditions and the sustainable use of natural resources. Introducing new technologies and tools have guaranteed the quality of craftsmanship and aggregates value to the product. Each product developed on the project focused on valuing popular knowledge, recognizing traditions, skills and the proper use of materials. As a result, designer and craftsman create product lines in which forms, textures and colors reflect the social and cultural values of the communities. The excellence of the product and its compatibility with market demands makes the sustainability of the activity possible (see next Figure) (CAVALCANTI et al., 2007).

Figure 12 – Example of Products Developed Through the Pernambuco Imaginary Project

For the purposes of generating information capable of raising the awareness and mobilizing public opinion to the value of craftwork and the rights of their creators, the Pernambuco Imaginary promoted strategic communication actions. For each of the project's partner communities, the design team has devised a visual identity which reaffirmed the history, the culture and the sense of belonging to a group. This was done by printing a seal of origin and quality on all that is produced by the community.

3 2.3 Case on Planned Change: An Incubator of Cooperatives at UFPR

Universities have been involved on supporting the organization of the bottom up social movement in Brazil through incubators of cooperatives, helping the creation of new jobs for groups

of people with low income. Such organizations focus on income generation and social inclusiveness by transferring technical and scientific know-how produced within the university (Penin, Chiara, 2005). The implementation of such incubators within the university makes it easier to bring together social forces and, also, promotes more competences on future graduates on the promotion of social changes. According to Almeida (2005) there are currently 237 incubators in Brazil, of which 107 are incubators of technology based companies.

At the Federal University of Paraná, the Cooperative Incubator is an outreach program that started in 1999. As the next figure illustrates the process of incubating a cooperative starts from a deep understanding of the community. That is achieved through activities such as a social-cultural diagnose, an assessment of the economical potential and a workshop on solidarity economy. The phase of incubation itself involves training/coaching on issues such as cooperativism, law and management of cooperatives, on accounting, financial management and entrepreneurship. Also, during this stage the university provide consultancy on administration, law, accounting and economics

Figure 13 – The process of incubating a cooperative

At this incubator there is no on-the-shelf solution: the problem solving is carried out in partnership with the community, with the aim of developing capability of self-organization. Currently the team involves academics from Psicology, Geography, Economics, Social Sciences, Administration, Law and others.

4. Discussion

Brazil is often painted abroad by means of its darkest colors: urban violence, widespread poverty, poor human rights record and so on. Struggle to survive and lack of government efficiency and effectiveness result on a society where norms and regulations are often ignored (or creatively improved). Due to the lack of money, a large portion of its society has learnt to live with fewer resources, paradoxically surrounded by an abundance of resources. Innovative solutions in such environment often emerge from pure necessity rather than careful planning. Indeed, more recently an increase on the education levels, political awareness and information access has induced a widespread of locally-based social initiatives that in many cases represent truly innovative social changes towards sustainable consumption and production.

Based on this context, this article presents emblematic case studies gathered in Brazil, trying to understand their underlying strategies to radically change current patterns of consumption and production. Next figure shows their connection with the theoretical structure adopted in this paper to discuss change towards sustainability.

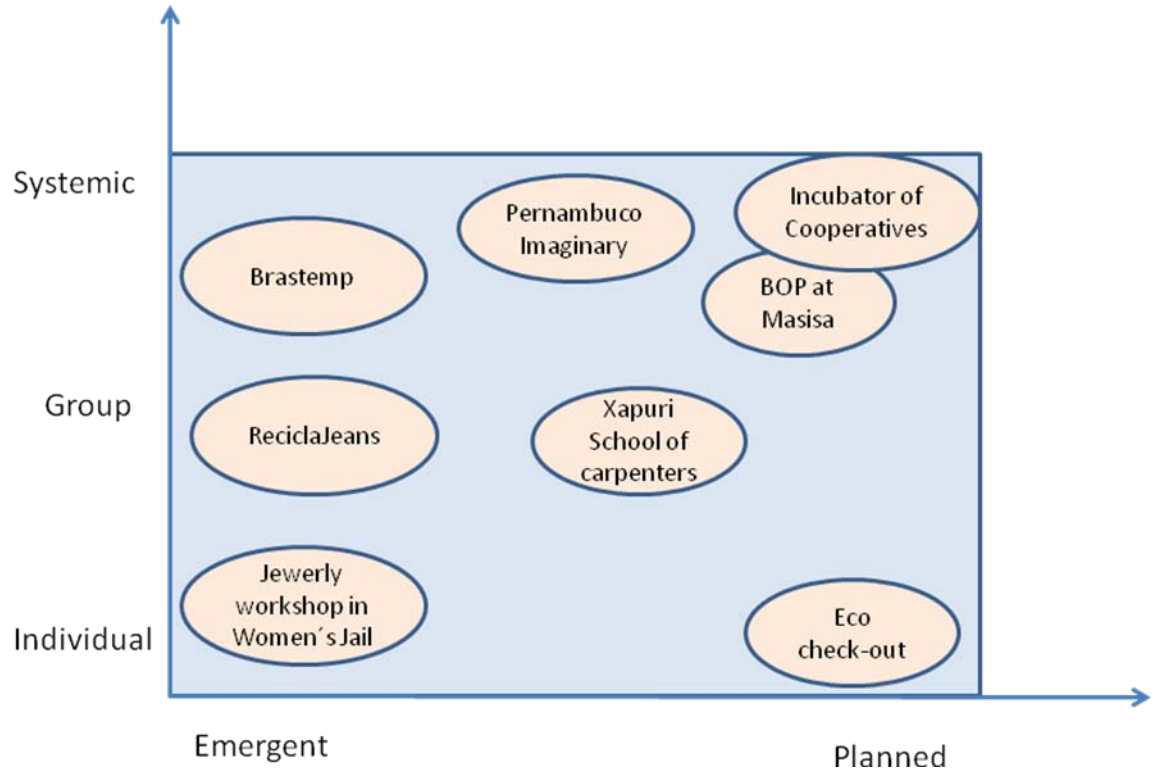

Figure 14 – Set of Case Studies and their Connection with General Change Strategies

Some underlying characteristics of the Brazilian culture need to be addressed in order to understand these case studies. Entrepeneurship, skill to deal with uncertainty and flexibility to change consumer and production patterns are characteristics of Brazilian people that are helping to speed up the change towards sustainability. Past experience on dealing with high inflation has contribute to this cultural attributes. Entrepreneurship, in particular, is a characteristic required from the poor population in this region on a daily basis in order to guarantee their survival. Indeed, according to the Global Entrepreneurship Monitor (REYNOLDS et al. 2001) Brazil has entrepreneurial activity equal to that of the United States. However, a higher proportion of entrepreneurs in the country are involved through necessity rather than opportunity.

According to the GreenIndex (2007) Brazil's consumers are tied with India's as the highest-ranked on the 14-country index of environmentally sustainable behavior[12]. Brazilian consumers earn higher Greendex scores than all others for housing. That is driven by small residence size as measured by number of rooms per household (96% have four rooms or fewer in their homes), the least use of home heating (found in only 9% of homes), relatively widespread use of on-demand water heaters (rather than tank heaters), and wide penetration of renewable electricity (generated from biofuels/biomass in this case). Brazilian consumers — like their counterparts in Mexico and Australia — overwhelmingly wash laundry in cold water, and they are far above average on minimizing their use of fresh water (GREENINDEX, 2007). Obviously, this presents a distorted view of sustainability since environmental performance in this case do not bring along economical and social bennefits.

A cinical analysis can surely put poverty as a driver for more sustainable life styles. It has induced social practices in Brazil related to housing, for instance, that would otherwise be difficult to implement on a planned (but artificial) setting. For instance, whilst in other parts of the world people talk about co-housing as an innovative practice for achieving sustainability, it is in practice within Brazilian chanty towns for a long time. The houses are diminute, requiring a more intensive share of common facilities and more intense interaction with their neighboroud. Activities such as

[12] The GreenIndex Survey in 2007 included the following countries: Australia, China, India, Japan, Canada, United States, Mexico, Brazil, France, Germany, Hungary, Russia, Spain, United Kingdom

cooking for the community or helping out with the child-care are regular activities in this communities.

Brazilian consumers are far below average on their ownership of vehicles and likelihood to drive alone in a vehicle to their daily destinations. The GreenIndex survey shows that they are much more likely than most others to walk, bike, take public transportation, own a fuel-efficient vehicle and drive compact cars. However, food is the one area where Brazilian consumers do not rank particularly well (10th out of 14). While they are above average in their consumption of locally grown foods, as they frequently consume beef: 16% daily, 62% several times a week or more. Brazilians are also far above average in their consumption of convenient (prepared/packaged/processed) foods, and 35% say they drink bottled water daily, about average for all countries surveyed and on par with U.S. consumers. Also, Brazilian consumers are the most likely to prefere green products and reject environmentally unfriendly products (GREENINDEX, 2007).

Brazil as well as the entire South American continent present large environmental, economical and social changes that in many instances replicate mistakes that have already being made by developed nations in the past. The challenge is to cope with the urge for consumption amongst the poorest people, moving the focus from democratization of consumption to democratization of satisfaction. There is no single answer for this challenge but learning from successful experiences in Brazil and elsewhere can help bringing light to other parts of the world and even to other parts of Brazil itself. Next sections present some of these cases.

Fortunately, cases on planned and emergent changes on the direction of sustainability in Brazil are expanding in numbers, involving since large corporations until self-employed workers operating in their own home. On many of these cases the change is so positive that the theme for design could be more about “supporting-the-change” or “disseminating-the-change” than actually change the change. However, most design research groups in Brazil working on the field of sustainability present fragmented and unconnected actions that are relatively low profile and with relatively low impact. Hence, there is clearly a need for a general framework for action that put together the (fragmented and unconnected) existing actions and provides shelter for new actions.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Calling for "She Ji":
Rethinking and Changing the Changes in China

LOU Yongqi [13]

Abstract

This paper gives special attention to China's traditional "She Ji (design)" system which almost been replaced by western oriented modern design disciplines for century. The advantages of "She Ji" notion have become increasingly obvious according to the criteria of sustainability. The considering of sustainable develop provide a pause for rethink, revaluate, and redesign many phases and changes in China. The re-initiation of the "SheJi" notion can offer new philosophies and methodologies for Chinese design, design education and design research. The ways in which design can play important roles in culturally conscious and be an agent for sustainability in China is also explored with cases in a microscopic viewpoint.

13 Tongji University, Art & Design Department, China, Deputy Head, Associate Professor, Lou.yongqi@gmail.com

1. Establishing a strategy: China's traditional "She Ji (design)" notion

The original meaning of Chinese word "She Ji (design)" was "to establish a strategy"; it originated from military affairs (Yang, YuFu, 1997, 3). "She Ji (design)" was dominated by two different classes in ancient China, the literati and the artisans. The former mainly used "She Ji" on the level of 'Tao' (Philosophy, ideology), focusing on military, political, social and cultural purposes, and the latter mainly used design on the level of 'QI' (Materiality), covering the fields of technique, arts and crafts[14].

This dual-structure of the 'TAO' and 'QI' integrated various aspects of society, although the communication between the two levels have barely been examined[15]. Systems such as "She Ji (design)" have been running successfully in China for thousands of years.

2. From "SheJi" to Design: development, Criticism and opportunities of Chinese cotemporary design

The military failures of the Opium War became the fuse to the social and cultural revolutions. A century of turbulence brought about the crash of the traditional culture and social structures. Westernization and globalization became the mainstream of all kinds of changes, especially since the reform and opening started in 1976. The history of Chinese modern design education and practice shares the patterns of Chinese society.

From "Sheji" to design, this phrase summed up the developing processes of China's modern design education and practice. This paper lists some of the most important criticisms and opportunities for Chinese design as follows:

Excessive Westernization

As a part of the whole higher education system, the development of design education in China is also a process of compromise in line with The West, while adhering to traditional culture. The slogan of "Chinese Learning as the Fundamental Structure, Western Learning for Practical Use"[16], was widely disseminated for a century in China. The development of the latter however, is far more advanced than the former.

The introduction and dissemination of modern Western design education and practice theories, such as those derived from "The Beaux-Arts" and "The Bauhaus" provided a shortcut to the development of design education and practice in China[17] (Gu, 2007). Consequently, the

14 For example, the capitals of the empire were always recorded been designed by the Prime Minister or even the emperor himself. ChangAn (Xian) City, capital city of Han Dynasty (206 BC – 220 AD), was recorded been designed by Xiao He, the first Prime Minister in Han Dynasty. Later it was redesigned by Yuwen Kai, the Prime Minister in Sui Dynasty (581 AD – 618 AD), been the capital of Sui & Tang Dynasty (618 AD – 907 AD). Also, the design concept of most of the Chinese Gardens always came from literati while the technical work and detail were finished by the craftsmen. The villages and rural areas were always designed by Fengshui Master.

15 In traditional Chinese value system, the distinction of 'TAO' and 'QI' forms a Social consensus that the knowledge of the humanities is much more important than the technical ones. The former was mainly being spread and inherited by text and books and latter mainly being spread and inherited by personal example as well as verbal instruction. The policy of 'Strengthening Agriculture and Inhibiting Commerce' lasted for two thousands of years also inhibited the development of industries which is the soil for the emergence and development of modern design disciplines.

16 At the end of Qing dynasty when modern Chinese education ideologies were undergoing changes from the old to the new, some literati advocated learning from the west and attaching importance to education and personnel training.

17 As early as in 1930s, western Arts and Crafts education system began to influence China by the Chinese students studied in USA, France, Japan and other countries. The Beaux-Arts education became the mainstream in architecture design education from1920s and lasted for 50 years. In Shanghai, Bauhaus system architecture and design education in

possibilities of developing China's own design theory and way of practice are limited.

Traditional "SheJi" notion has been discarded, as it was not clear enough according to the standards of modern discipline, and also too soft compared to the Western ones. At the same time, the craftsmen along with their skills were also seriously marginalized due to a lack of an adequate voice. This situation became more and more accentuated in many aspects, during the changes of lifestyle and economic structures.

Driven by the market rather than driving the market.

The rapid development in the economy throughout the past thirty years provides enormous opportunities for the development of Chinese design. The market's growing demand of designers consequently has lead to a boom of Art and Design schools. At present, China has more than one thousand art & design schools. This alarming number is the result of both the market demand and the "industrialization of higher education," (Wang, 2008).The market-driven design education is obvious, but the whole design industry lacks the preparation and ability to take the initiative to drive the economic market.

Large numbers, high speed, low payment terms, lack of strategic thinking and consumer knowledge are common characteristics of most Chinese design practices. Rem Koolhaas once said that a Chinese architect is as efficient as 2500 European architects, as they have designed the largest number of building complexes in the world within the shortest time and at the lowest cost. The practice of choosing quantity over quality, skills over ideology, and style over substance, is quite common in both design practice and design education.

The role of design is still limited

The boom of Chinese design education and practice is closely related to economic development. However, if not for the weakness in mechanism, design could play a more active role in a broader socio-economic and cultural stage; the importance of design has not been fully exploited. Social, economic, political and ecological awareness in design education and practice are rare and outdated. Some design areas are still underdeveloped in China, such as strategic design, branding, design management, human centered design, sustainable design etc. This is mainly because the effect of design can only be visible in the long-term and not directly in these areas. This situation will not change unless the role of design is expanded from a kind of tool to a strategy or policy. To achieve this, design discipline needs to adopt a more open attitude, participate in socio-economic innovation, and integrate itself into the Chinese political and social system.

Sustainable Design consideration: a pause for steering towards a better future

Today, sustainable development may be one of the few universal ethics in the world. More and more Chinese people find that the rapid changes have led their country in the opposite direction of sustainability. We Chinese have to admit in shame that our ancestors lived a far more sustainable life style than we do today[18].

The whole world today depends on sustainable solutions for its salvation, and China is no exception. Sustainability has already become new criteria for re-evaluating the changes that are happening or have happened in our life and world. We need to pause and rethink before taking further steps: to rethink the rationality of modern industrial civilization; to rethink and compare the present physical spaces, social-culture and life styles with what they used to be; to rethink the positions, values, trends and possible social responsibilities of design education, design practice and design research.

An International design platform is established

Now, the whole world is focused on China. The big market together with the great platform for

---

Tongji University (including St. John's University) was booming since 1940s. Central Academy of Art and Crafts in Beijing, the first technology-based Institute of Art and Crafts, was established in 1956, it's major covered dyeing art, ceramics and other applied decorative arts.

18 In traditional Chinese ideology, human and nature have always been regarded as a whole; the human body and the outside world are both complicated systems sharing many common characteristics. This kind of understanding together with respect and love of nature leads to a world of balance and harmony (the Chinese meaning of "sustainable"). The traditional philosophy, ways of thinking and life styles which were once rashly abandoned, may exactly meet the needs of sustainable development.

design practice and research has attracted designers and researchers all over the world. Never before have Chinese people felt the world so close. Various design ideas and experimental practices have appeared on the stage in China simultaneously, their characteristics and how they are defined have become particularly clear. This undoubtedly provides a higher and boarder platform for the development of Chinese design disciplines at a lower cost and higher speed. The integration of international and localization is can also to be achieved more easily.

The awakening of national culture consciousness

In this era of globalization, Far Eastern designers are duty-bound to put forward their views as critical regionalists （Frampton, 1992）. A large number of cases indicate that China's design community has adopted much more open thinking, in order to explore the route of original Chinese innovation. This quest for a "cultural consciousness" indicates the opportunity for original Chinese design thinking to flourish. Thinking Chinese and acting international will be the character of most Chinese designers of new generations, based on their own "life world" (Harbermas,1987).

3. Calling for "Sheji": Why and How?

The advantages of "She Ji" notion

In today's point of view, the core of the Chinese "SheJi" notion can be described as follows:

*Soft definition: ambiguity but higher applicability, immaterial design rather than physical design,

*Systemic strategy: synthesis of the micro and the macro level, dual-structure of "Tao" and "Qi",

* Involvement with decision makers: Collaborative work with top-down mode, integration with the social system

The softer Chinese "SheJi" concept extended the application field for design, and it also coincides with certain tendencies in today's design circles, such as 'vision', 'social', 'system' or 'strategic' design, etc. (Valtonen, Anna, 2007, 308) In John Heskett's notion "Design is to design a design that will produce a design" (Heskett, 2002, 3), we can easily find a meeting point between the East and the West.

According to the "SheJi (design)" notion, the product of "SheJi (design)" is a strategy. To realize a strategy, a systematic approach is necessary. It will cover the field of "Tao" and "Qi". At the cultural and socio-economic level, the dual-structure of "SheJi (design)" system provides a platform to combine many aspects of traditional culture and social-economic life together[19].

In the highly organized and government-driven society of China, the renaissance of traditional "SheJi" concept can easily gain support from the ancestral existing social structures and decision-making system to push China's social development to a more sustainable direction. The interpretation based on traditional culture also makes this notion much more open and acceptable for the society.

The advantages of China's "SheJi" notion have become increasingly obvious in line with to the criteria of sustainability. In China, re-initiation of the notion of "SheJi" has positive significance, but it does not mean that Chinese design will go in the opposite direction from the rest of the world. It is not a kind of restoration, but a kind of renaissance. Calling for "SheJi" also means that a design strategy in China can be designed.

Introduction of some cases: Visions of design in China

According to the notion of "SheJi", Chinese design move in the following directions:

* Integrate with the top-down social and political pattern;

* Active intervention in political, economical, social and cultural field;

* Use of design as strategic and systematic tools to achieve Chinese social, economic and cultural sustainability;

* Focus on the folk wisdom with a sustainable lifestyle;

* Redesign the Chinese contemporary life-style without losing its cultural essence ;

19 China's ancient strategy books have been widely used in the micro-economics and business management, and involve in people's daily life. It's easy to find a mass of such kind of books in the bookstore of every Chinese airport.

This paper will focus on some projects in one design school, CAUP Tongji University, and provide a microscopic vision on what is happening and will happen in Chinese design, design education and design research.

·Case 1: Urban leaders' course in CAUP-Tongji.

China has a long tradition of top-down social and political systems. If design wants to play an important role, either designers need to be at the decision makers' level or the decision makers need to realize the importance of design. Twenty years ago, CAUP of Tongji University established the Training Centre of Urban Leaders together with the Ministry of Construction of P.R.China. The centre provided a kind of short term course for mayors, directors of urban planning bureau or construction bureau all over the country. All together, 20,000 official students have graduated. From 2008 on, we have begun to teach students courses on design innovation. We communicate with decision makers in the classroom and let them understand design to help promote the role of design in local areas.

·Case 2: GreenChain-Tongji

GREENCHAIN (GREENCHAIN Art & Design Consulting Enterprise Alliance) is an alliance between Tongji University and enterprise focusing on design education and sustainable design research. It was established at the end of 2007 and is supported by the Tongji University and the Shanghai Creative Industry Center[20]. It was established for integrating business innovation with design education and research. Now, it has 14 members including manufacturing, software, service, design, and consulting companies, such as China Telecom, S-Point Design, China Bridge, AutoDesk (USA), Herman Miller (USA), American Greetings (USA), Electrolux (Sweden), CPH Design (Denmark), Silver lining (UK) etc. It provides an inter-disciplinary platform for sharing ideas and resources within the alliance, but also promotes the communications and collaborations between industries, education, research, government and commerce.

·Case 3: Eco-Community construction of China new countryside on Chongming Island[21]

Tongji University together with Stanford University, California Polytechnic State University, Yale University and China-US Center for Sustainable Development, are now working on a research project on Chongming Island. The partners will work together to design and build a pilot version of a model sustainable rural community on Chongming Island. It is envisioned that this community will be a fully-functioning, net zero CO^2 emission community designed according to cradle-to-cradle principles that meet the economic and social needs of the rural residents at or below current costs for rural community development. The scope of the project includes a holistic design of the villager's local economy, their individual and community dwellings, transportation systems, and all associated subsystems. The project goals will be achieved by collaborating in teams ideally consisting of engineering, social science, science, business, agricultural, architectural and design experts from both China and US partners. How design can improve the local development in a sustainable way is one of the most important research topics for this project.

·Case 4: Etopian[22]

Etopian is a newly established company by a group of young designers from different areas whose aim is to establish a revolutionary system for housing industry in the criteria. The core of this system is the industrial assembly housing system based on web2.0[23]. The system attempts to achieve the integration of the industrial chain and social resources. Based on web 2.0 technology

20 Shanghai Creative Industry Center is a semi-official specialized organization in promoting the development of Shanghai's creative industries. The center's mission is to coordinate resources, formulate development targets and strategies, strengthen the guidance, construct a platform, promote the assembly, and establish a system, thus gradually forming a modern industry structure supported by the individual creative industry enterprises and clusters on the platform of "Shanghai Centre of Creative Industry", and driving the overall development of Shanghai creative industry. See http://www.scic.gov.cn/english/introduction/index.htm

21 Chongming Island is located in north of Shanghai. With an area of 1041 km², it is the third largest island in the People's Republic of China after Hainan. With the construction of a trans-Yangtze tunnel, the island is expected to be developed as the first Eco-Island in China.

22 www.etopia.cn

23 Industrial assembly housing system is not a new concept. But in history, it fell to success and get popular because of such kinds of houses were always thought as low-grade, monotonous and lack of personality, and related with Slum. But in eras of web2.0, there's a clear vision that shortages above can be avoided.

and platform, personalized needs can be realized. Etopian housing system is based on the entire life cycle. It integrates products, services and market with the intensive use of resources. Different kinds of designers, suppliers of construction materials and home appliances, contractors, and the customers are integrated in this system. The system will be presented at one of the villages in the earthquake area in China's Sichuan Province. The first experimental house will be donated to local areas.

·Case 5: Folk artists and 'Grass root' creation

In Chinese traditional history, Tao and Qi belong to two different classes. The dialogue in between was always inadequate. Although the number of art and design schools is booming, many traditional arts and crafts have vanished or face the crisis of vanishing. Some universities in China are acting to protect such kind of immaterial cultural heritage. Together with World Heritage Institute of Training and Research-Asia and Pacific[24], folk artists are invited to Tongji University to participate in the design education. Some professors in Tongji are also working on the long term research on Chinese 'grass root' wisdom and creation for sustainability. Such kind of design education and research programs provide a platform to start conversations in wide ranges of society.

4. Epilogue

China is experiencing the most rapid change in the world, and at the same time. China may also be the most ideal place to realize any strategies for change. We need to "She (set up)" a right and good "Ji (vision and strategy)" for our future, enables people live as they like, and in a sustainable way (Manzini, 2006). It's not only for the design discipline itself but also for all of humanity. To achieve this ideal, not only is science and technology needed at a physical level, but ethics and culture are also needed at the systemic and strategic level.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Asian view of sustainable future

The big rapid change going on in Asia is an unique opportunity for steering the region toward a sustainable path.

Fumikazu Masuda[25]

Abstract

In order to explain possibilities and evidences of “Changing the Change”, the paper will start from the historical background of Japanese craftsmanship and will arrive to outline the on-going tendencies in eco-design, and in the emerging consciousness that eco-design is not just to improve products, but is the actualization of sustainable society.

As conclusion, the paper will propose the idea that, although Asian societies certainly are going through a radical change, there are also unchanging cultural aspects. One of this is flexibility in change. Historically, both natural and cultural sustainability had been secured through this flexibility and hopefully this system will be able to work out for the future to come

[25] Professor; Tokyo Zokei University. fumi@zokei.ac.jp

1. Introduction

First of all, in order to explain possibilities and evidences of “Changing the Change”, the following is the tendency of changes concerning the Asian designs, through a Japanese eye.

Before considering the designs in Japan, I think I should mention the historical background behind it. It's after 1950's since so-called the specialty of designs or the field of the professional occupation had established.

In Japan, we have a long historical background on the traditional crafts which had been cultivated by professional craftsman who have excellent skills and manufacturing technology, utilizing various materials. Even though many other countries from all over the world also have excellent handicrafts, yet the characteristics of traditional handicrafts of Japan lie in the continuation of practical use of the products.

According to the Japanese law, which is related to the promotion of traditional handicrafts industry, appointed by the Minister of Economic Planning Agency, such as textiles, bamboo work, dyeing, woodwork, lacquered ware, metalwork, ceramics, stonework and so on, over 210 kinds of products are registered as traditional handiwork. They are required to be created in the same area with the same materials and technology for, at least one hundred years. Today they are still utilized by people as daily products. The foundation of major traditional handiworks were establish in Edo Era, the era from 17th to 19th century, which produced the most mature culture in Japanese history, and at the same time, the whole country were said to be one of the most unprecedented sustainable society throughout the world.

Another characteristic of Japanese traditional handicrafts lie in its anonymousness. They put names of the places of the production but it's rare to put the artisans’ name on the product. This continuation and the namelessness is passed on today. This fact tells that design in this country has been on a demand side rather than on supply side.

Fig. 1: The traditional Japanese paper combined with the most advanced paper molding technique

2. Trends of change in Japanese design

In the middle of rapid industrialization in 5O's, designers' profession in Japan seems to be classified into a part of product development and sales promotion. And at the same time, the majority were hired and paid salaries by major industries. Currently, majority of Japanese

designers are still employees. They work for the Brand Company and merchandise to compete one another. Ever since the recession in 90's, the tempo for the Japanese enterprises to expand marketing scales and development of products are descending, and a huge number of designers (i.e. automobile makers or electric household appliances companies, which probably own 200～300 people, or at the most over 500 people) are forced to change their positions and the average scale of the design section is getting smaller.

The values on the products for consumers are shifting. Simply convenient products or good looking or unique products seem to be less attractive. Thus, consumers' demands in buying products are changing. The old way of thinking that design is a synonym for appearance is no longer the mainstream. The marketing values are rapidly changing with diversity, instead. Some look for quality and rare products even if it's expensive, and on the contrary, others look for something plain and inexpensive. There are consumers who concern for environmental aspects and social justice, while other people concern much about their own merit.

While some designers make an objection to the namelessness and go into new business perceiving the design as a piece of work, others find themselves feel more comfortable standing on a social ground, where some important new themes of design are arising. There are concerns about the aged, the disabled and other people, dealing with various conditions, which is called universal design or inclusive design. Furthermore, by focusing on children as new generation to come, so-called kid's design would lead to solutions by making the object of design more clear. And there is eco-design that put more emphasis on the environmental aspects and to enhance environmental efficiency by saving resources and energy consumption.

Fig. 2: An example of universal design; a pair of chopsticks for the elderly and disabled users

At the bottom of these seemingly opposing movement regarding design, there must be a reconsideration and criticism toward the contemporary civilization, such as mass production, mass consumption, and mass waste based on social-economic principle.

But, for instance, some of the newly developed products in the name of universal design are producing hit merchandise, by creating new needs for those who were not in need of things as such before then. Also, eco-design brings about merit for the consumers; fuel-efficiency, less electric consumption, saving water or compact and light-weight product. Meantime, it contributes for the makers by high productivity and cutting off the cost or creating a good brand image. It's been encouraging marketing competition and established win-win relationship between producers and the market for the past 10 years and made a remarkable progress.

Since 1999, the eco-products expo in Tokyo has expanded its scales each year. For the last year, more than 600 enterprises and groups took a part and 165,000 people were visiting in three days. I have been picking up one product each on the cover of Nikkei Ecology monthly magazine and writing about it’s environmental quality. I have had no problem, so far, in finding out over a houndred of so-called eco-products during this nine years.

However, the fact is the more those design movement turns out to be a success; ironically it increased more consumption and more environmental impacts such as global-warming gas exhaustion instead of bringing out sustainable social condition. Comparing to 1990, the exhaustion of CO2 from each electric house-hold appliances had been improved up to 50% less, yet as people buy more house-hold appliances and use them more, the total amounts of CO2 exhaustion's been increasing over 30% for the last 10 years.

This typical rebound phenomena is due to the economic growth without decoupling resource consumption and also owing to the lack of awareness of consumers accepting the companies' campaign without doubt. We have to capture this trend of people's objective of interest changing from something new to something good for environment and change the direction of the change from better consumption to better way of life.

The crucial theme of design competition held in Japan last year was environment and sustainability and I myself had related with 6 of them as a judge. This fact shows what designers are more interesed in this area, these days. After 50 years of Japanese Good Design Awards' history, they decided to replace all different special prizes with Sustainable Design Awards.

G8 SUMMIT will be held in Hokkaido, Japan from July 7th to 9th.The main theme is global environmental problems, focusing especially on the global warming. The chairman, our Prime Minister Yasuo Fukuda will declare the decrease of CO2 exhaustion up to 60-80% by the year 2050. It seems that eco-something, like eco-innovation, eco-fund, eco-products and eco-design is a vogue word today in Japan.

But the destination of eco-design or design for sustainability is not just to improve products. The realization of sustainable society is what we've been aiming at. It is already proven that we cannot access to sustainable path by buying and consuming more eco-designed products. I, as a designer, believe that it is our mission to construct images or, blue prints, of possible sustainable society while sharing the sympathy and reaching an agreement with current society on our common future, and draw a concrete road map to reach out for the destination.

第2回サステナブルデザイン国際会議
Destination 2025
デスティネーション2007-2025
The 2nd International Conference of Design for Sustainability

Fig. 3: The second international design conference of sustainable design was held at Shirakawago

For this purpose of drawing the images of sustainable society; We had held international conferences and workshops twice; "Destination 2026" in 2006 and "Destination 2025" in 2007. More than 200 participants for the first conference held in Tokyo were from various professional areas including design, architecture, business, NPO and so on. The second conference took place in snow-covered mountain area called Shirakawa-go, a well-known world's cultural and natural heritage. Over 120 people had joined the 3 days workshop, and about half of them were current designers and design managers from industries. Many students and young designers also joined in and they were seriously making debate with the veterans.

Just about recently, Japanese government and the industries are going through the paradigm shift of civilization. The designers must function with new values of life as a steering role. The big changing era that tends to put more priority on the social benefits rather than that of the enterprises is a chance for Changing peoples' mind and behavior.

Although it is quite doubtful if the majority of Japanese is aware of the fact that the coming decades must be a very tough era for our economy and so is true for the life of ourselves, we are about to face a national crisis. Because, Japan is a densely populated country relying on the imports concerning foods and most of natural resources like petroleum oils and it seems that they are not available anymore in the near future. Taking this into account, if Japan could tranform itself to be a model of sustainable society, it will definitely be a hope for Asian countries as well as other countries throughout the world.

3. Trends of change in Asian design

Now I'd like to talk about other Asian countries regarding the design situation. Both in China and India, massive economic growth is on the rise. It is obvious that these two gigantic countries have the keys to actualize sustainability in cooperation with other Asian countries and the rest of the world. Korea, Taiwan, Hong Kong and Singapore are now very active in terms of design.

Industrial designs of Korean automobile and electric products are renowned both in Europe and USA and the brands are establishing a high position in the International market. Also in Asia, Korean companies and their design are making a crucial influence. But as for sustainability related discussions, it seems to be rather quiet while the focus is placed on the relationships between industry and the marketing role of design. But the reality is that there are designers who are enthusiastic for eco-design and sustainable design. Chonggyecheon project is a good example showing their power of changing the shape of the city environment.

Taiwan has been working on green design with zeal for the last 10 years. They have been working on the issue also in the education field. I visited Taiwan every year for the past few years and I did seminars and workshops regarding eco-design at several different cities. Thus, their awareness on the environmental issues are high, yet as the Taiwanese companies are making their way to the Chinese market, the eagerness seem to be rather stagnant. But I hope the historical name of this island “Formosa”, or a beautiful island in Portuguese, indicates their sustainable future.

Hong Kong has a strong influence from U.K. and other European design education in historical terms. Today they try to establish a strong economical relations mainland China, while they keep their own identity and they work hard on the development of design in the industrial, governmental and educational level. They are preparing for the latest educational program dealing with eco-design and sustainable design. On the other hand, H.K. is playing a role of leading consuming market in Asia. They have conflict to be solved.

Singapore has similar characteristics as Hong Kong. But, recently they are playing a new role in dealing with the natural disaster such as huge Tsunami that attacked South East Asia a couple of years ago. They seem to be committing themselves strongly with social issues. The climate change on a world wide scale is said to be unavoidable, so the disaster or the environmental destruction of nature would increase more and more in the future to come. The idea of design to protect ourselves from such stress would play a major role in the future.

Other Southeast Asian countries are also working out on their economical development while coping with other various issues.

Surrounded by mountains and the ocean, though the destruction of nature is taking place, people in Thai try to shift their awareness towards environmental improvement and social reform. At some universities, they have started new sustainable design researches, and they look quite optimistic as they have a fruitful sense of beauty in their traditional culture.

The industrialization of Vietnam is remarkable like chasing after China. The 4th Eco Products International Fair was held in Hanoi this March (The first one was held in Kuala Lumpur, the second one in Singapore, and the third one in Bangkok). Nearly 100,000 people gathered, during three days’ session. Most of them were young people. The development in the city areas should be treated with cares so that there will be no regret in the future.

The tropical forest in Indonesia are facing a serious problem of illegal cutting down, yet meantime there's a good news that designers are trying to show a new business model focusing on sustainable design, and the business is going well.

Fig. 4:Indonesian wooden products “magno” series by Singgih Kartono

There was a collision between wild elephants and the people in a village in Sri Lanka. The extinction of the wild animals was once apprehended but now they found their way. They are making papers out of dung of elephants. The paper products made in Sri Lanka are designed specially to fit Japanese market and now sold at most of the zoos in Japan successfully and the profit is reinvested to Sri Lanka to expand local people’s employment and to make elephants and human be able to coexist.

Fig. 5: Sri Lanka’s elephant dung paper products at a paper show in Tokyo

In the Philippines, a project is going on by utilizing the remnants of bananas and pineapples, applying the technology to make washi, which is a traditional Japanese paper. The products are imported to Japan and used for interior design materials.

To put in words, the Asian characteristics may be expressed as having diversity of both nature and culture. Although Asian societies certainly are going through a radical change, there are also unchanging cultural aspects. The multi dimensional quality should work towards flexibility in change. Historically, both natural and cultural sustainability had been secured through this flexibility and hopefully this system will be able to work out for the future to come.

Changing the change: an European perspective

In which way in EUROPE design research is, or is not, an agent for sustainability?

Luisa Collina[26]

Abstract

European PhD programs are mainly characterized by a theoretical approach –historical, methodological - finalized to the education of the future academic bodies.

Important research centres promote a kind of research in the field of sustainability mainly based on a technological approach, rather than on a design approach. Other organisations have developed projects in the field of sustainability acting in a more incisive way as a stimulator of debates - with an entrepreneurial and professional attitude. EU funded projects are rarely focalized on design and sustainability.

In the paper that follows some cases are presented in order to offer a concrete view of the different way of developing design research on sustainability in Europe.

1. Introduction

It is difficult to try to give an answer to the question mentioned in the title of this paper for different reasons: lack of information, lack of already given studies about the state of the art, high heterogeneity of design research and high complexity.

The following text has not the aim to give a neutral quantitative analysis of design research in Europe, on the contrary it will try to give a very personal qualitative picture of the main characteristics and the more interesting recent initiatives of design research towards sustainability in this continent.

2. Design research in Europe

In Europe since several years some different PhD programs in the field of design have been established. Like most of the PhD programs worldwide, the PhD programs in Europe are mainly characterized by a theoretical or /and by a methodological approach and are mainly finalized to the education of future academic professors and researchers.

[26] Dipartimento INDACO, Politecnico di Milano, luisa.collina@polimi.it

Research *on* Design (from a sociological, historical, philosophical point of view) and research *for* Design (etnoghraphy, semiotics, ergonomy, technology etc.) are the major fields of the studies.

Design research, mainly focused on theoretical/methodological matters, has generally been hosted within this program. In fact, even if some PhD programs are considered to be "project based", most of the outcomes are not dealing with the design of possible desirable futures and haven't had a relevant impact -even in its follow up- in reality.

The criteria of evaluation of this kind of researches are mainly based on the methodology adopted rather than on the impact generated on reality. The results of these researches are generally diffused through internationally recognized academic networks and conferences (originally mainly localized in UK, today widespread but still closed in an academic circuit).

A less academic and more technological and manufacturing approach is perused in Europe in the big research centers that have been established in different countries and that are highly involved in EU funded research projects: TNO in the Netherland, INETI in Portugal, CNR in Italy are only a few examples for a kind of research mainly based on a technological approach rather than on a design based approach, with a high involvement of engineers rather than of designers.

Regarding the research *for* design PhD programs, in general, universitiesas well as large technological research institutions mentioned above have developed several different tools and methods for the design activity (in some cases we can truly recognize a sort of over-production of methodologies and tools): life cycle design, system design; solution oriented partnership etc. are just a few examples for that.

Kathalys, the institute run by TNO and TU Delft, has developed for example a system design methodology structured in five different phases (exploratory research and definition; system design; product/service specification; elaboration and practical experiment; implementation) and five different tracks along which sustainable product innovation takes place (development of product-service combination; sustainability; organisation; user; economic feasibility). This methodology is at the base of several projects finalized to the design of sustainable and innovative products.

Tracks **Phase**	**The product / service combination**	**Sustainability**	**Organisation**	**The user**	**The economical feasibility**
1 1. Future exploration	Innovation vision	Environmental bottleneck(s) and vision on the environmental opportunity	Actor overview	Vision on needs and consumer trends	Economical opportunity
2. System Design	System definition	Quantitative environmental targets	Commitment by partners for the project plan	User profile	Turnover target
3. Product / Service specification	Testable product / service combination	(hypothetical) environmental assessment	Partner agreement	Evaluation of acceptance	Economical assessment
4. Drawing in detail and testing	Tested product / service combination	(practical founded) environmental assessment	Business agreement	Practical foundation for acceptance and use behaviour	Investment and exploitation estimation
5. Implementation	Developed product / service combination	Environmental gain	New Business	Fulfilment of needs in a sustainable way	Profit

Table 1: Table with the expected deliverables per phase and per track. Helma Luiten, "The Kathalys method: a method for the development of Sustainable Product Service Innovations", *Hics – Higly Customerized Solutions*, Deliverable 1, 2001

These two realities (European PhD community and the European technological research centers) are not the only actors active in the design research field. In addition if the goal of this paper is to identify some interesting examples of research *through* design, able to generate changes in the society, it is important to enlarge the field of analysis and to include other design research initiatives.

Design research through design: the Italian Radical Design tradition

The proposal is to look a little bit back to our past, at the end of the 60's in Italy: to the work of Ettore Sottsass and to the Italian Radical Design a design and architectural movement that was extremely active between the 1966 and the early 70's thanks to two major cultural groups: Archizoom (Andrea Branzi, Gilberto Corretti, Paolo Deganello, Massimo Morozzi, Dario Bartolini and Lucia Morozzi) active from1966 to1974 and Superstudio (Adolfo Natalini and Cristiano Toraldo di Francia) active from 1966 to 1973.

The radical design brings into the discussion the role of the designer and his relationship towards the industrial production and the clients. Their design is no more pure functionalism, subjected to the industrial production, nor (or not only) pure answer to the expectations of the client: radical design is a critical design. The radical design groups were active both as professional designers (Sottsass was art director of Poltronova; he was designer at Olivetti etc.) as well as design researchers: designing visions for possible futures able to feed, in concrete, their future projects.

Archizoom developed for example *No-Stop city* in 1969; Superstudio, *The twelve ideal cities* (*Le dodici città ideali*) in 1971: two different but extremely interesting cases. *The twelve ideal cities* was a research of 12 visions, 12 dreams independent from the consumer culture. In 1971 the twelve ideal cities were abstract visions of fantasy feasible worlds, they were considered as an anticipation of a re-birth of urbanism. They have been published on a magazine directed by Italo Calvino (*Il Mondo*), who at that time was writing the *Invisibile Cities* (*Le Città Invisibili* published one year later).

The Italian magazines *Domus* and *Casabella* as well (the last one directed by Alessandro Mendini from 1970 to 1977) were the media for disseminating the radical design projects and essays. However, the most powerful moment for the presentation of the radical design has been the Italian exhibition: *The new domestic landascape*, in 1972, organized at MoMa in New York with Emilio Ambasz as curator:

In the same years the radical design groups were active also in the didactic activity. Ettore Sottsass, together with Archizoom, for example, organized some didactic design studios called *Global Tools* with the aim to disseminate their ideas to the future generations. These design studios were not very successful, but some years later some of the same people were involved in a new didactic and research project: the foundation of Domus Academy Research Center in Milan in 1982, a school (in Italy at that time there were no universities in design) but also, or mainly, a cultural laboratory. Since its origin (or mainly at his origin) it has developed research on urban development and new sustainable models. With Ezio Manzini, who has been director of Domus Academy, Andrea Branzi, Clino Trini Castelli, Chris Ryan, Stefano Marzano, Antonio Petrillo, they have given birth to researches through the development of projects, in connection to companies, but not directly answering to specific companies demands.

Agronica (1995) is a good example in this context: it has been a project of Domus Academy for Philips Design about models of weak urbanization. The idea was to experiment an idea of architecture based on a free supply of mobile constructional components, spread in an agricultural, semi-urbanized park. If for long time architecture and design were strictly linked to industry, in this project they are linked to agriculture: not with a view to the past but to the future; considering agriculture as an advanced self-regulated model of industrial production based on natural, renewable energies and not as a romantic landscape.

The city of *Agronica* was not a completely ideal city, but it was Eindhoven. The outcomes were not collected in some archives but they feeded a project for Eindhoven by Philips Design and "Bottega dell'Arte", directed by Stefano Marzano.

Design research *through* design nowadays

If we come back to nowadays and if we focalize on sustainability, where can we find examples of interesting (from the "Changing the Change" point of view) design research activities?

Regarding the research *through* design other different organisations have actively developed projects in the field of sustainability, with an attention mainly focused on the "impact factor" of their activities rather than on methodological aspects.

These organisations have different nature and different ways of acting:

6. as concrete **agents of innovation** with a more entrepreneurial and professional attitude;
7. as a **think tank** for future sustainable innovations in collaboration with private and public institutions;
8. as **stimulator** of more broad debates with a high bottom up approach.

The first point is represented by professional design offices that traditionally are interested in combining short term design activity and long term design of future scenarios: Philips Design and Design Continuum, are both two good examples of bridging professional design activity towards design research.

The second cluster is represented by some multi-cultural and multi-disciplinary, generally small, research centres in some cases related to a university (the Centre for Sustainable Design - CfSD was established in 1995 within the Faculty of Design at The Surrey Institute of Art & Design, University College, in the UK; Imagination Lancaster[27], a recent multidisciplinary research institute, co-directed by Rachel Cooper is fore example connected to Lancaster University, UK; The Art and Design Research Centre within the Sheffield Hallam University in UK[28]) or to public institutions (for example RED unit leaded by Hilary Cottam[29] as Director of the Design Council or to the Young Foundation[30] formed in 2005 from the merger of the Institute of Community Studies and the Mutual Aid Centre in London in order to re-energise the powerful combination of research and action).

Their goal is to provide advanced multidisciplinary projects (provocative pilot projects as well as longer term studies) in some specific selected thematic fields. The focus is mainly on the user, depending on the kind of institution, the innovation is mainly social based rather than technological[31].

A case able to exemplify this kind of activities is given by *EMUDE_ Emerging Users Demands for Sustainable Solutions*[32] a specific support action funded by the European Commission the aim of which was to outline comprehensive maps of emerging sustainable users demands and to generate a set of qualitative scenarios (on how these demands, and the consequent products and services innovation, may co-evolve). The final goal of EMUDE was to translate these scenarios into roadmaps for future research and development activities, to inform and inspire the decision-makers and to influence the future end-user's perceptions and demands. The "core" of the whole project was given by the collection of information on "promising cases" of emerging phenomena on sustainable consumption and bottom-up innovation in Europe. This activity has been performed through the creation of a design school network: the design school members became a sort of

[27] Imagination, co-directed by Rachel Cooper, is focalizing its researches on topics like "design in the built environment; urban regeneration; design against crime and socially responsible design", as well as healthcare, education, open innovation, sustainability and wellbeing.

[28] The Art and Design Research Centre with the Centre for Health and Social Care Research is part of the Lab4Living collaborative research group. Lab4Living has the aim to propose creative strategies, based on a holistic, human-centered approach, for the development of future living environments for people of all ages and abilities.

[29] Hilary Cottam deals with social issues of our day, specifically on education, health and criminal justice. It comes out a very interesting thematic picture that integrates the traditional fields of design.

[30] The Michael Young Foundation, formed in 2005, is active in different fields like health, learning, wellbeing, neighborhoods and material consumption.

[31] The areas of design are no more related to a merchandise approach (lamps, electric appliances, furniture, etc.) but to problematic areas of our present society that need to be solved trough a set of different design outcomes (new products + new services + new interfaces + new spaces, etc.).

[32] E-Mude_Emerging Users' Demands for Sustainable Solutions with the European Commission 6th Framework Program – EU, 2004-2006. *Integrated projects_The creation of "knowledge communities" in production technologies*; (scientific coordination by Ezio Manzini; project management by Luisa Collina);

European antennas; design students were like “coolhunters” of innovative and sustainable solutions; the schools and the students together had a role of “catalysators” able to generate visions of sustainable futures.

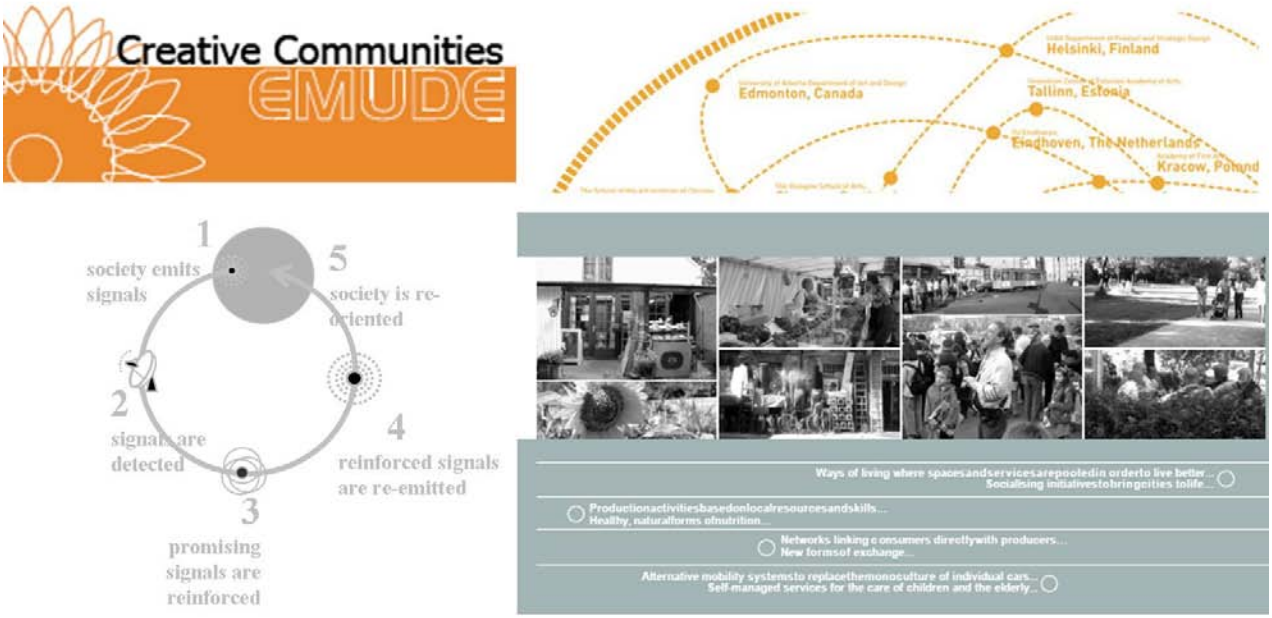

Fig. 1: EMUDE_Emerging Users Demands for Sustainable Solutions Design School Network as a research infrastructure for the detection of “promising cases” on sustainable consumption in Europe. (Meroni Anna, 2007)

The third “family” of research actors is a bit further away form the institutional or professional design research and is closer to the communities of associations, programs and non profit organizations active in promoting a broad debate on our sustainable future. The ways of rising awareness of the people are very different: from organizing nomadic exhibitions (*SEP - Sustainable Every day Project*) to successful conferences and on line debates (*Doors of Perception*) or to events finalized to experiment new possible sustainable solutions and services (*esterni*).

An interesting Italian case is given by *esterni*. *Esterni* is a non profit association based in Milan, founded 12 years ago by a group of architects and designers. Among the other projects they are promoting *Design Pubblico*: a design activity for public spaces, considered as spaces for socialization, for experimentation and for sharing. Street furniture like socializing signs, services for the city like the extraordinary lines, or events are only some of the “concrete ideas for the city” designed by *esterni*. In addition they are working on topics like co-housing, bed sharing and temporary hotels in order to rise the level of hospitality of the city and to permit the contact between local citizens and visitors.

Fig. 2: Esterni_Design Pubblico and other activities (photo by Luisa Collina and www.esterni.org)

These cases are good, positive examples for innovative design driven experimentations towards sustainability.

If we observe this broader community of design researches we can try to find some main characters, that could be considered as a contribution of the European design to the worldwide demand of design research for “changing the change”.

3. A European approach towards design: the product service system approach

Differently from the Anglo-Saxon tradition of design in which the different areas of design are very well defined and isolated, in Italy and in Southern Europe these separations have never been rooted inside the design culture, both in the profession as well as in the academic environment: for example the *made in Italy* design tradition with architects/designers active in the different fields (from furniture to electronics) as well as on different scale (from the micro of the single object to the macro of urban scale visions); similarly in the universities the borderlines between industrial design and product design; furniture design and interior design; interior design and architecture etc. have always been an interesting intellectual opportunity to be crossed; to try to eliminate them; to enlarge them etc.

In the tracks of this tradition the concept of product-service-system design has taken form and has been further theorized[33].

The new concept of PSSD is based on the recognition of the changes that have invested the products, the spaces and the communication artifacts around us and that in some cases have increasingly weakened the traditional borders of the different design disciplines: products become

[33] Francesco Mauri (with Francesco Bergonzi, Gianluca Brugnoli, Diego Canneri), *Progettare progettando strategia: il design del sistema prodotto*, Dunod, Milano 1996

more and more immaterial incorporating digital advanced technologies; spaces become more and more complex with envelopes of interior spaces (as well as of entire buildings) assuming the function of giant communication screens and interfaces with the individuals; environments become intelligent; materials become smart, able to change colour, shape and to emit light responding to a touch, communication is no more static, but dynamic, constantly interactive, and so on.

Just as an example a store, in the past considered as the specific area of interest of interior designers, is nowadays defined, from different authors, as a "hypermedial site", a "communicative artefact", a "relationship platform", "a brand stage" or a "service evidence": different ways of pointing out the interlinked relations between communication, interactions, strategies, branding and services that are hosted in this kind of physical spaces.

In addition the increasing sensibility for the environmental impact of products and services has asked for so called "holistic" methodologies and design approaches.

In this framework the necessity to overcome the traditional disciplinary borders of design in favour of a systematic, multidisciplinary approach emerges: Product Service System Design (PSSD) is one way in which this approach is identified: a term that has more than one "identity" at the present moment and that can be considered in a broader sense as an interesting macro area of researches and activities, more than an already stable design approach.

In fact, the ways in which this term is used are very heterogeneous: different focuses, different forms, different perspectives and in different contexts; with a more technological approach or socio-cultural approach; with a top down approach (starting from enterprises and institutions that could promote PSSD) or bottom-up approach (starting for the users and from the society in general); focalized on the strategies of a company or institution towards its market, on the production process and on the entire life cycle; on services; on experiences; on interaction between users and objects and so on. A very complex picture difficult to classify through simple categories. In the following paragraphs some hypothesis of clusters are proposed:

9. the **"extension"** of one of the design fields into the others: in some cases the design process starts from a new service, product, interior or piece of furniture; the approach, in these cases, is to observe and design the impact of this new item on the other branches of design: from product to packaging to display….; from a service to the communication, to the web site……; from the retail space to the communication system and services, etc. …in order to design "seamless" a complete and coherent solution;
10. the **problem-based approach**[34] : to answer to a problem-based design brief means, very often, to recognize the interdependency of each single element and/or process form the others. Single products, in this perspective, are not isolated from other items and from their contexts; on the contrary their design is connected to the study of the entire chain and of their environment; in other words it involves the design of all single parts and processes that make up the product-chain and the product-system. *"It is for example not about redesigning one office chair that deals with choosing another material that is better to recycle, has less toxic elements or has a lower energy content. But it is about developing a complete new sustainable office. Now we have to think of how to reduce paper use and energy use (in the office and during the period of going to the office) and dealing with efficient use of space. The solutions go beyond the boarders of one product and one company. In the office case you have to deal with office furniture, copy machines, data communication, telecommunication, etc. The result is in most cases not only one product, but moreover a system of product(s) and services."*[35] This problem-based approach in many cases is carried out, since the start of the project, by multidisciplinary design teams:
11. the physical evidence of **abstract concepts**: some other ways of considering PSSD start from more abstract concepts that find the way of materialization in terms of a set of different design outcomes: the design, for example, of "experiences", "solutions",

[34] The focus of Kathalys, the institute established by the Dutch Ministries of economic Affairs, Housing, Spatial Planning and Environment involving TNO and TU Delft, was concentrated in three areas: home life, work and mobility.
[35] Helma Luiten, "The Kathalys method: a method for the development of Sustainable Product Service Innovations", Hics – Higly Customerized Solutions, Deliverable 1, 2001

"strategies", "brands", etc. means to enter into the design of several different material or immaterial elements trough which these concepts come into reality;

12. the **design role play**: other interpretation of PSSD are based on the selection of a specific perspective of the design process: like in a cash dispenser, where the user has a "frontal" interaction with the machine, the bank worker a "back" one and the person in charge for the logistic a "zenithal" one, the same can be observed in relation to the product service system design: user centred design and experience design; strategic design and brand design; product-chain design, life cycle design and system design cover for example these three different perspectives.
13. the **innovation** goal: an important criteria for classifying the different interpretations of PSSD is related to the goal of the design process in terms of innovation: highly technological, marketing oriented or social, for example; these differentiation origins very different systematic approaches towards design.

4. A design focus: not only object but spaces, services, lifestyles, territories

Considering the Italian tradition of Radical Design, in Southern Europe we assist nowadays to a further enlargement of the PSSD area: the territory and the activities related to it, enter the design system approach, both as a resources as well as the target of design activities.

Italian design has in fact in its DNA a strong relationship towards local resources: it is thanks to the constructive dialogue and proposals between craftsmen/small businesses and designers that the *Made in Italy* phenomenon has reached such success. Enlarging this view and not limiting the perspective to the manufacturing system of small and micro enterprises, design acquires the capabilities to strengthen the local resources in general (like agriculture, handcraft, cultural heritages, natural landscape and oenogastronomy), valorising energies, vocations, and traditions of local territories; redesigning products, services, spaces, communication and distribution systems related to these fields.

MEDEsign: strategies, instruments and operations in industrial design for valorising and boosting resources in the Mediterranean area[36] is an Italian research focused on the idea that design can contribute to the development of the territories, considered as a place of sedimentation of different values: the knowledge and competences of handcrafts; the natural landscape, the agro alimentary tradition; the architectural emergences and cultural heritages. These are extremely valuable resources, deeply localized, related to an idea of physical well being, hospitality, beauty and cultural growing, in the tradition of the *Made in Italy* sectors.

[36] Italian Ministry of the University and Scientific and Technological Research (MIUR 2001 – 2003). *Me.Design: strategies, instruments and operations in industrial design for valorizing and boosting resources in the Mediterranean area from local to global*, coordinated by INDACO Department, Politecnico di Milano

Fig. 3: MeDesign_ Action researches themes (picture by Beatrice Villari)

More recently, some contemporary projects have been indirectly generated by these visions like for example *Agricultural Park South Milan*, a research funded by the Italian Ministry for Univeristy and Research (2005-2007), developed by Politecnico di Milano and other partners, focalized on the reinforcement of the relation between the park localized in the south of Milan and the city through the redesign of the agricultural and food distribution system; or *La città degli orti*, a project designed by Aldo Cibic in 2008 for *Progetti e Paesaggi* a fair about products, materials and services for in-outdoor in Bologna.

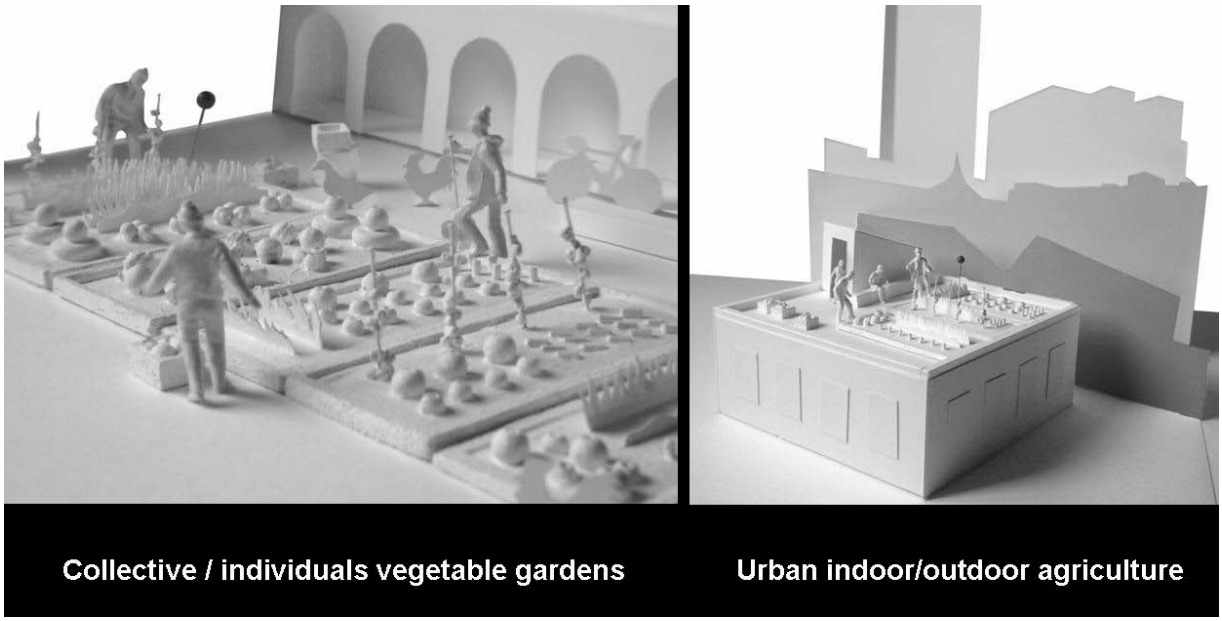

Fig. 4: Agricultural Park South Milan_Urban countrysides in rururban areas (responsible of the project and photo by Anna Meroni)

The sustainable development of territories is, from this point of view, a very interesting and strategic area of research. The summer schools organized with the framework of *Turin World Design Capital* want to be a sort of experimentation on this field: asking to international world known designers to interpretate this kind of "bottom up", territorial local design approach, tutoring the students in developing new solutions.

The aim of the conference *Changing the Change*, of the summer schools related to the conference and of this proceeding is in fact to strengthen the capability of design research to turn into action. This means to remind us, with the words of Lewis Mumford, that *"human beings walk with their feet on the earth and with their head in the clouds"* combining our history and our reality with the design of **"*utopia*"**, that comes (always with the words of Mumford,1922) from the greak words **"*eutopia*"** which means **"*the good place*"** rather the place that does not exists.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

DESIGN EDUCATION AS A CHANGE AGENT:

Intersections of Need, Learning and Knowledge Transfer Represented in the Designmatters Initiative

Mariana Amatullo[1]

Abstract

The multiple environmental and socioeconomic challenges confronting humanity today, and a contemporary context that presents the promise of perpetual connectivity and accelerated patterns in information consumption and creation, represent powerful global forces that are shaping the way we live, work, and learn. Such pressures and opportunities at an international scale are affecting design education in significant ways, creating an unprecedented need to deliver knowledge, experience, and sophistication amidst a global playing field. The college-wide initiative Designmatters at Art Center College of Design advocates for applied research approaches to complex humanitarian issues and provides unique methodologies for creative reform and change, empowering a new generation of designers to imagine critical solutions for society's well being into the future.

mariana.amatullo@artcenter.edu

Introduction

For over 77 years, Art Center College of Design, located in Pasadena, California, has been one of the world's leading institutions for design education. Art Center offers undergraduate and advanced degrees in a wide variety of design and fine art disciplines, and the college's pragmatic, real-world approach provides graduates with the education and experience to become creative leaders in their chosen professions. Art Center's curricula are multidisciplinary, rigorous, and dynamic in nature, responding to a fundamental belief that interchanges among disparate fields of knowledge and design disciplines have become essential to contemporary higher education in general – and to design education in particular. Today the college also maintains its top-ranked position by evolving its philosophy and practices in response to the rapid technological and socioeconomic changes of our era. The institution is a laboratory for innovation, a locus for partnerships and collaborations with industry and public sector development agencies, and a center of international public dialogue on the larger role of design.

The *Changing the Change* Conference takes as point of departure the accelerated global transformations of today world to offer a provocative inquiry about the evolving role of design as an overall instrument for positive change in the context of the World Design Capital Torino 2008.[2] The conference also presents a terrific platform for designers and researchers to discuss research methodologies and practices that can respond to this rather bold--but indispensable--call to action, which in turn is deeply synergetic with Art Center's institutional educational agenda as epitomized by Designmatters, a college-wide examination of social and humanitarian applications of design and responsible business practices.[3] This paper presents two Designmatters project case studies, the Mpala Project, and a Public Awareness Campaign for Climate Change, which have been selected for the connection they make between sustainable human development issues, and design, across multidisciplinary fields including industrial, communication, and narrative design. An in-depth discussion of the core methodologies and perspectives gained from these projects also aims at underlying the value of linking real-world issues with academic practices, in order to promote a deeper awareness and understanding of the global context, which results in turn in more empathetic students.[4]

The Mpala Project: A Case Study for Participatory Design

1. A Unique Partnership in the Context of A Global Competition

In the fall of 2006, Art Center College of Design partnered with a small community-based organization in northern Kenya, Mpala Community Trust (MCT), to enter the World Bank 2007 Development Marketplace Global Competition: *Innovations in Health, Nutrition,*

[2] Changing the Change, http://emma.polimi.it/emma/showEvent.do?idEvent=23.
[3] For a comprehensive overview of the initiative and portfolio of projects see http://www.artcenter.edu/designmatters.

and Population for Poor People.[5] With the motto "turning ideas into action," and its support for social projects with high potential for impact and scalability, this prestigious competition functions as a social entrepreneurship incubator and grant-making program that rewards grass-roots innovation, and has been responsible over time for highly successful development projects, such as, for example, a water play pump that doubles as a merry-go-round.[6]

The competition's mission of building partnerships among public, private, and civil society sectors that foster dialogue, understanding, and truly sustainable solutions, represented and ideal platform for Art Center's Designmatters initiative to identify critical design interventions that could benefit a strategic partner by harnessing creativity for social impact.

As the sole professional and reliable health care provider in a region roughly the size of Wales, MCT serves approximately a hundred thousand people scattered in remote communities far from any existing medical center. The clinic's infrastructure consists of a couple of modest sized rooms at base camp, and an integrated outreach system that relies on specially outfitted Land Rover vehicles, a few bicycles, and periodic camel convoys to deliver critically needed medicine and health education to the nomadic population who live in the vast plateaus of Laikipia and Samburu, northwest of Mount Kenya.[7] The integrated mobile clinic system utilizes local nurses, and counselors who are trained to deliver a wide range of health services, and share knowledge about healthy lifestyle practices, HIV/AIDS prevention and family planning, among key health issues. From an operations standpoint, MCT works within a participatory framework, recruiting its health workers from the community. This model has led to MCT's widespread acceptance in the region since its inception in 1999, and an increase in demand for services by these underserved communities.[8]

[5] The project was among the 105 finalists selected from over 2,900 proposals worldwide. The World Bank, Washington, D.C. , http://siteresources.worldbank.org/DEVMARKETPLACE/4416738-1196093766795/21583185/DM.htm.

[6] The Playpump® water system, the core product of a small company in South Africa, Roundabout Outdoor Water Solutions, was a winner of the 2000 Development Marketplace Competition. The play pump functions in tandem with an ingenious merry-go-round device, which was initially adopted throughout village schools in South-Africa. Community members install it above wells that harness the power of children at play to pump water to a holding tank that displays health education messages. The funding and visibility of the competition enabled the project to scale up. Today, with its international partner, the US-based non-profit Playpumps International, the goal is to install 4,000 PlayPump® water systems in 10 countries in sub-Saharan Africa by 2010, bringing the benefits of clean water to up to 10 million people. For further information about the history of this development marketplace winner, see http://web.worldbank.org/WBSITE/EXTERNAL/NEWS/ and http://www.playpumps.org/site.

[7] For further information about Mpala Community Trust (MCT) and its sister organization, Nomadic Community Trust, see http://www.mpala.org/.

[8] The communities that MCT and NCT serve are among the poorest in Kenya. Data collected by MCT points to a population that has been mostly untested for HIV/AIDS leaving a gap in the data set for Kenya, and one that urgently needs basic medical services and counseling in HIV/AIDS, reproductive health and female genital mutilation (FGM). Samburu district's population is approximately 150,000 scattered over an area of 21,000 sq. km. Laikipia's population numbers approximately 322,190 people over 9,000 sq. km. Over 70% of population in Laikipia and over 90% in Samburu is nomadic or semi-nomadic, creating great challenges in providing health services. Livelihoods revolve primarily around livestock movement to a seasonal calendar.

For the competition submission process, Designmatters at Art Center oversaw a core project team of Art Center staff, alumni, and faculty[9] that worked together with MCT staff and counselors over an eight-month period (from fall 2006 up to May 2007). The outcomes of initial fieldwork in Kenya, and joint research between the design team and MCT were the basis of a proposal that underwent two rigorous rounds of judging by international and public policy experts. MCT identified two key areas of critical need to improve upon the health care delivery system that in turn became two main opportunities for design intervention:
1) Expansion of the mobility and outreach capacity of the clinic by designing a system of transport, packaging and solar-powered refrigeration that would allow camel convoys to carry medicines such as vaccines that they currently cannot, because they spoil under heat conditions; and 2) visually-based and culturally sensitive materials to support the health education efforts of the MCT counselors, who work with a population that is 80% non-literate.

2. A Breakthrough Mobility System

The project's significance to both design research and application made it one of the top hundred finalists in the competition.[10] While ultimately not funded by the Bank, development has continued to date beyond the competition's framework, and presents an interesting case study about what can be characterized as a certain "nimbleness" and entrepreneurship quality at the core of how the Designmatters program operates at Art Center.

While all Designmatters projects are closely tied to the college's undergraduate and graduate curricula in all design disciplines, and typically take the form of course assignments, studios, or independent study projects that are selected for their educational enrichment value and real-world impact; the program also allows for "special projects." These are loosely defined opportunities that present breakthrough design potential, but may not necessarily fit the timing and purview of a course that takes place in the college's traditional fourteen-week academic terms. "Special projects" are usually comprised by hybrid design teams and research investigators recruited amongst students, faculty, expert advisors from other institutions, and alumni.

The design of the first generation prototype for the mobility system proposed for MCT fits the profile of this "special project" category within Designmatters. It is an ongoing effort at this writing, made possible by a small team of industrial design faculty at Art Center (which includes the lead industrial designer of the project, Kenyan alumnus Patrick Kiruki), collaborating closely with a team of engineers led by Winston O. Soboyejo, the Director of the Undergraduate Program at the Princeton Institute for the Science & Technology of Materials, Mechanical & Aerospace Engineering, Princeton University.

The system improves the efficiency of the loads carried by the camel caravans that navigate the rugged terrain where MCT operates, and the new long-range solar-powered

[9] Principals in the competition project team included Mariana Amatullo, Karen Germaine, Patrick Kiruki, Wendy MacNaughton, Elisa Ruffino, Geoff Wardle and Gaylord Eckles from Art Center, and Shannon Wreford- Smith, Molly Smith, Rose Kimanzi, and Rodgers Ade from MCT.
[10] The project was among the 105 finalists selected from over 2,900 proposals worldwide, http://web.worldbank.org/WBSITE/EXTERNAL/OPPORTUNITIES/GRANTS/DEVMARKETPLACE/0,,contentMDK:21213381~pagePK:180691~piPK:174492~theSitePK:205098,00.html.

refrigeration units proposed would eventually allow the clinic to deliver crucial vaccines and medicines that are currently inaccessible to distant recipients. The project blends relatively affordable technologies (use of flexible solar panels to power batteries for portable refrigeration units) with the application of advanced engineering and design, and an overall people-centered approach to service delivery. After several months of development that has taken place in the labs of Princeton, the prototype is now undergoing final stages of refinement for ease of assembly, stability, and durability. A number of sessions and fittings of the saddle system on camels at the Bronx Zoo (Fig.1) in March and April 2008 have in this regard provided key insight to the team.[11] Currently, the prototype is nearing the stage for field-testing in Sub-Saharan Africa, which is anticipated for late 2008. The potential lasting, transformational benefits of the innovations designed, and their broad application beyond the beneficial impact recognized by MCT, have already been identified by the Art Center-Princeton team and a number of prospective partners of the project.[12]

In retrospect, incubating this aspect of the Mpala Project beyond the Development Marketplace Competition has allowed the original ideas proposed to be designed in a robust way through the partnership with Princeton, with outcomes that can be hopefully replicated and adapted to other countries where similar terrain and remote communities are in existence. Ultimately, as Josephine Green from the Social Foresight and Innovation team of Philips points out when addressing the question of designing new healthcare solutions, *"the goal is to see this new health delivery system be successful, not primarily because of its technology but because it redefines the access and delivery of health and wellbeing in a way that makes sense socially and culturally to the various users."*[13]

3. Shedding Preconceptions to design a visually based health-education campaign

"The Mpala Project's success started and ended with the same idea: keeping an open mind. We began by asking the students to look inside themselves to try to gain an understanding of what they believed—about illustration, about semi-literate people, about people of Kenya, about nomadic tribes, and about themselves. This turned into a conversation that lasted the whole semester."[14] -Esther Pearl Watson, Faculty, Department of Illustration, Art Center College of Design.

This statement encapsulates the sensitive and inquisitive approach that the faculty team from the Department of Illustration at Art Center took in guiding a group of undergraduate Illustration and Photography students throughout a dedicated studio that

[11] Multiple testing sessions of the system at the Bronx Zoo have been occurring since March 2008. Data compiled by Niyi Olubuyi, Princeton University, in correspondence with author, April 25, 2008.
[12] In addition to field-testing planned with MCT staff in Kenya, Designmatters has partnered with Project Concern International (http://www.projectconcern.org), a development agency focusing on health care delivery to explore the adaptability of the system in other regions with similar challenges. The first round of testing will take place in partnership with the field office team of Project Concern International in Afar, Ethiopia.

[14] Martha Rich and Esther Pearl Watson, Eds. *Images Speak*, (Designmatters at Art Center College of Design, forthcoming in 2008), p. 19.

Designmatters facilitated for this component of the Mpala project during the Fall 2007 academic term.

With a very complex brief calling for the design of viable and visually-based health education tools for non-literate nomadic communities in Kenya, this project presents a good case study of the applied research methodologies that the Designmatters program advocates for in these "wall-less classroom" initiatives, which, in the words of Watson, require students to be "thinkers first, designers second." In the case of Mpala, as Ann Field, Art Center's Department Chairman of Illustration has remarked, the brief called for students to let go of their personal drawing styles to focus on what messages their images needed to communicate. In order to reach their target audience, students had to operate outside their own frame of reference, and go through the difficult process of *"unlearning so much of what they knew."*[15] Grounding this process of opening intercultural doors in a rigorous research framework was key to the success of this educational journey for the students, but also paramount to constructing media sensitive to the values and cultural framings of the communities at hand.

As point of departure for the research, field and user-centered data brought back by the lead designers of the competition team became a backbone of visual references and resources. The data was complemented by several sessions with the original competition team, and expert advisors in communication and media.[16] Key among them, Professor Doe Mayer from the Annenberg School for Communication and School of Cinematic Arts, University of Southern California, qualified the Mpala Project as *"an ambitious idea, in which students rose to the design brief and the research challenge."*[17]

Specifically, the brief for the Mpala project called for culturally appropriate HIV/AIDS awareness and family planning messages and media. Working in teams, students developed six distinct health education pieces that ranged from chalkboard schoolbooks with simple illustrations meant to show the benefits of family planning, to a canvas flipbook for MCT counselors to use in the field when instructing about safe sex practices (Fig.2).[18] All solutions had to be designed at the finished level of a solid first prototype. Considerations of affordability, durability, and sustainability dictated the materials and techniques that were ultimately selected to bring concepts to life. Students were asked to synthesize research and feedback from the advisors that supported the Illustration faculty team at Art Center, but also from MCT staff and counselors who participated remotely throughout the progression of the studio at several key junctures. From a pedagogical standpoint, all Designmatters studios have these strategic sessions throughout the conceptual exploration and development stages of every project; they serve as critical moments for students (and faculty) to run creative directions through a sieve of questioning, self-examination, and true listening. Wendy MacNaughton, the creative director of the competition phase of the project and a guest faculty in the Mpala

[18] The campaigns included Notebook and Chalkboard, Impressions on Recycled Aluminum, Grandmother's Kit, Pouch, Slide-Viewing Device, Safe Sex Fabric Book and Safe Sex Flipbook, which can be found in Martha Rich and Esther Pearl Watson, Eds. *Images Speak*, (Designmatters at Art Center College of Design, forthcoming in 2008), pp. 37-81.

studio, stresses the transformative importance of this listening aspect of the process, and sums it up nicely when stating: *"The biggest challenge for creatives working in social design is to approach each project with fresh eyes and open ears."*[19]

Ultimately, beyond complex content, the collaborative framework of the Mpala project is characteristic of the increasingly multifaceted nature of projects in the Designmatters portfolio.[20] As attested by MacNaughton, it forces the experience of a certain openness, an element of surprise and vulnerability in the design process, what anthropologist Genevieve Bell, Director of User Experience within Intel's Digital Home Group, qualifies as *"humility [that] brings with it grace."* Suddenly, the fundamental criterion for successful outcomes rely in answering the question: "But does it work?"[21]

By the same token, as students become progressively connected with the issues and people they are to design for, a sense of real purpose and empathy develops. Sara Hofmann, a student in the Mpala studio speaks to this sentiment very eloquently: *"I was most challenged by coming up with a concept that works not only in a California classroom, but one that really helps people in Kenya. It was not about being concerned about style or personal artistic voice, but rather in finding a way to tell a story that is understood by another."*[22]

Whether the story that Sara and her teammates conceived achieves its desired impact is a question that awaits an answer shortly: all six of the health education prototypes produced by the studio are in the hands of MCT counselors and will undergo field-testing through fall.

There are many valuable insights to be gained from the Mpala project as a case study for the typology of projects that Designmatters at Art Center undertakes. From a pedagogical perspective, pushing students outside their comfort zones to experience the challenges and rewards of real-world constraints brings an unequivocal sense of empowerment and responsibility, a sense of "awakening."[23] From a broader perspective, such projects also allow students to establish connections and bridges between global and local concerns that ultimately make for better design outcomes.

Public Awareness Campaign on Climate Change

In collaboration with the Department of Film, Designmatters facilitates ongoing studios that produce public service announcements and integrated media campaigns on critical social and humanitarian issues. The campaign for climate change awareness produced in summer 2007 for premiere in September of that same year at the United Nations

Department of Public Information (DPI)[24] represents an interesting counterpoint to the Mpala Project case study, and illustrates yet another dimension of the methodologies of the program.

According to Designmatters Producer, Elisa Ruffino, *"the potency of combining media-savvy young minds with proficient creative and technical production talent is so exciting because it can yield an especially compelling message as well as head-turning vehicle for its delivery."*[25] The PSA production studio allows students to research, conceptualize, develop, shoot, and edit into thirty-to-sixty-second spots that are dissemination-ready by the time the fourteen weeks of the academic term conclude. In any given term, the thematic focus of the studio varies and can be driven by a funded commission from an outside partner, or be the result of individual students' personal interests. In the latter case, Designmatters and the film faculty typically support students with key research resources and expert advisors, as they create public messaging of their own choice. The PSAs produced are subsequently matched to agencies that disseminate them.[26] Both scenarios have been equally successful in the distribution range and quality of the PSAs— and both are equally thrilling in presenting an opportunity for new social commentary and immerse the students in a process of activism.

In the case of the global warming campaign, the organizers of the annual DPI/NGO conference invited Art Center to contribute to the central theme, *"Climate Change: How it Affects us All," with a commission that was intended to be* somewhat "edgy" in tone, and be able to resonate with cable and network television audiences beyond the forum of the conference and the UN (Fig.3). Students were encouraged to develop messaging that focused on a sense of personal responsibility around the issue. As Ruffino remarks, the result overall was *"a very visceral reaction to this invitation. Students were excited to imagine their personal contribution to a global dialogue on a subject that is so ubiquitous in mainstream media. They had a lot to say, and best of all, possessed the tools with which to say it."*[27]

With comprehensive research on climate change, the students found certain threads and nuances that particularly resonated with them, both as individuals and as young members of a society flooded with multi-disciplinary discourse on the issue. The approach they took was often characterized by a sense of self-effacing humor that resonated with a demographic of peers that are certainly rather immune to 'do-good' commercials. The testimonial of Alice Park, the student director of a piece called "The G.G. meeting*,"* which depicts a group of individuals of various ages who come together in a mock alcohol anonymous meeting to wrestle with the mistakes of their daily actions, refers to a bold sense of confidence that Ruffino found in all student directors: "The piece is purely to stimulate our social consciousness on the topic of climate change. *Once in the ether, the easier and more willing people are to have an open forum on the subject, and take action… The concept lends itself to reflection and awareness on*

[24] Art Center is the first design school to hold Non-Governmental Organization status with the United Nations Department of Public Information since 2003. The College is also an NGO with the United Nations Population Fund and the Organization of American States.
[25] Elisa Ruffino, in correspondence with author, May 2008.
[26] A recent successful example of a student-generated concept that received international recognition is Jonas Mayabb 's "Fat Lane," a young director first prize award at the 2007 Cannes Film Festival and a piece optioned by Participant Productions in conjunction with the social action campaign for the motion picture "Fast Food Nation."

climate change in its lighthearted, self-effacing approach to the eminent issue, and with a sense of community."[28]

All four climate change PSAs produced as part of this studio represent a "best-case scenario" of an extremely proficient campaign that touched a nerve and transcended its initial outreach objectives and audiences, with broadcast by multiple partners, which included Participant Productions and "Inconvenient Truth" producer Laurie David's non-profit, StopGlobalWarming.org. In addition, the work has been screened as part of the 2008 "Green Screen Series" of the Film Society at Lincoln Center, New York and has received multiple accolades. The critical acclaim of one of the PSAs in particular, "Blowing Smoke" by Jonas Mayabb, is also an extraordinary testament to the very well honed messages and technical prowess of the work. Since its premiere a year ago, the PSA has picked up several advertising and filmmaking honors, including the top honor in the U.S., an Emmy from the Academy of Television Arts and Sciences.[29]

Conclusion

The Mpala Project and the Public Awareness Campaign for Climate Change are two distinct project case studies from the Designmatters portfolio at Art Center College of Design that demonstrate how design education can be aligned with a rigorous exploration of the great social transformations and global issues that are affecting the world today, to in turn generate tangible outcomes and real solutions that can make a difference in society.

Peter Drucker's definition of knowledge as "information that changes something or somebody--either by becoming grounds for action, or by making an individual or an institution capable of different and more effective action" [30] offers insight into the paradigm shift that the Designmatters initiative has generated at the college. Designmatters has enabled the "DNA" of the entire institution to evolve with a new emphasis on imbuing the educational experience with critical content and a sense of contemporary relevance and commitment. Indeed, "research transformed by action" could be the underlying motto of the initiative.

As an international competitive institution of higher education for the 21st century, and as an advocate for the larger role of design, Art Center's mandate is inexorably linked to the responsibility to chart new territory for graduates to be design leaders and to "lead by design."[31]

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

An Industrial solution for Kenya and Africa

Using home-grown ideas to create sustainable livelihoods

Lorraine Amollo[1]

Abstract

The poor performance of large scale industries that is characteristic of most African countries has led to the emergence of micro and small scale industries. These industries remain small and uncompetitive and therefore do not offer sustainable livelihoods.

African Governments and other stakeholders have failed to create an enabling environment for these small industries to grow. On the other hand, the efforts at large scale production have been mostly fruitless.

This paper looks at two case studies of small scale producers with the aim to explore their potential to grow into sustainable Medium sized industries. In its conclusion the paper proposes ways in which stakeholders can forge the path towards industrialization and in so doing create sustainable livelihoods.

[1] Maseno University (KENYA) – DESIGN department. Lecturer, amollol@yahoo.com

1. The industrial situation

In Africa, the Western model of industrialisation has not met with much success. This remarkable failure at industrializing that is characteristic of most African countries has been blamed on a host of problems ranging from poor governance to the transfer and use of inappropriate technologies. The strategies that governments have adopted in an effort to industrialise have been proven to be unsustainable.

The collapse of the manufacturing industry in Kenya is a case in point of these failed efforts. This failure has further been two-fold as industrialisation efforts have been unable to create adequate employment and have also led to the loss of employment opportunities in the indigenous industries. Pottery production is an example of a once vibrant industry in many rural areas in Kenya. This indigenous industry provided local communities with containers used for preparation and storage of food. It was an off-farm activity that supplemented the incomes that women received from subsistence farming. Today, plastic wares and metal containers that are longer lasting and therefore considered cheaper and also seen as a sign of modernity have replaced the traditional earthenwares. The plastic and metal wares are produced in factories that require few employees and use imported raw materials and technologies. Even cheaper are finished wares that are imported into the country from industries abroad.

2. Transfer of Technology

The transfer of technology world wide has been viewed as one of the main agents necessary for economic growth. The acquisition of technology and its proper adoption should lead to production growth. The invention and creation of these technologies have however overwhelmingly remained the stronghold of the OECD countries. Developing countries therefore find themselves at the receiving end of these imported technologies. (Hoekman et al 2004, 1).

As earlier mentioned the transfer of inappropriate technologies to Africa has been blamed for the poor performance of large scale industries. The term appropriate technology also referred to as intermediate technology was originally a concept involving the application or adaptation of technology to fit a particular context (Jeans 1999, 69-170). The popularisation of the concept of Intermediate technology is attributed to Eugene Schumacher in the 1960s who called for the use of modern technology to solve the problems of creating work rather than concepts of efficiency and increased outputs that displace workers. Its emphasis is on the needs of people rather than products (Heskett 1980, 10). Unfortunately, almost all new technologies are designed to meet the demands of industrialised countries. Technical expertise today that is geared towards large scale production is unaware of the technological problems of the Small and micro industries. (Jeans 1999, 169-170).

Another argument for the poor transfer of technology is attributed to the fact that the nature of technology has not been fully understood. Viewed as any other commodity in a free and fair market, then technology would be easily transferred and used fittingly from one place to another. This theory however assumes that technology merely consists of techniques and methods that are created in developed countries and transferred to developing countries at little or no cost. However the reality is that technology is complex and cannot be expressed as the sum of the material inputs and technical know-how. In light of this then technological transfer to developed countries needs to be looked at in the broader context whereby the receiving countries need the capability to make use of the acquired technology, absorb it and adapt it local conditions. (Archipugi and Pietrobelli, 2002, 862-863).

3. The informal sector

The consequence of failure to industrialise has led to the abundance in Africa of small scale industries most of which have remained informal. In Kenya, as in most of Africa the informal sector has as a result attracted much attention. Governments as well as a host of Non-governmental organisations have become embroiled in this hot subject with little or no benefit trickling down to the small scale producers.

The term Informal sector was first used by Keith Hart whose studies were focused on the work done by Frara migrants in Accra, Ghana. It was however in Kenya that the informal sector was first regarded as a policy priority in the employment mission done by the International Labour Organisation in 1971. In Kenya however, it is increasingly became more common to use the term 'Micro and Small Enterprises (MSEs) of the *Jua Kali* sector' or 'Non-farm activities' in the rural areas. The use of Jua kali as a term dates back to the 1980s when the then minister of Technical training and Applied technology endorsed the use of the term *Jua kali* sector in place of the informal sector in 1988 (King 1995, 24-30).

The term 'Jua Kali' is Swahili for 'Hot sun' referring to the open air working conditions of the entrepreneurs. Most Jua Kali industries start off and remain as informal enterprises as their owners often cannot afford the expensive and rigorous process of registering with the relevant Government bodies. This informality means that the *Jua kali* businesses have found it hard to access business development services or export markets as compared to the formal and larger industries. (King 1995, 24-30). The *Jua Kali* producers as result remain poor and their businesses small and uncompetitive. Though the Government has recognized the potential of the *Jua kali* sector as an employment opportunity for many Kenyans, it has failed to create an enabling and sustainable environment for these micro and small industries to grow.

Policy makers in the government as well as Non governmental organisations (NGOs) and donors have adopted appropriate technology and business development as the way forward in the effort to empower the small scale producers. The Government of Kenya (GOK) has set up several departments under the ministry of Trade and Industry aimed at better serving the needs of small scale businesses. Further, the GOK has written several policy papers such as sessional paper number one of 1956 and number two of 1991 and 1992, all these in relation to the Jua kali sector. In its latest efforts, the GOK has set a ministry of industrialisation that is wholly focused on propelling Kenya to industrilisaton in the near future.

4. Jua kali producers

Most of the businesses in the *Jua kali* sector are family-based with skills acquired through traditional apprenticeship. The techniques used in production are simple and do not require complex machinery. The informality of the *Jua kali* makes it easy to set up businesses, as they require minimum start up capital. The negative side of this is that there is a proliferation of enterprises that remain small due to high competition and lack of investment opportunities.

A study done by the International Labour Organisation on the Jua kali, sites constraints such as inadequate skills, technology, support services and infrastructure. The National MSE baseline survey 1999 shows that the major constraint facing MSEs nationwide is lack of market. Numerous researches endorsed by both the GOK and NGOs have been carried out on the MSEs. It would therefore seem that a lot of attention is being paid to this sector. The GOK particularly in all its policy papers, places a premium on its intervention efforts to upgrade MSEs by creating an enabling environment for their establishment and growth. Government plans however continue to be criticised for having frameworks that are too general and unimplementable. These frameworks are hardly ever followed by budgetary allocations or the institutions to implement them (King 1995, 35-50).

The interventionist policies adopted by both the government and the NGOs have been misplaced and have achieved poor results in improving the livelihoods of *Jua kali* producers. The NGOs have over the years funded micro-enterprise development heavily with the result that certain projects have become heavily dependant on this assistance. This over dependence on external support causes entrepreneurial set ups to collapse as soon as the external support is withdrawn. Other forms of support have been the provision of training programmes for the entrepreneurs. In craft training in particular, academic based programmes that have no regard for economic viability of the craft, renders trainees unable to engage in lucrative business activities when they enter the real market (King 1995, 35-50).

Inadequate access to markets is another major set back for the *Jua kali* producers. In Kenya, poor access to local markets is partly caused by a narrow product range which leads to high competition and market congestion. This is evident from the horizontal rather than the vertical growth of most enterprises. Another set back is poor product design and packaging, low quality of products, poor pricing and lack of product improvement. In the international scene, the *Jua kali* producers face greater challenges such as lack of information and access to external markets which prevent them from exporting their products. They also lack the financial and promotional support from the government to enable them to access external markets.

5. Another attempt at Industrialisation

On the other hand, the Government of Kenya has since independence tried its hand at large scale industrialisation, an effort at which it has singularly failed. In one of its renewed attempts, it enacted an Act of parliament that saw the setting up of Export processing zones (EPZs) in various parts of the country. The EPZs provided incentives such as 10 year tax withholding, quick project approval and provision of machinery and business inputs among other things.

According to the Cover story on *Marketing Africa* of June 2005, though the EPZs have attracted investors to Kenya, they have been blamed for encouraging production of specific export products as well as importation of raw materials, technology and expertise. There are therefore no backward or forward linkages between the EPZ industries and local industries. In 2008 as has been the case in other years, the workers at some of the major EPZ factories have gone on strike over poor pay. They are paid minimal wages with little or no benefits. The owners of these factories therefore make a large killing from their profits which they neither share with the government as they have tax waivers nor with their underpaid unskilled workers. Certain industries such as horticultural farms that were hitherto performing well before the establishment of the EPZs have also joined the scheme in an effort to increase their profits by paying less tax.

The Government has therefore concentrated its efforts in creating large scale industries without taking into account the resources available in the country or the benefits that would accrue from such a venture. This focus on efficiency and high productivity is a Western concept of Industrialisation that largely makes use of non-renewable sources of energy and is geared towards catering for the needs and wants of a consumerist society. Africa on the other hand, struggles to adopt these western concepts, which do not absorb the large labour force that most African countries boast of.

6. Two cases of small scale producers

In light of these facts on the situation of Industrialisation in Kenya and Africa at large, this paper uses two case studies of Jua Kali enterprises in Nairobi and Kisumu, Kenya to explore their potential to grow into medium sized industries. The two enterprises are *Paro* in Nairobi which produces pottery and KICK in Kisumu which mainly engages in metalwork. The two cases are considered small industries as they are owned and managed two individuals in the case of Paro and no more than 10 shareholders in the case of KICK.

Paro cultural project is an entrepreneurship that deals in the production and sale of earthenware and is owned and run by two men. The business has been in existence for four years to the present and has its workshop in Nairobi. It is registered as a youth project with the ministry of Gender, sports and Culture a move which allows the enterprise to operate without the necessity to file tax returns as would be the case if it was a registered company. The enterprise is also registered with the Local authorities as is required of all businesses that operate in the city.

The two potters at Paro are engaged in the pottery business to generate income for their families and therefore strive to make it a profitable endeavor. Both potters also agree that self-employed is more fulfilling as they reap the fruits of their own labour. They intend to expand the business in future and thereby provide employment for others. These two needs of generating income and achieving self-fulfilment seem to be the main drive for engaging in the pottery business. Prior experience in the pottery industry is also a strong reason for choosing pottery as a business. Both potters are from the Luo community in the Nyanza province of Kenya where pottery has long been an indigenous vibrant industry. This has been attributed to the location of the province in the Lake basin area that is abundant with the raw materials necessary for the production of pottery.

The type and design of wares the potters at Paro produce is largely conditioned by their customers' needs as well as the availability of materials and technology. The potters mostly work on the orders they receive from customers most of whom come with their own specifications. Most of these customers want decorative items though some use the wares for cooking and serving food. It is becoming common in the catering business in Nairobi to use earthenware in serving African cuisines to create an 'authentic' traditional feel. Paro has therefore benefited from this interest as they have sold good number of there wares to several restaurants around the city.

As mentioned earlier, the methods of production used at Paro are largely rudimentary as they use basic tools common to traditional potters. The potters at Paro have gone further and developed and constructed larger turn-tables and a charcoal kiln mostly from recycled materials. The kiln is however too open and therefore burns alot of charcoal. The potters have also over the years developed a recipe for mixing clay with feldspar and kaolin to allow the wares to fire at higher temperatures and are therefore not are breakable as the traditional wares. Through interaction with customers, the potters have developed a range of products such as dinnerware and water coolers that are not produced in the rural areas.

KICK Trading is an enterprise based in Kisumu city, in the lake basin region of the country. It is a registered company with shareholders most of whom are the artisans who produce the wares that the company deals in. The business is managed by Isaac who is experienced in product design and development as well as business management. This sort of arrangement is unusual in the *Jua kal*i sector as most businesses are small and owned by one or two individuals who also work in the enterprise. KICK Trading has offices and a show room where the artisans can rent space and display their wares for sale. A small workshop space is also available for artisans to do their work. Most of the artisans who produce for KICK are however based in their own workshops in the nearby Jua kali market.

KICK trading deals in a variety of products most of which are decorative items made in recycled metal, wood, clay, water hyacinth and recycled paper. Recycled metal has long been used as a raw material in the Jua kali business with its products ranging from cooking pots commonly known as sufurias and metal suit cases that are popular with boarding school children

as they are not easy to break into. Most the products at KICK Trading are made of recycled metal which is obtained from the soda bottling company Cocacola. One design that is popular with their customers is smaller versions of the metal suit case that now serves as a decorative item. As the sheets of metal from the bottling company comes with the brand design of Cocacola products, most Jua kali artisans prefer to finish off the suit cases with spray paint. At KICK however, the artisans leave the finished product with the Cocacola brand designs which gives them an identity that soda drinkers anywhere are familiar with.

The miniature suit case idea also evokes nostalgic feelings for any Kenyan who had to drag their big and heavy metal suit case to school every new term. Other innovative products at KICK are pen and file holders, jewellery as well as danglers all made in metal. Some of these are painted decoratively to add variety to the range. The use of water hyacinth fibre as a raw material in furniture making is also innovative. Hyacinth is a weed that is currently choking the shores of Lake Victoria and has greatly hampered fishing which is the main source of livehood in Kisimu and its environs. Efforts to rid the lake of this weed have so far been futile. Its fast growing nature makes it spread at alarming speeds. Most lakeside dwellers therefore view hyacinth as a nuisance and are not keen to see it at a ready source of fibre. A few artisans though like those working with KICK are experimenting with hyacinth and earning an income from it.

7. Potential

It is clear that the two enterprises discussed above have great potential to grow into medium sized enterprises. They both exhibit a good level of innovation by experimenting with new materials and improving on already existing designs. Paro potters are creating a niche market for themselves by targeting establishments such as restaurants which have thus far provided a relatively decent source of income. At KICK, the artisans have developed a range of products that are both appealing and evocative to their customers. In both cases, the entrepreneurs have made efforts to access the export market with some measure of success. Exportation has hitherto proven to be a daunting task for most Jua kali producers in the country.

The use of recycled materials as is common in Jua kali production mitigates to a large extent the degradation caused to the environment by the manufacturing process. The methods of production are also labour intensive and require little or no burning of fuel as is the case in metal work. In pottery however, the use of kilns to bake the wares necessitates the burning of charcoal or wood which is a non-renewable source of energy. One way would be to design a more closed, energy efficient kiln that uses less charcoal.

8. Proposals

Having demonstrated the innovative potential that Jua kali producers possess through the two case studies with potters at Paro and metal workers at KICK, the paper puts forward certain proposals that would act as catalysts to this innovative process. The proposals identify some of the stakeholders in this process as the:

- Government(s) of Kenya and other African countries,
- Researchers and research institutions such as Local universities and Non-governmental organizations engaged in active research,
- Market movers such as local distributors and exporters
- *Jua kali* producers themselves

The above named stakeholders are best placed in their respective capacities to creating an enabling environment that will encourage the growth of small scale industries into Medium

sized enterprises that are competitive and lucrative. This would create sustainable livelihoods for the entrepreneurs as well as provide opportunities for employment for a larger population.

The proposed measures to be taken in an effort towards sustainability are:

- Provision for accessible and affordable licensing and registration for *Jua kali* entrepreneurs by the relevant Government ministries. Currently the registration process is arduous and expensive and most entrepreneurs prefer to remain informal with the result that they have little or no access to business development services such as credit facilities or training. A one-stop-shop process of registration that is also cheap would encourage the producers to formalize their businesses.
- Research and development programmes by Local universities and other research institutions to improve *Jua kali* production and entrepreneurship. Research into the extrinsic and intrinsic processes that affect and influence Micro and small entrepreneurship would provide possibilities for greater innovation through experimentation and collaboration. Presently Research institutions such as universities operate in isolation as they do not actively involve other stakeholders into the research process. Programmes that would bring together researchers and Jua kali producers in a mutually collaborative process would provide a platform for the improvement of design and production processes as well identify marketing opportunities for their finished products.
- Use of Indigenous Knowledge systems to design products for local use and export. The exploitation of indigenous knowledge has been ongoing but it has brought little benefit to the locals who own the knowledge. It is therefore necessary to allow the locals who own the knowledge systems to also own the process by which these indigenous knowledge systems are exploited. This can be done by involving the locals in the marketing and distribution of products as well providing information that would enable the local producers to access export markets.
- The use of recycled materials and renewable sources of energy as sustainable means for Jua kali production. Jua kali producers have become adept at using recycled materials to produce their wares. This can be attributed more to the availability and cheapness of these materials rather than the producers' sensitivity towards preserving the environment. It would be important therefore to provide information on the need and benefits of preserving the environment through recycling and efficient use of energy.

These proposals are in no way conclusive and should be buoyed on a foundation of good governance which has sadly been lacking in most African countries including Kenya. It is important for governments, the academia, the civil society and private enterprise to rise to the occasion and forge the path towards industrialisation for Kenya and the rest of Africa by carrying out their respective roles as well as collaborating in ventures that will improve the lot of the Micro and small scale entrepreneurs who form a majority of the population.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Beyond Abundance

Motivations and perceived benefits underlying choices for more sustainable lifestyles

Anne Marchand[1], Stuart Walker[2], Tim Cooper[3]

Abstract

The paper presents the results of a study that explores the implications of responsible consumption for sustainable product design. The study forms part of a larger research program that examines material culture and design and production for sustainability. Within this present study, information gathered from citizens attempting to follow sustainable lifestyles shows that the adoption of sustainable consumption patterns is not only motivated by altruistic and environmental considerations, but also, significantly, by perceived personal benefits, including an expected increase in personal well-being. These motivations, together with how they unfold into preferences for particular product characteristics, are discussed. The paper underlines that the understanding of such motives may warrant more emphasis as it seems to represent a key incentive for change.

1. Introduction

The need for 'lighter' patterns of consumption, particularly in industrialized countries, is widely recognized as an essential step towards a more sustainable future (United Nations 2002; OECD 2002). The idea that people's choices, behaviours and lifestyles play a vital role in moving towards more sustainable patterns of consumption in particular, and towards sustainable development in general, is a point of agreement in international environmental policy debates (Jackson 2004).

For the individual, participation in the vital but still fuzzy project that is 'sustainability' can be realized by adopting more responsible consumption patterns. Broadly speaking, responsible consumption refers to minimizing the negative environmental and socio-cultural impacts related to consumption choices, the amount of goods and/or services consumed, and the acquisition, use, maintenance and disposal of a product. It involves consuming less and consuming differently (Cooper 2000). Furthermore, it could be said that sustainable consumption requires "getting more with less, not more stuff but more satisfaction" (Manno 2002, p. 67). However, UNEP suggests that "sustainable consumption is not about consuming less, it is about consuming differently, consuming efficiently, and having an improved quality of life" (UNEP 2000). One could be sceptical with respect to such a statement, where 'differently' mainly refers to the consumption of more eco-efficient products and does not necessarily include consuming 'less'. Indeed, "[e]vidences suggest that environmental gains from technical improvements in product efficiency have historically been outweighed by an overall increase in consumption" (Carley, Spapens 1998, cited by Cooper 2000, p. 51). As discussed by Fuchs and Lorek (2005, p. 261), "[t]here is a substantial amount of controversy regarding our ability to achieve sustainable consumption on the basis of improvement in efficiency alone".

More directly with regard to product design, sustainable consumption " […] involves rethinking how needs are met and products are conceived" and " […] will involve finding a mix of products and services through which consumers will be able to buy less, use less, and dispose of less without suffering a loss of well-being" (Cooper 2005, p. 50). Within the larger research program, of which this current study is a part, relationships are emerging that bring these issues together: getting more satisfaction from goods, consuming less, recovering and maintaining goods locally, re-presenting older goods in new ways, and re-designing products for ease of upgrading (Walker 2008a; Walker 2008b; Marchand and Walker 2008; Walker 2007; Dogan and Walker 2006). These directions represent a significant challenge and offer new opportunities that recognise not only the functionality of 'things', but also how we relate to them.

Responsible consumption implies important lifestyle changes and the development of different attitudes towards the material world. With regards to lifestyle choices, this is an area where design can play an especially important role. Imagining the unknown, visualizing alternatives, and proposing desirable scenarios and solutions are the areas of skill and expertise that characterize the profession. Design has a significant contribution to make, since it has the potential to envision new practices and ways of organizing daily life (Manzini and Jégou 2003).

To develop such solutions and to present them in ways that are both feasible and appealing to a broad public, it seems essential to understand the motivations that have already led some people to adopt more sustainable lifestyles and the nature of those products they especially appreciate. These understandings can contribute to the development of design solutions that are in accord with the needs and preferences of people already choosing to consider responsible consumption. Potentially, they can support new initiatives among others by offering alternative forms of products, perhaps in conjunction with a locally available service, and by positioning them in a way so they gain added value with regard to social, environmental and individual benefits.

This paper presents results from a qualitative study conducted among citizens who, on a voluntary basis, have decided to diminish their levels of consumption and opt for more ecologically sound products. The study examined motivations underlying the re-orientation of their lifestyles and how these changes in lifestyle and attitude were expressed through product preferences. An important assumption underling the research is that, by seeking a better understanding of the positive changes that are currently part of the social fabric (as is the case with responsible consumption initiatives), design has the potential to support these transformations and to participate more actively in the project of sustainable development.

In the second section, the methodology used to gather the information is presented. In the third section, the results of the study are presented. These show that the respondents choose to adopt more responsible consumption practices not only for eco- and socio-altruistic motives, but also because of perceived individual gains. The relationship of these perceived benefits to preferences for particular product qualities is described. In section four, the authors discuss the potential advantages of simultaneously promoting the environmental, social and *personal* benefits of responsible consumption and sustainable lifestyles in general. Finally, section five outlines the potential design implications of giving greater recognition to the self-interest motives behind moderating our consumption habits.

2. Motivations Behind More Sustainable Lifestyles

The research program, of which this present study is a part, examines material culture and *design and production for sustainability* from two principal perspectives: from the design and production side, including the integration of scales of production so that product production, maintenance, upgrading and recovery can be achieved at the local level; and from the design and consumption side, which investigates different factors driving consumption and lifestyle changes. The various strands within these two broad, integrated themes, include design-centred research as a significant element of the methodological process and in which the development of many notional or conceptual designed artefacts are created, as an essential aspect of the knowledge advancement. Hence, the research program explores new interpretations of product production that begin to include 'localization', perceptions and values of what might be termed responsible consumers, and these are integrated via concurrent engagement in the activity of designing.

The goals of this present study were a) to gain insights into what might be termed a responsible, sustainable material culture by seeking to understand the choices, preferences and perspectives of identified sustainable consumers, and b) to use this information to identify key implications of sustainable consumption for the design of products, especially in the areas of sustainable product design and aesthetics. The study sought to understand the potential of sustainable consumption and lifestyles, the lessons it holds for product design and production, and its implications for material culture. The paper focuses on one element, among others, that emerged from this study, that is, the observation of self-interest motives for responsible consumption (RC) and lifestyles and its relationship to product preferences. Broader findings are presented in an earlier paper (Marchand and Walker 2008).

In order to gain insights among citizens who choose to integrate ecological considerations in their consumption practices, and more globally in their daily life, research has been conducted among citizens who practice some form of simple living or voluntary simplicity (VS). From a research point of view, voluntary simplicity presents a number of interesting characteristics: its adherents constitute a recognized group with a relatively well defined culture; they present themselves as responsible consumers; the movement is documented in academic literature (Grigsby 2004; Zavestoski 2002; Shaw and Newholm 2002) and people who adhere to voluntary simplicity principles are accessible (e.g., through organizations, conferences, activities, and

various discussion forums on the internet). As described by Porritt (2005, p. 11), the VS philosophy can be expressed through: "[…] maximizing one's quality of life while minimizing one's dependence upon a wasteful, energy-intensive standard of living […]". Voluntary simplifiers, who not only consume less but also consume in a more environmentally and socially responsible manner, can provide interesting and important insights for research into product design for sustainability.

Many authors (Reisch and Scherhorn, 1999; De Graaf et al. 2001; Maniates 2002; Etzioni 2003; Porritt 2005) see voluntary simplicity as a response to consumer culture that holds lessons for a more viable, sustainable society. With regard to what might be termed 'regular consumption' and 'regular living' in contemporary, industrially developed countries, voluntary simplicity adepts are more likely to adopt attitudes and practices (based on a study conducted by Craig-Lees and Hill 2002) that include:

- limiting their consumption in terms of the volume and quantity of products purchased;
- choosing more socially and ecologically sound products and/or services (including more 'local' products;
- using product-service-systems;
- repairing, exchanging, and creating products;
- investing in their communities;
- consuming less meat and processed food;
- favouring natural materials and organic food;
- favouring living in dense cities or in rural areas (rather than in suburbs);
- placing less value or importance on work as an activity while still wishing to have a meaningful and interesting job and/or reduced work hours;
- practicing 'low' environmental impact leisure activities.

Firstly, the study included participant observation through researcher participation in existing voluntary simplicity group meetings at which people discuss, among other things, their experiences in relation to responsible consumption and sustainable lifestyles. More than forty (40) meetings of two hours duration were attended, representing over eighty (80) hours of participant observation. Field notes were taken as a means of data collection. Belonging to the tradition of ethnography in anthropology, participant observation requires that the researcher becomes a participant in the culture or context being observed. This first phase of the study permitted the examination of different profiles of people interested in voluntary simplicity lifestyles and responsible consumption. It allowed the identification and documentation of comparable and contrasting profiles and led to the AAAA Model of Sustainable Consumers (Marchand, Walker & De Coninck 2004, based on Hansen and Schrader 1997 and Cooper 2000):

- **Abstention**: refraining from consumption or, in some cases, consuming less;
- **Attitude**: regarding consumption that exceeds one's basic needs as rather negative;
- **Awareness**: choosing products on the basis of their broad-based ecological qualities;
- **Alternative**: identifying substitutes to traditional consumption (e.g. switching from product to service; borrowing instead than buying).

Secondly, in-depth semi-directed individual interviews were undertaken with eleven (11) participants who especially fitted the AAAA Model in their attitudes and reported actions.

Simplifiers who report consuming less while not significantly opting for greener products and/or practices, as well as those likely to opt for greener goods while not considerably reducing their level of consumption, were not included in the individual interview stage. The interviews, of one to three hours duration (depending on whether respondents wanted to meet once or twice) were recorded and transcribed, and analyzed using qualitative research methods. The interview guide used to conduct the semi-directed interviews focused on the following themes:

- the ways in which respondents experience responsible consumption and their underlying motives;
- the place functional objects occupy in their lives;
- the qualities they value in functional objects;
- their representations surrounding the concept of sustainable product;
- the way positive aesthetic experiences are lived;
- the resulting visual culture.

To stimulate exchanges with the researcher, participants were invited to photograph objects they value. In addition, products and/or photographs of products were presented to the interviewees, and they were invited to comment on the meanings and values they felt were embodied in the object's formal qualities, and the relationship of these meaning and values to sustainability.

With the permission of the participants, the interviews were recorded using an audio recording device. These data were transcribed and coded following themes emerging from the data (eg. search for autonomy; time in relation to object; products' affordance; life span; relevance and purpose of objects; source and origins; quantity of material; etc.)

Based on the key informant interviews conducted, and the work of other researchers in the field, the following section describes some self-interest motives that have been identified as important incentives for engaging in responsible consumption patterns. Links are considered between these motives and particular product characteristics that are appreciated by the interviewees.

3. Perceived 'Individual' Benefits and Product's Qualities

"To have useless things, or semi-useless things around, it clutters my thoughts"

"I think that in some ways, getting rid of things you don't really need allows you to gain the time you were using to maintain this stuff, so primarily it gives you more time to spend with people"

"You need to think in terms of durability and not to be too dependent on money and having to work like a fool in order to afford everything the companies try to make you believe that you need."

"Stuff is complicating life"

"Commuting by either biking or running to my work allows me to incorporate a way to get some exercise while also saving money"

> *"The more you want time for yourself, the less you need to spend. The more you spend, the more you need to work and the less time you have, so for me luxury is not about a gold ring or a gold watch, for me luxury is time"*
>
> *"In thinking about my relationship with things, I want to be in charge, I don't want them to run my life, it is there for me to use"*

Among key informant interviewees, perceived individual or family benefits acted as important motivations for adopting sustainable modes of consumption, and more sustainable lifestyles in general. As reported by participants, such lifestyles are considered as ways of achieving a better quality of life while participating in the larger project of sustainable development. This finding is not surprising since this position is part of the voluntary simplicity culture to which the interviewees belong. Here, it is important to remind the reader that this paper focuses on the *self-interest* motives for responsible consumption and that participants' commitments to responsible consumption also include significant eco- and socio-altruistic motives that are not discussed here.

With regard to self-interest or perceived individual benefits, the following elements emerged from the individual interviews as central factors:

- having more time;
- reducing stress;
- having a healthier, balanced lifestyle.

Among these respondents, consuming and possessing a 'large' quantity of goods, and the associated dependence on work and/or credit to acquire these goods, as well as the pursuit of income growth, is perceived as having severe negative impacts on the individual, family, and on the quality of social relations with others. Such motives for 'downshifting' are well documented by authors such as Juliet B. Schor in *The Overspent American: Why We Want What We don't Need* (1998) and by Tim Kasser in *The High Price of Materialism* (2002); both authors discuss the hidden costs of high consumption. As mentioned above, based on the interviews conducted, these motives are linked to product preferences and attitudes towards the material world.

The eleven participants interviewed all said that they regard possessing a large number of products as a source of stress because these products have to be maintained and repaired and, in addition, protected. They stated that having 'too much' is a burden because of the energy and time required to care for and care about these possessions. All respondents reported trying to reduce the number of objects they possess by giving away goods they don't use or that aren't important to them, or by avoiding or reducing purchases to minimize accumulation.

> *"Responsible consumption is also a way to tend towards a reduction of purchases and, more globally, a reduction of everything that is material around you, I think we all need to do this because we are cluttered by a bulk of objects"*

When acquiring products, they tend to prefer objects with a limited number of features. 'Simpler' objects, characterized among other things as those offering less features and options than most commercial mass-consumption products, are perceived as less likely to break and, therefore, less likely to require repair or replacement. Objects offering fewer but carefully selected features and options are appreciated.

> *"In general I try to avoid objects full of gadgets of superfluous options and I try to take the ones that are as simple as possible […] in terms of functions and accessories, sometimes I will go with the middle because some functions are sometimes interesting, but usually I take those that are as simple as possible"*

Participants were more likely to rent objects and to make use of product/service systems, such as car sharing or children toys rental services. The car sharing system was presented an option allowing them to benefit from the utility of a car when needed while investing less energy, money and time in the different aspects of its maintenance. One participant also mentioned a

service he found very interesting, and to which he planned to adhere, which allows citizens to rent art pieces created within the community and to exchange them every month or two with others subscribers. He appreciated that these artefacts are becoming accessible through this service and that this service challenges the traditional 'owning' and 'possessing' culture, while supporting the local artistic community. In such ways, participants sought alternative ways to respond to their needs.

> *"The first question that I ask myself is do I really need this and can I rent it instead of buying it, can I borrow it, and often finally the answer is yes, there are other ways, we don't always need to go and buy a product"*

In relation to time, as they reduce the level of their consumption, and by extension their expenses related to the consumption of goods, respondents commonly express a feeling of being less dependent on work and income. Several people reported having shifted from a full-time job to a part-time job or had reduced their working hours – all in an attempt to overcome the work/spend cycle. Partly because alternatives are not easy to find, but also to reduce expenses, 'do it yourself' (DIY) appears to be a popular practice among respondents who, for instance, report being inclined to make food from basic fresh produce, and make, as well as repair, their own products and take pleasure and pride in doing so. While the creative interventions of participants with regard to objects are modest, untrained and amateur - and therefore, in comparison to more 'designerly' examples might appear inept or undistinguished - their benefit and contribution does not lie so much in their professionalism or refinement as objects but in the fact that they are user-generated and represent an individual, conscientious counter-response to consumerism.

> *"If you work a lot, you may get a lot of money but […] you don't have time at home. When you decide to evaluate what are your real needs and how many hours of work are necessary to meet these, with a part time job, you can have enough for everything that you really need and then you get time with your family, you get some time to make things that you will not buy because you have time to make them […] It's a different way to see the relationship between work, time and money."*

With regard to second-hand goods, some interviewees participate in locally organised goods exchange groups. For example, one respondent uses *FreeCycle*, a platform available on the Web that allows people to give and acquire products for free in their geographical area.

> *"If we are making less money then we are almost forced to be more creative in the objects, the things and the way we are consuming"*

Participants share a preference for products that they perceive as long lasting, which can reduce the need for product replacement. On this topic, one respondent suggested that designers should create products that can evolve and be updated. Products designed for one specific use, in contrast to multifunctional products, are perceived as more likely to last over time. Although they report preferring "products that do one thing but do it well" as one participant has put it, in turn, many specify not hesitating to use objects for functions other than the initially intended one. For example, one respondent, who preferred having fewer objects in her kitchen environment, but used them in different ways, explains using the lower part of a cake tray to serve vegetables or other foods. She also uses a self-standing pasta and vegetable colander as a fruit bowl even if she has to remove the fruits from it when needed for the intended function of the object. She was directly pointing out that she can do 'more with less' and that, in many cases, only conventions prevent us from transforming object functions so as to respond to our needs with fewer goods.

> *"Commercials are trying to sell things to do a function that could be done with stuff that we probably already have"*

Finally, and in sum, throught the interviews, participants expressed the idea that consuming in a more sustainable way plays a positive role in the pursuit of the 'good life' at the level of the individual. Before presenting some potential design implications related to greater acknowledgement of self-interest motives for responsible consumption, the next section offers a

brief perspective on the notion of self-interest as an important factor for RC, together with more eco-altruistic and socio- altruistic motives, as shown during the interviews. This notion of self-interest appears to be a somewhat sensitive issue in the context of sustainability because it can be perceived as a cause of our underlying environmental and social problems.

4. Self-Interest and Altruism

According to De Young (2000), self-interest is traditionally seen as a major source of environmental problems. He reports that this 'presumption' was central to much of the early research on environmentally responsible behaviours. Self-interest was strongly associated with the egocentric nature of humans as "[…] gain-maximizers, having evolved to consume resources with little or no concern for efficiency, to pass waste and costs on the others, and to form small groups that exclude and neglect the interest of others" (p. 514). These behaviours would seem to be in stark contrast to socio-centric and eco-centric motives needed for environmentally responsible behaviour. However, De Young notes that more recent research suggests that self-interest and personal benefits derived from environmentally responsible behaviours can be part of the solution to environmental problems and can work in concert with altruistic motives. According to De Young, it is important to distinguish self-interest from selfishness since the former is often not acknowledged as a constructive and positive motive because it is, mistakenly, equated with the latter (after Perloff 1987). He further argues that "[…] selfishly consuming resources or creating waste without concerns for others is quite different from taking care of yourself […]" in order to be in "[…] a much better position to take care of others who cannot take care of themselves or to advocate for the environment" (p. 515).

In the same vein, Kaplan (2000) sees the altruism-centred approach as "[…] having several inadvertent consequences, including contributing to helplessness and stressing sacrifice rather than quality-of-life-enhancing solutions" (p. 491). Kaplan argues that the altruistic model, closely linked with the 'dour environmentalist stereotype', undermines appeals for environmentally responsible behaviour and may prevent powerful linkages with critiques of materialism as unhealthy and unsatisfying at the level of the individual. The author further writes:

> *At an intuitive level it is not surprising that people resist making changes that they perceive as reducing their quality of life. It is also not surprising that people are concerned about the future of the environment. Perhaps a broader view of human nature, one that encompasses more than material gain, could provide a way out of this impasse. A central failing to the altruistic position is that it attempts to put aside the issue of gain, of self-interest, in human behavior. The 'economic man' position, by contrast, argues that all gain is all that matters. Neither position is satisfactory; there is need for a position that is neither so extreme with respect to the issue of gain nor so narrow in its focus". (p. 496)*

Kaplan proposes that self-interest and altruism should no longer be seen as opposite poles. This present research suggests that, in design, developing solutions that more significantly consider both these motivations, and that are positioned as such, have the potential to support sustainable lifestyles. Essentially, the *self-interest motivators* that have emerged from this research are strongly linked to notions of self-realization and of living a meaningful life; they involve things such as spending more time with family and friends, and are associated with reducing the causes of worry and stress, and alleveating a sense of discontent. These motivators align with Kaplan's 'broader view of human nature' that includes more than material gain, as well as long standing philosophies that recognise human needs as both physical and metaphysical,

individual and social. The next section explores initial and potential implications of recognizing self-interest motives for responsible consumption in the product design field.

5. Some Design Implications

Based on the study conducted, greater acknowledgement of perceived individual benefits for responsible consumption would foster design of longer-lasting, maintainable products. On the one hand, the consumption of long-lasting products could be encouraged on the basis of potential larger personal benefits to the broader public. On the other hand, designers would need to be capable of developing products that are physically and emotionally durable and potentially modular, updatable, easily repairable, and reusable. Clearly, to be economically attractive, new interpretations of business purpose would have to be developed in parallel. Businesses that currently see themselves solely as product providers would need to transform themselves into product/service providers which create economic opportunities through product maintenance and refurbishment, and through building longer terms relationships with the users of their product.

To further encourage increased product life spans, design would potentially have to extend its role to be more involved in maintaining, repairing and reusing activities - as users would be expected to look after their products and to have them maintained and repaired. Designers could be called upon to enlarge their practice fieldwork and act in the context of repair, reuse, and re-design within locally or regionally based facilities (Walker 2006, p. 76). A new area of practice in the domain of product life extension could emerge. Ideally, increased maintenance, repair and re-actualization or update of products, as well as more highly skilled and craft based methods, would provide employment opportunities and, to some extent, minimize the effect of reduced demand for new products on employment and on the economy (Cooper 2005). It is clear that increased product life spans, through better intrinsic durability and/or better care, maintenance and products' re-actualization, seriously challenges many aspects of our current economic system and this, too, will require development and transformation of more sustainable ways of living and working are to advance.

In terms of positioning design solutions that further respond to the self-interest motives of responsible consumption, an important communication and marketing element would be needed to reinforce the personal advantages of these solutions, in addition to the environmental and social benefits. This could potentially allow such solutions to reach people who are not already significantly committed to responsible consumption. These messages could emphasise the benefits of more personal time, less stress and healthier lifestyles, as recognised by the respondents in this study, notably, through the use of product-services or rental services, through a general reduction of consumption in order to be less dependant on work, and via the consumption of products that, by their 'intrinsic' qualities, are more likely to pass over time. Further research would be needed to understand the relationship between self-interest motives and how they can unfold into successful, meaningful messages. Research looking at motives of responsible consumption and its implications for the design and development of products would also be necessary since there is little data on this specific issue. The present research represents an initial contribution to this area, as the main research project to which the presented results belong was not only or specifically focussing on the issue of product design and self-interest for RC.

From the information gathered during this study, DIY activities appear as a noticeable practice among respondents. This has been expressed through the creation and/or redevelopment of objects and through practices such as cooking - to ensure the quality of the ingredients being used, amongst other things. This seems to be in line with an important trend in the recent years in which users initiate and are directly involved in design activities. An example

of changing realities where users are taking a greater part in the design process is the development of open-source software (ex. Linux, OpenOffice, Firefox) via the Web. Another example of this search for greater autonomy on the part of users may be found in the ecologically oriented *ReadyMade* magazine where readers can find recipes for making and remaking things, often re-using materials. It is uncertain whether such 'design-it-yourself' and/or 'do-it-yourself' approaches are more ecological. However, the desire to gain a greater sense of self-empowerment among some citizens is surely positive from a sustainable perspective. Such initiatives remind us that designers could also act as facilitators for users who wish to engage in design activities by providing suggestions and projects, and serving as a resource.

The interviews have also revealed a link between self-interest motives for responsible consumption and a preference for products offering a limited range of options, which are perceived as longer lasting. Such qualities give respondents the feeling that they have greater control over their products and that they can repair them if broken, or at least understand what is wrong. As with aesthetic qualities, it seems increasingly important for designers to be aware of and to understand these perceptions and ideas in order to design products that are adapted to the expectations of responsible consumers.

The study also reveals that participants are disposed to switch from products to product/service systems because, in cases such as car sharing, the product/service system allows them to benefit from the utility of the product when they need it while investing less energy, money and time in caring for, being worried about, and maintaining the product. Therefore, design would further need to be able to propose not only *product focussed* outcomes, but also imaginative *solution focussed* outcomes where the same benefit is achieved in a more sustainable way.

To develop appropriate, alternative design solutions that encompass individual benefits related to responsible consumption, an inclusive, 'interactive' and dynamic relation between users, enterprises and designers will be essential. Scenario building methods (Manzini and Jégou 2000), through which design solutions for the present are derived from desirable futures (i.e. backcasting) that are imagined conjointly with users, is a good example of a methodology that can be used for research and development (R&D) purposes.

6. Conclusions

The conference *Changing the Change* seeks to make a significant contribution to a necessary transformation that involves altering the direction of current changes toward the project of a sustainable future. In this regard, this research suggests that design can contribute to this endeavour by proposing sustainable solutions which, by their very nature and by the way they are presented to the broader public, gives greater consideration to self-interest motives for responsible consumption. We argue that individual benefits resulting from the adoption of sustainable lifestyles should be more directly recognized in the development of more responsible and sustainable products and product/service solutions, and that these factors can take a much greater role in the marketing and positioning of such solutions to the public. Interdisciplinary research in this direction should be conducted in order to further explore the potential and viability of such a proposal.

Here, results have been presented of a study that looked at the motivations related to the perceived gains in quality of life among individuals who already act as responsible consumers. The study revealed how these motivators are expressed through preferences for product qualities. Among the participants at least, the seeking of more time, less stress and a healthier lifestyle are associated with a preference for design solutions that require less care in their maintenance phase and a reduced need for replacement. Information gathered during the fieldwork has been

used to identify initial design responses in relation with the findings. In terms of design methodologies, integration of contributions by responsible consumers in the design process has been proposed as an appropriate method for better understanding the role of objects in their lives and for developing alternative outcomes. With regards to product qualities, the possibility of creating products and structures that allow products to be upgraded, re-designed and re-presented has been suggested. Finally, the results indicate that there is a need to recognise altruistic *and* self-interest motives in the sustainability discourse within design circles, in order to broaden the debate about sustainable design solutions that are capable of connecting with people.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

DAC_Link

A 2.0 tool for SMEs' design innovation

Venanzio Arquilla[1], Davide Genco[2]

Abstract

This paper describes a specific tool (DAC_Link) aimed to create a permanent meeting place to exchange knowledge and generate innovative projects by using ICT, supported by both University and Entrepreneurial Associations as trust generators (Fukuyama 1996).

DAC_Link represents the systematization of a two-year experience and concrete experimentations (DAC and DAC_Tool) based upon the action-research framework and the mechanism of the design knowledge and technology transfer (Tasch A.F. 1995) through the physical transfer of innovation agents (newly graduate designers) into companies.

DAC_Link aims to create an open source creative arena for designers and companies, low cost and low impact, a place to generate collective intelligence (Lévy 1996), changing the relation between young designers and Italian SME's.

1. Introduction

Since the Eighties, the modern economy hasn't followed a standard model, on the contrary it has been organized in several different national capitalisms, each having different stories, cultures, behaviors and institutions (Bonomi, 2005).

The fast and fluid changing market place in a competitive global context (Bauman, 2002), the increasingly aggressive competition (due to the reduction of production costs and not only) and the high variability in the usage and mixing of products and services imposes to companies, especially SMEs and Craftsman Firms, the development of new abilities, in order to generate visions and interpret the signs of these changes.

In this context the industrial structure in Italy looks highly fragmented: it shows originality in the path and in the strongly characterized competitiveness. This has lead to the development of an articulated system of small companies and local systems, generally within traditional sectors that comprise the so-called "made in Italy".

The products that are worldwide known as design masterpieces belong to those sectors; they fill the main specialized magazines, win awards and are exhibited in the most important museums. We are referring to products of the traditional manufacturing sectors that Fortis M. and Quadrio Curzio A. synthetically defined as *made in Italy,* meaning those sectors producing personal goods (Fashion, Apparel) and house goods (Furniture), as well as mechanics and last but not least food. They all fall under the following definition: "*all the excellent products of the Italian production system in their whole: not just fashion, which is one of the most famous examples, but also the other manufacturing products for which Italy has become, after the Second World War, international leader…thanks to design, innovation and quality of the products…"*

Many systems, with different degrees of complexity, to share the work among several small and mainly B2B companies were developed in these kinds of sector, protected by lower technological and financial barriers than others. Those companies are supported by local networks (industrial districts) or by supply and sub-supply chains (production lines) (Becattini 2000), which cross several places, nowadays even non-contiguous ones (meta districts)[3].

The network production of the Italian meta-districts, districts and production lines is able to offer, at a low cost, a wide variety – niches, a prompt variability – adjustment speed and a strong capability of managing unplanned situations which might occur throughout the process – on demand production, and flexibility in answering the customers needs (Bonomi and Rullani 2005).

The main issue regarding this system is that there is no detailed analysis of opportunities, risks, market trends aimed to develop new products consciously and efficiently: innovation still follows a Darwinian architecture, where the market is the final filter and the input to trigger new ideas (Legrenzi 2005). On top of this, there is a deeply rooted mistrust toward ICT, both for internal issues tied to the managerial and organizational adjustment, and for the tendency of the companies to protect their own established "physical" distributional network ("Questione dimensionale", Traù 1999).

It has already been proved that, in the future, companies won't be able to innovate only by means of a strictly technological investment. From this perspective, where companies move toward strategic requirements, design is becoming essential as a value of the product-system. In its latest definition (even if not yet univocally established) the design discipline has definitely evolved from the status of "applied-art" or "artistic-creative" discipline, thanks to its multi-

[3] In 2001 Regione Lombardia was the first Institution to introduce the idea of Metadistrict: a thematic intervention area of a horizontal nature, non geographically restricted and pushed toward a strong inter-sectorial integration, characterized by applying the knowledge gathered.

disciplinary (or multiversa) (Bertola and Manzini, 2004) core, acquiring dignity, as well as at the economic and managerial level (Fortis 2005, Bettiol Micelli 2005, Rullani 2004…)., as a possible or even unique way to innovate the system of Italian SMEs.

There should be a dialogue and a link among the industrial production centers and centers for knowledge and thoughts management (universities and research centers), and there should be a contamination among traditional jobs and new contemporary visions, visions that can be brought to the company by young creative designers.

The emerging need is to create fields in which designers can establish more intense knowledge-sharing relations, in order to trigger initiatives for knowledge investigation and enrichment, originating from the professional practice within the specific district context.

An innovation process, the heterogeneous nature of which implies the connection with globally wide experts networks and with the scientific (research centers, universities…) and technological (R&D labs) research networks, is required to be triggered; in fact the designers' creativity has to be integrated and developed through the comparison with different cognitive fields and skills which can give stimuli, ideas, original point of views to be transformed into product innovation.

The design and unaware SMEs world are apparently different from one another, each comprising a wide set of values, knowledge systems, skills, abilities. However, they both need to meet in order to shape sustainable development plans for the national economy. In this framework the design research system, in a country such as Italy where structured actions in the design field are not foreseen, is the one and only possible bonding agent which can link all these distant worlds. It is the tool that can make the design innovation capabilities clear to the business, institutions, bureaus world, and to the design world the field in which the global competition takes place.

Facing the changes of the design discipline, also the university research has changed, non taking the shape of a closed academic model, but of a system that proactively aims to get universities and the SMEs world close to one another, suggesting ideas, projects, services.

There is a strong need for a design culture by the companies with a production know-how, but very far away from the current market trends and from the necessary vision to realize products that meet the taste of increasingly demanding customers, which don't look for products but for "experience" (Pine and Gilmore 2000) and "emotions"(Norman 2004).

Thus, there is the need for triggering a design-driven innovation model (Verganti 2006), based upon radical innovation, while trying to re-trigger innovative processes which led to the Italian design historical successes of micro-companies which currently are real brands (Artemide, Alessi,…)

However, in these terms, the work to leverage design and to re-launch the Made in Italy should mainly proceed along two parallel routes: one aiming to strengthen the presence of designers in the luxury market (Celaschi 2003), collaborating with the main companies, the other one aiming to shape a basic culture about design in less structured SMEs, in order for them to make the dimensional change, to relate with design and produce design.

2. The design research for SMEs. The DAC case, Design for Arts&Crafts

With a series of pioneering research and further on action-research projects, the Dipartimento INDACO, the Facoltà del Design and the Consorzio POLI.design of Politecnico di Milano, together with the other Italian Universities relating to the SDI | Sistema Design Italia network, started a research path and a series of actions which led to test, at a national level and in some districts, innovative collaboration and knowledge transfer models between official design

system and companies. The most recent experience is represented by the DAC project: Design for Arts&Crafts.

Its main objective, which has become real with the DAC | Tool project, was the creation and testing of a *replicable model* aiming to spread the design culture as a distinctive element for SMEs and Italian handicraft businesses.

Based upon the action-research framework, DAC uses the mechanism of the design knowledge and technology transfer (Tasch A.F. 1995) through the physical transfer of innovation agents (newly graduate designers) into companies. With the researchers' support, this mechanism leads to develop product, service and communication projects together with the companies themselves. This model is so called human capital growth (Romer 1989) and adds expertise to the company, in an action-based perspective. The project was developed through a practical process of learning by doing and learning by interacting, through which the companies (previously unfamiliar with design) had the chance to understand and apply the design innovation potentials, while young designers experienced real working situations, deepening technical knowledge on products and production processes (Arquilla 2006).

In its two editions the project resulted in the development of 38 specific projects for and with 34 Lombardy companies at all levels of the production line, in collaboration with 38 young designers, newly graduates from Politecnico di Milano, for a testing period of over 36 months. During the development time of each business project, there has been a *continuous knowledge exchange*, a mutual growth between the designer and the company and a fruitful communication about the respective methods.

The final results show that designers have given to the companies stimuli and suggestions coming from the global contexts, especially regarding the market trends, the new habits and the users lifestyles, according to their systemic vision, bringing to the company some elements of a renewed design culture. On the other end the entrepreneurs gave their contribution in concretizing the design activity, steering the choices in relation to the abilities and typical competencies of the product culture. The dialogue between the design culture and the product culture generated a positive cognitive circuit, which allowed, in each instance, the projects to be realized, going over the objectives set by both companies and designers. Furthermore, the relations established with the companies went beyond the project duration, often generating new businesses founded by the participant young designers, on the basis of the experience.

3. The DAC_Link project

DAC_Link, the project presented in this paper, is based upon the results gained by the DACs: it aims to bring the previous experimental experiences at a level that allows Designers and Companies to have continuity and self-generation in the design and innovative impulse.

While the ICT saw its success, the knowledge coding, transmission and acquisition costs have been largely reduced; as a consequence, knowledge has become a more replicable and mobile resource, increasingly independent from space and time (Rullani 2004). These evolutions support virtual remote cooperation contexts. The new forms of cognitive work division take the shape of virtual communities, social learning platforms which find in the network technologies the main support to their activities (Micelli 2000).

Thus, if designers and SMEs found their success upon the network organization in which they operate, it is evident how the Web can become an extremely functional supporting tool; from online trend analysis, it has emerged that social networking, a community format allowing to get quickly in touch with whoever shares the same needs or interests, is currently the ideal expedient to boost direct and transversal collaboration and generate the sense of belonging to a productive community which pursues innovation.

Yet, if creative professionals are surely ready to put their profession at stake on the web, as the success of sites such as Coroflot of Core77, (www.coroflot.com), LinkedIn (www.linkedin.com) and the Italian Qoob (www.qoob.tv) shows, we can't assert the same for companies, still far away from the online sharing logics. The aim of the project is to gradually reach a communicative symmetry allowing both actors to extend their line, and consequently their competitive and innovative potential while articulating the community, which can maintain a balance between company and creative world, while identifying uses and benefits for both of them.

This kind of intervention needs to be supported by a design project that can satisfy the need of its main interlocutors to participate and cooperate through the use of a communicative and functional language and interaction modalities: a design solution that we believe deserves to be discussed and investigated in this paper.

The DAC and DAC_Tool projects represented, at the Lombardy region level, the concretization of that professional network thanks to which the University communicates with young professional from one side and SMEs from the other, while the associations are the intermediaries.

DAC_Link aims to widen this network to a national, maybe global, level, through the use of ICT mediated by a design-oriented approach in a soft and mediate social networking way.

DAC_Link aims to create a permanent meeting place for knowledge exchange and to generate innovative projects, while changing the relation between young designers and SMEs unfamiliar with design. The tool aims to define a virtually shared arena, a place to generate collective intelligence (Lévy 1996), supported by both University and Entrepreneurial Associations as trust generators (Fukuyama 1996).

In this perspective, DAC_Link is a design project thought to promote design at a systemic level: if design could get certain kinds of users close to new technologies, it could be possible to trigger the same dynamic to get users unfamiliar with design close to design itself.

4. Methodology

Since the very beginning, the design approach had to face the need of an innovative proposal to live together with the pursuit for simple solutions, in order to attract from one side actors coming from a creative and extremely productive and open design world (young designers), from the other companies, as stated above, culturally wary of the use of new technologies and of knowledge sharing.

As already mentioned, the project is based on the Internet technology: the preliminary analysis was then aimed to investigate first of all the main aspects of the evolution of the Network intended as Web 2.0, then to verify where those characteristics were successfully applied in relevant case histories.

The main aspect that characterizes the Web in its current evolution is the collaborative and participatory use of tools and network services with high added value in terms of user experience. Some obvious examples are blogs (on line diaries), Wikipedia ("the free encyclopedia that anyone can edit"), Skype (the peer-to-peer phone service), OpenOffice (the co-developed and open-source platform for document processing), Flickr (where contents are shared), and the customization and immediacy of Feed RSS.

Nowadays we talk about Social Read/Write Web (srww), in which each user is editor, user, distributor and collaborator at the same time. Internet is more and more considered as a platform supplying services while leveraging on collective intelligence, able to guarantee shared information and OnDemand contents. Its value is generated and measured by the users themselves, reaching the extreme example of the UGC (user Generated Content); other decisive concepts in srww are Perpetual Beta: continuously evolving products/services always subject to collective tests, and LongTail as the base for stable business models.

Thus, Internet becomes more and more the tool to create and strengthen relations among people. The quality of the users' experience in using new srww services is a crucial factor in determining how successful is a web service: users look for the environment (and markets) in which conversations and relations with other users are exalted.

The online social networking definitely belongs in this field: it is based among the 6 degrees of separation concept, which the sociologist Stanley Milgram introduced in 1967: it refers to the idea that everyone is an average of six "steps" away from any person on Earth.

This finds application in virtual spaces which start by linking to one another people that already know each other; connections with friends and acquaintances then allow to establish relations with unknown people, friends of friends, exponentially widening the personal virtual network, as well as the real one, potentially –and ideally– comprising the whole world population. The users aggregation can develop around specific contents and subjects, or simply aim to develop friendly relationships, meet new people or establish professional relations.

In this instance, the interaction among professionals from different geographic areas and production fields is developed to establish relations which often become real business opportunities: for this reason, it is of extreme importance to be able to leverage the resources of a virtual community, as it represents a starting point to establish possible contacts within specific sectors or tied to complementary competencies. The social network then represents the main modality through which the concept of unlimited interaction and knowledge sharing at the basis of the Web evolution ambitions is developed.

On another side of the investigation, an in-depth analysis was carried out on successful case histories with similar objectives. The examined and analyzed sites are national and international, mainly institutional: from the research and innovation centers web sites (e.g. Politecnico Innovazione, MIP, Flanders DC), to the main international design centers (e.g. Design Council, BCD, DDI, CIDEM, Bai Bizkaia, CDRA, Design Vlaanderen, CPD, NORSK DESIGN).

These have been mapped in a graph that highlighted the relation between the communicative impact and the value of the service, trying to verify at the same time if, while playing the role of a "hinge", they'd be more targeted towards designers or companies, and using what language.

The sites were then evaluated identifying parameters (update; communication; information; tools; accessibility) which would take into consideration the contents, with special attention to the supplied services, for which a frequency index was defined. This index, appropriately adjusted to the Italian situation, led to the definition of the new offer (Fig. 2).

The result of the research highlighted that most of these sites, which share the aim to promote the design discipline as a crucial resource in the business field, prefer to communicate information through institutional texts (report, education, persuasion) rather than through the use of interactive areas which could transform the site itself into an intervention – not just support – tool. In the event of this last possibility being foreseen by the organization, it is assigned to an external site, a real project in itself.

A clear limit of these systems is that the actors are catalogued (database and directory) based on a typical system of databases (filtered lists of addresses/contacts). It was thus decided that the contact between companies and designers should be pursued with a much less technical approach, in favor of a more semantic and visual one, aimed to gain the interest of companies seeking for immediate feedback and to illustrate the benefits that design can bring in the long run.

The possibility to share computer-based resources, i.e. non mediated by a specific employed, cuts costs and time but, especially in regard to the Italian business situation, is not enough to go beyond the still existing limits in accessing the technologies.

This is where the idea of a further step generates from: using the social networking, counting on the easy participation, contents relevance, spontaneous generation of dialogue, continuity in the relation, intuitive information gathering and more effective tools to build and cultivate one's personal reputation on line, which will then reflect on the real world.

5. System's architecture

DAC_Link is based on a system which starts from the hypothetic online participation of all the actors in the innovation network: the creative class, comprising of professionals, newly graduates and creative companies, and the national districts companies will be involved in the site, in a regulated process, coordinated by the University and facilitated by trade associations, through physical and virtual windows. The aim is to generate a community, which establishes collaborative long-term relations, widening the network of relations and competencies thanks to the site's presence and activity.

Getting closer to the specific dynamics of the project, the home page plays a crucial role in catalyzing and publishing the activities of the community, and becomes the hub around which the whole service revolves. The home page should lead to a continuous access to the site, thanks to its visual appeal but most of all to the reliability of the contents: according to the philosophy of Web 2.0 it has to guarantee the constant update and the sources' trustworthiness. The DAC_Link home page was designed to respond to these needs, acting as a "shared board", the contents of which (mainly public bans, news and press releases) are published by the member of the community themselves.

The core of the site in terms of complexity of the information lies in the two sections dedicated to the Companies and Designers respectively. These two areas are extremely similar as they have advanced tools to search for competencies within the database of the community and they also have a selection of the users in the given category according to the latest update they made.

There is a "Services" area in which the technical and knowledge resources that the University puts at the companies disposal are communicated, and a "Best Practices" area which is named after DAC_Lab; in this area the design projects which were developed thanks to the online interaction –on the site– will be published. At last, a "Download" area will allow to view informative design material.

Other informative and institutional sections have been set up (information on promoters, press area, F.A.Q. etc..); they visually differ in the navigation menu, which hierarchies the site's contents to communicate where the core of the initiative is, meaning where it differs from a common window-site.

This is how the system works: from the home page, companies and designer can get a free subscription, and manage their personal profile including images and information about their activity. All contents are selected and published by the users, upon validation by the site's Admin.

The advantage represented by owning a personal space as part of the community lies in the possibility of building direct relationships among the different profiles, encouraged by the sites' architecture, which gives visibility and reputation to those who show themselves as the most active within the community, using the tools that it puts at their disposal.

Furthermore, the fact of being in the same space, a space which has a high reputation as it is managed by actors that already have a high reputation in the physical world, represent to the participants a further positive element in comparison with other realities outside the community: to subscribe to the service means to believe in the same design and business values interpreted by actuators and promoters, making the shift from simple "company/studio/professional with an internet site" to "active protagonist of the creative and business Italian community".

More in detail, subscribed Companies and Designers:

- manage a public personal profile with a gallery of selected images;
- can visualize entire profiles, including personal data (i.e. contacts);
- can publish news and update regarding their own activity;

- can participate and interact with the site through aggregation solution (e.g. blog/agenda, feed rss);
- can activate a working platform to develop projects with other people subscribed. The projects will become candidates for being published on DAC_Lab.

There is a third participation modality, especially dedicated to research institutions and trade association willing to participate in the initiative: this typology, defined as “Partner”, put at the subscriber disposal a description page and the possibility of publishing bans and information regarding funding – which also become visible on the home page.

Finally, those users which aren’t involved in any of the above mentioned categories (Companies, Designers and Associations), but which want to get updates on the activities published on the site, can subscribe to information and participatory services such as newsletters, free RSS and forums.

At this point it is easy to guess the importance of the backoffice, meaning the management panel which allows the subscribers to upload their content: usability and simplicity are factors that couldn’t be left out of consideration. This personal area also allows to develop design projects online, throughout all the design steps.

A very intuitive navigation system was designed, which defines 5 macro-areas of primary importance, and another 6 areas with the same depth but with “archive”, information “collector” functions.

The site architecture is designed so that the relationships that the community users can build are heterogeneous: not only among just companies or just designers, but the relations can and should transversally interlace among creative professionals, entrepreneurs and associations. For this very reason, the decision was made of considering the several areas not as monads not communicating with each other, but to always highlight the connections among areas.

A key role in the success of the system was played by the technological aspect: the level of innovation is not measured on the technical complexity of the available functions, but on the level of response to the requirements of the actors involved in the community: the technology shouldn’t represent the final goal, but be the “invisible” tool for the communication among the actors. The service was built using some of the best practices of the tools used by the Web 2.0. Furthermore, the Active Collab platform, an open-source tool for cooperative development of projects in the private area, was integrated in the system.

6. Visual interface

The graphics of the interface was designed thinking of an extremely heterogeneous target: in fact from one side an innovation project aimed at the creative class has to show a strong graphic character which is visually appealing. From the other side though, it was necessary to mediate the contents and information complexity of the service opting for aesthetic choices which represent both clear and simple solutions without becoming too conceptually synthetic, but privileging an explicit communication which uses pictograms, colors and well known metaphores.

Each affiliation modalities is represented by its own pictogram and color, which symbolizes the contents related to either companies, designer or partners/services.

If we examine the home page (Fig.3), it is possible to see that the main navigation menu (A) was designed to communicate clearly the contents hierarchy: the links to the DAC_link main services are in the biggest box, while the links to the descriptive static areas are in the smallest box, placed under the other one. Many web sites use a horizontal menu on the top and a vertical menu on the site to express this semantic difference: in this instance, the main area needed to be entirely dedicated to the visualization of the profiles, thus the idea of placing the whole navigation bar on the left hand side, which results in a sort of intuitive and always available site map.

The subscription form and the access to the control panel (B) are found in all pages, as well as a dynamic header, which presents some excellent case histories of collaborations established through the site (C).

As regards the contents of the main area, there are 3 levels of information in the home page. A short animation, which presents the community's actors, the advantages and the vision of the service, occupies the upper part (D); this area has a mainly illustrative function: it has to describe the service and encourage the subscription. The central part (E) shows the updates of the community and thus of the contents: especially the news that companies and designers publish, together with an image and a brief description, and the bans and funding opportunities published by partners and site's administrators.

Finally it is possible to see the updates in the single personal profiles in the column at the far left (F), at the bottom of which there is a mini-menu which allows to access to the participatory services dedicated to the site's subscribers. These contents show the dynamicity of the site according to the web 2.0 philosophy, even if they are visualized at a secondary level: news and financing calls represent the core activity of the system and the main motivation for users to subscribe.

The Companies and Designers areas look alike: the features and the actions allowed to the two kinds of subscribers are the same.

In the first area (G) the advantages of the subscription are described: below (H) there is a list of subscribers in the given category, presented according to the latest update and completed by a preview of the subscribers' avatar. Finally, in the lower area (I), a high importance – and space – is given to the form for the advanced search, which allows users to search in the database through multiple keys such as the name, geographic area, field and specific competencies of the subscriber. These last two parameters represent the most relevant functionality: they vary when searching for a company or a designer, and are selected by a basic taxonomy, which can be integrated with new fields even by the users of the community; this shows once again that the system is open, and in a perpetual beta version. The companies can be searched by typology and position in the production chain, defining the competencies in terms of manufacturing process and machinery. The designers are organized according to the design fields officially acknowledged in Italy (product, communication, fashion, interior and service) and the technical skills.

It is possible to access the profiles of the single elements of the community in two ways: through a spontaneous and intuitive approach that shows the elements through an update and networking activity, and through a more mediated and schematic approach that leads to the univocal selections of the profile's characteristics.

The same analogy in the interface architecture is used for the look and the layout of the users' public profiles. The aim was to synthesize useful information, avoiding redundancies and excessive complexity; the idea is not to create a web site, but a window that can illustrate the user's "mood", competencies and contacts. More specifically, users can upload an avatar image and organize their photo gallery, write a brief description of their professional profile and a short list of contacts.

In order to guarantee that users can upload these contents in the more usable and intuitive possible way, an online management panel was created. The graphic architecture of the site is kept, to help the user, but the navigation bar for the back office functions substitutes the general menu.

The web panel allows to publish descriptions, work images of products/projects/events (it is possible to determine the order in which the images are viewed and with which layout), news about the activities. Designers and companies can also require to have a dedicated area for remote, where contents and progresses can be shared.

The financing calls represent the last very important objective of the service: associations and research centers can publish, for a wide audience, information regarding calls and funding

opportunities. This represents a crucial tool for the success of the community and to attract external visitors.

The calls can also be searched in the two different ways mentioned above: they can be read through the latest news on the home page, or can be searched through a form, as detailed as that to search companies, designers and associations.

The static pages dedicated to the services and download complete the “features” offered by the site. The first one shows the possibility of collaboration with which the University and the associations aim to support SMEs and designers even in the real world. The second one allows to share specific material about design and innovation.

The advantage for the company to be subscribed should be represented by the possibility of reaching competencies otherwise external to their usual network, with no communication and HR cost, thus starting a low-risk innovation strategy (limited investments).

The designer, on the other hand, has the possibility of developing the gained skills while becoming closer to the production dynamics, learning to manage the relationship with clients and introducing an important element in the resume, on top of having the possibility of self-promoting within a different network than the university one.

It is evident that, considered the heterogeneity of the target users, the relations and interactions run on both a horizontal and a vertical level, and they can significantly increase: among professionals in the same field, among complementary companies, among creative professionals and entrepreneurs, among and with associations and research centers.

At the same time, it is important to highlight the experimental nature of the project, which is still in its kickoff phase: it should not be taken for granted that both designers and companies will perceive the benefit of service in the same way. If, for example, companies would seem to have difficulties in using the service, changes will have to be made in order to get closer to the most receptive target. Even considering these uncertainties, the service was designed according to the “perpetual beta” idea, thus thinking about its contents update and adaptability according to how the users and the actors involved will use it.

7. Conclusion

The DAC_Link project has to be analyzed considering the high variability of the rapidly evolving socio-economic scenario: for these reasons, the site should not be considered as a final solution, despite the success of the initiative.

One of the possible development factors is definitely the technology permeability on one side and the design methodologies within the SMEs on the other. If the project will contribute to the growth of the production system, which is the main trigger for the initiative, a new intervention will then be required, to widen the offer of interaction tools that the subscribers can use, and to intensify the multiplicity and heterogeneity of the contacts within the community.

The service could also evolve widening the innovation model both at a geographical level (from a national to an international scale) and at an organizational level, involving new actors, new competencies and integrating it with a network of “physical” services.

As we have already seen, DAC_Link is created as a specific answer to the current business and professional Italian scenario, trying to give a virtual dimension to those dynamics which historically determined the success of the Made in Italy, and strengthen the relationship between creativity and market in the global scenario. Though, this doesn’t prevent the collaboration model to be used in Countries with similarities to the Italian system.

The “physical” dimension, on the other side, is not replaced or left out, but it remains a crucial element to spontaneously involve more actors and offer an innovation service as integrated and complete as possible.

The project suggests a model: its evolution is strictly tied to the same actors and contexts to whom it is addressed and which tries to train, promote, stimulate.

In conclusion, the DAC_Link challenge is multi-layered:

- filling the gap between Design, SMEs and Hi-Tech Innovation by communicating how a low risk strategy design-based can produce long-term profitable results;
- using Technology itself (Web) to Communicate innovation (supporting knowledge-sharing processes) through new and empirically effective forms of communication (social networking);
- strengthening the relationship between Young Designers, University and SMEs through the Trade Associations' channels;
- offering a service able to interpret the needs of young designers according to the constantly changing professional context, granting them a future after Graduation;
- finally, defining an online format that could best synthesize all these aspects into a usable and, above all, useful device.

DAC_Link shows at last that to fill the gap between SMEs and Technology through Design means to fill the gap between SMEs and Design in a sustainable way; this system aims to change the actual model of generating innovation by supporting new and unusual creative processes.

The Evolving Role of Design:

Opportunities and challenges for the Australian Packaging Industry towards sustainable design.

Areli Avendano[1]

Abstract

While the role of design has been widely acknowledged as a significant contributor to sustainability by some Australian Industries and government associations; yet the Packaging Industry has not fully taken advantage of design as a key strategy to achieve sustainable solutions.

This paper is based on existing literature as well as on key findings resulting from a range of face-to face interviews carried out with experts among the Australian Food and Beverage packaging supply chain.

A summary of opportunities as well as specific challenges for design in the Australian packaging industry towards packaging sustainability is listed.

[1] Royal Melbourne Institute of Technology (AUSTRALIA) – Centre for Design. PhD Scholar, areli.avendano@rmit.edu.au

1. Introduction

According to a United Nations (UN) report, a key issue to achieve sustainable development is the integration of production and consumption patterns; product designers are identified as an influential link between production and consumption by incorporating sustainable principles into the development of products (UNEP 2004, p.6).

The role of the industrial/product designer has been largely discussed throughout time; however, it has been generally regarded as the activity of translating an idea or concept into a product that satisfies a real need; combining manufacturing, technical, economical, ergonomics and aesthetics aspects to make it perform efficiently (Powell 2004, p.1). Donald Norman (1988, p. 190), in his book *The Design of Everyday Things*, states that an essential responsibility of the designer is to deliver objects based upon real needs of the potential users whether it is as a society or a single individual. Designers form the interface between 'the user' and 'the product'.

On the other hand, as sustainability concerns are becoming increasingly important to business, the role of designers has been inevitably challenged by this concept; environmental, economical and ethical considerations must be included in the new product development process. This is not to say that design typically did not approach such issues, but they frequently are vaguely considered or in a very limited way as the field has been dominated by financial profit (Thorpe 2007, p. 10). Conversely, it would be fair to mention that some companies are genuinely addressing environmental and social issues; they have acknowledged that current production and consumption practices inevitability have to adapt to the new contexts we face. Products will be continually developed but it should be essential to consider whether or not they are making a significant contribution to material culture (Walker 2006, p.33) in order to maintain growth in the term.

For more than 3 decades, products associated to the packaging industry have received substantial attention in the global sustainability debate as they are perceived as principal users of material resources as well as waste generator. Yet, the most significant environmental impacts resulting from packaging are lock-in at early stages of the development and manufacturing of packaging-products: raw material extraction, energy and water consumption as well as greenhouse gas emissions are critical factors (Lewis & Gertsakis 2001).

The fundamental role of packaging that it performs in our society is often disregarded: content, protect, preserve, inform as well as ensure safety and healthy requirements and, in the case of food packaging it ultimately reduce the spoilage or damage of products along the supply chain (Design Council, 1997). Consequently, to adequately assess a packaging overall environmental performance it is essential to consider its role along the entire supply chain.

Currently, a diverse number of tools, methods, strategies and principles for incorporating sustainable design have been developed: from guidelines and checklists that are concerned in reducing the amount of materials, reducing waste or using recycled materials (all of them with a product focus), to more sophisticated models such as life cycle assessment (LCA). Whilst important levels of improvement have been achieved: such solutions do not necessarily address all three levels related to packaging sustainability (social, economical and environmental). Broader concepts have to be embraced to extend beyond single products and incorporate larger ecological and social aspects, which draw from principles of ecology, biology and a vision of a future sustainable society that supports the design of product and services (Tischner 2006, p. 6).

The Australian packaging industry is still in early stages of addressing environmental impacts of their activities and products; particularly there are concerns about how to address them through changes in manufacturing, design, logistics, marketing and business structures and

relationships (Fitzpatrick et al., 2007 p. 157). On the other hand there seems not to be a general understanding of the meaning of sustainable packaging: different approaches are needed to incorporate environmental issues as well as economical and social ones into the development of packaging. In addition, it is essential that those concepts are integrated early in the development process and it is at that point where designers could potentially address them appropriately.

In respond to those concerns, in 1999 the Australian National Packaging Covenant (NPC) was first introduced as a voluntary agreement between all levels of government (Federal, State and Local) and the packaging supply chain (brand owners, manufacturers, retailers and fillers). The Covenant is based on the principles of shared responsibility through product stewardship, including the effective design and operation of kerbside recycling systems. Some of the key performance indicators are related to the packaging manufactured by a company or specifically to the design, manufacture and distributions processes. Some relevant objectives are (NPC 2005, p. 3):

- To engage the packaging supply chain, consumers, environment groups and policy makers in a debate about sustainable packaging principles, goals and strategies.
- To assist the packaging supply chain and users to make responsible choices, including design, purchasing, recycling, reuse and disposal.
- To reach consensus within key stakeholder groups about the need to integrate sustainability objectives in the design and management of packaging systems along the supply chain.

2. Aims

The NPC proposes as a strategy to address environmental issues the use of an improved product design process which considers carefully decisions made regarding material's selection, material's efficiency and manufacturing processes, as well as end-of-life management during the development of the packaging. It is widely recognised that it is important to include this type of decision making early in the product development when packaging designers in coordination with other professionals (marketers, environmental managers, supply chain managers, manufactures, retailers, etc) have the greatest opportunity to address environmental pressures and as a result develop effective sustainable packaging systems.

However, the NPC does not provide clear leadership on how product design could improve the environmental performance of packaging while effectively meet essential functional and business requirements. Furthermore, it is not only through better design and development processes that the issues should be addressed; pursuing sustainability requires to consider the trade-offs and requirements of all stakeholders along the packaging supply chain. It is also necessary to incorporate consumer perspectives into the process to deliver more holistic solutions.

However, the question remains in the air: how can design promote the development of sustainable packaging. In order to understand the current status and perception of the role of design in the Australian Packaging Industry and be able to identify the opportunities and challenges towards sustainable packaging design, the research aims are the following:

- to review and assess the roles and responsibilities of key stakeholders throughout the supply chain (e.g. packaging technologists, environmental manager, designers, marketers) to identify gaps and limitations in the decision-making processes for designing packaging.

- to identify of opportunities, trade-offs and challenges for Australia towards sustainable packaging design.

3. Australian Packaging Industry Overview

The context of the study presented in this paper is within the Food and Beverage Packaging Industry as it is currently the largest sector in the packaging industry accounting for around 65-70% of the total amount of packaging produced in Australia (PCA 2001).

Currently, there is an emergent demand for businesses to offer more environmentally responsible choices in their products as well as their packaging. Therefore, sustainability has become a great concern to the Australian Packaging Industry; whether it is a genuine concern or as a part of a global trend, but some commitments have been made to improve the packaging supply chain. Such integration of economics, environmental and social performance into the development process of products is recognised as a strategic business challenge for upcoming future (James et al. 2005, p.117).

However, assessing the sustainability of packaging is not an easy task, as mentioned before, mainly because the packaging itself is part of the product and the most significant environmental impacts are related to the production of the actual product and the packaging accounts for a minimal percentage of the overall impact. A great emphasis has been put in packaging waste and recycling issues and these have diverted the efforts to address major issues towards packaging sustainable, such as climate change and green house emissions as well as natural resources depletion. This is in part as a result of the NPC has significantly focused on packaging recycling targets. However, this has started to become an issue and some pressures have been put against the approach taken as recycling might not be the more sustainable approach for some packaging solutions. For instance, light weighting and down gauging might be a more appropriate strategy. In addition, some other criteria has been pushed to be part of the sustainability assessment more relevant to the Australian context such as: water consumption and energy intensity in packaging manufacturing and recovery.

Current patterns of production and consumption cannot be continued in a world of growing population, rising human aspirations, and limited carrying capacity. In addition, companies will increasingly be urged to implement producer responsibility and corporate social responsibility throughout the whole life-cycle by laws and regulations.

3.1 Industry drivers for sustainability

According to the NPC (2005, p.3) some drivers for sustainability are:

- Policy developments in the management and disposal of used consumer packaging and paper occurred, both domestically and internationally.
- The expansion and maintenance of kerbside recycling services by Australian local governments to over 90% of the Australian population and substantial efforts to improve their yield and cost effectiveness.
- Community awareness and concern about environmental issues, including packaging, remains high. There continues to be considerable community support for kerbside recycling services which results in an increased supply of recyclable materials.
- Recognition on the part of all governments and industry that there is a need for a nationally consistent approach to the lifecycle management of consumer packaging and paper including its recovery, re-utilisation and disposal.
- Changes in consumer demand and demographics are affecting the way products are packaged.
- Changes in packaging design and technology that are providing a wider range of

packaging options as well as reducing material usage at source.

- Increasing exposure to international competition for Australian business.
- A growing global trade in recyclables as commodities.

However, to create change it is important to note that all parts of the packaging supply chain have to make their contribution by committing to consider the whole lifecycle of a packaging-product from raw material extraction to end-of-life management.

4. Methodology

The fundings presented in this paper are a combination of literature already existing and a series of interviews among stakeholders in the Australian Food and Beverage packaging industry.

The proposed methodology for this project is Grounded theory, as it is a qualitative research analysis technique whereby theory is generated from the collected data (Glaser&Strauss 1978). Inductive processes are used to collect and analyse the data; and theories, concepts, hypotheses and propositions are developed from the collected data and not from prior theories, assumptions or other research.

All the interviews, with the exception of 2, were audio-taped (interviewees gave written permission for it) to facilitate the transcription and analysis of them. The interview time varied from 25 min to 1hr 10 min; depending on the level of engagement of the interviewee (particularly interviews with designers and marketers took the longest time). The transcription of the interviews (word-by-word) has been carried out by the author, which facilitate the analysis process. Participant's name and their organisations has been removed from the transcriptions and was replaced by a code that only the researcher is able to identify.The data analysis process consists of three activities: data reduction, data display and conclusion drawing and verification.

While the transcription process is still in progress and its expected conclusion is by July 2008. Once the data is reduced to the categories, themes and patterns, the data will be displayed in matrices, graphs and network diagrams. However, for the purposes of this paper, some data has being reduced by a process of selection, simplification, abstraction and transformation to enable categories, themes and patterns to be identified. Data organised and compressed in such displays has provide an opportunity for emergent hypotheses to be tested against the literature data. Following the data display, propositions will be developed emphasasing relevant aspects for design.

Iniatially a list of 40 potential participants was proposed: official invitations to participate were sent via e-mail / telephone conversation: the responses periods varied from 1 day to 1 month which made the process considerably complex, taking over a year to finalise with all interviews. From those initial 40, a positive response was obtained from 27; as a result a second list of 15 people was prepared to have a more significant sample. A total of 37 interviews were carried out. The participant companies ranged from brand owners, consultancies and design studios to packaging manufacturers, retailers and govermnet agencies; from which 11 designers, 8 marketers, 7 packaging technologists, 5 packaging experts, 3 environmental managers, 2 retailers and 1 policy maker were interviewed. The diversity of companies provided a broad perspective of the current status of the Australian Packaging Industry.

The interviews involved a semi-structured questionnaire with 12 questions divided in 3 sections:

- Packaging Industry Issues

- Packaging Developing process
- Packaging Sustainability

Key questions relevant to design have been selected and presented in the following section.

5. Preliminary Results

The focus of this section is to describe some preliminary results of selected questions from the series of interviews where the following points were discussed:

- Identifying people involved in the packaging development process and decisions made by them.
- Description of the interactions between those involved in the process as well as additional types of interactions derived from considering sustainability in the process.
- People involved in the incorporation of sustainability principles in packaging.
- Discussion regarding barriers for the development of more sustainable packaging.
- Perceptions on potential contributors to the sustainability of the product.
- Opportunities for a more efficient implementation of sustainable packaging design.

5.1 Current role of packaging in society

- Packaging has a fundamental role in our modern society: in the particular case of food and beverage packaging, preserving the quality and the freshness of products is fundamental (Robertson 2006, 3) as shown in **Figure** 1 .

Figure 1 : The fundamental role of packaging. (Photo: Areli Avendano)

The Packaging Council of Australia (2001) has defined packaging to encompass the following functions:

- Must contain the product.
- Must preserve and protect its contents.
- Safely deliver products to consumer

A communication device providing details about the product, including price, contents, ingredients and nutritional value as well as cooking instructions and recommended use by dates.

In the first section of the interview (Packaging Industry Issues), participants were asked: "*What makes a successful packaging from their role's perspective?"*

The answers varied from those that did mentioned most of the above functions (mostly packaging technologists) to those others that emphasised the aesthetics, performance and cost (mostly designers and some packaging technologists).

"Successful packaging is one that does the job and offers consumers benefits".

"It the one that performs its job in the most cost-effective way and the customers wants to have it."

"It varies from customer to customer, but in general for the food industry it needs to perform its function such as barrier to extend its shelf life and withstand filling processes such as temperatures and finally transportation…"

Some others focused in the branding part of the packaging; it was highly regarded as an essential medium for communicating the brand values to consumers as well as a product differentiation means (marketers):

> "It is fundamental, as it allows products to be transported and make them available to consumers…even though we try to reduce the use of packaging we know that is the most marketable type of pack the packaging that is going to sell the most".
>
> "It has to stand out on shelf the way we use the designs, it's one of the most important things…"

Environmental managers as well as some designers mentioned that minimising the environmental impact of packaging was a pursued objective. Some mentioned that addressing sustainability issues has been incorporated in their mission statement. However, it is not the priority and probably in most cases is not even in the top 3 requirements that made a successful packaging:

"Even if the CEO is aware of the environmental impacts of our packaging, the message does not necessarily goes down to the marketing area that it is a bit hazy about it… a lot of the marketing innovation is not driven in those lines."

"Packaging that has the best selection of materials within the constraints of cost, the constraints of our factories… and also within the constraints of the marketers. Unfortunately at this point, the environmental aspects are not a deciding factor."

This is particularly worth noting as it is a reference to understand better the factors taken into account and gives a background on the decisions made when developing a new packaging. It also demonstrates that the role of packaging has significantly moved far from only content and protect the product to be an almost essential branding tool.

5.2 Packaging design and developing process

The mainstream design process consists of a non-linear series of different phases for the development of a product (i.e. it is an iterative process). The process engages meeting marketing, manufacturing and financial requirements as well as environmental and government regulations. In practice, companies use a combination of approaches and tools to design and develop their products. In industry, the product design and development process most of the times is a formalised approach with fixed milestones and gateway management, whereas in small companies one or several people, working in an informal and more intuitive manner can carry out product development (Green 2003).

The design process starts with the preparation of a brief. Generally designers work within a written design brief given by the client, or ideally shaped in conjunction with them. The brief summarises what is required for the development of a product, such as functionality, form, usability issues and performance and technical aspects. It also specifies any important constraints as well as environmental regulations and legal terms related to the product.

Environmental regulations include use of natural resources, energy and pollution resulting from the manufacturing process as well as the end-of-life management. It is important to ensure the decisions taken regarding environmental issues satisfy the requirements of the project and have clear deliverables at the end. Once the brief is finished, the next phase is the idea generation commonly presented by sketches or models.

Frequently, the idea generation phase involves several meetings with the client, and eventually an idea is chosen and the concept development starts. The concept is worked in more detail considering all the requirements in a statement in the brief and determination of components and materials and manufacture phase to the marketing of the products, user's interaction (product language) and finally, the end of life management with the product (DIA 1997).

Many important considerations can be addressed from this early phase of the process, such as detailed design, design for reuse, recycling or composting, determination of manufacturing costs and investment as well as sustainable aspects regarding the production of the product. It is at this phase where product design plays an important contribution to promote sustainable practices due to assisting the decision-making process during all stages of the product development. It is also at this point where most of the environmental impact is "locked in" due to specific material and technology choices made in the design. The typical stages of the product design process are illustrated in Figure 2.

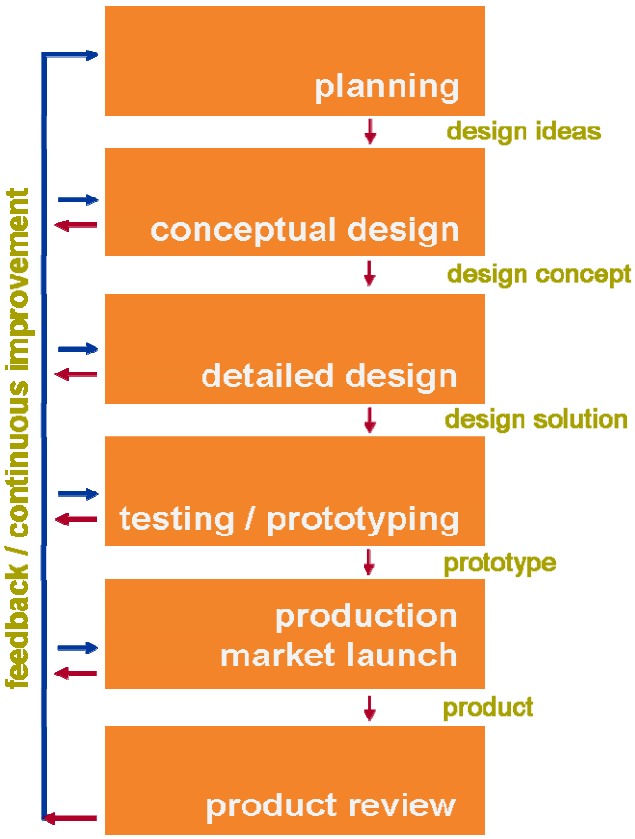

Figure 2 : Pr**oduct design process (source: adapted from ISO 14062-2003)**

In the second section of the interviews (Packaging development process), participants were asked:

"How would you describe the development process of a new packaging system: from initial idea to final product?"

The process varied accordingly to the type of company; for example brand owners have a "formalised" procedure where the initial idea normally starts at the marketing area. Generally that idea is driven by making financial profit, increasing sales or brand plans. Then a brief is written and given to the "design team", whether they are actual designers or packaging technologists.

The norm seemed to be that Marketing had the influence to make decisions such as packaging materials; packaging formats and sizes; and some times even labelling and colours have been already chosen in the brief. This leaves very little flexibility to designers/ packaging technologists to develop some concepts and be more creative. It is a common practice within brand owner companies that the designer/packaging technologist is in charge of the packaging specifications whereas in design studios designers are more focused in the packaging aesthetics.

Then the design team will start to develop concepts or ideas (sketches); 5 to 15 ideas are generated and then the top 3-5 are selected and they will be taken into a proper development process. Those go back to the marketing department or to the customer. For brand owners

companies, generally these decisions are made in meetings where the “full team” is present: technical person, sales person, marketing person and in some cases operation representatives from across business. And what would happen is they then look across at the ideas they like, talk about which ones they want to send to the level or basically which ones do they want to advance.

Then they start to advance those, always working as a joint group, some mock ups are done. It is at that moment that where operational cost and commercial implications start to be considered, and then they start to move through that process to eventually it’s commercialised.

It is important to say that in more than 70% of the participants said that environmental issues are “normally” taken into account at late stages of the process when developing time has been invested already and decisions of going back in the process are restricted by time and money.

“… and it is at this stage when we would have a brief discussion of the environmental issues that might arise from this particular packaging solution, and try to figure out ways to minimise that impact within cost constraints”.

It is important to acknowledge that moving towards sustainability involves re-assessing the way processes are undertaken and decisions are taken in the development process: typically the packaging development responds to a brief written in most of the cases by marketers, where the input of the designer is still limited as they rarely have the profile or context to be involved in decisions early in the development process (ISO 14062 2003, p.26).

5.3 **Sustainable packaging**

It is important to make a clear distinction between ecological and sustainable product design:

- **Design for Environment (DfE)** is concern with economical and environmental aspects, whereas Sustainable Design embraces a more holistic approach taking into account the social aspects in conjunction with economical and environmental aspects. According to Lewis & Gertsakis (2001, p 13), DfE is:

“…an approach to make critical interventions early in the product development process and eliminate, avoid or reduce downstream environmental impacts whilst still producing a high quality, cost-effective product”.

- **Sustainable product development and design** is defined by the UK Department of Trade and Industry (2005) as:

“…concerned with balancing economic, environmental and social aspects in the creation of products and services. Sustainable product development and design looks to minimise adverse sustainability impacts and maximise sustainable value throughout the life-cycle of the product, building or service. To create sustainable products and services that increase stakeholders’ ‘quality of life’, whilst at the same time achieving major reductions in resource and energy use, will require a significant emphasis on stimulating new ideas through higher levels of creativity and innovation.”

The same design principles apply for packaging. However, it is important to say that it would depend on the specific context and type of product is considered. It also has to addres economical and social issues. The australian-based Sustainable Packaging Alliance describes a sustainable packaging must be: effective, efficient, cyclic and safe as shown in Figure 3:

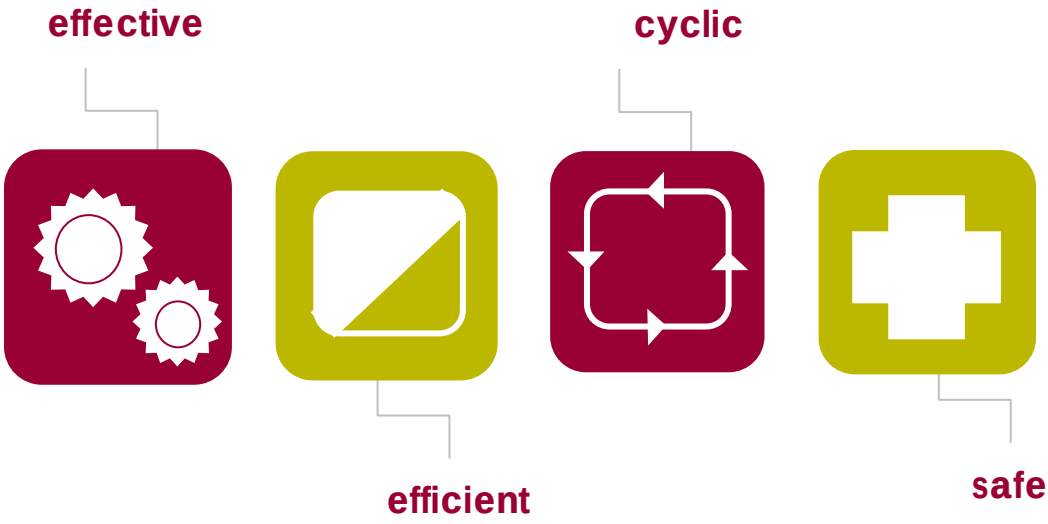

Figure 3 : Sustainable packaging principles (adapted from James et al 2005)

When intervieews were asked: “Define what sustainable packaging is from your perspective?” most of the answers refered to materials, i.e. recyclability, light weighting, etc. Very few did mention water and energy concumption. In general, there is a confusion on what could be sustainable and what are the biggest issues when talking about packaging sustainability.

6. Remarks

To this point no final conclusions can be made, however significant amount of data has been analysed and general views on packaging sustainability in the Australian context can be identified:

- Design is recognised as a key influence towards mor sustainble production and consumption practices, however, it has to overcome the missconception of being an “extra” cost to the process.
- Retailers dictate a lot of what happen in the market, so they could set the parameters to define what means sustainable packaging for Australia, instead of adopting isolated solutions from overseas.
- A lot is driven by consumer expectations, however educating the consumer as a key issue to achieve sustainable packaging systems and this could be done through design
- More emphasis needs to be put to critical links between packaging design and its ability to be collected and recycled through various materials recovery systems.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Being Here

Attitude, place, and design for sustainability

Craig Badke[1], Stuart Walker[2]

Abstract

This paper offers an original contribution to the current debate about *design for sustainability* by considering two quite different understandings of our relationship to the world – namely, *having* and *being*. The differences between these two notions emerge from a reflection on two places of outstanding national beauty – one in Canada and one in England. The discussion then moves to the urban context to consider the notion of *being,* rather than *having* within the contemporary city. There emerges an understanding of meaning that is deeply related to connecting – with people and place, and a notion of design that is both from and for context.

[1] University of Calgary (CANADA) – Faculty of Environmental Design. PhD Student, cbadke@telusplanet.net
[2] Lancaster University (UK) – Imaginationlancaster. Professor and Co-Director, s.walker@lancaster.ac.uk

Introduction

This discussion explores the shift in understandings that must prefigure any lasting change towards sustainable behaviours. More specifically, it considers a shift from *having*, which is implicit in the term 'consumer society', to *being*, a term that suggests a quite different and potentially more sustainable relationship to the physical environment.

The discussion begins with a reflection on two places – one in Canada and one in England – both of which are renowned internationally for their outstanding natural beauty. It considers our relationships to these places within our contemporary, consumer-oriented culture. These include more traditional, rural relationships to place, and the contemporary relationship of urban dwellers who visit such places for recreation and sport. The discussion then moves to the urban environment itself – and insights gleaned from reflecting on natural environments inform the discussion about what a meaningful and less consumptive response within the urban context might mean. The result challenges our current norms and conventions and offers direction for 're-connecting' within our everyday environment. Finally, the paper indicates what such a re-connection implies for the way we go about designing our material culture.

Banff | Keswick

Place and Consumer Culture

One of the authors lives a short distance from the town of Banff in the heart of Canada's first national park, the other lives close to Keswick, in the centre of the English Lake District National Park. Both places are areas of outstanding natural beauty. A walk along the main street of Banff townsite reveals a busy shopping thoroughfare; almost every other store is an 'outdoor gear' retailer selling apparel, hiking boots, skis, mountain bikes, canoes and climbing tackle. There are a host of outlets offering whitewater rafting experiences, trail rides, glacier trips and heli-skiing. The highstreet of Keswick in the United Kingdom offers a surprisingly similar array of shops, selling the same clothes, boots and packs, along with cross-country biking, boat tours, climbing excursions and GPS training days. Both regions have annual mountain film festivals that screen identical movies of people engaging in extreme activities within the natural environment. The 'great outdoors' is a major focus of both towns and it is the basis of their economies, it is also the case that the emphasis of both towns is tourism and therefore consumeristic. Both offer very similar visitor expressions and these are both about *having* – having the right gear and having the right experience. This emphasis is in accord with

contemporary capitalist societies, and it helps create wealth and jobs. Despite the fact that these two places are thousands of miles apart, that they have different histories, climates, and geographies, their commercial offerings in terms of possessions and experiences, are almost indistinguishable. Despite the fact that both towns are in the heart of major national parks, their stress on retail and shopping would seem deeply ironic, given the evident relationship between consumption and environmental destruction. More importantly in the context of this present discussion, this emphasis on consumerism is indicative of attitudes and behaviours that have come to favour *having* over *being*.

Banff | Keswick

Here we ask, “What does it mean *to be* in the environment, rather than *to have an experience* in the environment; an experience that, in turn, is dependent on *having* the right ‘stuff’. The distinction here between *being* and *having* is crucial to our understandings of, and responses to, sustainability. *Having* such experiences means that the environment is appreciated primarily for its instrumental value, for its ability to provide us with an exhilarating view, or mountain bike ride or ski route. *Having to have* just the right gear, in order to *have* the right experience only reinforces attitudes that are consumer-oriented and, perhaps, too-readily justified - often on rather tenuous grounds that are already primed for us by clever marketers.

How might a different understanding begin to change our relationship with the world, one in which the emphasis shifts from primarily *having* to a more balanced understanding that includes *being*? And what might this imply for advancing our approaches to wealth creation and ensuring human wellbeing? More specifically, what might this imply for design - what we design and how we design?

The notion of *being* rather than *having* is more in line with long held ideas about meaning and the notion of living a meaningful life, a contented life. By contrast, continually wanting, buying, acquiring - be it outdoor gear, outdoor experiences, or any other form of consumeristic behaviour for that matter, implies a discontentedness. Wanting something implies getting, working towards having, possessing. This type of thinking is part of our contemporary *having* culture - a culture that is associated with consumption and discontent or lack of fulfillment. Beyond a certain, moderate point of material satisfaction the premise at the heart of consumer-based capitalist systems is not only hollow but clearly highly destructive. It suggests that we can acquire happiness through wanting and then having, but this is patently false, at least according to the great philosophical and spiritual traditions from all cultures.

This discussion is about design for sustainability, not national parks. However, the example of our experiences and expectations in relation to national parks is symptomatic of our wider attitudes and behaviours. When we find ourselves on a hiking trail, ski slope, or mountain bike route we are usually there to satisfy our personal desire to have an exhilarating experience. In which case we are not *being* we are *doing, using,* or *consuming*; we are there *to have* an

experience. We walk along a trail in our ‘gear’, made by North Face or Columbia - seemingly, the label *is* important - until we arrive at a viewing point where we are invited, via a sign or strategically placed park bench, to appreciate ‘the view’, little realizing, perhaps, that the very notion of ‘the view’ is itself a Modern construct, a product of how we relate to the natural world, where we see it as something to be viewed, as an aesthetic object, a commodity (Eagleton, 1990, 78).

Having? | Being?

Place and Traditional Culture

Our contemporary relationships to the natural environment within the economically and industrially dependent societies are quite different to those of other cultures. Traditional aboriginal cultures, such as the Blackfoot, once thrived in Alberta before Canada was created as a colony of the British Empire. Their way of life was sustained for over 6,000 years through the hunting of the buffalo. Their hunting grounds, like the one at Head-Smashed-In Buffalo Jump, just south of Banff, where the great plains meet the foothills of the Rocky Mountains, exist now only as a UNESCO World Heritage Site (Head-Smashed-In, 2008), but provide a record of their relationship to the land and to nature. Such cultures lived with abundance as we do, but they took only what they needed - practising reverence for the way they took life, which was ritualized in every aspect of their culture. Every facet of their lives was imbued with significance, and for them their way of life was not divided into means and ends. The entire act of hunting, from the creation of tools and weapons to a social life, centered on following the herds, killing, cleaning and using every part of the animal. In everything they did they gave thanks for the sacrifice that the animal had made, which allowed them to live. In this way they were profoundly connected to the means of their existence (Snow, 1977, 76).

Similarly, today, an Albertan cattle rancher with his horse or an English sheep farmer with his dog also have a deep knowledge of, and connection to, their respective environments, to the weather, the land, their animals, their community, and even their tools. Such rural cultures are so dependent on and reflective of land and place that one’s life and how one lives are fused together. That life is pursued alongside people with similar understandings of and relationships to the land, which, in turn, generates a complex web of ties and interdependencies that are not merely instrumental. These types of relationships to place are ones of deep connection, where the whole of one’s existence is reflected and recognizable in the patterns of one’s life, one’s actions, artefacts, and surroundings.

Banff | Keswick

In so many ways, these kinds of relationships, exemplified here through the Blackfoot, the cattle rancher and the sheep farmer, can be characterised as more ***being* relationships**, and they stand in stark contrast to the ***having* relationships** discussed earlier.

The Urban Environment

To *be* in our environment means to be in our everyday, ordinary environment. For a majority of the world's population this context of living has become the contemporary urban environment. Are there narratives for our lives today – lives lived out within these modern urban contexts – that are in any way similar, in terms of *being*, to those discussed above in relation to buffalo hunters and farmers? Are such meaningful narratives applicable within today's urban context? Or are such notions misguided or simply nostalgic? Are deep connections to place and the natural environment, and attitudes of *being*, at all relevant to the average city dweller today?

Both authors have spent a significant amount of time in Calgary, located just 90 minutes from Banff, as all the brochures state. Calgary represents a fairly typical North American urban experience, with a few distinctions due to its location and youth. Although the city itself is increasingly cosmopolitan it is archetypal in its suburban sprawl and generic shopping malls. It is a place of enterprise and opportunity that creates a character of newness, but also transience and anonymity. It is a place of immigration where people can re-invent themselves and create a new identify without judgment or the shackles of tradition, home culture, or family. All in all it is an experience that is not particularly unique among urban centres and one that could be had in any number of places around the world.

Given this type of urban context, what does place, and its relationship to *being*, mean to us now, if anything?

The basic tenets of a secular liberal society are that people have the right to live the lives they choose, where they choose, and social cohesions between them are voluntary (Rawls 1993, xv-lxxi). But a disconnection emerges if the only relationships between people are voluntary and/or social. Most people came to Calgary, and perhaps to Canada, for instrumental reasons. These might be very good reasons - seeking a better life, escaping from a negative situation, for opportunity, or for safety and security. Nevertheless, the reasons are often instrumental in nature. What is the meaning of 'place' for these urbanised, relatively new settlers? For many there are few established, deep connections to the context of 'here' – the land, the history, the meaning – primarily, 'here' is a place that is both new and one that offers instrumental opportunity.

In contrast to Banff and western Canada, the English Lake District has a very long history of settlement, rural farming and literary culture – it is a place of mountains and streams, of ancient stone villages, of sheep farming, small scale industry, and poetry and story – it is the country of Wordsworth, Coleridge, Beatrix Potter and John Ruskin. Despite its profound differences, for the weekend visitor from the nearby cities of Manchester or Leeds, the

experience is not so very different to that of the average Calgarian visiting Banff. The relationship is again predominantly instrumental and consumeristic.

Meaning

The modern world is strongly connected to the urban context – but how do we connect in a meaningful way to places within and from such a context? While we cannot, nor necessarily would we wish to, go back to some more 'natural' state of living within the environment, our contemporary use of natural places, such as Banff and Keswick, as recreational areas and weekend playgrounds, which serve as *escapes* from the city, perhaps indicates that we see our places of living and working as environments to be *escaped from* because they fail to provide the kind of nourishment, on a daily basis, that we need and seek.

As Taylor indicates, perhaps many of the problems we are faced with in modern life – a sense of meaninglessness and disconnection, an emphasis on instrumental reason, and a sense of alienation – all stem from the fact that, unlike hunter gatherers, who saw meaning and intention in everything, we no longer do (Taylor 1991, 3). Native peoples saw everything in their world as meaningful, full of intent and significance, a part of who they were (King 2003). Many such traditional lifestyles were afforded plenty of time to contemplate connections. For them there were no divisions between the aesthetic, art, religion, or science, because they were all interrelated. It is only in the modern world that we have such words and distinctions.

With the decline of traditional sources of meaning (religion, class, family, work, etc.) our identities have become increasingly hinged upon design and consumption (Lansley, 1994, p100-101). More and more we tend to be defined by the products we buy, the spaces we inhabit, and activities in which we partake (Sparke, 2006). With this shift in relationships, products have increasingly taken on greater social roles far beyond their functional utility. Consumption has become not just the major force driving the economy, but also a dominant source of social meaning. In this context, products are valued less for what they do for us and more for what they say about us (Lansley, 98). A car is not just a means to get you from A to B, it is a means of projecting your identity, a symbol of status, social difference and connection.

Happiness

With such relationships we separate things into means and ends, where we seek to attain some abstract, ill-defined notion of a desirable end, be it happiness, pleasure, or identity and everything in the world becomes simply a means to that end. As a result, everything that gets you to your goal loses any intrinsic meaning - all that remains is its instrumental value. In turning everything into a mere instrument we shift the meaning from a whole process to only the end result.

We have long known that pleasure and happiness associated with consumerism is fleeting at best, as there will always be a newer, *better*, market-offering that creates dissatisfaction with the things we currently own (Pye, 150). An identity built on such grounds is similarly one of transience - and therefore can be seen as rather superficial. Taylor warns that in order to avoid such triviality one's identity must be defined against a background of things that matter, whether that be history, nature, society, duty, religion, or something else of that order (Taylor 1991, 40). It would seem that many of our consumer relations have no such foundation, especially when they are tied to superficial notions of progress, technological determinism, marginal and often questionable notions of 'improvement', or technical or aesthetic obsolescence. Therefore, we see that the contemporary, marketed path to happiness as philosophically lacking – it does not bear scrutiny. Its false promise of happiness creates dissatisfaction and anxiety.

Davidson suggests that to understand an object, and to be able to judge the appropriateness and significance of our relationship to it, we need to understand not only how we

relate personally to that object, but also its relationship to others around us (Kent 1993). Thus the notion of background becomes significant. Emerging from the traditional Axial philosophies and teachings of Buddhism, Confucianism, Taoism, Socrates, or the Old Testament, all of which developed within urban environments, the notion of being is one where we see ourselves as part of a larger whole, be it community, the planet, the whole of creation (Armstrong, 2006, xiv-xvi). These ancient teachings have all said, essentially, that to see oneself truly, without delusion, one must know oneself and see oneself as part of the whole. Such teachings also tell us that self-knowledge against a background of meaning is essential to the notion of happiness. This is a very different path to happiness than that advocated by the advertising and marketing of product acquisition.

Alienation

Scruton takes this notion one step further, with the Hegelian theory of self-knowledge, to suggest that not only is there no form of self-knowledge in a 'private world', but *"there can be no self-knowledge in a world that does not [also] bear the mark of human action."* Implicit in this is seeing those marks of human action, the world of objects and our built environment, as reflective of us, our values, and our conceptions of ourselves.

If, however, those objects and environments are conceived, in an instrumental fashion, whether for wealth creation or utility, and determined by a cost-benefit ratio rather than being considered more holistically the result can be alienating for those who inhabit that world. This alienation arises in part because ordinary people perceive themselves as having little effect on the shaping of that world – seeing themselves merely as passive consumers of it. Scruton gives an account of this alienation, the alienation *"of a man so treated by his environment that, finding himself nowhere outside himself, he can find himself nowhere within."* The cure for such alienation and meaninglessness in the world, he goes on to suggest is that *"only by transforming the world into a visible and tangible record of things rationally pursued, can a man find a place for himself there: without that place there will be no self to furnish it."* (Scruton, 245)

Perhaps the problem within urban contexts is not that opportunities are instrumental, but, due in part to this alienating character, they *remain* instrumental and do not evolve and develop the layers of significance and complex web of ties and interdependencies that we see in rural or traditional cultures.

McLuhan and others have suggested that, given the connectedness possible as a result of mass-media and global communications technology, we are a global village (McLuhan 1962, 97-106). Does this mean we see the world as our place? Can the problems in the world ever be perceivable, understandable, and tangible at that kind of scale? Even with widespread knowledge of the scale of the current ecological situation, behavioural change has been very slow. The problem with globalized production and consumption is that we do not see what we take. We are disconnected from the resources and natural systems that provide us with the materials we use and dispose of. In other words, we are disconnected from the consequences of the way we live. This disconnection makes the problems in the world simply a set of abstract concepts that are 'out there' and 'somewhere else' – we understand them intellectually not intuitively, factually but not viscerally; and this is why we can so easily set them aside.

Independence

Independence and freedom from ties, is illusory in our world, a misperception born of abundance, fuelled by suburban living, the grocery store and shopping mall, the image of the car, work saving appliances, personal entertainment devices, cheap travel, and a whole host of concepts and objects that drive our economy - all of which were built upon a cheap and abundant source of energy.

However, the rising price of oil has led to the development of a new term, ‘fuel poverty’ (BBC 2008). It refers to people who can no longer afford to pay to heat their homes or run their ovens or stove top. This is a current example that shows the consequences when unsustainable practices begin to take a grip. Currently governments are planning to help vulnerable groups such as retired people and low income families with subsidies. This look to the government for help is telling of how fleeting our independence really is. This notion of independence is shallow and freedom without connection is meaningless (Taylor 1991, 4-12). We are never really autonomous, it is just a perception, a self-delusion created by abundance.

As long as the oil keeps flowing and the electricity, water, sewage and gas all work, and as long as the supermarket shelves are always well stocked and there's money in the bank we can continue with the delusion. But it is inherently false and inherently transient. It is also highly consumptive and very damaging - not only to the planet, but to our understanding of ourselves, our relationship with and dependence on others, and our relationship to the natural environment. It creates an attitude and outlook of atomism - of seeing only our individual selves and our individual needs and wants - without consequence, and without reference to the larger picture. It emphasizes individual rather than community, independence rather interdependence.

Connection

From their different perspectives, Wolff, a designer and Ratzinger, a theologian, have both written about getting things in the right order. Essentially, they say, if one gets things in the right order, in terms of priorities and values, then everything else will fall into place accordingly. Its about connecting ourselves to the entire process of living where creating, building, eating, moving, working, learning, recreation, and place all have significance, not as a means to something else, but all mutually interdependent and mutually informing.

Henry Miller, in Big Sur and the Oranges of Hieronymus Bosch, discusses this notion further in reference to the idea of community:

> *"What we are trying to suggest is that the solution for a cluttered, frustrated existence is not merely in moving to the country and attempting to practice 'the simple life.' The solution is in an attitude towards human experience which gives to its lesser enterprises-the obtaining of food, shelter and clothing-their essential harmony and balance. So often people dream of an ideal life "in community," forgetting that a "community" is not an end in itself, but a frame for higher qualities-the qualities of the mind and the heart. Making a community is the result of the happiness and the good which people already possess in principle, and the community, whether of one family or several, is the infinitely variable expression of the excellences of human beings, and not their cause...." (Miller 1957, 18)*
>
> Big Sur and the Oranges of Hieronymus Bosch, by Henry Miller, 1957

Design for Being – the heart of sustainability

Design reflects us and what we do. As designers, every time we specify a material, energy source, or manufacturing process, we set in motion consequences, effects, and impacts that can have a global reach in terms of transportation, labour, and wealth distribution. The products we conceive and launch into the world are propositions of how to live that have implications for the way we consume and waste, create identity and social connection, and think about community. We either reinforce ways of living or we create new ones, new behaviours, new ways of being, not all of which are predictable or controllable. Our values, our priorities, our choices, determine what we get. Design creates a tangible record of the way we live and act in the world.

Banff, Keswick and Torino all reflect the way we see, use, act, and live, they are a reflection of conscious choices and decisions by their citizens, designers, and civic officials.

While there are many efficiencies associated with globalized capitalism and production, it has in many ways led to an increasing sameness around the world; the mass-produced, global 'having' experience tending to wash away differences and the particularness of place. Sustainability emphasises the local, not only for instrumental benefit such as creating local jobs or reducing transportation, but also because there is a qualitative difference of cultural and aesthetic diversity, connection and appropriateness. Design for the local emphasises 'fit' and 'aptness', as seen in the vernacular architecture of Pueblo homes in New Mexico, the stone cottages of rural England, or the circular yurt structures still used by nomadic tribes in Afghanistan. Such design is born of intimate knowledge developed in response to the particularities of place, material, function, and culture. Design for the local encourages stewardship, responsibility, connection, and meaning, where our problems are not *'out there'* in the world, externalized and easily objectifiable, but *here*, local, accountable, tangible, vested. This is design within and for an interdependent, connected culture; a culture that is aware of and responsible for its social and ecological effects. It is design for a culture of *being*.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Designer as Agent of Change

A Vision for Catalyzing Rapid Change

Banny Banerjee[1]

Abstract

Sustainability is a problem of a magnitude and urgency that compels a fundamental reconsideration of the manner in we approach complex challenges. Traditional means that have brought us here need to make way for new trans-disciplinary paradigms.

The design field has demonstrated an ability to bring about effective transformation in abstract multi-dimensional issues. The paper examines the strengths and weaknesses of the "design complex" and makes a case for a trans-disciplinary approach shaped around design methodologies to meet complex problems such as sustainability.

This paper suggests a mechanism for design to assume a "meta-disciplinary" role, developing heuristics for creating trans-disciplinary systems with the "designer complex" being a core *meme*. In this new form of design, the identity of the designer would shift from "definer of systems" to "agent of change".

.

[1] Stanford University (USA) – Associate Professor, Director, Stanford Design Program, banny@stanford.edu

> *"Our task is not to predict the future; our task is to design a future for a sustainable and acceptable world, and then devote our efforts to bringing that future about. We are not observers of the future; we are actors who, whether we wish to or not, by our actions and our very existence, will determine the future's shape" [Simon 2000, 601]*

1. Introduction

As the design field finds itself drawn into larger issues such as social innovation and sustainability, it prompts the question *"What role will Design have in the future in addressing the complex problems facing society and mutual survival?"*

The field of design due to its heterogeneity resists commentary or *operations* that apply evenly. Design is akin to a cosmological phenomenon containing many diverse worlds. Designers assume different roles as specialists in sub-fields such as industrial design or generalists who simply assume different modalities over varying periods of time. In its short history as a recognized field, the design field has undergone several transformations from craft based design, to applied esthetics, to applied (human and social) science, to a more involved science. (Findeli 2001, 7-9) Currently, the field is at an inflexion point where the larger forces are causing a widespread re-examination of traditional value systems within each design sub-culture. Given this tense moment in the history of civilization, with its unique challenges and the core attributes of the design field, it would be appropriate for the design field to assume a new identity with a fundamentally altered set of implications and sphere of influence.

2. A Shift in the Design Field

It is manifest that the design field is in the midst of a paradigm shift. While traditional forms of design, such as product design and furniture design remain in place, the centroid of the design field is in flux, with expanding boundaries creating a move towards much more complex and abstract issues. Accounts from diverse sources in industry indicate that the nature of design briefs, the sphere of project influence, average size of projects, the level of organizational hierarchy among client personnel, the degree to which projects are interdisciplinary, and the number of projects that are directed towards longer-term futures have all undergone rapid change. These indicators are more discernable in leading design companies, which might emblematic of a pervasive trend across the design profession. This trend is also manifest in the types of projects being undertaken in all major academic design programs in the world.

In industry, skills based design is yielding to "design thinking" which is being directed towards a different set of problems such as organizational transformation, defining new markets, designing new experiences, and contributing to corporate strategy. (Beckman and Barry 2007, 25) Due to an increased demand for a differentiation based on innovative offerings, designers are being asked to work on both the problem and the solution sides in increasingly ambiguous problems. In addition, business schools around the world are looking to embed design thinking in their curricula.

3. An Urgent Need for Sytemic and Accelerated Change

> "The time scales of modernity have collided with the time scales that governed life on Earth in premodern times. Every year, our industrial systems burn as much fossil fuel as Earth has stored up in a period of nearly a million years. At this rate, we'll use up the planet's fossil fuel reserves within the equivalent of a

second in geological time. The acceleration of the speed of human population growth means that in a single human lifetime, the Earth may lose half of its living species, species that took tens of millions of years for evolution to create through the process of speciation." (Thackara 2005, 32)

The 2007, the Intergovernmental Panel on Climate Control, presented a grim picture on global climate change: "warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice and rising global average sea level." (Bernsein et al, IPCC, 2007, 30) One of the most critical attributes of these the large-scale issues is that they tend to have positive feedback loops and are likely to be growing at an exponential rates, creating a increased trend towards widespread instability. It is possible that the forces at play are beyond human intervention and it is too late to thwart dire consequences. However, in the absence of knowledge that it is so, the question that still stares us in the face is "*can we design ourselves out of the predicament we have designed ourselves into?"*

As Manzini pointed out, "what is taking place is actually a structural crisis, and that the global model of development is the true issue under discussion" (Manzini, 1994, 38). This structural crisis needs to be met with change that is rapid and exponential in its magnitude. There is no doubt that time is of extreme essence. But the human race lacks a good track record of initiating widespread changes that are rapid that yield results that are beneficial in the long run. Industrialization is a candidate for being such an example. Methodologies directed towards systemic change need to balance urgency with caution. If we are to attempt to find ways of addressing these issues, the approaches need to have the following characteristics:

- Be designed around an understanding of points of leverage (Meadows 1999, 3-19)
- Be creative, bringing about balance through innovative leverage of meager means.
- Designed for rapid change with built-in propagation mechanisms so that limited resources are directed towards self-sustaining phenomena bringing about change. Exponentially growing threats need to be met with exponentially scaled interventions.
- The mediated phenomena need to adapt to varying conditions: designers need to think in terms of paradigms and platforms rather than solutions.
- The approaches need to be built with control systems that regulate runaway trends and guide it away from undesirable results
- The methodologies need to be integrated and holistic in their function being sensitive to the tertiary effects on the entire ecosystem that it affects

Merely finding novel solutions vis-a-vis complex situations would be less meaningful than finding ways of creating platforms that support shifts in paradigms.

4. Design, a Uniquely Promising Player

Design is being recognized by the world of business for its ability to bring about radically innovative approaches. On one hand "design thinking" has demonstrated efficacy in dealing with abstract undefined problems. On the other, there is an increased recognition that the critical problems facing society such as sustainability are not to be met by the devices of any single field. The philosophies, with which we have conducted business, made decisions, desired growth, consumed resources, and in which various disciplines have acted in good faith all need to be fundamentally restructured if we are to meet the critical nature of the challenges facing us.

Many of the fields in the sciences and humanities are concerned primarily with characterizing phenomena and thus generating resources in the domains of knowledge and understanding that can then be utilized by the fields that *act*. Of the fields that place value in *action,* design is one of the few fields that places an emphasis on "what is the right thing to do" over "how to do things right". In addition, it is a field at the crossroads of the human condition,

technology, business needs, placing value in both the abstract level, and the operational details. As such it is singularly well suited to *generate* trans-disciplinary spaces.

The "Design Complex"

Nigel Cross, referring to The Royal College of Art report of 1979, casts design as a third distinct "*culture*" (Cross 2006, 1), one that has been neglected compared to the other two, namely humanities and the sciences. The structural aspects that render design into a distinct culture also lends it a certain promise in the face of the urgent and critical problems facing civilization.

What makes the designer a promising agent is not a single attribute, but the gestalt of the skills, cognitive processes, design methodologies, attitudes, and structural aspects. I will refer to this as the "design complex". The following are among the attributes are pertinent for casting designers in increasingly strategic roles, and the combination of which make design unique.

(A) Structural attributes that differentiate Design
   a. Designers are primarily concerned about what the future *ought to be*, rather than the defensibility of information borne out by the past. It is a deeply applied field.
   b. It is the designer's mandate to be *creative*. They simultaneously expand the problem space and the solution space. (Cross and Dorst, 2001, 425-437) Design activity begets new design problems allowing the use of "*design to design"*.
   c. Designers *multiplex* between the abstract and the operational, allowing each stratum to gain from the constraints and potential of the other.
   d. Designers create transformations between concept space and knowledge space (Hatcheul and Weil, 2001, 13) and hence have the potential to generate new paradigms, a key point of leverage (Meadows, 1999, 16-18)

(B) Cognitive models that are core to the design field
   a. Design uses *abductive* thinking (March, 1976), the "logic of the possible" in addition to inductive and deductive thinking, the mainstays of other disciplines
   b. Designers practice *eduction*, pulling out hidden insights and latent opportunities from obfuscated scenarios
   c. Design uses *retroductive* thinking, a cognition model that allows the designer to guess at the conditions under which a given phenomenon will emerge.
   d. The iterative method of working involving prototyping is a key derived cognitive model that is a highly effective alternate to pure analysis. This cognitive process possesses an inherent power of weeding out failure modes in *integrated* scenarios. I coin the term *helical cognition* since it is iterative and yet advances the concept state. This mode is particularly well suited to working on complex problems whereby inexpensive iterations allow for development of concepts on multiple fronts integrated within the complexity of the real context.
   e. Designers perform cognitive operations that yield novel configurations, which cannot be arrived at merely as a result of a prescribed process. Designers practice cognitive processes such as imaginal reasoning (Tversky 1969, 255), visio-spatial cognition, representational mediation (Suchman 1988, 325) and symbolic representation enabling "creative leaps" resulting in an increased potential for outcomes that have disproportionate impact compared to the means. (Prahalad, 2006, 2)

(C) Modalities of operation that are strategic:
   a. Designers conduct *synthesis*, creating configurations of value far greater than that of the components. It is particularly significant given resource sensitive scenarios
   b. Designers are comfortable with ambiguity, and have the attitudinal equipment for working on wicked problems (Buchanan 1995,14)
   c. Designers have the creativity and skills to create and communicate novel visions of the future which could then serve as a beacon for strategic roadmaps

d. Designers are effective in multi-disciplinary scenarios, catalyzing focus, fostering a culture of creativity, generating a shared vision and vocabulary to allow rich communication between disciplines that are otherwise language-blocked. Designers perform the important activity of story telling.

(D) Attitudinal, stylistic and cultural attributes

a. The designer is allowed to *opine* and to openly express that they *care.* The design community draws people with passion and emotion.
b. Designers are proactive and are inclined to act as opposed to simply gaining satisfaction from characterizing phenomena. Design is marked by pragmatism, ingenuity, and an impatience for tangible results. Designers, at heart, are builders.
c. Designers are empathic and human centered while at the same time being comfortable in scenarios involving technology and business. Design is one of the few fields that have an ability to integrate across psychological, cognitive, technological, social, economic, and business issues along with the ability to implement plans.
d. Designers share their methods and have the ability to transform people from other disciplines into "design-thinkers", allowing them to tap into their creativity and using methods other than induction and deduction.

While the "designer complex" holds much promise, the increase in the complexity of challenges in the design field has also exposed some limitations in the current tool-sets. The field simply has not had the time to generate methodologies to meet the new challenges it is faced with. This gap presents a significant risk of causing a swing in the pendulum, creating a premature loss of faith in the design field, thus resulting in the real value of the field to remain unrealized. While the value of the "design complex" is perhaps far more profound than is easily recognized, the gaps also create a significant impediment in earning the credibility that is needed among other disciplines without which designers would not be invited to take part in decision-making at the highest levels. New tools need to be developed such as ones to identify leverage points in a large system. The current methodologies serve to meet latent human desires and as such, the methodologies for "Human Centered Design" are at odds with the needs of the larger human condition, and I propose a move away from the term to "Impact Focused Design".

Key Areas Requiring Growth:

(A) Structural issues:

a. The design field is still in the process of finding a cohesive internal logic, and remains heterogeneous. Not all designers possess the training or breadth to work on multi-dimensional problems. The field lacks adequate labels that demarcate one school of thought from another.
b. Design projects tend to be one-offs. The field lacks the culture of extracting values and developing heuristics with universal applicability. By comparison, other disciplines such as business tend to track their one-off cases and maintain a universally accepted rubric.
c. Design is mostly carried out in the scope of a project rather than expanding on the needs of a sub-discipline. For example, the field of Mechanical Engineering might spawn a new sub-discipline such as bio-mimetic micro-robotics, which subsequently would form its own community and draw from the core practices of Mechanical Engineering. In contrast, design harbors generalists and designers capable of addressing multi-dimensional problems are habitual nomads, getting pulled into a health project on one day and an energy problem the next. An opportunity to create sub-disciplines around recurring problems is often missed.
d. Since design stands at the nexus of multiple disciplines, with the purview growing sharply with each passing year, it is impossible for a designer to be an expert in all the disciplines. And yet, often they find themselves having to make decisions that are best made with the help of a specialist.

e. Design is largely qualitative and resists dealing with numbers. But many of the arguments in important decisions are carried on the backs of numerical arguments. While emphasis on the qualitative gives power to abductive thinking and intuition, it creates a weakened platform for objective decisions.

(B) Cultural issues:

a. Design tends to rely on its creativity and often overlooks existing knowledge.
b. The culture of abductive and retroductive thinking places a higher value on novelty, ingenuity and effect, rather than defensibility, or the theoretical basis for action. This falls foul of the scientific community whose cultural emphasis lies in objectivity, repeatability, and the use of data to defend claims.
c. There exists an absence of a clear rubric for evaluation of quality. Quality tends to be ascribed in a manner that lacks consistency across the design field. Rigor is a personal choice rather than being forced by the inherent quality of the field. For example, it is possible to be far less rigorous in designing a new K-12 education system through design methodologies than a shell concrete dam that needs to resist an earthquake of a certain magnitude and nomenclature.
d. Designers tend not to be systematic about documenting their work. The inadequacy of data in the field prevents evaluation of the field by outside agencies or by themselves at a later point in time.
e. Designers design, they tend not to write. And much of the writing is carried out by observers of design and design theorists rather than by designers. This creates a gulf between design practitioners and design theorists, not unlike Art and Art History. Designed objects, while rich vessels for semiotics, falls far short of supporting communication that can enable the discourse needed to expand a field.

(C) Inadequate toolsets:

a. Design lacks the adequate research methods to query large-scale trends and phenomena. Qualitative tools such as ethnographic research are effective for identifying latent needs and uncovering incisive insights that inspire design but the same tools are not as effective in identifying system wide needs. An emphasis on ethnography often puts the value on human desire rather than the health of the systems that sustain humans.
b. Design lacks the tool-sets for mediating selection of solutions among a large array of possible concepts in complex multi-stakeholder scenarios when counter-intuitive optimization or conflict resolution is called for.
c. Designers do not possess adequate tools to assess large-scale implications of a proposed concept. Fields such as development economics are far better suited for such evaluations. Standard tools such as prototyping sometimes have limited scalability e.g. the effects of a new freeway system on a community cannot be probed through prototyping, however, with better documenting conditions, we might find that a given project might serve as a prototype for another.
d. Designers tend to identify points of leverage by intuition rather than by identifying the category of leverage, for instance the gain on a positive feedback loop. Often, points of leverage are counter-intuitive.
e. Designers often fail to express the value of their outcomes to another field when there has not been the opportunity to create common vocabulary. For example, for years the design field resisted the comparatively simple and potentially lucrative argument for a Return On Investment analysis on design activity, and to this date, fails to sell its wares to uninitiated businesses in the language of business.

(D) Lack of adequate mechanisms for advancement:

a. Design needs to build platforms for increased credibility. Peer-reviewed design journals are scarce, and the readership among designers is limited. There is a need for platforms that have means of maintaining credibility and yet suited to the designer's modalities of authoring and the type of content prevalent in design.
b. Academic institutions offer inadequate mechanisms for advancement in this field. There are too few world-class universities that offer PhD programs in Design, thus

creating a very small cadre of people who are working to advance the field. It is not surprising that many of the recent advancements in methodologies that have been adopted widely have come from leading design firms.

c. Designers in PhD programs, in order to conduct doctoral level work, often turn into "designologists" rather than remaining designers. Of the various categories of research work connected to design, namely research *of* design, research *for* design, research *through* design, and research *with* design, (Frayling 1991) the latter two have been neglected and need to be expanded in academic practice.
d. Designers have demonstrated an ability to be catalysts in fostering a multi-disciplinary culture, and yet there has been little thought given to developing heuristics for trans-disciplinary configurations, with methodologies for each class of complex problem.

5. A Meta-Discipline

Design is uniquely positioned to engage in complex multi-dimensional problems, and yet to do so effectively, there are many areas it needs to buttress itself in through collaborations with other fields. But in filling the gaps in its own methodologies, the bigger opportunity is for design to find ways of systematizing and expanding the nature of collaborations with other disciplines.

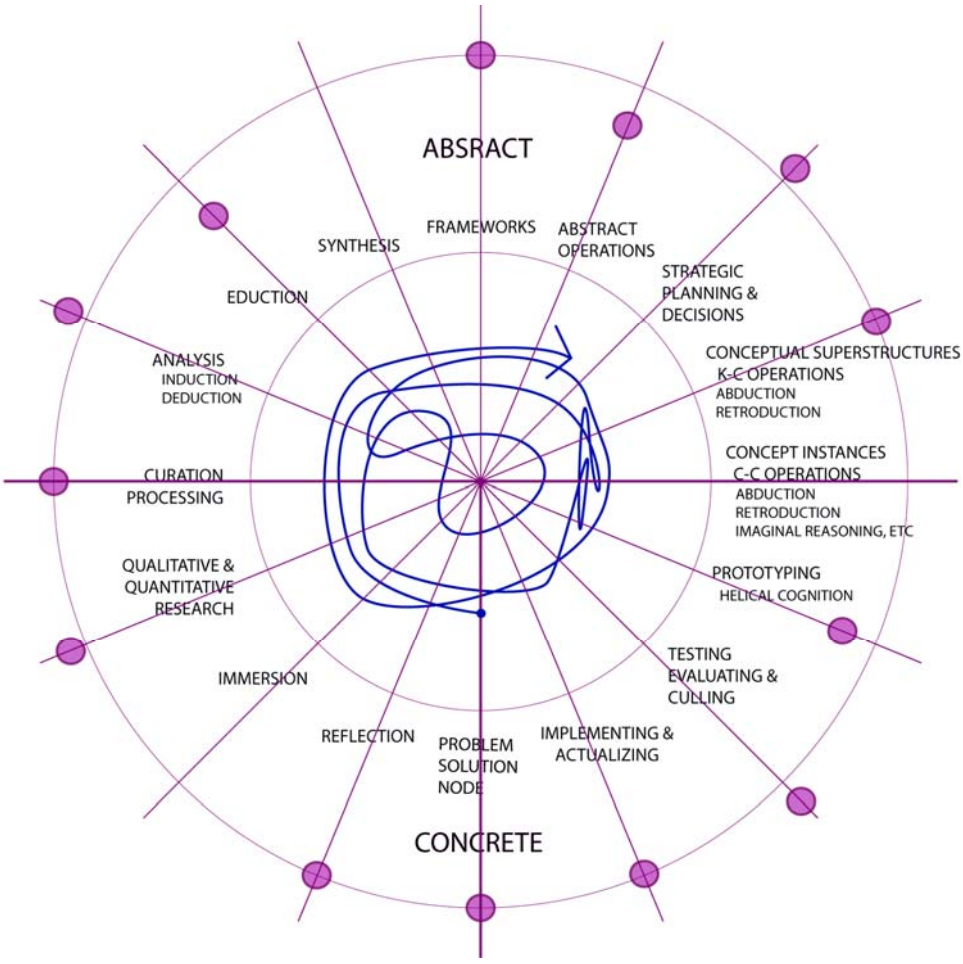

Fig. 1: The various modalities in the design process. The dots represent areas of possible collaboration.

Figure 1 depicts some of the modalities that the design process traverses in alternating between the problem domain and the solution domain, in both cases pulsating with phases of expansion and convergence. This process does not move necessarily in an orderly cyclical

fashion, and there are jumps taken between modalities, often with a rapid multiplexing between modes and between the abstract and the operational. The dots on the figure indicate strategic collaborations that would expand the field. The dots on the outside of the larger circle denote an expansion of large amplitude along a particular modality. For example, the dot on the analysis modality suggests collaboration with deeply analytical fields such as applied physics, systems analysis, or engineering research. On the other hand, the dot on the conceptual superstructure line might involve artists, science fiction authors, filmmakers, and visionaries.

A trans-disciplinary system integrates methodologies contained within discrete disciplines, sharing epistemologies and boundaries of practices within a common framework with a relevance to the special overall context and goals. Given that a trans-discipline creates a culture of its own, it can be seen as a vessel for a meta-level cognition. (Hutchins 1995, 354) The strategic and choreographed combination of discipline suggests a methodology for the creation of trans-disciplinary systems with pertinence to the specific class of problem. I will refer to this system of crafting trans-disciplines as “meta-discipline” (Figure 2). Meta-disciplinary methodologies are ones concerned with the creation of optimal trans-disciplinary systems that define boundary conditions, information exchange mechanisms, heuristics, a common syntax, shared epistemologies, temporal engagement patterns, handover protocols, and areas of discrete action, and above all, the rules and core values of the new discipline.

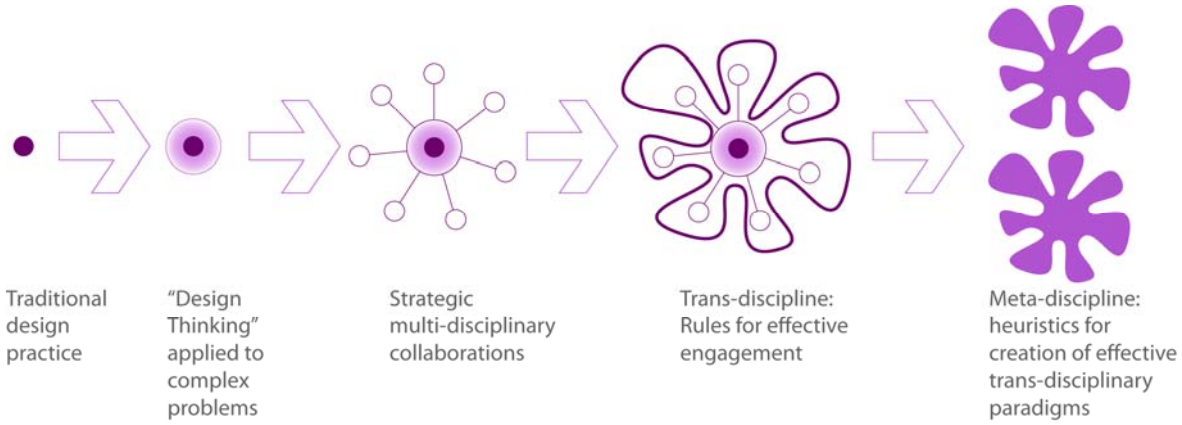

Fig. 2: The stages of progression from core design practice to Meta-discipline.

Figure 2 depicts how core design practice became more generalized in applying “design thinking” to problems not traditionally considered within the purview of design. We are beginning to see multi-disciplinary collaborations take place across institutions and academic programs. Systematization of the rules of engagement between sets of discipline yields a trans-discipline. The process of creating trans-disciplinary paradigms attuned to a given class of problems would constitute a meta-disciplinary practice.

Another way to look at this is through the use of a sports metaphor. If the objective in the game of soccer is to win by scoring as many goals while blocking all possible goals, then it makes sense for the ball to be passed to the player who is in a better position and with the skills to generate the best play. And while one player is in possession of the ball, the others move to positions that allow for optimal passing. The roles and skills of the players are different but sometimes interchangeable. Sometimes a play involves a pre-planned sequence, and at others a combination of finely honed skills and improvised moves. And everyone on the field agrees to play by the rules of soccer rather than lacrosse, but in special conditions like penalty kick-offs, the game assumes a certain different flavor. With soccer as a metaphor, a trans-disciplinary system exists in the context of a class of problems. The interplay of the different disciplines is to be choreographed such that the key strength of each discipline is leveraged, and the opportunities

for gestalt phenomena and emergent synergies are maximized. For instance, if the strength of development economics is in evaluation of large scale implications of a given option, and that of design in generating an array of creative options in response to a certain goal, then it makes sense to sequence the engagement of the fields such that the designers generate creative options, and the economist evaluates their potential large impact at a large scale. Rather than a discrete handover, if the process involves a deep collaboration, then the insights from the economist would inform the design, and vice versa.

In trying to create multi-disciplinary initiatives, we still find it hard to escape the philosophies of fields that were formed around the study of simple or "discipline-bounded" phenomena, As Hayek put it in 1964,

> "What we must get rid of is the naïve belief that the world must be so organized that it is possible to direct observation to discover simple regularities between all phenomena, and that this is a necessary presupposition for the application of scientific method. What we have by now discovered about the organization of many complex structure should be sufficient to teach us that there is no reason to expect this, and that if we want to get ahead in these fields our aims will have to be somewhat different from aims in the fields of simple phenomena" (Hayek 1964, 349)

Complexity requires that we rethink the way we approach problems. In the words of Herbert Simon,

> "We have learned very well that many of the systems that we are trying to deal with in our contemporary science and engineering are very complex indeed. They are so complex that it is not obvious that the powerful tricks and procedures that served us for four centuries or more in the development of modern science and engineering will enable us to understand and deal with them.."(Simon, 2000, 601)

While it might be philosophically befitting to think of the designer operating in a more rhizomatic paradigm (Deleuze and Guattari, 1987), acting as agents *within* a multi-stakeholder ecosystem, it is also appropriate to put design in the center of the action, and look at its potential in catalyzing trans-disciplinary systems to solve complex problems.

Currently, despite the number of multi-disciplinary teams coming together to work on complex problems, the process often involves exploring the *intersection set* of the view points rather than the *super-set* of possibilities for the unique combination. The rules of engagement seem to rely on finding a "common ground" which might limit the extent of the collaboration. While it accounts for some ground gained in empathy, shared epistemologies and vocabularies, the meetings often fall into a negotiation between the value systems of the different fields. In academia, another problem that arises is that of credibility within each domain. A truly trans-disciplinary endeavor stands outside of the rubric of any of the member disciplines and as such casts "projections" on the plane of each discipline, rather than being evaluated *in terms of* the core values of each discipline.

A trans-disciplinary outcome might be truly remarkable in effect and yet fall short of gaining credibility because it does not adequately push the boundary within each of the member disciplines. As such the credibility of a trans-disciplinary outcome needs to be measured within the rubric created for itself as a new discipline, or be pieced together by combining the viewpoints of each discipline, much as the geometry of a three-dimensional object can be inferred from multiple projections. Academic systems currently fail to provide adequate mechanisms for trans-disciplinary endeavors to gain credibility unless the work is exemplary within each member discipline. At a pragmatic level, universities tend to be compartmentalized, and a truly multi-disciplinary doctoral student finds it difficult to locate a patron who would fund them, without also having their study artificially skewed by the requirements of the department of their primary affiliation.

6. Agent of Change: A New Designer in a New Design Paradigm

The design field is uniquely positioned to be one of the key players bringing about change. The key attributes of the design field makes it a strong candidate in working on challenges such as sustainability, but this expanded role for the design field implies a fundamental shift in the designer's identity.

The identity of the designer is currently that as an "identifier of needs and definer of systems" (human, technological, business). The core values in design are practicality, ingenuity, empathy, and a concern for appropriateness (Cross 2006, 2). Without a radical modification in core values, it would be a subtle yet important shift if the identity of the designer were to be altered from being an "identifier of needs and definer of systems" to "agent of appropriate change" or "a catalyst for systemic transformation". A transformation of the identity would shift the inbuilt fetishism from the "elegance" of one's work, to the "impact" it generates. Albeit a subtle move, it spells a profound difference in the choice of tools and approaches, especially for those in the design field who aim to be thought-leaders and are willing to engage in trans-disciplinary work involving systemic change. Such a shift in identity would cause and be a result of fundamental changes to curricular structures, as well as in processes in design practice.

7. Meta-disciplinary Mechanisms

A mechanism that would allow for prototyping meta-disciplinary activity, and draw the right type profile of individuals to participate is not easily found. Academic departments tend to be insular and resist change. Laboratories that have a focus on a given domain build their processes around the needs of the domain. The problem lies in being broad enough to allow for meta-level questions, and yet be focused such that there are clear objectives. Such a mechanism must be designed to encourage sporadic and opportunistic membership, and yet serve as a mainstay for sustained work. It needs to be designed to redesign itself and morph to new structures as the understanding of meta-disciplinary work grows. It needs to be able to house multiple trans-disciplines so as to develop the meta-disciplinary practice. And it needs to work within real world constraints of resources and problem domains.

At Stanford University, we have been working on a formation of such an entity with an inherently meta-disciplinary structure. We have named it "The Design for Change Lab" (Figure 3) and its mission is to "Develop trans-disciplinary approaches to drive rapid change and large scale impact". The Lab's meta-disciplinary structure is aimed at expanding the design field, exploring means of bringing about rapid and large-scale change vis-a-vis critical problems. It is also forms a natural platform that would attract experts from different fields unified through common goals.

The Design for Change Lab provides opportunities for students and experts from diverse disciplines to engage in work with an *integrative* perspective. Part of the meta-disciplinary approach would not only be to configure the involvement of different disciplines, but also explore collaboration between different types of agencies. Rather than a specific domain, the ethos of this lab is structured around a set of values and principles.

The Design for Change Lab creates a novel precedence by combining the following values:

a. **Meta-Disciplinary**: A continual aim to define trans-disciplinary systems in response to a particular nomenclature of a complex problem. Integrating and configuring processes from different fields such as design, behavioral sciences, engineering, systems analysis, cognitive psychology, and economics to deliver a larger set of tools and processes. For instance, disciplines such as sociology that primarily *characterize* phenomena might now be asked to help craft tools that proactively create seeding functions of emergent behavior.

b. **Strategic combinations of players:** Creating unique configurations between groups such as universities, industry, individual experts, institutions, digital communities, venture capital, government bodies, non-profit organizations and social entrepreneurs to generate an integrated strategy. This combination allows research into *new methodologies and heuristics* for collaboration between disparate entities for effective deployment of ideas.
c. **Filter for large-scale impact:** Requiring projects to be directed towards those contexts and geographies, where scale, impact, and rate of change are critical parameters. However limited the scope of a single project, it is asked to be emblematic of a larger class of problem that is critical, allowing for extraction of value that is universal or transferable.
d. **Global Network:** Working as a node of an international network with active collaborations around the world will help including cultural issues and focus on projects of global relevance.
e. **Triangulation:** Work on multiple objectives at the same time in order to explore meaningful cross-pollination. The three main vectors i) Sustainability ii) Integrative Technology Futures iii) Dynamics of Change to afford a broad platform for trans-disciplinary work.

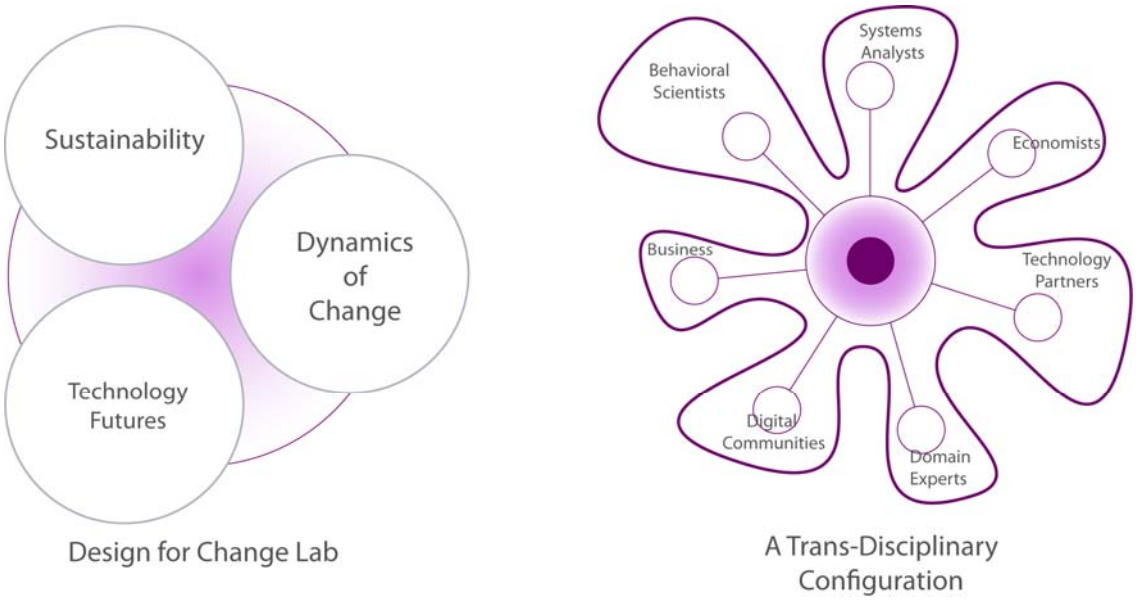

Fig. 3: The structure of the Design for Change Lab, and a proposed trans-disciplinary system.

The work in the lab will be organized along three vectors each of which might form a separate trans-discipline but the boundaries between them are meant to be porous:

a) **Sustainability**: Issues of global importance such as energy, water resources, climate change, and strategic initiatives involving environmental impact.

b) **Integrative Technology Futures**: Technology is one of the major frame-changers in society, and yet tends to not be directed with cogency of vision. Projects to carry out research on integrative technology configurations driven by long-term vision.

c) **Dynamics of Change:** Research on seeding functions of emergent behavior and the methodologies to catalyze and manage rapid change.

The creation of an aspirational, explorative meta-disciplinary entity such as the Design for Change lab will no doubt be challenging. It will have to attract the collaborative involvement of the right profile of people representing diverse disciplines, agencies, and roles. Apart from being a part of an international network, we feel that the being embedded in the Stanford Design Program and Stanford's "d.school", being located in Stanford University with its increasing openness to multi-disciplinary collaborations, on-campus multi-disciplinary institutes such as the Precourt Institute for Energy Efficiency, Woods Institute for the Environment, the proximity to other universities such as University of California Berkeley along with it's institutes, the entrepreneurial energy of Silicon valley along with its profusion of high technology companies, the increasing number of clean-tech companies in the area, and the proximity to design companies creates an rich setting for a node of such a meta-disciplinary endeavor.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Energy produced by its own territory

How outputs generate widespread business

Silvia Barbero[1], Franco Fassio[2], Cristian Campagnaro[3], Clara Ceppa[4]

Abstract

Two design solutions are described to suggest possible approaches for sustainable development in the field of energy. They concretely integrate production culture and design research in order to reveal the connections and congruencies, today still hidden, between artificial production and Nature. The first case deals with the production of renewable energy for the self-sustenance of a small-medium enterprise in synergy with the resources found on the local territory; the second case deals with the need to display products at environment-friendly fairs.

The challenge is to make even our daily actions sustainable, starting with our industrial energy needs. This is why social education is the most important element: a change in behaviors and greater sharing in the application of new lifestyles.

1. Introduction

Energy is one of the basic factors that determine the competitiveness of a country's economy and the quality of life of its population. In network societies everything is kept together by energy and material flows: air, water, earth and fire, the four basic elements used by Empedocles to describe the world in which we live, are connected to each other (Pallante et al. 2006). Global times and spaces require a permanent availability of energy in its various forms, especially electricity (Donolo 2006).

The economic evaluation of energy provides a quantitative index of its importance. Suffice it to say that the price of oil has gone way above $100 a barrel, but only when we are faced with emergencies, such as the blackouts occurring throughout the world in the past few years, do we start to realize the qualitative effects of insufficient energy. These crises are becoming more frequent due to the growing complexity of our system. Globalized society touches the limit of its development and is becoming aware of its dependency on energy sources and its need to achieve sustainability for its consumption requirements.

The raw materials that allow us to produce energy take on a crucial supranational role and create worldwide political and economic scenarios. The situation becomes worse when the resources are non-renewable sources or sources that generate high environmental risks. The greatest energy demand is actually met in two ways: by increasing exploitation of the planet's resources and by conducting a more intensive search for energy efficiency. These solutions, however, create a vicious cycle that does not guarantee the long-term sustainable development we are hoping for.

Energy is a human right for self-improvement but it also a common resource needed by society as a whole. The legitimate expectations of energy procurement are only valid in conditions of limit or sustainability, following the ethical principles of responsibility and precaution.

A radically new approach to this issue, which goes beyond specific technological solutions, is therefore necessary to lead "global civil society" (Capra 2002) to redesign its flow of resources and relationships within its local context and generate multiple and complex solutions.

Below we have presented two design solutions that suggest possible approaches for sustainable development in the field of energy. The first case deals with the production of renewable energy for the self-sustenance of a small-medium enterprise in synergy with the resources found on the local territory; the second case deals with the need to display products at environment-friendly fairs that exemplify and demonstrate the environmental commitment of a company which is making physical contact with its customers/consumers.

2. Energy as product from territory

The broad scope of the first project proposed, involving a Piedmontese SME, Agrindustria, is to generate a new manufacturing and territorial scenario that modifies geopolitical relations and promotes development that is closely connected to the setting in which it is located.

This study focuses on a production, distribution and consumer context circumscribed and defined in the province of Cuneo, and involving active local entities on the territory:

- The Politecnico di Torino, with its course on Industrial Design, provided the theoretical instruments for an innovative approach to design according to the idea that "innovation is not found in continuous technological upgrades but in the angle from which you look at problems" (Bistagnino 2008) with a farsighted gaze. The ongoing research through the culture of the project, precisely because of its intrinsic characteristics, provides a change in how environmental issues are confronted.
- The Science and Technology Park for agribusiness, Tecnogranda of Dronero (CN), contributed to make the project's execution feasible, particularly regarding technical practicability; it verified the actual practicability of the technological details, the

economic feasibility by verifying whether the resources needed to build the system were justified by the foreseen returns expressed in the form of advantages, thereby contributing to the search for funding; lastly, it verified the legislative feasibility by exploring legal constraints and laws regarding the issues of energy, waste and the environment.

- The company, Agrindustria snc of Cuneo, contributed to the project in the way of organization to make sure the proposal could be carried out within its existing organization; it examined the logistics for providing the energy flows required; it provided a monitoring system to identify the parameters needed to correctly evaluate the trend of the project; it examined the motivational aspects to verify the actual degree of acceptability that users could express regarding the new system after it was built.

These actors helped make the results complete because to solve the same problem they became involved in a multi-layered discussion with each other to jointly find new directions in which to move. This enabled them to listen to voices from various sectors: design, industry, politics, the environment, social bodies, economic agencies, etc. None of these is autonomous. Quite the contrary, they are closely related to each other and together form a complex multifaceted system.

Specifically they discussed how to reduce the emissions of the Agrindustria production process by converting it from a linear industrial system, which produces waste as well as products, into a ramified system whose outputs become a resource for the company itself and other local enterprises. The system was designed in this specific company and territorial context because in order to acquire independence and autonomy the company must be in symbiosis with the local community and therefore the model cannot be exported *tout court* to other areas.

The narrow vision of the critical points and single productions of Agrindustria and the broader vision of the entire Piedmont system enabled us to delineate a complex systemic project and discover the "*hidden connections*" (Capra 1996) that add value to waste. The study thus structured led to the design of a complex system that broadens the production capabilities of the company and develops new activities in the local community.

The company achieved energy autonomy, both electricity and heat, by using renewable resources found directly in-house and on the local territory within a maximum radius of 40 km. The technical and technological decisions responded well to the company's needs and know-how, deriving from its 10 years of experience in handling and transforming biomass from farming activities. The production of energy from renewable resources, such as biomass, not only adds value to the company but also to the surrounding territory because it contributes to conserving the natural heritage of the area. This particular case involved cleaning out the underbrush of the mountain communities, eliminating manufacturing waste deriving from the production of pallets and crates. It favored the biodiversity of Cuneo farm products through the cultivation of mixed associated woodland using the biodynamic method.

Agrindustria currently transforms materials considered secondary in the farming and industrial processes (e.g. nut shells and corn cobs) to obtain fibers, meal, granules and products used in myriad production sectors (from mechanics to cosmetics). At the same time it obtains byproduct flour and sells it at low cost as fuel for power plants. The specific solution of this industrial waste of plant origin has led to the study of its value-adding potential in a **biomass-fed power plant**, the design and construction of which are the key for transforming the single linear industrial processes of the company into one complex system.

This allows Agrindustria to make a *trait-d'union* between agriculture (the cultivation of mixed woodland of authoucthnous trees) and industry (adding value to waste products) ***by taking output from its own manufacturing process to be used as input and at the same time improve the territory***. In fact several types of biomass can be recovered from the surrounding area which currently are unrecognized as valuable, such as the derivatives of **local products** (poplar bark, wood chips, scraps from the production of crates and pallets) and by **cleaning out**

the woods of mountain communities. The company stands on a strategic spot that allows it to obtain virgin wood by cleaning out the woods of its territory. This business allows many families to remain in the valley because it is located at the natural bottom of the valleys of Gesso-Vermenagna-Pesio, Stura, Grana and Maira.

The project of converting biomass into clean energy (electricity and heat) responds safely and locally to the problem of energy supply that affects our entire nation. Italy is later than the rest of Europe in its use of renewable resources. European Directive 2006/32/CE on the efficiency of the final use of electrical energy and energy services sets the goal for member states to adopt measures for obtaining an energy savings of 9% by the ninth year of application starting in 2008. In addition to a general savings in energy, the EU also establishes targets regarding renewable energy[5]. Italy has also drafted important program documents to promote and incentivize the use of biomass[6], but the ITABIA statistics (*Italian Biomass Association*)[7] show a steep divide between current trends and expected goals[8]. In order to reach these goals, it is vital that we respect the obligations of the Kyoto protocol (1992) for reducing greenhouse gas emissions and become more independent in our procurement of energy[9].

The project for a micro power plant for Agrindustria specifically entails conversion by combustion in an **adiabatic oven with an average capacity of 1.6 MWe** of biomass such as chipped virgin wood with the addition of flour from nutshells and corn cobs derived from the in-house production of granules. Though this plant is small it adopts **innovative** technology and has an important feature: it is easy to **operate** and **maintain**. Moreover, it required only a **small investment**. The production project entails the combustion of chipped virgin wood on a movable flat grill. The chips have 35-40% moisture and the latent heat contained in the combustible gases is recovered by means of a vapor generator to create electricity and heat. The **electricity** is produced by means of a combined turbine with an alternator. The vapor of the cycle must be condensed by means of a secondary fluid (water) with a low temperature rise (4°C). The water comes from a phytopurified fire-prevention pond [10] having swamp vegetation and water plants and is fed to the plant by means of a pump. The **heat** produced by the plant is directly used by the company and its production processes to desiccate, pasteurize and cook". In particular the virgin wood chips are used for the production of pellets to burn in household stoves. It also dries legumes and cereals, which are abundant in the Cuneo area[11]. The corn is dehydrated on the cob to obtain cornmeal for polenta in a controlled productive chain and cob, already used and processed by Agrindustria.

Cogeneration not only produces energy but also many high-quality products such as corn dried on the cob, which creates meal of high quality and organoleptic value.

In short the principal **products** produced by this new production scenario are:

- Virgin wood pellets from authoucthnous trees for domestic stoves;
- Corn granules for polenta controlled in the productive chain; the high quality of the product derives from the fact that it is dried on the cob, something that is hardly ever

[5] Directive 20001/77/CE, Directive 2003/30/CE and Reg. CE N. 1782/2003).

[6] The *Programma Nazionale Energia Rinnovabile da Biomasse* (PNERB), the *Programma Nazionale per la Valorizzazione delle Biomasse Agricole e Forestali* (PNVBAF) and *Libro Bianco per la Valorizzazione Energetica delle Fonti Rinnovabili*.

[7] Report *Le biomasse per l'energia e l'ambiente.*

[8] The total primary energy obtained from biomass in 2005 was 5.2 MTEP, which makes up 2.7% of total consumption.

[9] Based on the current trends, by 2030 the EU will be dependent on imports for 90% of its oil needs and 80% of its gas needs.

[10] The same fire-prevention pond was studied in a systemic vision to ensure the multiplicity of advantages to the entire company. Firstly the water resource on the property of Agrindustria was exploited: the water from a stream was used to irrigate the fields. This source is purified by phytopurification by authoucthnous plants and is oxygenated by small cascades and fountains. Then it ends up in pond with a high level of cleanliness. The water of the pond can be used not only for fire prevention (required by law) but also to cool the heating system of the power plant and to allow the proliferation of fish and algae (which expands into new business sectors). On the banks of the stream and the pond it would be possible to start an educational workshop for children from the elementary and middle schools so that they understand how environmental sustainability is not only an abstract concept but tangible even in industrial scenarios.

[11] A parallel study of all the farming products of Cuneo (grains, grapes, fruit in general) has led to the prioritization of certain typical products to be valued (Cuneo beans) and some discards that are still not used could be inputs in certain well-established processes of Agrindustria, particularly the scraps of the fruit orchard processes (kiwi, apples and peaches).

done anymore in Italy. Moreover the importance of this product has been endorsed by the establishment of the ONLUS Association *Antichi Mais Piemontesi* (Ancient Piedmontese Maize) whose members are local farmers and factories that cultivate or use traditional maize varieties (yellow and red Pignoletto, yellow, red and white Ottofile, Ostenga and Nostrano dell'Isola);

- Biodegradable compounds obtained by joining bioplastics and plant fibers to achieve high level mechanical, physical and environmental services/performances.

Several new **services** are also provided:

- green electricity, which is more valuable than electricity produced by using fossil fuels because it does not create the gases responsible for the greenhouse effect or other harmful emissions; what is more, it is renewable thanks to natural cycles[12];
- thermal energy, which entails the exploitation of the heat naturally dissipated by the micro-plant;
- education about sustainability, the desire to open the company up to the public to become an educational workshop is intrinsic to the philosophy of Agrindustria. To create an educational process that illustrates the content and potentialities of the project **reinforces the bond between the company and the local community**; acknowledgment of the qualities of the project and the company's way of operating in the territory becomes an instrument for spreading the culture of sustainability and the community's self-identification in and recognition of its local excellence.

The projects **strong points** are:

- The systemic vision of the entire company which enables it to reduce waste;
- An appreciation of the local territory and its biodiversity with the cultivation of mixed woods (elm trees, wild cherry trees, beech trees and cherry-plum) in associated 3-5 year cycles;
- Adding value to wood byproducts from the local SMEs (palette and crate making companies);
- Creating new jobs, in particular for the families who live in the valleys;
- A stimulus to clean out the woods in the surrounding mountain communities;
- The utilization of innovative technology compatible with the company's know-how and at low cost;
- The production of clean energy from renewable sources;
- The reduction of energy used by the production processes of the company thanks to the exploitation of the heat dissipated by the power plant;
- The increase in the number of services offered (electricity and heat);
- The production of new high-quality products (maize for polenta, virgin wood pellets, dry nut shells, corn cobs) with an consequent increase in revenue;
- A plot project that can be taken as an example, even though it may not be entirely exportable.

The project proposes a valid alternative to developing the discourse of energy procurement and emissions from power production worldwide[13]. The increase in natural catastrophes, in the

[12] Green certifications are the new instrument to incentivize the use of renewable sources of energy after the liberalization of the energy industry governed by D. Lgs. 79/99 (the so-called Bersani Decree). The previous law was based on Law No. 9 and Law No. E 10/91 and the CIP 6/92 provision: this legislation has succeeded in raising the awareness of society that the production of renewable or "clean" energy is not just a slogan but a focal point of sustainable development, the viaticum of progress which must not be perpetuated to the detriment of ecosystem.

course of the past decade are a clear indicator that climatic instability is intensifying; precisely while humans are abusing those services that would be offered by a healthy ecosystem. The analysis of the dynamics behind the present natural disasters shows that environmental tension and social tension are closely related. Poverty, the scarcity of resources and population growth create vicious cycles that lead to the deterioration of systems and local communities (Lanzavecchia 2000).

This global issue finds effective solutions only through local actions that are coordinated in a complex and all-inclusive way.

In this context it becomes increasingly urgent to implement actions that are sustainable both environmentally and economically. Agrindustria responds loud and clear to this need, made plain by the European Community[14], with its design and production system having low emissions and high energy efficiency. All the company's previous outputs are now properly used as inputs for other production processes.

Therefore the research demonstrated the design advantages of the systemic approach, leading Agrindustria to a change in human production activities in relation to the territory. Starting with the critical points closely related to a specific local scenario, we arrived at achieving widespread benefits for the environment, economy and society in general which have the potential to change local as well as international dynamics and relations that are both complex and delicate.

3. Energy as subject of the trade fair

To communicate these results to a greater and more diversified public we thought about trade fairs as a place where companies display the fruits of their skills in a given sector.

As a means for development, growth, consumption and as the "driving force" of the market energy serves humanity in as much as it feeds our "industrial" muscle as well as our "artificial stage sets", i.e. the trade fairs that display so many of the products generated by the economic system.

Trade fairs, an instrument for global exchange, are currently facing the energy issue mainly in the form of an opportunity for the company to exhibit. The stand is a likely reproduction of the enterprise placed in physical contact with customers/consumers: a stage which is set up to make known the organization and its products by establishing a contact between the company itself and its potential customers.

Energy at trade fairs has a dual purpose: it is an "object to be promoted [15] and presented in its various forms and as an "actor" of the exhibition, i.e. the power used to carry out the event. The latter aspect, however, until now has only been confronted shyly. Some bodies propose forms of certification [16] that prove the "clean" origin of the energy that feeds the event. The renewable resource that supplies the fair does not necessarily derive from the hosting organization; market strategies allow the input into the network of the amount required for the

[13] On 11 December 1997 the Kyoto protocol was signed by more than 160 countries during the COP3 Conference of the Framework Conference of the United Nations on climate change (UNFCCC) and global warming. The agreement contemplates that industrialized countries lower their pollutant emissions by 5.2% from the values of 1990 within the time span of 2008-2012. The agreement was drafted on an international level because the effects of climate change go beyond national borders and its repercussions are not only environmental.

[14] The European Union, which often acts as the champion of the Kyoto protocol, sets itself the ambitious goal of obtaining 25% of its primary energy from renewable sources by 2020. Particularly the Directive 2001/77/CE of the European Parliament and the European Council of 27 December 2007 lay out basic guidelines to promote the production of electricity from renewable sources and declare that the national goals indicated must be compatible with the global goal of 12% of gross domestic consumption by 2010 and in particular 22.1% of the total consumption of electricity in the European Union must be produced by renewable energy sources.

[15] Numerous events have been organized to promote the sale of products and services associated with "more sustainable" forms of energy, amongst which we cite as examples the Renewable Energy Exhibition 2007 (14-17 February 2007, in Lyon France), Genera 2007-Energy and Environment International Fair (28 February-2 March 2007, Madrid, Spain), Energymed 2007 (Mostra Convegno sulle Fonti Rinnovabili and Efficienza Energetica nei Paesi del Mediterraneo, 8-10 March 2007, Naples, Mostra D'Oltremare).

[16] For example: 100% Energia Pulita-Multiutility, Energia rinnovabile-Life Gate.

trade fair. From this perspective we see a mechanism similar to the one set up with the credit market for the emissions of CO_2: formulas for global balancing that, if not controlled, do not necessarily favor local ad hoc projects or the development of the economy of the country where the event is being held.

The major risk, through the use of a certification, is sending the immediate short-lived message to visitors that – in a concise and often simplistic way – summarizes a broad-ranging and delicate issue such as energy production.

Otherwise, it is vital to communicate not only by content but also by form the strategies adopted by the companies to reduce energy needs of trade fairs by creating a direct and local connection between the source and the event without the mediation of certifications.

This approach was undertaken in-depth as part of a broader long-term project called ***"Salone Sistemico: un modello esportabile di manifestazione fieristica a ridotto impatto ambientale"*** which, in addition to energy procurement, considers all the other incoming and outgoing flows of the trade fair system:

- Stand construction;
- Waste production;
- Packing materials;
- Materials for onsite food consumption;
- Logistics for transporting the goods;
- CO2 emissions;
- The mobility of persons;
- Water resources.

Every area analyzed presented a comprehensive design scenario that aims at reducing the environmental impact of the trade fairs in the study: ***Salone Internazionale del Gusto and Terra Madre***.

The amount of energy needed to carry out and sustain these events must therefore confront a prioritization process of reduction and rationalization that takes into account the aforesaid factors. Only in this way can it adopt energy procurement policies deriving from the use of local renewable energy sources.

To this end **Slow Food** in collaboration with **Industrial Design of the Politecnico di Torino** and Fondazione ZERI, as well as numerous other partners, launched a design process to apply the systemic approach to the 2006 Salone Internazionale del Gusto and Terra Madre.

The systemic approach is coherent with the principles of the Slow Food manifesto:***"Good Clean and Right"***: three fundamental adjectives, closely connected to reach other, indeed inseparable, and which define in a very basic way the characteristics that food must have. Today food is entrusted with the communication of a cultural identity where biodiversity must be protected in the name of the new **"eco-gastronomy"**. In its search for genuine food, the original core of the Slow Food philosophy has become the foundation for a broader-ranging mission that urges us to consider, when defining the quality of a product, not only the importance of the food's taste and organoleptic qualities, but the food in its entire lifecycle. This includes the phases of production, promotion, sale, consumption and, lastly, the disposal or "casting off" of the product. From this **new** definition of **quality** comes the ethical obligation to take action to reduce the environmental impacts made by the trade fairs and other events organized by Slow Food: places where over 6000 wine and food products are presented, tasted, and sold.

The goal of this project, as part of the program of **Torino World Design Capital 2008**, is therefore the progressive reduction of the environmental impact of Salone Internazionale del Gusto and Terra Madre by creating a **network of interdisciplinary expertise** that examines the

different and complex design areas for promoting **new sustainable consumption scenarios and the management of outputs on a territorial level.**

The results of this research will be applied starting at the 2008 event, which will be the starting point for a **multi-annual evolutional process that makes the container congruent with its content** and promotes a Piedmontese model of trade fair events with reduced environmental impact, claiming its role as innovator and its function as educator that the *kermis* has had since its first edition in 1996.

Therefore the systemic approach as the "driving force" of a *sustainable development of trade fairs* makes consumers, producers and designers think about concepts such as **local**, **territorial identity**, **the reduction of environmental impact within the entire lifecycle of products, an output-input connection that values waste products**. This involves implementing a process of "**behavioral innovation**" that does not sacrifice the elements of trade fair under examination but optimizes the flows of promotion, exhibition and commerce, adapting them to the local territorial qualities for the purpose of **educating, protecting and promoting** a pervasive and shared environmental culture.

According to this outline, by joining ethics and expertise creatively, the study took its first steps during the 2006 fair and took a snapshot of the **current status** of environmental impact of the trade fairs being studied.[17]

From the energy point of view, to host the event during its entire lifecycle (pre-and post-organizational phase as well as the phase when it is open to the public) the trade fair structure needs a supply of approximately 9.200 kWh of electricity and approximately 250 m³ of gas. The amounts calculated in 2006 were not high but with other factors such as the production of stands, the energy cost of eliminating waste, the transportation of goods, the design of components and packing for food consumption at the fair, concur in an overall balance of implicit energy consumption that quite a bit more extensive. This is why it was necessary, first and foremost, to **verify the environmental correctness and reduction** of these single consumption levels and the many consumption opportunities provided during the trade fair to the human visitors before thinking about how to supply energy to the facility itself.

Without a doubt the major problems were singled out in the instability of the system for **the management of solid wastes** produced during all of the phases of the trade fair lifecycle (design, mounting the stands, fair activities and dismantling the stands), and the resulting accumulation of mixed waste material[18]. This also included places near the location of the actual exhibition of enogastronomic products.

If we compare the incidence of the trade fair event to the production of waste in the city of Turin and surrounding municipalities during the five days of the event, it is a significant percentage. The number of inhabitants is approximately 2,243,625 and the number of visitors was approximately 172,500[19]. These numbers clearly show how inside the trade fair there are too many opportunities for people to produce waste. Therefore it becomes necessary to use **eco-compatible materials for the stands various other situations at the end of the fair**, i.e. use paint and fabrics of natural origin, and when possible eliminate furnishings having a brief lifecycle (e.g. carpeting), choosing materials and components that are recyclable and reusable, **increase**

[17] **Salone Internazionale del Gusto** is the answer in the food trade fair field to homologation determined by the globalized market which penalizes small high-quality production. It is based on the concept of preserving cultural and environmental heritage associated with enogastronomy while revitalizing local micro economies. The simultaneous international meeting of food communities, **Terra Madre**, transforms Turin into a "*global food village*" by bringing together operators of the food sector from five continents to share ideas about the problems caused by intensive farming that harms natural resources. The aim is to build a genuine network of contacts and connections to reinforce the methods of local, traditional and sustainable production throughout the world. **Salone Internazionale del Gusto and Terra Madre** function as one big event in which the commercial trade fair, a place where excellent traditional food products measures swords with the market, coexists with the gathering of Food Communities which represent the life blood world wide agricultural biodiversity, the positive and concrete alternative to the damaging effects of the homologation of tastes and the globalization of produce.

[18] About 189,06 tons of which was differentiated and therefore properly appreciation by about 17%

[19] Statistics obtained from the *Rapporto sullo stato di gestione dei rifiuti* in the Provincia di Torino, 2005

proper differentiated collection of waste inside the trade fair and **confer the remaining outputs to appropriate plants that will add value to them or eliminate them.**

Moreover an important role is played by **the materials used for on-site food consumption** during the phases of food tasting. In fact at the last edition the use of plastic for these purposes generated about six tons of waste: plates, cutlery and cups of various sizes and types that could not be reused due to organic residues left on their surface. This led to the decision to use tableware that is completely biodegradable and made with natural materials.[20]

The means used for this new and hoped-for attention to environmental needs, even in the **packaging** of the food and wine products, must start heading down a path of self-analysis and redesign. The packaging must be an instrument that suggests new lifestyles and sustainable behaviors, going beyond the sole function of defense/protection and arriving at a new communicative function. A place where symbols and signs, the immediate messengers of new cultural values and territorial rituals that strongly challenge social changes already in progress (e.g., eating rapidly, the concept of food as a souvenir, single portions) in respect of the organoleptic values traditionally correlated to any given food product.

The modalities for transporting the goods and the delegates of Terra Madre, transporting visitors and operators who are exhibiting, are all factors that play a decisive role in the initial strategic decisions that aim to put in place corrective feedback and reduce implicit energy consumption upstream as well as the consequent emissions it produces. The volume of CO_2 emissions is estimated at about 1600 tons [21] to which we must add 6.2 tons of CO_2 emissions produced by the energy consumption of the facility itself.[22] Therefore we must think about good practices that might reduce these emissions and incentivize the visitors at the trade fair to use sustainable means of transportation, promote the use of local products for catering and adopt a logistics system for transportation of the exhibited goods designed to create as little environmental impact as possible.

Further attention should also be given to the control of the liquids that enter the plumbing system so they do not go beyond the normal amount of harmful substances established for households.

After adopting and promoting good practices and new design guidelines to reduce the overall energy needs of the area required to carry out the event, we drew up a strategy for procuring energy from local renewable sources. From an analysis of the Piedmontese territory we discovered a company that was particularly diligent and efficient in the production of alternative energies: the name of this company is Marcopolo Environmental Group. The ecological journey of this company started in the 1970s when it needed to treat the sewage it produced from cattle breeding. Today the group is an international entity operating in the environmental field with numerous patents and production processes for the "active" industrial valuing of waste and the production of energy from renewable sources.

The group is a strategic partner of the project “Salone Sistemico”, and will provide the necessary energy to the trade fair, putting on the market an amount of energy equal to the energy from the biomass plants using the residues of companies located in Piedmont.

- The main advantages of this energy production system are:
- The treatment of materials currently considered waste,
- The abundance of available resources that regenerate seasonally,

[20] This research and the development of products generated by renewable raw materials of agricultural origin have been contributing for years to this sector to reduce greenhouse gas emissions, energy consumption and the consumption of nonrenewable resources and completes a virtuous cycle in which the raw materials from agriculture return to the earth through processes of biodegradation and composting which do not produce pollution.

[21] The amount of CO_2 is calculated on the basis of the consumption of paper, CD-ROMs, and the mobility of the participants.

[22] It was therefore calculated that about 75,000 sqm of wooded areas, equivalent to the surface of Oval plus Lingotto, would be required to absorb the total CO_2 produced by the Fair (the time needed to absorb the emissions depends on the location of the wooded area, the type of trees there and their stage of growth).

- The easiness of extracting the energy,
- The low economic costs,
- Its potential fertilizing power,
- The nonexistent environmental impact of the amount of CO_2 released during energy production is equal to the amount stored during the growth of the biomass used.

The use of renewable sources for supplying electricity and gas needed for these trade fairs will allow us to take the first step (the research involves the evolution of design and applications distributed over several editions of the Salone Internazionale del Gusto and Terra Madre) to promote trade fair energy development with less environmental impact. The energy comes from the same territory and is generated by valuing outputs from different manufacturing processes.

The Salone Internazionale del Gusto e Terra Madre can therefore be considered a "*live/living event*" due to its dynamicity, its continuous involving that puts it at the center of the most recent internationalization dynamics of the country-system and sees it Increasingly connected to network processes oriented towards the development of the territory and visitor dialogue-education policies. It is a workshop where projects such as "Salone Sistemico" find room to represent, design and metabolize new trends and lifestyles, new alliances amongst producers, promoters and distributors, new languages that will accelerate the pace of dissemination of an innovation that restores dignity to the environment and in which development occurs by forming, informing, raising awareness, a sense of responsibility and the sharing of the same principles.[23]

4. Conclusion

In conclusion, these two projects concretely integrate production culture and design research in order to reveal the connections and congruencies, today still hidden, between artificial production and Nature. This will lead us toward efficient and sustainable scenarios. The application of the systemic approach in these areas enables us to reconsider the current industrial setup and distance ourselves from the consumerist vision, associated exclusively with the figure of The Product. We intend to put forth a new paradigm that considers **Humans** the center of an "ecological equation" that acknowledges the interdependency of social and natural structures. In this vision the role of life itself once again becomes essential in biological, ethical and cultural terms. We must recover our cultural and practical capacity **to delineate and program a flow of material from one system to another** in a continuous metabolization that reflects the way **Nature** operates, where even surpluses are valued by the system.

The challenge is to make even our daily actions sustainable, starting with our industrial energy needs. This is why social education is the most important element: a change in behaviors and greater sharing in the application of new lifestyles. The two studies debunk the preconceptions that sustainability is equivalent to hardship. Our habits and concept of well-being are still bound to the logic of "The more I have, the more I consume, the better I feel". These studies show us that a feasible sustainable future is no longer a technical issue and not even a conceptual issue but an issue involving values and economic-political will.

A company and a trade fair that develop new energy efficiencies with a sense of moral responsibility offer an economic model and new consumer scenarios that incentivize a change in mentality and spur people to take on the issue of facilitating energy procurement and reducing energy needs.

[23] The study will be presented at Salone Internazionale del Gusto in an installation placed at the entrance of Pavilion 2. It will show the design aspects, the applications of solutions to the 2008 edition, the partners involved and future goals.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Nomadic way of life
Design tools and policies

Lara Leite Barbosa[1], Maria Cecília Loschiavo dos Santos[2]

Abstract

The present article aims to enable designers to develop nomadic tools. Design policies that considers nomadism and sustainability at the same time are highly recommended.

The introduction defines some differences between travelling and nomadic life. After a brief description of the theoretical background, some possible nomadic groups are presented. According to sustainability, the nomadic tools are revised and design policies are defined. At the end of this article, a comparative table shows different possibilities of design solutions.

The results of this doctorate research are based on interviews, visits to design offices and a survey about mobile design and portable architecture solutions. The final purpose of this research is to produce design policies for everyday life of people with nomadic behavior.

1. Travelling life is not a nomadic life.

According to the contributions of some authors such as Bernard Rudofsky, Victor Papanek, Ezio Manzini, Maria Cecília Loschiavo dos Santos, Robert Kronenburg, a revision about nomadism is presented. Teshome H. Gabriel, Jennifer Siegal and Robert Kronenburg were interviewed and their opinion gives support to the argument that there is a growing number of people moving from place to place.

The focus of the three interviews is to introduce conceptual and operational devices enabling designers to propose better ways for people who are constantly on the move practicing their everyday life. The survey focuses on the question "How can we sleep, eat, or practice any other basic activity considering the nomadic way of life?"

Teshome H. Gabriel was interviewed at University of California Los Angeles (UCLA) on february 7, 2008. He is professor at UCLA and he has written extensively on memory and the cinema, theories of Third Cinema, on the aesthetics of nomadic thought in cinema, and on weaving and the digital in developing countries. His philosophy is that the destiny of humanity is nomadic. The future of society is becoming more and more nomadic. The competition forces people to move around. And, most of times, the early life influences chooses on the adult life. To live in a nomadic way is one of them. Experiences teach us and travel is good to forget things. According to Gabriel, an urban nomadism seams like a contradictory idea. In a film Dersu Uzala by Akira Kurosawa, the cultural differences between a mongol peasant and a russian militar becomes very clear. The real nomad cannot live in a city: he needs to be close to the nature and to be free. But the city has a lot of rules and the space is almost claustrophobic. There is an ambiguous character in urban nomadism (Simpson and Stollmann 2007, 37-38). The contemporary urban nomads use the trash to survive, like the “free resources”, because the natural is over. Most of times, there are more opportunities in urban than in countryside areas.

Jennifer Siegal works in creating the Prefab home of the 21st century, she is founder and principal of the Los Angeles-based firm Office of Mobile Design (OMD). During her interview, in her opinion, the american economy of nomadism is very, very wealthy people or very, very poor people. Either they are forced to move, or they choose to move. Everybody in between, specifically people who are having children, tend to be more settled. At the same time, she thinks that anyone that is living anywhere has all the same needs. People who live in a kind of nomadism spent a lot of time outdoors and they have to be able to find security and shelter from natural elements, from the rain, from the sun. But they also look for places to clean themselves, take a shower, use the restrooms, socialize. We are all the same, no matter where we live or how we live, whatever economic structure, as human beings, a kind of needs are similar.

Robert Kronenburg teaches studio design, drawing and communication skills and contributes to the history of architecture lecture course at University of Liverpool. He is curatorial advisor on exhibitions like Living in Motion and Portable Architecture, subject which he has written and has published books about it. For Kronenburg there is a difference between travelling life and nomadic life. Nomad is people who lives in different places, with a repetitive cycle. Nomadism is about limited resources because they move when the subsistence is over. Sometimes it is controlled by the weather conditions, sometimes by work opportunities.

On the ther hand, flexible architecture, mobile architecture, is not necessarily about few or nomadic resources, because they have lots of resources, you choose to do it, but in a flexible way. One travelling aspect is that people go to other places, and back again. When people take their place with them and are moving from different homes, what changes is not only different geographic locations but the homes itselves. This kind of homes are not mobile. And so, in that sense, we need to adapt that place for a home. That is not nomadism. Kronenburg call this behaviour as anti-nomadic. Because the point of moving to those places is actually, embrace that different environment, and to be possed by, to learn about different environments. What happens

when people go to a new city is to look for familiar things, international institutions that are similar in all over the world and try to make you feel “at home”. The leisure nomads are attracted to go to somewhere, instead of the nomads who are forced to go, they migrate to survive.

This introduction aims to summarize the theoretical background of nomadic way of life according to the Teshome H. Gabriel, Jennifer Siegal and Robert Kronenburg interviews to Lara L. Barbosa. The nomadism specific meaning defines what are the mobility situations and the possible subjects involved with this.

2. Changing the work, changing the home.

The specific goals of this exploration are:

- Discover and find who these users are;
- Understand some needs and expectations in mobility situations;
- Produce databases of design solutions related to the research subject.

In view of these aims, this investigation can also verify examples of sustainable design for mobility situations. Two mobility situations are defined in this study: the change of home and the change of work. People are moving more and more over greater distances. Professionals have been transferred several times in short period of time. The nomadic groups can be those who stay in one place no more than a few months although, the period of stay may range from a couple of months up to five years. Distances follow the same pattern, having people moving to a neighbouring city or another country. But, in all cases, the equipment should be easily carried.

Although the characteristics between different users are very similar, there are details that have to be precisely accurate. Even so, in all cases the way that these groups transport their artifacts is one of the most important design problems. The design policies indicates that designers have to provide visibility for nomadic users quickly recognize what they need. The security is a problem as much for business nomadic workers as for recyclable materials collectors.

The research results about possible users notice that two possible groups are nomadic workers (NWs) and recyclable materials collectors (homeless).

The nomadic workers (NWs) travel to where the work is. To be considered a nomadic worker they must travel most of their time; they don’t have any bound with a particular office; their place is where they happen to be; they are constantly carrying and reconfiguring their own resources. This type is very urban, their site is the organization and the technologies represent their basic needs. The challenges that strategic design must focus are: to make easier the assemblage of actants, the way of seeking resouces and integrating with others (Su and Mark 2008).

David Craven and Nicola Morelli wrote about Logical Spaces for Urban Nomads: “the globalised society is leading more people to lead significantly nomadic lifestyles. Transportability can now be defined as consisting of either logical recreation of an environment or its physical relocation” (Kronenburg 2003, 22).

Since the pioneer Krzysztof Wodiczko starts to develop his critical vehicles in 1971, he attracted the designers attention. The recyclable materials collectors everyday life is concerned with the matter of mobility. So many times these collectors are homeless. They have to deal with very limited resources, they are forced to known and to adapt to different environments. The design challenges here are: preserve different termic and acoustic conditions from the streets to realize the basic needs, such as sleep or eat and to remain safe from people (Wodiczko 1999, 79). The home for homeless is like a portable home, without a specific place it can be anywhere in the city (Santos 2003, 32).

3. Nomadic tools according to sustainability.

They do complement each other: the nomadism and sustainability. The revision about nomadic tools suggested that it might be mountable and demountable human-made environment.

This tools could be portable, retract or wearable design, collapsible structures, itinerants and temporary services and the use of mobile equipment. Bearing in mind that those instruments are flexible, adjustable or transportable design, the first criteria could be the facilitation of the disassembly. This will benefit the transport and the recycling. But, there are new visions for how designers could develop nomadic tools if they include as possible answers strategic solutions such as the use of urban services. They can interfere in a building, a landscape, a sculptural yet usable object or an interior space considering different interactions.

For mobile consumption, different types of objects are created. Some utensils associated with eating on the move are very familiar in everyday life. The design solutions listed in this paper represents a growing sector in different cities all over the world. “From 2003 to 2005 the number of Swiss men and women breakfasting on the move increased by 246% (St. Gallen University), while takeaway packaging accounts for 35% of litter in Switzerland (Basle University)” (Wild and Reble 2006, 4). The wallet fish and chips tool, a display card made by recycled stainless steel, is a simple example of how design can change (fig.1). Starting from the Britains favourite take-away, this light and resistant object is develop to fit in the urban nomads pocket, with a credit card size.

Fig. 1: wallet fish and chips tool in United Kingdom, created by touch of ginger.

It is understood by the well-known sustainable design criteria the reduction of material and energetical resources. If you live in a smaller or compact way, you take less resources and became more sustainable because you don’t have space enough to unnecessary things. Even when you transport belongings using a car, or a truck, or go on a boat, or on a train, you force to deal with spaces, that are more compact. Also, when you arrive in a new location, that can be a desert environment, you need to find another way to survive without the urban cities infrastructure that you normally take it for granted . Who camps knows that you can create new communities, knew new people and it also makes you appreciate those aspects, like not having much water or not having electricity.

From another point of view, flexibility is like a design obligation. Constructions or buildings that can be used in different ways, in different locations, extends the life cycle design. In fact all design really extends the use, which means that is more efficient. And if is more efficient, is more sustainable. Nomads are doing this all the time: they need to re-adapt their resources to a new location everytime they move. If they don’t have access on where this knowledge about the local resources are, they have to research and memorize the information. When they do a constant route, they go deeper into a knowledge about the place and where is everything they need. This is essencial for diversity of uses.

Kronenburg also presents the advantages of portable architecture, such as:

- Ecological approach- they are recyclable, can be built using renewable resources, have a low site impact during deployment and minimal residual effect after departure.
- User friendly- the provision of a physically and psychologically rewarding environment for the building's user and occupants.
- Life-cycle costs- the long term value of the building in capital, maintenance and operating costs (Kronenburg 2003, 54-55).

The life extension design occur in different ways for nomadic communities because the time issues are very important for them. If we think in sustainability and consider the durability related with the understanding of how past, present and future are connected we can learn a lot of lessons. Where are the resources from? What is the best way to use them? How is possible to discard it or reuse it when the resource became obsolete? Nomads usually unifies this knowledge to live. Their transitional identity requires a more economic use of the territory which one demand that they leave the place when the local resource has finished.

4. Comparing design solutions.

Few references are found in contemporary knowledge. Not intending to exhaust this subject, this research seeks to bring visibility to significant results in São Paulo, Curitiba, Los Angeles, London and Liverpool. In every city, the goal is to collect different cases of nomadic behaviour and their design instruments.

It is recurrent the use of public space for nomadic groups, which means city equipments can be added to this investigation. Some solutions rise from forgotten places like abandoned sites, space under viaducts, shelters and bridges. In this emergent aesthetics, the resources are not only discarded products, but spaces as well (Santos 2003, 26). It is important to consider if the user interaction is passive or active, individual or collective, which will guide the project.

Compiled according to the similarity criteria, this selection has two kinds of answers: in a situation of living or working in motion. Most of the design ideas are like carts, what proves the importance of carrying things. Some of them are portable and lightweight objects, but are only used in specific situations. The proposals for mobility situations are, mainly, adaptable, and cannot be divided in usual cathegories. The examples are hybrid, between product and architecture, or even between service and design ideas. They combine a container function, like a bag or a box, with a vehicle solution, providing means of transportation.

The comparative table reveal how everyday life habits, when done on the move, requires different design solutions. Sometimes, trash is used as off the cuff material resource. Another times, the materials like the steel container, could be melted down and recycled.

Everyday life activity	São Paulo, Curitiba/ Brazil	Los Angeles/ United States	London, Liverpool/ United Kingdom
To live on the move	Plastic and cardboard solutions used by homeless (fig.2).	Shopping carts used by homeless (fig.4).	Budget Hotel, built with steel shipping containers (fig.6).
To work on the move	Textile apparatus with the system of "umbrella" (fig.3).	Baggage carts (fig.5).	Food Shop Traillers (fig.7).

Fig. 7: Food Shop Trailler, trustingly parked near his rival in Liverpool, United Kingdom. Photograph by Lara L. Barbosa.

5. Changing to a nomadic way

In this sense, one positive contribution to "changing the change" could be a transformation in a nomadic life towards more sustainable use of resources. The design recommendations follows the nomads lesson:

- Facilitate the information researching and memorizing. Provide information about the place for multiple users, including where are the free resources like wireless internet or discarted materials or even about the weather conditions.
- Motivate the local adaptation, avoid importing cultures and behaviours extremely different.
- Develop alternative ways of finding security and shelter from natural elements, like the rain or the sun. The ability to adapt to different infrastructures conceives a creative knowledge. The “do it yourself” ability is essential for assembling.
- The integration with others must be motivate for collaboration, mainly in outdoors activities. The use of urban services can be combined with the possibility to share things.
- Develop a strategic use of the lightweight objects and materials. It can include the recycled ones, such as plastic and cardboard.
- Provide better and easy means of transportation. When the purpose is carry things, the weight must be low.
- The equipment can be mobile, portable or wearable. Sometimes the belongings could be carried with the wheels support or could be kept together with the body.

Possible nomads can teach us about better ways to practice our everyday life in a more sustainable prospect.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The Influence of Design – Examples from Bangladesh

Design visions

Hannah Bauhoff[1]

Abstract

Globalization means media and new technology reach every corner of the world. TVs are found lighting the mud huts where villagers consume images from all over the world. More than ever lifestyle articles and products containing western ideas and values reach people who live in a totally contrary environment marked by poorness, bad infrastructure and less developed products. What happens when western glamour and products meet poverty? What means developing aid in the context of design in these countries? Based on my phenomenological studies and interviews with designers and journalists from Bangladesh this paper will show projects from Bangladesh, which symbolizes different attitudes concerning developing aid, the role of design, national identity and its adaptation to globalization.

1. Introduction

There is a popular thesis about globalization and culture: Western economic power rules or changes traditional cultures. The result: the variety of different cultures – analog to the process of biodiversity – disappears (Juniou, 1998). Consumer goods, images and visions of life of different cultures and the overall pattern of living become equal. Daily life and popculture such as popmusic, fashion or productdesign look alike and become homogeneous.

Media plays a special role in these context. Media transports images of the western world and distributes them successfully. Whether in India, China oder Iran, Western goods are enthusiastically welcomed: Western popmusic displaces traditional music, traditional clothing as the sari is replaced with jeans and T-shirts and instead of tea the people drink cafe latte (Klein, 2005[i]). It seems that there is a generation growing up that is no longer sceptical, this new generation is “hugging the Western world” (Doctoroff, 2006).

This opening gives rise to many observations and is used as a point of departure for a discussion on the role of design in the context of development aid. The research question of this statement is: How could design be used to create self-awareness in least developed countries and economic success on world markets?

First of all, the definition of developmend aid has to be considered. Then – to answer this question – examples from Bangaldesh will be provided to give an historical overview of development aid since the 1970s for a better understanding of the delvelopment aid definition and function. Based on these examples, new directions for design are described to point out that it is possible to create a new direction in future development aid concepts. In addition the role of media and the question of national identity are discussed. Finally conditions for this vision are specified.

2. About development aid

The definition of development aid – the present term is development cooperation – means aid for so called least developed countries. It is given by governmental, private and economic organizations in form of technical aid and cooperation, knowledge, food to support the economic, social and political development. The overall goal of aid is to improve the living standard, the general economic, political and social climate in these countries, and support measures to improve the legitimacy and effectiveness of the state. Development aid is conflict prevention and aims to create a strong civil society.

In 1961 when the term developing aid was used the first time and the Organisation for Economic Co-operation and Development (OECD) in Paris was founded, the main idea was to increase benefits by giving former colonies financial support in form of credits – analogous to the Marshall plan in West Germany after World War II. In addition the donor countries suggested that food for the world population will be guaranteed by providing modern technologies for agriculture. Later conventions were designed to provide for most agricultural and mineral exports to enter the European market free of duties, but still the preferential access based on a quota system and all donnations were linked with guidelines.

However, from the 1970s the focus was put on women as a reliable partner for development aid. Women, so the experience, think more than men about their family and their enviroment. To support women will help finally more people in a sustainable way.

This fact was noticed by an American-Canadian non-governmental organisation (NGO) called Mennonite Central Committee (MCC), which was involved in development aid in Bangladesh since the independence in 1971 from Pakistan.

At that time Bangladesh (an it has not changed very much) was a small country with 150,000 km2, and one of the most populated countries in world. Its most important economic sector is agriculture where about two-thirds of the working population is currently employed. Bangladesh has only few mineral sources like oil, gas and coal. The manufaturing industry is less developped, the few big facilities produce jute fibre and textiles for the export. However, Bangladesh imports much more than it exports, so the trade deficit is high and the country depends on foreign help and foreign currency. Besides that, the parliamentary democracy is not stable, but a corruption and inefficient bureaucracy. The lack of public order and security makes daily life and business very difficult.

3. Fair trade by Aarong

The development concept of MCC is based on the high command of the village women who weave and embroider in special ways (Sajid, 2004). As women keep traditions alive, they have deep knowledge of old techniques in arts and crafts. The knowledge of these rural women was used and transferred to modern products designed by the staff of MCC. Actually, most of the product ideas came from the rural women, which had been surveyed by MCC. First the products were sold in the office of MCC mostly to development workers as a presents for home. Then a shop called Aarong, which means “a village fair”, was founded. The objective of Aarong was to provide a stable and gainful source of employment for the underprivileged rural artisans.

In 1978 Aarong was sold to BRAC (Bangladesh Rural Advancement Committee), a local NGO. In the process Aarong contributes to BRAC’s goal of poverty alleviation and empowerment of the poor. BRAC researched how to develop more items and to design more products based on old traditions, e.g. bloc printing for carpets. They revived old patterns and collected old techniques.

The concept of Aarong was and still is successful. Aarong has earned over the years a reputation as one of the finest rural craft producers and marketers in Bangladesh. About 300 people are working in the Aarong shop in administration, controlling, design or as shop assistants. There are 8 shops in Bangladesh, and one in London. In 1996 Aarong had a turnover of eight million Euros. The profit goes to BRAC and represents about a tenth of BRAC's total income.

Nowadays in Bangladesh Aarong customers are mostly middle class people. To Bangladeshis people means buying something at Aarong to offer something special or precious, but typically Bengali like Nakshi Kantha, a revivaled textile. Nakshi Kantha is an embroidered quilt said to be indigenous to Bangladesh. It is made from old discarded cloth, from utilitarian quilts to exquisitely embroidered heirlooms. Traditionally, thread drawn from coloured sari borders would be used to embroider motifs or border patterns imitative of sari borders. Yarn used for weaving is also used for kantha embroidery (Rahman, 2004).

Bengalis are proud of Aarong, although Aarong is not successful outside of Bangladesh. Aarong tried to open shops in Canada as in Europe but most of them failed. There are many reasons why Aarong products are not popular in Western countries and on Western markets. (Vogelsang, 1999[ii]): Western target group claim is different and depends on the consumer’s attitude or on the consumer’s life style than Bangaldeshis. And: clients want to satisfy their composition claims and impression claims, which is not possible with products from Aarong that could be found only in fair trade shops like tradecraft in UK, Caritas in Germany or Fair Trade Assistance. In fair trade shops Western people can find mostly products of low quality, or a lack of attraction beside “exotic” forms or material like bamboo (Koppelmann, 1997). It is the luxury/ the goodwill/ the philosophy to buy fair trade products but not the desire or benefit from the product. However, Aarong clothes and garments products do not fit to Western way of live. Especially users from industrialized countries are expecting a satisfaction of their composition claims. Aarong was and still is the typical fair trade company and it is a blue print for many other

fair trade companys as a result of an idea of development aid, which worked in the countries themselves. As the Aarong-idea is from the 1970s, new concept which adapts t globalization was demanded.

4. The idea of the Design and Technology Centre

Due to the changes in policies of the global RMG buyers, implementation of WTO agreements and significant growth of competing countries like China, Bangladesh was still unable to develop and diversify its industrial base and expand its export range. The narrow concentration on a few export items and a generally low value addition in the export-dominating RMG industry have kept the country increasingly dependent on a global trade environment. As consequence Bangaldesh is still dependent on its main trading partners like EU and the US and has to accept the conditions for development aid and for the RMG sector (see United Nations, 2002). Concerning the ideas of development cooperation contrary to the experience of Aarong, new approaches have been demanded. One new approach emerged in 1998 when the Dhaka Chamber of Commerce and Industry (DCCI) in financial and technical cooperation with the German Technical Cooperation (GTZ), a German NGO, created the Design and Technology Centre (DTC). Its goal was "creating awareness of design and product development as a tool of obtaining competitiveness" (Rashid, 2006[iii]) and its objective of DTC was to establish a product development centre where small and medium enterprises (SME) of selected sectors (primarily leather, natural fibre and wood) will be trained in design. Furthermore the idea of DTC was to provide SMEs with consultancy for better design and technology for their products so that they could be competitive in the domestic and the international market. In other wrords: DTC was a reaction on the dependency of Bangladesh on the Ready Made Garments Sectors (RMG) and the idea was to trhough enhancing hugely design knowdlegde Bangladeshi products would become interesting for international markets. Products made in Bangladesh are typically of low quality, absence of professional design input and – because of the practice of widespread copying – a distinct product identity. Even in the country itself the interest on design was very small – except for journalists who have started writing about fashion design while copying Indian and English articles from the Internet.

One endeavour to solve most of these problems meant to improve the design. This assumed solution raised a new problem: Bangladesh did not have any product designers because of the lack of design education at the university. DTC created a concept that tried to promote and institutionalized the profession product design. The concept was made according to the 1961 India Report by Charles Eames, an American industrial designer, and his wife and colleague Ray Eames. The Government of India had asked the Eames couple for recommendations on a program of training in design that would serve as an aid to SMEs and that would resist the rapid deterioration in design and quality of consumer goods. The Eames visited India for three months and explored the problems of design. The result of their study and discussions was a recommendation for a training programme that resulted to establishment in the National School of Design (NID). As teachers they recommended architects which had been sent to different design schools abroad to get an idea of different design education. They should be trained not only to solve problems, but what more importantly, they should be trained to help others solve their own problems.

DTC took up to this idea and "imported" German design know-how and machinery with the aim to transfer of technology, design knowledge and production modes. Undergraduate design students from Germany as well as local architects provided the design education. Since DTC' self-image was and is being a service provider in product design for SME in the sector of product development, it also offered services such as training for selected sectors and on-the-job training as awareness programs like design competitions. With the different facilities, a small library, workshop facilities with selected machines for different materials (wood, textiles, paper

and leather), one small seminar room and one room for exhibition or seminars, DTC tried to create the awareness among the local industry and handcrafts.

But still, DTC efforts – to create accessibility to new markets of Bangladeshi products and to create employment opportunities – failed more or less (Rashid, 2008), although the DTC got more fundings from the Eurpean Union after the financial cooperation with Germany has ended after five years. Reason for this failure are diverse, but the lack in the information policy of DTC with the consequence of little awareness of DTC project in Bangaldesh and abroad. It would have been better to investigate in parallel the overall professional presentation and appearance of the idea. Linked to DTC objective to raise awareness about design, journalists should have been contacted and trained to become design experts for having profound discussions about design that are eeded to develop the own design knowledge and identity. should have been started. The existing magazines and articles are only copies of Western or Indian magazines/ articles. The absence of information exchange with the international market created the problem. Besides the service staff, the executive, marketing and finance department, DTC employs one local senior designer, two local junior architects, one local junior graphic designer and one local secretary. Instead of working with so called junior experts from Germany who had been undergraduate students without any working and teaching experience, the GTZ- team leaders could have contacted senior experts with more profound experience in product design and who would have been able to teach the locals. Besides the “old” problem of quality, a profound analysis for new products and the research and exchange of ideas on products, designs and the international markets were missing in the DTC concept: some more training and study to help the SMEs in becoming competitive in the export market would have been necessary.

5. The Motherhouse Concept

A successful way for any cooperation with least developed countries seems to be that of Eriko Yamaguchi. In 2006 Yamaguchi founded Motherhouse, “a company that aims to establish the brand of developing countries by making high-quality products in developing countries with the design, production process and the quality control of developed countries” (Yamaguchi, 2008[iv]). This idea does resembles the idea of DTC but the approach and the modalities of realization are different:

Driven by her own difficult childhood Yamaguchi is highly dedicated to this project because she wants her dream come true: giving the “poor pride and hope” (Yamaguchi, 2008). The name “Motherhouse” is already a composition of two strong symbols: Mother stands for “Mother Teresa”, “-house” comes from “house for street children”.

To analyse the living conditions of Bangladeshis and the implemetation of development cooperation concepts Yamaguchi moved to Bangaldesh, learnt Bengal and completed a Masters in Development Studies as first foreign student ever in Bangladesh at BRAC University. Instead of donations and foreign aid that may not help the target group because of the high corruption in LLDCs, Yamaguchi relies on the power of the free market economy. She believes that products with a good design and good quality combined with her own story will be so attractive to Western consumers that these products will be sold easily.

In her research for a sustainable idea to help she up with bags made out of jute fiber and leather that look like the bags of the fashion brand Marco Polo. As jute fiber is produced in Bangaldesh and has a positive environmental track record, it fits in her idea of social and enviromental responsibility. She started to design bags, produced a first collection of 4 different models and 160 pieces under difficult conditions and shipped them to Japan. As Yamaguchi was not a sales person, she despaired at the Japanese ditribution system which was not interested in her articles. Because of the low interest Yamaguchi started to sell her own story. She wrote a book about her life and her busisness of Motherhouse, named “The Naked life. I am always on

my own” and opened a flagship store in Tokio one year later. In addition she started a media campaign. Articles appeared in “ELLE” and other life style and business magazines like “Ecoloco” and “Business week” in Japan and abroad. She won a prize as women entrepreneur. As the interest in her, her company and finally her bags rose, so did the demand in her products. Although high quality production is very difficult in Bangaldesh and despite two failures concerning producing fabric and corruption by her own employees in the contracted factories, Yamaguchi did not stop her high level commitment in the country. Actually she is building her own factory. In the near future she plans to build a school and kindergarden to provide mothers work and chilrdren eductaion. Currently Motherhouse has three different collections of bags, made out of high level jute fiber and leather and a small collection of wooden goods which reflect the needs and demands of her Western and Japanes customers e.g. an i-pod-Stand which looks like a mini-deck chair and which is made in Bangladesh. In Japan there are three flagships stores.

Motherhouse is successful in the number of sales, but still there are a lot of problems especially in market research, design and in brand strategie. Presently the design is made by Yamaguchi herself, more or less copies typical bag designs but as she is interested getting design from Bangaldeshis she needs to address the lack of education. Therefore she has started to cooperate with DTC to implement design and find ways how designers could be trained. Because of the strong relation to DTC, the contact to Germany is very intense, and Motherhouse hopes to use this relation to establish a stronger presence in Western Europe: Yamaguchi and the CEO of DTC Atif Rashid regulary attend international tradeshows in Europe, like Ambiente oder “Tendence and Style”, to learn more about the new designs for the next saison.

6. Conclusion

These examples illustrate three different approaches and provide a historical view of development cooperation as it relates to design and product creation. Global media and communications play a major role in the potential and limits of the different strategies. Approaches like that of Aarong show that developing countries are capable of creating sustainable ventures that can simultaneously meet the larger goals of poverty alleviation and empowerment. However, these "traditional" strategies can be limited in their success in world markets, where consumers demand different quality and designs. Aarong understands its local markets and production very well but only sells in the fair trade markets. Within the globalized world, this is akin to providing developing countries with access to niche markets. DTC's approach of educating designers reflects the new development paradigm of empowerment and growth from within. Combining Western design with Bandladeshi creativity could have created entirely new designs and markets. Yet, as the Motherhouse approach illustrates the world markets are stubborn in their demands, and more communication and contact with the Western media may be critical to success. Motherhouse succeeds because of its intimate understanding of local production capabilities and personal investment of its founder. Similar to development initiatives from private philanthropy such as the Gates Foundation, Motherhouse's mission is narrowly focused in its goals and intervention. Importantly, for Motherhouse media and communications are critical and serve as more than a source of information. Through its media campaigns and targeting of design trends, it almost shapes the opinion about its products. As global media becomes ever more important, understanding and shaping consumer preferences and steering local production accordingly appears to be critical to success to create change in developing countries.

In addition global media also shapes local preferences, making an understanding of its impacts on consumers in developing countries critical to success in the home market. As the purchasing power increases, consumers will increasingly demand differentiated products that meets their aspirations which in turn are influenced by images and trends in industrialized countries. Yet this information does not directly translates into preferences but is mediated by

national culture and identity. Just as development is no longer about creating opportunities to export, design also needs to target the local market.

7. Vision

"Going shopping helps to make the world better." This slogan describes Lohas, an acronym for Lifestyles of Health and Sustainibility. Lohas is a particular market segment and relates to "green" ecological initiatives. Generally composed of a relatively upscale and well-educated population segment Lohas consumers are "interested in products covering a range of market sectors and sub-sectors, including: Green building supplies, socially responsible investing and "green stocks", alternative healthcare, organic clothing and food, personal development media, yoga and other fitness products, eco-tourism and more." (LOHAS, 2008[v]). The LOHAS Market, was found in 2000 when globalization has started change the world. Due to media consumers get an idea of the consequences of their shopping attitudes but contrary to the fair trade trend, Lohas consumers want to enjoy their messages: Lohas goods have to be sexy, useful and representable. Business, media and entertainment can educate, shape and influence consumer behavior and purchasing decisions while promoting lifestyles of health and sustainability. Development projects which deal with design could profite of LOHAS and their market power. They could bring companies, the entertainment industry, as well as celebrities together to gain a greater sustainable output. Instead of collecting money or raising awarenes or "pity design" of developed countries, LOHAS could show the creative potential of the countries. The successful recipe for design in context of development cooperation seems to be to adapt each of the products made in LLDCs here in Europe, in order to enhance the appeal of these items for people in LLDCs. Consumers' attitudes towards product labels cold be used in combination with development cooperation in the areas of health and wellness products, sustainable business and social consciousness. The international community — the donor community — still needs to sustain and increase the volume of official development assistance in order to create seek strong partnership. Design could act as mediator to create, beside cultural differences, a common language and understanding. Therefore communication needs to be interactive: Developed countries should learn more about life apart of poorness in undeveloped countries, and the other way round, people in LLDC should get to know that Western tastes. The aim should be to build a network of organizations, designers and media and celebrities to enhance partnerships and development.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Sustainable Use

Changing consumer behaviour through product design

T A Bhamra[1], D Lilley[2], T Tang[3]

Abstract

The paper presents the results of research investigating how design can be used to change consumer use behaviour. It analyses selected behaviour models from social-psychological theories and highlights the barriers to sustainable consumption. A model is developed to illustrate the factors stimulating changes in behaviour and design intervention strategies are higlighted and their application within Design for Behavioural Change discussed. Two case studies, one examining social impacts of mobile phones and the other environmental imapcts of household fridges are outlined. These are used to illustrate how Design for Behavioural Change could be applied to enable users to adopt more sustianable patterns of use. Conclusions are drawn on the appropriateness of these strategies and the potential for designers to change use behaviour.

1. Introduction

Designers shape the development of products and services which directly impact upon society and the environment. The application of sustainable design can greatly reduce the environmental and social impacts of these products and services. However, many impacts such as energy consumption during the use of electronic products are mainly determined by the consumer's behaviour. Government and NGO measures through a range of information campaigns have been ineffective in creating the long term behavioural shift needed to reduce the impact of product use. Users have to make the link between the information, their own behaviour and the environmental and social impact and this makes it difficult to motivate a change in the majority of user's behaviour.

By considering the use phase of products designers have great potential to decrease environmental and social impacts, however, this stage of the lifecycle is often not considered in detail. Designers are in a position to plan and shape the way in which consumption occurs as well as to bridge the considerable intention - behaviour gap between values and everyday user actions (Sustainable Consumption Roundtable, 2006). To date few attempts have been made to change consumption behaviour through product-led interventions to limit environmental and social impacts.

Consumption is not only purchasing, but developing routines and rituals of use and modifying the product concretely or symbolically. According to Koskijoki (1997), consumption involves the selection, purchase, use, maintenance, repair, disposal and recycling of any product or service, as opposed to their design, production and marketing. Multi sociological and psychological motivators behind the consumption behaviour impel people to consume insatiable quantities of products and services. Environmental and social benefits of the wider global community, compared with the desires of the individual are not strong enough to motivate a different lifestyle. On the other hand, the manner of consumer interaction with the product has large impacts. (Environmental Change Unit, 1997; Sherwin and Bhamra, 1998; Lilley, Lofthouse and Bhamra, 2005). Products, as the interface between consumers and consumption activities, can give immediate and direct responses to users' operations: how it is perceived, learned, and used. Designing a product means designing a user experience with the product, which also determines the compound impacts of this experience. A better understanding of what users do with, and how they interact with products as well as the hidden factors behind the daily decision-making process should be gained in order to develop a valid critique of environmentally and socially significant consumption.

This paper begins by analyzing some selected behaviour models in social-psychological theories. Then by highlighting strategies to facilitate design for behavioural change, the breakthrough points that potentially enable design to influence the consumer behaviour and habits are identified. Two case studies are outlined one focusing on changing social impacts of mobile phones and the other reducing environmental impacts of household fridges and freezers. Finally the paper discusses the potential for Design for Behavioral Change to be applied within design.

2. Consumption Behaviour and Habits

Focusing on individual behaviour, a number of existing theories try to answer the question: what factors contribute to behavioural change. The theory of planned behaviour (Ajzen, 2006) illustrates attitudes, the subjective norm together with perceived behavioural control as explanatory factors of human behaviour. Triandis (1977) proposed an integrated model of interpersonal behaviour which not only includes social factors and emotions in forming intentions

but also highlights the importance of habits as mediated factor of behavioural change. When the behaviour is “highly automated”, performed with a minimum of deliberation or little cognitive effort and often only limited awareness (Jackson, 2005), it becomes habitual. Meanwhile, attitudes, norms and perceived behavioural control become less able to predict future behaviour and people take less notice of contextual information (Verplanken & Wood, 2006). As Verplanken and Aarts (1999 in: Verplanken & Wood, 2006) defined, “habits are learned sequences of acts that have become automatic responses to specific cues, and are functional in obtaining certain goals or end-states”.

To encourage consumers to break old habits, two factors are suggested: repetition and reinforcement (Jager, 2003 in: Jackson, 2005). Andersen (1982) identifies three stages in the formation of a new habit - the declarative stage, the knowledge compilation stage and final procedural stage. It has been argued that the cognitive script for a habit to develop should be easy to follow and enable repeat the same action in similar, provided with the regular reinforcing reward as consequences of a new behaviour (Sustainable Consumption Roundtable 2006).

2.1 Habits

It has been recognised that although consumers express strong concern about the environmental and social impacts of their activities, their actions do not reflect their concerns. In reality, the practices ingrained in our life patterns are carried out without conscious deliberation (Jackson, 2005). As the studies of Verplanken and Wood (2006) showed, “approximately 45% of respondents’ everyday actions were habits in the sense that they were performed almost daily and usually in the same location”. Much of the literature (Jackson, 2005) argues that inconspicuous consumption has a significant environmental impact in terms of energy and resource consumption. It is argued that what users do with, and how they use products is important (Jackson, 2005). Habitual and routine behaviour contributes to the awareness - intention - behaviour gap between environmental and social values and everyday interaction with products.

3. Design for Behavioural Change (DfBC) Approaches

Prior research by the authors indicates that there is no one way to design for behavioural change and no hard and fast rules as to which approach to use (Lilley, Bhamra and Lofthouse, 2006). The authors’ investigations have identified seven strategies which can be applied within design, Table 1 illustrates these with examples of where they have been applied.

Table 1. Design Intervention strategies and Examples

Eco-Information – design oriented education	
to make consumables visible, understandable and accessible to inspire consumers to reflect upon their use of resources	
1 - Visualizing energy-Expressing the presence and consumption of energy	Examples-Power Aware Cord - Seeing Personal Energy Consumption (Interactive Institute, 2004)
2 - Experiencing energy - Design for interacting with energy	Examples-Tyranny of the Plug Kitchen Machines - Being involved for powering the product (Van Hoff 2003).
Eco-Choice – design oriented empowerment	
to encourage consumers to think about their use behaviour and to take responsibility of theirs actions through providing consumers with options	
Users have a choice and the product enables sustainable use to take place	Examples- Domestic Energy Display - household system level concept (Design Council 2005).
Eco-feedback – design oriented links to environmentally or socially responsible action	
to inform users clearly about what they are doing and to facilitate consumers to make environmentally and socially responsible decisions through offering real-time feedback	
Providing tangible aural, visual, or tactile signs as reminders to inform the situation	Examples- Eco-Kitchen (Sherwin, Bhamra and Evans, 2000)
Eco- spur – design oriented rewarding incentive and penalty	
to inspire users to explore more sustainable usage through providing rewordings to “prompt” good behaviour or penalties to “punish” unsustainable usage	
Design showing the consequences of actions to consumers through “rewarding incentives” and “penalties”	Examples- Flower Lamp - Rewarding Energy Behaviours (Interactive Institute, 2004)
Eco-steer – design oriented affordances and constraints	
to facilitate users to adopt more environmentally or socially desirable use habits through the prescriptions and/or constraints of use embedded in the product design.	
Designing “ease doing” affordances and constraints for adopting the instinctive sustainable use habits or reforming existing unsustainable habits	Examples- Unilever Powder Tablet - Counteracting excessive amounts of consumables consumption
Eco-technical intervention – design oriented technical intervention	
to restrain existing use habits and to persuade or control user behaviour automatically by design combined with advanced technology	
Product design combined with advanced science and technology for environmentally or socially responsible behaviour includes using new materials; renewable energy resource; and new technology such as advanced computing.	Examples- Energy Curtain - Interacting with Daily Light Cycles (Interactive Institute, 2004).
Clever design	
to automatically act environmentally or socially without raising awareness or changing user behaviour purely through innovative product design	
Purely design solution for decreasing environmental impacts without changing any user behaviour	Examples- Integration of toilet and washbasin.

These design intervention strategies whilst providing interesting considerations for designers have not been widely applied and there is lack of real data on the effectiveness in both theoretical and practical dimensions. It was for this reason that empirical research was conducted to understand further Design for Behavioural Change.

3.1 Linking the behaviour/habit model and design intervention strategies

As highlighted above intention, habits and controls are considered important to immediate and mediate antecedents of behavioural change. Due to the complexity of motivations for shifting behaviour, different levels of interventions need to be designed accordingly to ensure behavioural and habitual change. The understanding of the behaviour disintegration and formation and relationship between antecedents of change in behaviour/habit and different levels of design intervention is presented in Figure 1 below.

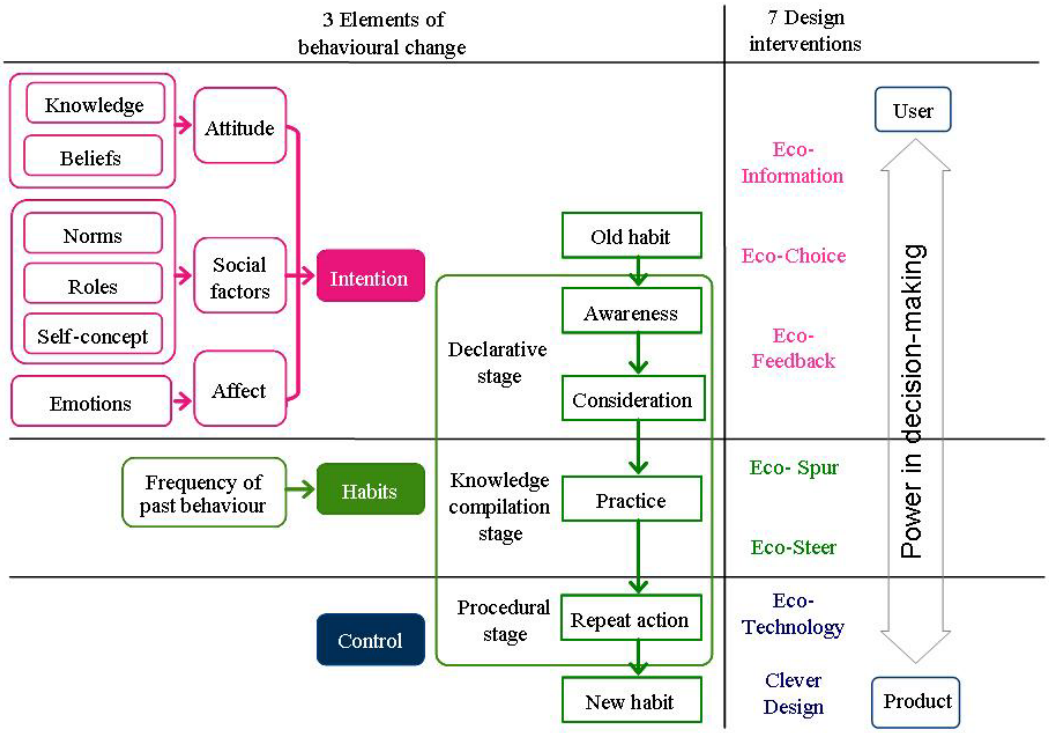

Fig. 1: Linking antecedents of behavioural and habitual change with varying levels of design intervention strategies

As demonstrated, design interventions are classified by the degree of power for decision making between the user and product. It is important to develop a balanced and ethical approach: weighing up the determinates of behavioural and habitual change and designing the sustainable products to bridge this gap

4. Case Study 1: Household Fridge and Freezer

There are very few pieces of equipment in the home that use energy 24 hours a day 365 days a year. Fridges and freezers are two such products and account for around one-fifth of domestic energy consumption (Energy Saving Trust, 2006). User-centred research techniques were used to capture opportunities for design to solve environmental problems of use behaviour and activities around the fridge and freezer relevant to energy and food consumption. Product-in-Use observations were carried out with aid of audio-visual equipment.

A series of user studies were developed to identify the most suitable design intervention strategies to be applied in the design of fridges and freezers. The studies aimed to collect information about the “actual” and “assumed” needs, the diversity in use context, the unsustainable and sustainable use patterns and the hidden factors behind the usage. A questionnaire and semi-structured interview were used to investigate what consumers thought about their fridge and freezer and the environmental impacts of their use. The use activities around the fridge and freezer were arranged into three related groups including condition and environment of product in use, food shopping unpacking and food preparation. Correspondingly, three observations of Product-in-Use were conducted.

4.1 Observation Studies

In the first study, the subjects were asked to fill out a kitchen user profile questionnaire and told that the study aimed to understand the relationship between the user and their kitchen. This cover story was used to avoid the unnatural desirable response tendencies (Verplanken & Faes, 1999). Two observations were then carried out to record food shopping unpacking and food preparation. Finally, a semi-structured interview and post intervention questionnaire provided a chance for participants to explain their behaviour in the observation sections. Three fridge and freezer users were involved in the first study and were aged between 21 and 40 and had owned their fridge or freezer for between 6 months and 6 years.

The second study added 24-hour recording to the observation section and a range of questions about the factors influencing decision making and behavioural change to the post-intervention questionnaire. Three families took part in the second study which recorded their fridge and freezer use in a “normal” week day over 24 hours. The participants were in the age group of 35-50 and had owned their fridge or freezer for between 1 year and 9 years.

The two studies were designed to test the effectiveness of the approaches which aimed to gain an insight into their actual use behaviours and habits, their problems and difficulties in operating the product, “actual” and “assumed” needs as well as look for opportunities for product design solution to bridging the gap between the intentioned use of a product and actual use patterns in order to reduce the environmental consequences.

4.1.1 Changing user behaviour through design

The data collected from the observation studies provides interesting evidence to support the theory that an understanding of real use behaviour is an essential starting point for improving product design for behavioural change to reduce environment impacts.

In the observation of unpacking grocery shopping, it was seen that most of the time spent putting food into the fridge and freezer was used for making room for new items and transferring items between shelves. In the 24 hour recording, it took more time to take desired items out, looking for the desired item inside the fridge i.e. at the back or bottom. However, this previous experience and knowledge saved time when returning to the fridge. Understanding what is an

operational principle of the consumer could help to reduce door opening time. The results of observations showed that consumers located items according to a range of principles including:

- Expired date of food: all subjects put newly purchased items at the back of the fridge and old or used food in an obvious place in the fridge such as in the front of shelf at eye-height level or in the top door bin;
- Food packaging: sealed and packed foods and drinks such as strawberries, ready meals, beers, are stuffed on the shelves and often overlap one another; meat often went to the bottom glass shelf because the packaging may be broken and “it will not drip on everything“(User-03);
- Weight of the items: “heavy” things, such as potatoes and carrots often were kept in the bottom of the drawer underneath the soft vegetables and fruit such as tomatoes and grapes;
- Temperature distribution in the fridge: consumers used the different temperatures inside the fridge to decide where to locate raw meat, cooked meat and cheese, this was usually at the back of the fridge, however this lower temperature often froze vegetables;
- Door bins: bottom always kept wine and milk and mid bin often small jars and bottles, and juice; items in top door bin varied and included cut onion, garlic, cheese;

These points in routine fridge and freezer use patterns can be used to develop more acceptable product-led solution to improving the loading efficiency. A more adaptable interior, for example, would enable consumers to create the optimum arrangement of their food and drinks in the fridge and freezer. Additionally, according to the type and shape of the food or food packaging, more behaviour constraints and affordances (Tang & Bhamra, 2008) can be designed to lock the location of the food. What is more, designing to display the contents better would reduce the opening time for seeking items inside the fridge or even seeing the foods without opening the door.

Providing consumers with options through product and system or service design could encourage them to think about their use behaviour and take responsibility for their actions. This may be achieved by designing a flexible modular system with separate temperature settings, and supplying a modular service with the customer to meet their needs during their different life stages. This could avoid unnecessary replacement and usage of a second cold appliance.

The findings also pointed to some potential opportunities for improving product design from an environmental perspective. To reduce door opening times, designers could create internal structures for organising food preparation and special milk and butter/margarine storage solutions for making quick meals and drinks, as in the case of through-the-door ice dispenser. What is more, in the user study, food hidden at the back of the shelf was one of the contributors to needless food purchase and food wastage. Using shallow drawers or software to keep a food shopping record can provide consumers with a clear view of the food inside the fridge and freezer decreasing food waste and the amount of time with the door open.

4.1.2 Guiding and maintaining changes in intention and habits

By analysing the interviews, the barriers that may prevent energy-conscious practices taking place are summarized below;

- Invisible energy: consumers were not aware of the amount of individual electronic equipment use.

- Unawareness of the link: in ordinary people's opinions, the way of using fridge had little effect on overall energy use in the home;
- Lack of Information: consumers felt that fridges and freezers are an essential part of modern life and it was more important to set lower temperature to ensure the quality and taste of the food and drinks than to be concerend with the energy use.
- Lack of concern: Product-in-Use observation showed that all young family members left the door open while transferring items;
- Lock in lifestyle: participants assume that the product is efficient enough by itself and there is no need for a conscious behaviour to improve the overall energy performance.

To address these, design-led interventions would need to build on energy conversation to guide a behavioural change. Designing an effective way of communicating makes sure consumers know how to use the product efficiently through a range of design interventions such as providing information, choice, feedback or behaviour spur (Tang & Bhamra, 2008).

4.1.3 Changing user behaviour through sustainable system design

Modern kitchens were identified by participants to be the main restriction of consumption behaviour with regard to fridges and freezers. It not only required a second, often empty counter fridge and freezer to fit in but also it was responsible for half of cold appliances in the study were built-in style fridges and freezers and one third were located next to the oven. What is more, limited storage space in the kitchen is another reason for refrigerating some items that do not need to be. Therefore, designing a food storage system in the kitchen could provide design-led solutions to facilitate sustainable energy and food consumption behaviour.

4.2 Reflections

To successfully integrate behavioural concerns into design practice, and to make this process repeatable, appropriate information and tools must be developed and incorporated into the design process. The findings of this design study have provided an insight into the type of information required by designers to consider these issues and appropriate formats for conveying this information. In addition a range of dsign intervention startegies will need to be adopted in the next stage of the work which is to develop concepts and prototype fridges to reduce the energy consumption in use.

5. Case Study 2: Mobile Phones

A design study was devised for Industrial Design Masters students at Loughborough University whereby the students were set the challenge of identifying and addressing a social issue resulting from the use of mobile phones in public spaces using a design intervention strategy for behavioural change. The main aim of this study was to observe the designers response to social issues identified and to record their research and design processes.

A design brief was generated, comprising of three elements; research & development, redesign and presentation of final concept. The students were given a preparatory lecture to introduce three of the design intervention strategies discussed above and a selection of design case studies which emerged from the literature. The first stage required each student to carry out user-centred research in order to identify social issues resulting from the use of mobile phones in

public. In the redesign stage the students were asked to select one design-intervention strategy and apply it within their design process.

5.1 Results of Design Study

Analysis of the students' logbooks and presentations revealed that most combined primary research (product analysis, interviews with users and observational studies) with secondary literature reviews. The secondary literature focused predominately on the social impacts of mobile phone use, few students actively sought out additional product design case studies as inspiration for their own concepts. Points of analysis included; body language, type of function carried out (e.g. texting, listening to voicemail), the location of the user in relation to others, the characteristics of the user (e.g. proficiency, age etc) and other people's response to behaviour displayed. Some students captured user behaviour using sequential photographs which were particularly useful in illustrating the series of actions taken by the subjects observed.

5.1.1 Application of Design Intervention Strategies for Behavioural Change

Some of the students found it difficult to distinguish one approach from another. The use of case study examples to explain each approach helped in some way to clarify their meaning and how they could be applied; *"The examples such as [the] Kambrook 'Axis' Kettle explain these concepts very clearly"* (Student 3). Most found eco-feedback easy to understand, but found eco steer hard to define. To some, the boundary between eco steer and eco technology was undefined and this made distinguishing one from the other quite difficult technology.

In terms of applying these approaches, most of the students advocated a 'mixed' approach, combining two or more approaches. Few students used the approaches as a starting point, preferring instead to apply one or more approach as part of their idea generation process to provide "a direction to think about the problems" (Student 5); as inspiration for concepts; or as a means to develop design ideas. "They are not only the lamps to my feet during the idea generation but they are helpful to understand what kind of solution can effect what kind of user behaviour during design development" (Student 3).

5.1.2 Perceived effectiveness of design intervention strategies

Eco-feedback would, some felt, not be as effective in changing ingrained anti-social behaviours. Eco technology products were seen as having greater potential for effecting change. However, some students felt that the balance of control may be weighted more heavily on the side of the product therefore users may feel controlled or restricted. It was felt that the consumers should be given the choice to behave in the 'right' way, only if they failed to do so should the product take action to prevent their behaviour. The students concluded that preventing choices straight away would annoy the customer and possibly cause a reduction in sales. Interestingly, only one student sought to analyse of the downstream effects which may arise through the use of his redesigned mobile phone.

5.3 Design Outcomes

Analysis of all ideas generated in sketch form and those detailed as final solutions revealed a range of approaches to solving the various social issues identified, however some commonalities could be observed in the type of solution proposed.

- Constraining or affording actions through the product form. Student 1 observed users' lack of concentration when using their mobile phone in public places and the resulting neglect of 'real conversations' to prioritise virtual ones. As a result a concept was developed whereby the mobile phone creates a physical sensation to provoke a response from the user. A loop sporadically tightens around the users thumb to remind them of where they are and to ground them in the 'real world', thereby attempting to address the problems caused by user's lack of attention when engaged in virtual interactions. Student 2 used his observational studies as inspiration for one of his design concepts, having observed some discreet users cupping their hands around the mouthpiece of the handset to mask the noise of their voice, he designed a mobile phone featuring four pressure points. These points must all be continuously depressed by the user to maintain the connection. The location of the four pressure points deliberately encourages the user to adopt a specific arrangement using both hands to shield the phone and conceal their mouth.
- Constraining or affording actions through the product function. Some of the design concepts featured limited functions represented as quick keys or shortcuts to enable rapid access. Student 3 designed 'fast keys' which are displayed in a simple keypad to enable fast and efficient use of basic functions such as listening to voicemail and sending texts. One of the 'fast keys' enables the mobile phone to respond to incoming messages or calls with a pre-prepared text message if it is in silent mode. This function also enables the user to press the button to indicate that they are busy.
- Eco-feedback strategies.Several design concepts which attempted to educate the user or influence their decision-making process through the provision of information were identified. The type of information provided typically included; the 'called's' status, location, and proximity to others. In many cases this was realised through the introduction of a supportive technology e.g. Bluetooth or a Global Positioning System (GPS). The information provided was, in many design concepts, depicted as a scale or symbols which illustrated the level of appropriateness or suitability of the call according to the environment. In most cases an over-ride facility was included for emergency situations. The student's concepts mostly focused on developing a user interface to provide information based on an assumption of technological capability, MIT's work is concerned with establishing a viable technological system to enable this process to operate.
- Supporting devices and systems. Some students chose to introduce supplementary devices and/or locate the product within a system which controls user behaviour. These systems typically consisted of a series of networked devices located in a public place which detect all mobile phones in a designated area. These devices send a signal to all active mobile phones to either; notify the user of appropriate conduct, switch the use profile of all mobiles automatically or disable function immediately.
- Wearable devices. Wearable devices were designed to address problems arising from incessant ringing of mobile phones left by their owners; situations in which users neglect to turn the phone off in public places; or instances where the ring tone is set too loud. The rationale described by some students who had devised wearable mobile phones was that by wearing the device the user's ability to hear the phone ringing would be increased and this would hasten their response reducing annoyance to others. It was also felt that wearable devices would allow the silent vibration mode to be used more effectively as an alert mechanism. Student 3 designed a mobile phone which the user wears on their wrist. The screen interface and keypad pivot on a fixed base attached to the wrist strap.

– Emotional response. One student developed a series of sketches exploring the potential for the mobile phone to produce an emotional or physical response to actions taken by the user. The first is a concept for a mobile which would automatically slide shut should the user's voice or the duration of the call exceed an acceptable level, terminating the offensive conversation for a predetermined length of time. Development of this concept led to the inclusion of an indicator to show the user the length of time left until the phone became operational. Another concept contains spikes which protrude when activated by an excessively loud speaking voice this is a particularly aggressive tactic on the part of the mobile phone.

5.3.1 Caller Hegemony Concept

Student 1 took the concept of caller hegemony as his starting point. Caller hegemony explores the dominance of the Caller over the Called. Having recognised the current imbalance of power between the Caller and the Called, this student sought to generate a solution to inform and guide the Caller and Called as to appropriate action to be taken in different social and environmental contexts.

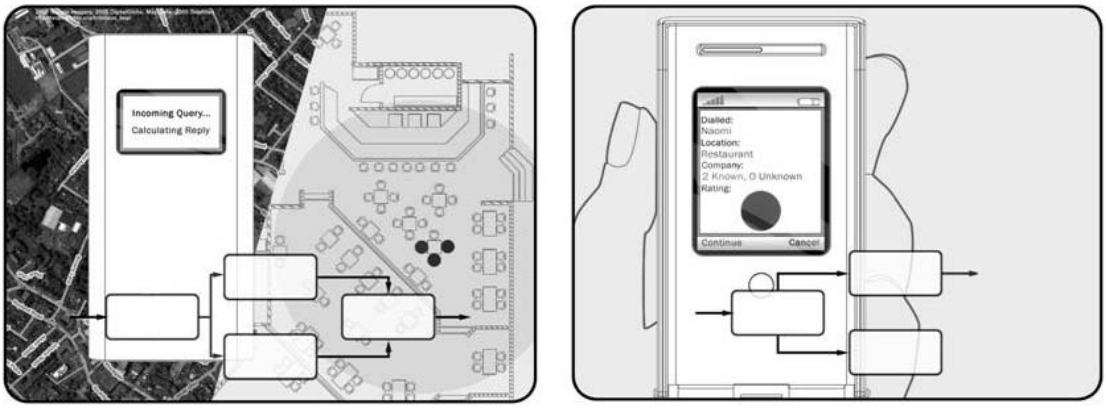

Fig. 2: An Intelligent mobile that can advise the user

This concept is based on a combination of two design intervention strategies; ecofeedback and eco technology. When placing a call, the Callers mobile phone uses Bluetooth and GPS technology to inform the Caller as to the Called's current location, proximity to other users and volume of company, figure 10. The Caller can then make an informed decision to continue the call, or call back. Should the Caller wish to continue the call, the Called's phone then vibrates or rings based upon information provided.

As a secondary layer of complexity the mobile phone makes a decision as to the appropriateness of the call based on its context of use. Should the Caller or the Called continue the call despite information provided to indicate the call is inadvisable; both handsets display their embarrassment at being made to behave in an inappropriate way. As part of his design development the student explored the ways in which the mobile phone could indicate its emotional state. These ranged from highly disruptive e.g. deleting content, delaying downloads in progress, or terminating the call to slightly less confrontational ideas e.g. shaking, stammering or vibrating. In the final design the phone displays its embarrassment by emitting a red light which disables functionality for a fixed period enabling the phone to calm down.

Student 1 acknowledged potential downstream social effects which could be caused through misuse of the product;

- The phone could be used to keep track of where people are and who they are with. Parents, for example, could check if their child is at school and companies could monitor the movement of employees.
- Those who wish their activities to remain a secret from others may purchase mobiles which are not Bluetooth enabled to allow them to hide their location from others.
- Finally, it may be possible for someone to purposefully disable another user's phone by deliberately raising their voice to trigger a shutdown.

5.4 Reflection

The student's debate concerning the moral and ethical issues inherent in designing for behavioural change reflects those of the authors' (Lilley et al, 2005). Concerns were raised regarding the level of control or influence which designers should ethically integrate into the product design. This debate was coupled with discussion relating to the effectiveness of design intervention strategies in changing user behaviour.

Eco-feedback was understood by most students and was arguably the easiest approach to apply within product design. However, the students questioned its effectiveness in changing ingrained user behaviours due to the potential for the user to ignore the feedback provided. Eco-feedback approaches provide users with information to enable them to change their behaviour, however, information does not necessarily lead to action as the consumer must be able to link their behaviour with the long and short terms consequences. Eco steer was the least understood approach, yet this may be due in some respects to the lack of tangible examples of how this approach could be applied within product design. Eco technology products were seen as having the greatest potential for effecting change. However, some students felt that if the product continuously regulated behaviour it would not encourage people to learn from their 'mistakes' and could result in the user feeling controlled or restricted by the product. Most students appeared to favour a combined approach which is a particularly interesting development especially as the brief originally stipulated that only one approach be used.

6 Conclusions

The findings of these studies has indicated that designers need to be made aware of potential problems caused by user behaviour through introducing the concept of designing for behavioural change as a design challenge.

The fridge and freezer use behaviour study highlight that understanding consumer behaviour can be the preliminary step for seeking solutions to minimizing environmental impacts of household consumption through improving product design. The observation studies not only uncovered the way in which the product is used and its unnecessary energy and food consumption, but also the gap between environmental awareness and real action, and the reasons for such a gap. Firstly, the results show there is a lack of consumer awareness of the link between their personal behaviour and the direct impact on the environment and energy use. In addition, the routine practice and habitual activities ingrained in our use patterns of energy-consuming products are performed automatically with little deliberation. What is more, the interaction of the consumer with the fridge and freezer exposes cultural and social values that shape consumption behaviour.

These observational studies pave the way for the future research. A series of main user studies is underway to detect what influences people's behaviour to reduce the impact of consumption. Furthermore, future work will investigate further how to design to shape the user

interaction with the product, as well aiming to bridge the considerable intention - behaviour gap between environmental values and consumer everyday action. The findings will be applied in design to illustrate how consumer behaviour can be improved through Design for behavoural change.

In terms of the effectiveness of the dsign intervention strateges in aiding the design process, it is interesting to note that rather than using these as a prescriptive method or tool, the design students viewed them as inspiration for concepts or as a means to develop or evaluate the effectiveness of design ideas. It has, therefore become clear that any outcome of this research should focus on providing potential directions or approaches, rather than prescriptive methodologies to follow.

Overall this paper has shown that design intervention strategies are useful and inspirational tools enabling designers to begin to address issues of use behaviour. Designing for behavioural change is, however, still a relatively underdeveloped research area and further work needs to be carried out with a wide range of different product types. Finally, 'behaviour changing' product ideas will be prototyped and tested with users to evaluate their effectiveness.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Systems Design Approach

interdisciplinary/systemic innovation

Luigi Bistagnino[1]

Abstract

Over the 30/40 years design efforts have been mainly devoted to the conception of new products and the use of raw materials, energy and production waste disposal, have been relegated to the mere technical sphere. But today's environmental issues should no more be regarded as extrinsic topics to the design process because they are integrating parts of a more complex system-product.

Henceforth more attention has to be devoted to outputs/inputs related to this kind of system.

If the outputs will be looked at as a resource (useful economic value for other production systems), they should be used as active parts of the entire industrial process in order to generate the future design innovation inspired to current Nature's working dynamics.

[1] Politecnico di Torino (ITALY) – 1 Facoltà di Architettura, DIPRADI department (Dipartimento di Progettazione Architettonica e Disegno Industriale), Full professor, luigi.bistagnino@polito.it

1. Preliminary considerations

All the choices made every day are inevitably influenced, spontaneously and subtly, by the consumerist habitus, so much so that we do not even realise we have become victimised. Environmental awareness, despite being widespread, proves to be useless when facing attitudes that have now become deep-rooted in our daily life and that end up denying this feeling of environmental friendliness. As a consequence it becomes difficult to assess the outcomes generated by this behaviour, in that shared culture is not conducive to a habitual consideration of daily choices, generating flows of matter and energy and involving the other components of our social and economic system. Goods and products are light heartedly purchased or thrown away, often with the mere purpose of making a statement of our own existence and of finding relief from temporary depression.

Also on a planning level, we show a lack of consciousness and awareness and our work is not carried out with the intention to pursue this goal, often blaming other people's weak environmental education and bad behaviour for the occurrence of the current ecological problems.

Considering that we measure the importance of life by the value and the qualities of what we own, it is inevitable that "having" becomes the heart of the values displayed in our cultural, social and economic systems, prioritising possession and looking at the product as a pivotal element upon which all considerations are made.

If we wish to undertake a new experiential journey aiming at building a different cultural and ethical system, it goes without saying that we need to see how limited this vision is, using this observation as a springboard for new angles of observation where deeper values, naturally and intrinsically linked to being are put at the centre of our thoughts.

This unusual but spontaneous outlook makes the ordinary and intimate relationships we establish in our life context, the focus of our attention and reflection, leading to a renewed real and cultural humanism.

Every time we need to design an object, we act thinking about the product to be realised, as well as the research we carry out in the pre-planning stage, trying to identify what we have to do to meet the consumer's requirements and what they will expect from it.

If we look at the product as the "main focus" of a project, we can see how a number of values intrinsically related to it, are subsequently and immediately singled out and concretised such as raw materials and economic value.

These influences, endowed with incredible strengths, reside in the fact that they make a symbolic function concrete.

Owing a product that enables us to feel part of a clan, or a social class, is particularly appealing to customers, in that a status symbol makes a precise statement of our place within the society, and gives us confidence.

Most of the times consumers end up buying the concept of the brand of that particular product. As a result possession fulfils an induced need, not a real one.

We buy mainly to assert our status, regardless of the function of our purchased object.

If in the post-war period the main need was to rebuild the social values, the boom of the 60s focused on unnecessary things. A must-do-thing, nowadays, is to have something our neighbour does not have yet, almost as if owing something special would make us special and unique too.

Only later on, when we actually use the object, do we realise what it was actually devised for, and when it wears off the user will realise it is not only made of a shell, but also of other elements that make it work, those being its parts.

Each object is considered as a whole, as a monobloc deprived of its constituent parts. Spectacles, a telephone, a car, are objects that are experienced and enjoyed for what they represent and for what they give, without realising, until they break down, that they are "boxes" enclosing a far more complex world.

It is not until they stop functioning and need to be thrown away, that we have the real perception of their life cycle.

The European legislation is focusing on the end-of-life cycle of the product, on disassembling and recycling. This partial approach aims to solve a problem after it has occurred, rather than before.

A good starting point would be to improve product maintenance so as to extend its useful life. In any case, just because we have no real perception of the internal components, we do not worry of what actually makes the product work. As we are not directly "involved" in it, our main concern is not so much to make sure it continues to perform satisfactorily, but to preserve the status it symbolises. [2]

In general, also the perception of human life, of environmental sustainability and of our own world, manifest themselves in the occurrence of a crisis, when facing the unavoidable.

Environmental catastrophes, global warming, increasing desertification and deforestation, depletion of non-renewable resources, pollution and the ozone hole have been widely discussed topics. However we have always talked with our eyes fixed on the future. Only now we have started to make reference to the present because it is "now" that we are reaching the point of no return. We can all tangibly ascertain its consequences as now we have a real perception. We needed to hit against the real evidence, as we tend to pay little attention to warning for the future, we had to see concrete signs at the present, rather then thrusting into the future.

If, on the one hand, we know we are faced with a necessary change, on the other we do not know how.

The real evolutionary opportunity seems to reside in a turnover of the values that are currently rooted. Putting **being** and not **having** at the heart of our future actions, will result in greater focus on our dearest value, **life**.

The perception of this value is linked to the primary needs: it is not reached through external means, but only through the individual perception of needs related to the preservation of our own existence, which can be kept only by harmoniously confronting what is "around" us.

We need to be aware that we all differ one from another, as such difference arises from the uniqueness and difference of social, ethical and cultural contexts our lives are woven around, so as to act effectively and in a focussed way, without mixing the different types of users as if they belonged to a blurred and indistinct unicum, lacking peculiar willingness and characterised just by undifferentiated and nebulous needs.

Being able to produce for differentiated markets enables the creation of non-globalised and indistinct markets, presenting specific and contextualised features, preventing the positive outcomes of the recirculation of money (profits and investments) from resulting in disastrous imbalances, as we have been able to assess.

Creating new markets means producing right products that can be positively incorporated by the society they have been devised for. This implies creating new jobs and more widespread wealth.

---

[2] Bistagnino, Luigi. 2008. *The outside shell seen from the inside. Design by Components within an integrated system.* Milano: CEA.

Investment profits are, in such a way, doubled, both from an economic and social point of view. This is why the product is, in this scenario, the last value to put at stake. Producing an object becomes a meaningless action if we do not make appropriate assessment of its real use for our existence, if we do not realise in advance that so many other values are far more important for human life.

Giving substantial emphasis to the values related to being, rather than having, will change our relational and evaluative priorities in a social context as well in the productive one.

As designers, we need to wonder whether we want to carry on "**planning** just **the product**" or if we'd rather "**plan for the man**", if we choose to prove our competences planning a form, or if we mean to use them to plan for the society; if we wish to express ourselves by means of an "hedonistic design" or if we opt for a "humanistic design".

Whatever our choice is and whatever decision we decide to take, jointly with the industry, we will need to have clearly in mind, from now on, what the positive or negative consequences of our action may be.

It is interesting to note that, also in an economic field, the belief that measuring the development of a society cannot be merely based upon economic parameters is spreading widely, but as a result of a deeper awareness of the need to adopt other thoroughly assessed values, in terms of quality and quantity, such as quality of life, of the environment, of education, of service, those being the markers showing the degree of prosperity, not so much from a material point of view but from the moral one of people (conference *"Beyond Gross Domestic Product. Beyond the Gross Domestic Product"* – established by the EEC and held in Brussels on 19 and 29 November 2007 – participants: Ashok Kosla co-president of the Club di Roma; Emeka Anyaoku of the WWF; Manuel Barroso President of the European Commission; Joaquin Almunia, Commissioner to Economy; Kristalina Georgieva, Director of World Bank).

Such a context calls for a deep change within industrial design practice. We will be required to face the responsibilities that we, as designers, have toward those who put the solution of real problems in our hands, as well as the realisation of wishes that have yet not been fulfilled, and the qualitative improvement of their lives.

Sustainability is not an individual property, but a shared value involving the whole community.

We are faced with a future where we will be able to plan and realise ecologically sustainable communities, built in a way that the technologies adopted and the political choices will not contrast with the system of the natural world.

We will be able to create naturally harmonious technologies that want to learn and exist in compliance with nature, rather than controlling it. Life or nature, in general, are not trade products, on the contrary they are an integral part of our existence. Therefore we need to be deeply aware of the designs and take them as models for our new future technologies.

2. Reasons for a change

Over the years design has been able to identify the outcropping needs of the society and to go along with the transformations, even anticipating new developmental fields. It has extended its boundaries getting more and more in touch with other sectors, offering more open viewpoints on problems, most of all making different types of know-how meet and interact aiming to discover new investigation contexts.

It has become an accredited point of reference for innovation development.

All this success geared at extending testing fields has generated new products, however it has relegated all the problems related to the use of raw materials, energy and production rejects disposal to a technical and technological area.

These issues need, on the contrary, to be an integral part of the planning process, so as to raise and develop awareness of production able to identify the correct types of resources and energy which have to be used in compliance with, rather than being an external factor of the process.

If up to now we have focused only on quantity and quality of raw materials and to their specific features, it will be equally important for our future to focus our attention toward not only on what can enter a system, but also to what can exit from it.

This insight results in the conception of a more developed project, interesting and complex, embracing the whole production chain, including all the problems regarding the production waste which are placed on the same level of supply and use of raw materials.

In the first place we will need to develop the output quality as well as the quantity, as they will be generating the real future uses. This means that different production situations may be correlated, so that the specific output qualities of a given production may turn into input for another process.

From this perspective, it is fundamental and unavoidable to elaborate a “multidisciplinary vision”, bringing together all the different kinds of scientific knowledge, hoping for the occurrence of an innovation inspired to the real dynamics and functioning of Nature.

The approach to the productive world will need to change, going from a “linear” type of action, to an advanced type of “interconnections”, drawing solutions from a truly interdisciplinary “new culture”.

Tests of this concept in an industrial field (see site <www.systemsdesign.polito.it>), have shown that the production activities may reflect the metabolism principles of nature, a reality which does not generate waste.

Design endorses this innovative approach of project of flow of matter and energy, investigating the positive transformation occurring in the production processes and becoming a systemic design.

It goes without saying that this renovated and fluid flowing of matter generates a new economic model which, enhancing the local resources, will give new life and revival to the territorial cultural and identification peculiarities.

Another important opportunity, arising from the outlined orientation, seems to be a change in the approach to the output of the production systems.

The existing legislation is based upon the fact that industrial process waste is something with little value, compared to the product, or that has been strongly polluted, so much so that manufacturers regard it as an issue to be solved as quickly and cheaply as possible. From this perspective it is easy to understand why the legislator wants to protect both the environment and the people, by means of obligatory regulations that aim to chart the course performed by substances regarded as hazardous.

Instead, if we turned the output of a problem into a resource, producing in such a way, an interesting economic value, we would consequently be interested in considering them as an active part of a process. As such we would try to enhance their intrinsic qualities and we would be inclined to change all the working processes that downgrade them. We would pay deeper attention to keep their appealing properties unchanged, in order not to lose their economic trading value, achieving at the same time a formidable result, that being a ZERO emission productive culture.

1. Systemic/interdisciplinary innovation

In our society we face situations, analyse cause-effect phenomena, solve technical problems, study strategies "per spot", using a linear approach. This is not innovation. We need to

attempt a change in the usual way we think. We will need to let our eyes, our intellect lead us in the most appropriate way if we wish to face the problem from different perspectives.

Innovation does not reside in the on-going technological update, but in the way we look at problems.

We feel it is time to activate an interdisciplinary culture, to create a network of know-how, to outline a dialogue between different interdisciplinary fields, one strictly connected to the other.

The knowledge to be spread does not exclusively refer to the process of putting up a product where the only aesthetic features is the enhanced one, but it is the awareness we are working within a system where special planning care needs to be devoted not only to the products but also to the system they relate to and where they have been generated, a system made of social, cultural and ethical values.

Guests sitting at a round table have to dine with traditional know-how and flavours, where local biodiversities are protected and natural cyclicality is respected, where information and education become food for thought.

By now, it is widespread knowledge that human beings' nourishment is closely connected to the **natural cycle** and of how modern industrialization has slashed these bonds, making food production timeless. Consumerist culture takes a leading role in the political and economic choices of a Country and affects the **value system** civil society has as a reference. On an industrial level, the logical linear process and development affect the perception of reality, as they are based merely upon cause-effect relationships, which generate huge quantities of waste, starting with the manufacturing process until the product "end of life".

With such an on-growing complexity as the one we are currently experiencing, it is necessary to withdraw from the exclusive focus given on the product and its life cycle, moving toward achieving greater competence in the context of the complex relationships which spring from the production process.

Planning only the product, although this also implies its coordination and integration of all factors (functional, symbolic, cultural, technical and productive) is an approach to surpass. We need to bring back within the total planning equation, the variable represented by those resources (generated as a result product or waste), that would otherwise be unused. We need to regain the cultural and practical skill to **outline and plan the flow of matter, running from one system to another, in an on-going metabolizing process which diminishes the ecological imprint and generates a remarkable economic flow.** Currently rejects generated during the manufacturing process, are only a cost.

Fig. 1: Output of a system, input to another one

This model draws heavily on the fundamentals of the Generative Science, based upon the assumption that, following any transformation of resource, all the sub products are conceived to obtain a generative added value, and a carefully studied object.

We are facing not only an environmental issue, but also a new economic model (bio-economy approach), which may also lead to new opportunity, if we please to look at the glass as half full, rather than half empty.

Fig. 2: Systemic Design approach

The approach of Systemic Design, a necessary cultural baggage conferred to the new operators, is likely to trigger a new economic model, based upon the planning of open industrial cycles.

It focuses on the Man, placed within the system where he lives and has his relationships.

This approach generates other **design plans** that come together with the relative **product,** where all the services and products relating to the systemic approach are defined, and with the **territory** where the relational system choices are acknowledged and made concrete.

A necessary step aiming to activate such an innovative strategic plan, would be to concretize the knowledge acquired within a university field, creating tight relationships both among the diverse analytical plans existing in the current context, and the planning needs.

In order to avoid handling utopian notions, just like a juggler, being stuck in an abstract dimension, I make reference to pilot projects, developed over the past few years, (see previously mentioned web-site), involving different but significant productive sectors of mechanics:

- with **NN euroball** where production outputs (oily mud) of the ball bearings have led toward planning a rethinking of the manufacturing process, focusing on the superficial tension of water, on its relapsing economic use and on its final launch, after being purified, on the environment and on trade fairs.
- with the **Salone del Gusto 08** where the project, rather than concentrating exclusively on the immediate message to send to the visitor, has concretely triggered a new economic development, converging all the considerations on the outputs generated by the exposition, replanning the way available resources (waste) can be replaced within the system, of energy.
- with **Agrindustria** which finds the material to be used to produce energy for its own manufacture, within 40/45 km, selling surplus and activating a number of positive economic outcomes, due to an optimized exploitation of outputs as inputs of other production systems.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design & Transition

What designers can learn from the Transition Movement

Jody Boehnert[1]

How can design participate in the great task of building a sustainable system? The primary tool in this transition is systems thinking. Design can facilitate change by learning to work with systems. Concepts such as design science, ecological literacy, footprinting and transformation design help. Yet a sustainable system is not something designers can deliver to communities. Communities are complex systems composed of people that need to engage with change to make change happen. The Transition movement engages communities in the collaborative design of a 'Local Energy Descent Plan'. The movement is a vision of UK permaculture teacher Rob Hopkins, and is now being enthusiastically adopted by communities worldwide. This paper explores new tools and concepts in design and the Transition movement.

[1] EcoLabs (UK), Eco-literacy initiative, founding director. jody@eco-labs.org.

Design & Transition

We have no alternative but to learn to live within the natural imperatives of the ecosystem. How can design participate in this change? The primary tool in this transition is systems thinking, a conceptual process necessary for reconfiguration of systems that are presently entirely unsustainable. Design has the potential to communicate systems thinking and help embed new cognitive facilities into public consciousness. Design must embrace its ability to facilitate change by developing a vision of itself as a facilitator of transition using new methods, tools, and approaches. A new design paradigm is taking shape defined by both the democratization and the dematerialization of design processes. Thanks to the work of researchers in fields studying the interface between ecological systems and human culture we now have tools to catalyze systemic transformation. This paper will examine the ideas that will inform this transition in the design industry. Informed by design science, ecological literacy, footprinting tools and the transformation design model - design is now posed for a radical change. What this paper will bring that is new is an examination of the Transition movement as a model for social innovation.

The Transition movement is a community design initiative that facilitates re-localization for mitigation and adaptation to post-peak oil and climate change. The Transition phenomenon started in South West England in 2005 and has already gone viral. There are now (May 2008) 61 towns, cities or areas that have Transition initiatives active (with another 700+ in the process of adopting the method). A Transition Town is a space that has initiated a community design process mapping ‘energy descent’; a timetabled strategy for weaning the locality off fossil fuels. The Transition process creates agency and encourages practical action. The movement is a result of communities concerned with the lack of systemic plans comprehensive enough to respond to what they perceive as the threats ahead. Here communities organize to meet environmental challenges directly when government, business, and institutions fail to respond adequately to the challenges of climate change and peak oil. The movement as described in this paper is the vision of permaculture teacher Rob Hopkins, now completing a PhD at Plymouth University while nurturing the growing Transition Network, and his local group; Transition Town Totnes.

The Transition movement can also be seen as design activism - led by non-designers. The professional design community would be clever to take notice. This paper will map out a proposal for change, first by examining concepts, tools, and processes within design that address ecological problems. Part Two will focus on the Transition movement as a model that brings insights from nature - via permaculture, into community design processes. In Part Three, I will synthesize all this information into a proposal for transition in the design industry.

New Design Thinking

1. Design Science

Many of the ideas in this paper have their genesis in Buckminster’s Fullers writings on design science. Fuller held that to in order to be comprehensive, problem solving should work from the whole towards the particular. The concept of design science that he promoted was an integration of disciplines. Design science is based on the idea that each individual within society will be better off when we address the needs of everyone. Fuller maintained we could provide for all, but it will take a concerted effort and initiative. He promoted the concept of ‘the design initiative’ which asks designers to obtain the most comprehensive perspective possible, determine what needs to be done and to set out to do it. Taking the design initiative means creating jobs that need to be done, not waiting for outside clients to create jobs (Burns et all 2006,18). It was Fuller’s approach to systems, to a holistic appraisal of design problems and his encouragement of designers taking the

initiative to proactively use their creativity to solve societal problems - that anticipates the pragmatic problem solving strategies in new design thinking.

2. Ecological Literacy

> *The first step in our endeavor to build sustainable communities must be to become 'ecologically literate', i.e. to understand of the principles of organization, common to all living systems, that ecosystems have evolved to sustain the web of life…This systemic understanding of life allows us to formulate a set of principles of organization that may be identified as the basic principles of ecology and used as guidelines for building sustainable human communities... Thus, ecological literacy, or 'ecoliteracy', must become a critical skill for politicians, business leaders, professionals in all spheres, and should be the most important part of education at all levels* (Capra 2002, 201).

Ecological literacy is a powerful concept. It demands that we consider ecological systems and an awareness of how society operates within natural imperatives as an educational staple. This is a concept for patterning thoughts, organizing information and eventually behavior. It is a cognitive faculty that our educational systems have failed to instill. American educator David Orr describes this failure as a 'sin of omission and commission. Not only are we failing to teach the basics about how the earth works, but we are in fact teaching a large amount of stuff that is simply wrong. By failing to include ecological perspectives in any number of subjects, students are taught that ecology is unimportant' (Orr 1992, 85). Educators must address this issue with urgency. Ecological literacy is fundamental to support 'a rapid transition to a more restrained and elegant condition called sustainability' (Orr 2002, 79).

3. Footprinting

Ecological literacy creates a conceptual basis for integrated thinking about sustainability. Informed by ecological systems, researchers have created the tools to help designers grasp complex environmental information. Footprinting and life cycle analysis allow us to make assessments of the environmental impacts of a system, process or product. Perhaps the most powerful of all the new concepts (because it is the simplest) is the One Planet Living™ model (developed by WWF and BioRegional) that offers a clear vision of living within the planet's carrying capacity. One Planet Living™ presents a formidable challenge to a culture that currently lives off the resources of three planets (European average). Footprinting and One Planet Living™ are powerful conceptual tools that have the potential to clarify the meaning of 'sustainability'. The problem with the term 'sustainability' is that it has mutated beyond recognition to more than 70 different definitions (Wood 2007, 100). By developing tangible characterizations of the often mis-used term 'sustainability', footprinting tools provide indispensable mechanisms able to assess environmental impacts, thereby helping not only with the design of better products, but also providing mechanisms able to highlight misleading communications and greenwashing. Designers must embrace these tools and implement them across design disciplines with haste.

4. Transformation Design

The British Design Council's RED group has defined a new evolving discipline: transformation design. Transformation design is a radical revision of the role of design in society. While it creates a methodology for socially engaged design practice, it also challenges designers' traditional sphere of authorship, authority and influence. The key

features in this new discipline as defined by the Red team are listed here (Cottam et all 2005, 20-21):

1 Defining and redefining the brief
2 Collaborating between disciplines
3 Employing participatory design techniques
4 Building capacity, not dependency
5 Designing beyond traditional solutions
6 Creating fundamental change

In their report, the RED team recognizes that transformation design cannot be done by designers alone, and that as non-designers now take up design roles - traditional designers are in an uncomfortable position. Philosophical and practical challenges facing designers encountered with transformational design are profound and will need to be addressed for the new process to be embraced widely by the design community. Meanwhile, the Transition movement can be seen as an active embodiment of transformation design by non-designers. The transformation design model creates a link between traditional design practice and the Transition movement that we will explore in the next section.

The Transition Movement

The Transition movement, according to fan Richard Heinberg is 'a replicable strategy for harnessing the talent, vision, and goodwill of ordinary people' (Hopkins 2008, 9). It is a community design process based on the processes and principles of permaculture. The Transition movement is based on the assumption that we are approaching the end of the age of cheap oil, and that climate change and peak oil are twin challenges that must be addressed simultaneously. Where it differs from other environmental projects is that it maintains that within the challenge to wean our communities off fossil fuels, exists the potential for an extraordinary renaissance. Rob Hopkins references the work by Thomas Homer-Dixon who describes historical examples of the decline (or collapse) of complex civilizations who faced resource depletion as a parallel to our own situation. Homer-Dixon develops the idea of *catagenesis* (breakdown leading to rebirth), a term used by ecologists. He proposes that within moments of contingency there will be possibilities for profound change. Whether the outcome is turmoil or renewal in our case will depend largely on how well prepared we are and how the situation is framed. A renewal will depend on people taking the initiative to catalyze positive change. This is no small feat. Within the Transition movement the environmental crisis is acknowledged as severe, and the changes necessary are massive & systemic. The Transition movement holds that in addition to cutting carbon emissions, we must create resilient communities. Despite the big changes ahead, the Transition movement holds that the move towards localized energy efficient living could make a world that is better than our own.

Four Key Assumptions of Transition (Hopkins 2008, 134)

1. That life with dramatically lower energy consumption is inevitable.
2. That communities presently lack resilience.
3. That we have to act collectively.
4. That the collectively genius of a community can be powerful.

1. Energy Descent (Peak Oil & Climate Change)

A. Peak Oil

At the centre of Transition initiatives are our relationships with energy. The movement is a response to the powerful driver of change that is peak oil – a threat suddenly becoming more apparent as oil prices have recently climbed to record highs. Peak oil is based on significant and wide-ranging research reporting that fossil fuels supplies are hitting a peak after which time liquid fuel prices will increase dramatically as finite supplies diminish. Furthermore, our social and economic dependence on oil and gas constitutes an enormous vulnerability. Jonathon Porritt, Director of the UK charity Forum for the Future explains;

> *…the end of cheap oil means the end of easy economic growth, and the end of that whole 'historic interlude' in which cheap oil fuelled fast growth, high living standards and the kind of 'live for today, live for yourself' lifestyle that has now become so destructive…. Conventional economic growth and cheap oil have marched hand in hand for the best part of 60 years; within just a few years, it will become increasingly apparent that both are on their last legs* (Porritt 2007, 84).

The ultimate authoritative document on the subject is the Hirsch report commission by the US department of Energy in 2005:

> *the peaking of world oil production presents the US and the world with an unprecedented risk management problem. As peaking is approached, liquid fuel prices volatility will increase dramatically, and without timely mitigation, the economic, social and political costs will be unprecedented. Viable mitigation options exist on both the supply and demand sides, but to have substantial impact, they must be initiated more than a decade in advance of peaking* (Hirsh 2005, 2459).

In interview Robert Hirsch says, 'The risks to our economies and civilization are enormous - this is really an incredibly difficult and incredibly severe problem' (Hopkins 2008, 41).

The Transition movement is a response to this energy security threat. While both the Hirst report on peak oil and the Stern report on climate change illustrate the perils of these two issues in isolation, the Transition movement attempts to respond to the twin challenges simultaneously. As fossil fuels go into decline (because of availability and also carbon reduction programmes) we will see an economic contraction. Economic re-localization will be one of the inevitable impacts of the end of cheap transportation fuels. The danger is that unless we wean ourselves of fossil fuels proactively, societal support systems could crash just as the global climate gets pushed passed a tipping point (Hopkins 2008, 9). The political volatility of this stark danger means that national governments have been slow to react and few have openly acknowledged peak oil as a problem (with the Swedish and Irish governments as the exceptions). Meanwhile, the Transition movement maintains that we are as energy rich a society as we are ever likely to be, and that we must actively plan to wean our communities off fossil fuels.

B. Climate Change

There should be no need to restate the urgent need to address this momentous societal level challenge. On an intellectual level, anyone who reads the paper is acquainted with the facts and realizes we must act, but this awareness has not sunk in very deep. So far we are not making it happen; evidenced by the significant gap between the proscriptive actions recommended by scientists and our collective response. After several decades of warnings we are currently struggling to even meet lenient Kyoto emission targets (5.2% by 2012). If we do not act decisively our legacy to our descendents is bound to be bleak.

Once we engage with this issue, it becomes obvious that scientists are far more worried than most of us. NASA scientist James Hansen tells us: 'We have at the most, ten years - not ten years to decide upon action, but ten year to alter fundamentally the trajectory of global greenhouse emissions' (Hopkins 2008, 30). One of the disturbing things about listening to scientists studying climate change is the fear in their voices. Intellectually, we might accept some of the facts, but if we truly acknowledge Hansen's statements; 'multiple positive feedbacks can lead to rapid non-linear collapse' (Hansen et al. 2005, 1431) - in reference to climatic tipping points triggered by feedback mechanisms such as melting ice and the Albedo effect, the Siberian permafrost melt, or ecosystem collapse in the rainforest - we would have no justification for anything other than immediate mobilization and dramatic response.

2. Energy Shock

Hopkins explains that 'climate change says we should change, whereas peak oil says we will be forced to change' (Hopkins 2008, 37). Either way, the sooner we start to change, the higher the likelihood of a successful transition. Responding to climate change on an adequate scale will be expensive and demand an unprecedented degree of global cooperation. Hopkins reminds us that an economic recession (or worse) caused by raising oil prices, could make tackling climate change 'slide rapidly down the list of priorities'. Facing climate change with a depressed economy is the scenario we really want to avoid (Hopkins 2008, 39).

We are a civilization completely dependent on oil for almost everything we make, eat and do. When prices of oil go up (which will be inevitable as we start our way down the slope of declining oil reserves and increasing demand from growing economies) every economic transaction will be effected. Rob Hopkins references studies claiming there are no renewable energy sources primed to completely replace fossil fuels, and builds his argument around the net energy available: 'Energy Return on Energy Invested' (EROEI) goes down dramatically with renewables (Hopkins 2008, 53). Hopkins maintains that renewable energy will not fill the energy gap.

Whether or not another energy source could replace fossil fuels to power our economy is a fact that is widely contested. One promising projects is the Euro-Supergrid. A similar idea was first proposed by Buckminster Fuller in the 1970s (Fuller 1981, xxxiii). Now it is being promoted by TREC (Trans-Mediterranean Renewable Energy Cooperation) - an initiative of The Club of Rome as the answer to Europe's electrical energy needs. Nevertheless, weaning our economy off fossil fuels will undoubtedly be a shocking process and the sooner we start planning the better.

3. Collective Action

The Transition approach attempts to engage entire communities in the process of change. We will have to see extraordinary levels of change if we are to navigate our societies away from dependence on fossil fuels in such a way that they will be able to retain their social and ecological coherence and stability. It has been recognized by government agencies that sustainable development cannot be imposed from above. It will not take root unless people across the country are activity engaged with it. The UK Government's Sustainable Development Strategy sees public involvement as 'essential'. New methods such as citizens juries or panels, round tables, visioning, charette and new 'consensus conferences' have become necessary, and they arise from the realisation that environmental values are not preformed, but rather that they 'emerge out of debate, discussion, and challenges, as people encounter the facts, insights, and judgments contributed by others' (Owens 2000, 1145). The Transition movement addresses the need for engagement and awareness through local awareness raising processes. Transition initiatives effect policy by demonstrating what communities can do to address local problems.

4. Collective Genius of Groups

The Transition method draws from the diversity and intelligence of a group. It could be seen as a good example of Ezio Manzini's creative communities as 'groups of innovative citizens organizing themselves to solve a problem or to open a new possibility and doing so as a positive step in the learning process towards social and environmental sustainability' (Manzini 2007, 78). The Transition movement resembles the convergence of creative communities & collaborative networks that Manzini proscribes. Transition groups encourage processes such as art & story telling while collaborating on community design using processes such as open space events and using on-line wikis for energy descent planning.

Six Principles of Transition (Hopkins 2008, 141)

Visioning, Inclusion, Awareness Raising, Resilience, Psychological Insights, Appropriate Scaled Solutions.

1. Visioning

Central to the Transition approach is the idea we can only pro-actively move towards something if we can imagine it. Hopkins claims that the vision we have in our mind when we set out on this work will go a long way towards determining where we end up (Hopkins 2008, 141). Creating this vision of our desired outcome is key, and the focus is placed on generating a sense of inspiration. By focusing on possibilities rather than probabilities we steer our future into greener pastures. This focus on the positive does not preclude dealing with the dangers. The Transition movement also works with visioning scenarios (adaptation / evolution / collapse) to come to terms with factors driving change. But Hopkins maintains that our best chance of a successful transition will not come from presenting people with the worst scenarios – but the best. We stand, according to Hopkins 'on the cusp of many things, one of which could be an economic, cultural and social renaissance' (Hopkins 2008, 133) - but only if we set about with a vision to bring this vision into reality. Our best chance of dealing with climate change and peak oil will emerge from our ability to engage people in a vision of transition to a lower energy future as an adventure, something in which we can invest our hope and energy (Hopkins 2008, 49).

One particularly useful vision that Rob Hopkins uses to describe the energy descent process is the inversion of the classic peak oil graph. Hopkins plots our decent into cheap oil as a dive into a murky swamp that allowed us to seriously lose touch with reality (Hopkins 2008, 93). Drunk on cheap oil we put the entire world at risk with lifestyles entirely out of touch with our interdependence with the natural world. We can only save ourselves by bolting upward - out from the fossil fuel swamp - to the clean fresh air at the surface.

2. Inclusion

The Transition movement seeks to facilitate dialogue between different groups in order to create innovative solutions from cross-fertilization of ideas. The TM does not align itself with any political or ideological position. In order to be accessible to everyone in a community, regardless of previous commitment to environmental initiatives, traditional green rhetoric and aesthetics are avoided. Transition groups make space, events and design processes to help environmentalists dialogue with business groups, pensioners with young entrepreneurs, artists with farmers, etc. Here we find innovative solutions to our collective local problems using the collective genius of a group.

3. Awareness Raising

The Transition movement holds that the end of the age of oil is a confusing time. We are constantly exposed to and bewildered by mixed messages. The Transition

movement aims to set out its case clearly by giving people key arguments (Hopkins 2008, 141). Awareness raising addresses the failures in the education system to impart basic ecological literacy. This prioritization of education and awareness raising is supported by design commentators on change. Alastair Fuad-Luke says; 'sustainability has to be a cooperative ambition, a societal ambition, it requires that a society has a universal awareness of its condition before taking the radical steps on the sustainability road' (Fuad-Luke 2007, 37). A similar idea is developed by Ezio Manzini;

> *Given the nature and the dimension of this change, we have to see transition towards sustainability (and in particular, towards sustainable ways of living), as a wide-reaching social learning process in which the most diversified forms of knowledge and organizational capacities must be valorised in the most open and flexible ways, Among these, a particular role will be played by local initiatives that, in some ways, can be seen as signals of new behaviour and new ways of thinking* (Manzini 2007, 78).

4. Resilience

Resilience refers to the ability of a system (an individual, a whole economy, or a entire ecosystems) to hold together and maintain its ability to function in the face of change and shocks from the outside. The Transition movement asks: will communities, faced with the shock of fossil fuel price increase and/or mandatory carbon rationing for mitigation against climate change - retain essentially same function, structure, identity and feedbacks? According to economist David Fleming, a community that is resilient can absorb shocks, has a wide diversity of relations, and can meet needs without substantial travel. According to ecologists resilient systems are said to have the following characteristics: diversity, modularity, and tightness of feedbacks (Hopkins 2008, 55).

- **Diversity** relates to the number of elements that compose a particular system, be they people, species, business, institutions, or sources of food. A rise of monocultures reduces diversity.

- **Modularity** is the manner in which the components of a system are linked. Maximizing modularity with internal connections reduce vulnerability to any disruptions of wider networks. The over-networked natures of modern highly connected systems allow shock to travel rapidly through them.

- **Feedbacks** - tightness of feedbacks refers to how quickly and strongly the consequences of a change in one part of the system are felt and responded to in another part. Centralization weakens feedbacks by increased risk of crossing a threshold without detecting it in time.

Rob Hopkins explains that there are two transitions at work in the world today; the main transition is far larger, more powerful, and better resourced. This transition is rapidly dismantling what resilience remains under the guise of economic globalization and growth. The Transition movement is the building blocks of a new vision, a regeneration of the complex, diverse and resilient economies of a pre-cheap oil world (Hopkins 2008, 59).

5. Psychological Insights

The Transition movement recognizes that engagement with the issues and especially confronting the environmental crisis can be an overwhelming process. With the understanding that key barriers to participation are the presence of powerlessness, isolation, and despair, Transition initiatives draws on insights from psychology. In order to address emotional resistance to confronting depressing and de-motivating information, the Transition approach attempts to use psychological tools to engage groups in the process of change. This process of making space to psychologically process disturbing information is powerful. The Transition movement provides a framework to build the psychological strength that provides the basis for healthy engagement with change. Psychologists

Winder and Kroger explain that: ‘healthy functioning requires that we have faith in the future, without this confidence; our trust in the world is damaged. Damaged trust can lead to many neurotic reactions, narcissism, depression, paranoia, and compulsion’ (Hopkins 2008, 49). This is a situation Hopkins has labelled as ‘post-petroleum stress disorder’. Unprecedented levels of mental illness indicate that this ‘disorder’ could well be a common syndrome.

Within the Transition movement denial is accepted as a natural response, but one that must not be over-indulged. Understanding the psychology of change, TM accepts denial as normal, but maintains the need to remain vigilant to it (Hopkins 2008, 82). Much of these insights are drawn from the body of work on addiction treatment. The Transition movement uses tools like the FRAMES Model (feedbacks, responsibility, advice, empathy, self-efficacy) that breaks down the process of weaning an addict off a substance by mapping the change in stages: from pre-contemplation to action (Hopkins 2008, 89).

6. Credible and Appropriate Scale Solutions

A major flaw with most environmental initiatives is the lack of solutions on a scale that could realistically address the crisis. While media often glosses over the nuts and bolts of change on the sort of level that could meet emission levels recommended by scientists. The Transition movement enables people to explore solutions on a credible scale. Part of the reason TM is able to do this is that it looks at change at the level where basic energy use occurs – in communities. Many people see only two scales of response, individual and government. The Transition model explores the ground in between. Certainly macro level solutions to climate change and peak oil are essential - but in democracies these can only happen with the support of the people. Sustainable development demands that people engage with change; it cannot be delivered ‘top down’ to the masses because people need to engage with the issues to understand the solutions.

The Basis of Transition: Permaculture

The Transition movement is inspired by permaculture, a design philosophy based on ecological principles and ethics for working with Nature in building systems to support human existence (Hopkins 2008, 137). The Transition movement attempts to mainstream permaculturist principles. Permaculture has a number of guiding principles that help it take account of existing systems and plan in complexity. It encourages strategies that contribute resilience and stability to ecosystems and other systems alike. The most important lesson, however, from permaculture is that it emphasizes the interdependence between human settlements and the natural world. The ecologist, Aldo Leopold wrote; “ethics is awareness of independence” (Burns et all 2006,17). With this awareness of natural processes and acknowledgement that every design affects the system as a whole, permaculture weaves ethics into its methodology. This brings us to the crux of the problem for designers. Ethics are a fundamental ingredient in any design problem, but have been conspicuously absent from design practice and discourse. The original environmentalist, Ralph Emerson, explained; ‘methodology without principles are useless or worse’. It is time for designers to end their vain attempt to separate ethics from design. Any designed item is part of a larger system and every design has ecological, social, and economic impacts. Ethics must inform all design disciplines – for the sake of all living systems.

Synthesis

Inherent within the Transition movement are the all the characteristics of transformation design except the designers themselves. The movement redefines community design processes, creates zones for collaboration and builds the capacity of ordinary people to create fundamental change. The movement is a sign of the radical democratization of design with everyday people designing energy descent in their own communities. Many of the challenges to designers described by the Red team in regards to transformation design apply here, as non-designers are actively designing processes and systems in their own communities to face the epic challenges ahead. Traditional designers will have to adapt to find their role in this process.

Designers are needed in the Transition process. The skills to build cohesion, focus and to communicate new agendas are needed in the Transition movement and designers have the skill set to do this. Unfortunately, according to Alastair Fuad-Luke, only 1% of 'iconic' designers are even engaged with sustainability (Fuad-Luke 2007, 25). Thus, the question that must be examined is: do designers themselves see enough of the bigger picture to want to engage in a process of change?

Design education has a responsibility to address the shortcomings in its current methodology. Designers could be of great value to the transition - if they decide to chart new territory. David Orr rightly claims that a well-educated person will make him/herself relevant to the crisis of our age (Orr 1992, 108). Educators must build awareness and methodologies in design to address social & environmental problems holistically - rather than the 'patchwork solutions on a larger pattern of disorder' (Orr 2002, 11) that dominates so much of the industry presently.

In order to be relevant in a changing world, designers need to engage with the powerful drivers of change that are peak oil and climate change. As explored in Part One, design science has mapped out the territory of systems design and the design initiative. Ecological literacy provides the cognitive framework to understand our basic systemic challenges. Footprinting tools allow designers to make and communicate realistic assessments of the value of systems, designs, and processes. Transformation design completely re-visions the role of the designer in a social context and allows designers to use their creativity to address social, economic and ecological problems. Meanwhile all these approaches/tools/ideas are incorporated in the Transition movement that is a holistic, inclusive and comprehensive methodology for designing transition in localised communities.

Conclusion

This paper has shown how the community design process of the Transition movement can inform the design industry in its attempt to confront the issues of sustainability. John Thackara calls on designers to become part of the solution, as 'global hunter-gatherers of models, processes, and ways of living that already exist, or used to… Creative design practice these days is about adapting solutions found in one context for use in another' (Thackara 2007, xvii). This borrowing and adapting is what the Transition movement does - and what this paper is doing. Thackara claims that most of the elements of a sustainable world already exist and the majority are social practices. The Transition movement is a synthesis of diverse practices and fields of study in order to address the pressing ecological problems of our age.

This paper first described several concepts within a designer's toolkit enabling her to confront the ecological crisis, then mapped out a vision and an approach to systemic change as defined by the Transition movement, and presented a potential synthesis. The Transition movement could be an inspiration for professional designers. What we require is the will to put the change in motion. We are at the precipice of an unprecedented ecological crisis, yet strangely - as noted by Thomas Homer-Dixon and Rob Hopkins, within this upheaval is the potential for profound renewal. According to Hopkins, energy

descent will be a journey towards sanity and wholeness; ‘Any response that is sufficient to the scale of the challenge is about coming home, about being aware that we are part of the networks around us, and that we need to nurture and rebuild them rather than imaging that we can survive independently of them’ (Hopkins 2008, 81). The Transition movement provides us with ‘scalable microcosms of hope’ that offer a collection of insights and processes to help communities navigate the transition ahead.

The design industry needs to recognize that a societal level challenge to avoid climatic tipping points is different from other issues that compete for industry attention. The design industry needs to realize that it functions at a strategic leverage point; it has the capacity to instigate radical change and influence many industries, cultures and communities. The speed, scope, and scale of the challenge are critical. This industry needs to respond to the unanimous call by the world’s climate scientists. We possibly have ten years to do this work (Hopkins 2008, 30).

Helping to embed ecological awareness into the cultural mindset is a formidable task. Helping to reconfigure infrastructures is an awesome feat. Designers will no longer be capable of feigning innocence in an era with a challenge as great as climate change and energy shocks. Design motivates action and our actions have implications; designers are implicit. Design is still part of the problem, but it is capable of becoming part of the solution. It is up to us - now, to make it happen.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Research in strategic design: a teaching experience

The design research school model to build a dialog between Brazilian university, society and industry.

Gustavo Severo de Borba[1], Paulo Belo Reyes[2], Roberto Galisai[3]

Abstract

The higher education reality in Brazilian universities, especially in design area, has faced some problems. Among them, the design research in Brazil, most of times, are developed inside the university walls and separated from industries. This is reinforced by a misunderstanding of the design concept generaly related to product design.

Considering these questions, University of Vale dos Sinos (UNISINOS), in a partnership with POLI.design, *Consorzio del Politecnico di Milano* proposed the construction of the first Design Research School, in Rio Grande do Sul.

This paper presents the principles of this new school, which considers the real necessities of Brazilian society; and propose a new model, where sustainability is a key factor to all areas, in the different school actuation levels.

1. Introduction

The higher education reality in Brazilian universities, especially in design area, has faced some problems. Among them, is important to consider the fact that design research in Brazil are, most of times, developed inside the university walls and separated from market and industries. This is reinforced by a misunderstanding of the design concept, perceived in our country, only related to product design. At the same time, the development of design disciplinary area in Brazilian universities is relatively young.

Considering these questions, University of Vale dos Sinos (UNISINOS), in a partnership with POLI.design, Consorzio del Politecnico di Milano proposed the construction of the first Design Research School, in Rio Grande do Sul, south of Brazil.

The result of this process was a new concept, comprehending the implementation of a design school, outside the original campus of UNISINOS – that is located in São Leopoldo. This campus was building in the heart of Porto Alegre, Rio Grande do Sul, south of Brazil.

The school is composing of three different areas (teaching, research and consultancy) and propose a space, that considers research as a key factor, to build a dialog between university, society and industry, achieving a new form of Sustainable development, a new model of change involving companies, university and local institutions.

This paper presents the principles of this new school, which considers the real necessities of Brazilian society; and proposes a new model, where sustainability is a key factor to all areas, in the different school actuation levels. Besides that, some cases are introduced. In the under graduation level, we will discuss a project developed by students for an industry that produces different products (door hangers, auxiliary tables, magazine holders, office accessories) using plastic components. The company had defined a project briefing and had followed all process, supporting students work. At the end, they had chosen some design concepts that will generate prototypes for new products.

Another important experience had occurred in a strategic design latu sensu course. In this case an entrepreneur had provided part of his land (in a rural area), to be used in a design applied exercise for developing a new kind local development project. As a result, our students developed a project that connects this region to the heart of Porto Alegre.

Finally, we present a case study developed in a furniture company. In this case, we present a project where the main objective was defining a new concept for product development. This cases are specified in this article, as examples of the methodology used in Design School of UNISINOS.

This paper is organized as follow: first, we present the principles of this new teaching and research structure, which consider market necessities and look for sustainability. Then, we describe the design concept used by our design school, which considers the strategic dimension of design. In this moment, we compare our understanding of design with concepts in use in others schools in Brazil. Following, we present three case studies that were developed by our students and consultants. Finally, we present the conclusion of this paper, considering the results obtained and future projects.

2. Research Context

There are several perspectives about the social context which sums up the globalization issue. Among these, the Bauman liquid modernity, the Castells Network modernity, the Maffesoli tribe modernity, and Baudrillard consumption society are visible. Besides their relationship, one of the concept related directly to the purpose of this paper is Lipovetsky hipermodern society.

For Lipovetsky, the thought and everyday practices configures a paradox between present conception and the future at the same time. Let´s review this context in the time.

The pre-modern societies had the social structure characterized by historical foundations and determined by the past. As the modernity emergence occurred, the values were changed and a new paradigm appeared: the society began to trust in human potential and technological capacity to act in the social field and organize the future efficiently.

In the end of 20th century, the modern project started to fail as efficiency proct. Several elements reinforce this disbelief in a new project: revolutionary projects failure, great ideologies and utopias breakdown, new individualism culture centered in the present, among others (Lipovetsky, 2004).

In this context, emerges a new concept designed as “post”. The new concept – post modernity – feeds a theoretical discussion about a paradigm shift that evokes the importance of the present, not the future, considering technological conquests, related to information technology.

The designation – post – refers to an ending. Regardless this question, Lipovestky affirms that this phase is not finished. In fact, the conceptual bases are amply in a new format called “late or hyper modernity”. The Characteristics of Hyper modernity including a deep faith in humanity's ability to understand, control, and manipulate aspects of human experience.

We are living a moment marked by a hyper-consumism, hyper-individualism and an uncertain future. Media are constantly presenting elements related to this subject. Figure 1 presents, two Brazilian magazines that discuss this question – hyper-consumism and sustentability.

3. Sustainability and design

Starting of this context, there’s an evident problem which arises in different debate’s forums: the planet’s sustainability and the turning responsible process of each person considering this question.

Clearly it’s not about counting some of the possible alternatives, but the purpose is to put in evidence an educational experience that adopts this question as ethical and esthetical principals in the professional designer’s formation and in its relation with the society.

Before the report of the educational experience, it’s necessary to introduce two concepts which form the basis of this experience: the concepts of sustainability and design.

The sustainability concept defined by the “World Commission for Environment and Development,” WCED, 1987, and which serves as basis for the “Rio Eco 92” event it’s “to supply the needs of the present generation without affecting the possibility of the future generations to supply them.” This concept can be discussed, according to Penin, as the following explanations: “means a social and productive systemic condition, where is possible to obtain at the same time: the overcoming of the environmental destruction, the economic development and the social and justice equality.” If we support the notion of sustainability in three dimensions: environmental, economical and social, the belief is that the action to deal with this problem should link these three dimensions. Despite the evidence of this argument, it’s important consider that the biggest part of those actions is restricted to environmental actions that don’t consider social and economical aspects.

Before a more intensive discussion about this question, it's important to turn clear the design concept that we are working with. Since the industrialization process, designers have been acting on products wanting to make them more valuable. Most recently, with changes in the economy, a great variety in products quality appears. The products are presented besides their materiality, but in its immateriality. The actual economy focused not just in the product but in its relationship with the consumer and its purchase ambient. The extended market confronts the designer with a dilemma: operate in a hyper-consumption society, or in opposition of it, in a conscious\ process about this consumption (Celaschi, 2007).

To Penin, it's possible to reduce these problems in two questions:

- Technologic-productive:

  garbage solutions;

  clean technologies and otimization of materials;

  design and re-design of sustainable products.

- Social-cultural innovation:

  Social behavior changes as new consumption posture and new notions about well being.

In the technological-productive perspective, we've been seeing lots of actions to confront the sustainability problem. About the garbage, each time more the population it's adopting as day-by-day practical the selective garbage collect. In the case of the clean technologies and optimization of materials usage, the actions are more restricts and in a smaller quantity, focusing in some production processes that already have the emphatic use of that practice as a production rule. In products design, the focus is even more restrict, concentrated in some designers who have transformed their work in a conscious practice.

Anyway, all of those three precedent points are focused on consumption products. So, if we want to compose a logical of the opposition of the productive process, that gives emphasis to the hyper consumption, is necessary that besides the operative practical about sustainable quality of the products, it should be more focus in process than in products. This means, the precedent actions are necessaries, but not enough to an effective action.

With this, we move to the second question: social-cultural innovation. In this eration is more focused in the process than in the products. This means that the consumption focus it's not anymore in products but in the experiences and services. Thus, the market operates less with materialitie and more with the immaterialities. The products reduction in the marketplace turns into a consequence that provides from changes in the purchasing posture.

Like this, we indicate a behavior change much more than solve the objects problems and theirs hyper-consumptions.

4. Behavior's changes

Many cases, internationally, has been presenting themselves as alternatives to the process of globalization and hyper-consumption. Cases as the EMUDE, the CCSL, and the IVIS, indicates and systematize these new purchasing practices.

In EMUDE's case, Emerging User Demands for Sustainable Solutions, social innovation solutions are analyzed, concentrated in actions realized in European communities.

The CCSL, Comunidades Criativas e Estilos de Vida Sustentáveis, aims to investigate study of cases in Brazil, Índia and China of social innovation of communitarian basis and its implication in the dissemination of a more sustainable day-by-day life in urban contexts and new sustainable life-styles, visualized by Ezio Manzini & François Jegou. This project was part of a conference

called “creative communities” organized by Laboratório e Desenvolvimento Social (LTDS) of COPPE/UFRJ, coordinated by Professor Roberto Bartholo and it happens in April 2007.

The result from that conference was the constitution of IVIS, Instituto Virtual de Inovação Social e Design which has as goal, the identification and systematization of design practices with focus in social sustainability as innovation process in the Brazilian territory.

In this context, of enlargement of the designer acting, as well as the sustainable process valorization, becomes necessary a new teaching model, which interacts with society and with productive system to generate knowledge. The propose built by UNISINOS can be seen as an answer to this scenery.

5. School of Design - Unisinos

The university in Brazil is going through a period of inevitable and hard change. Beside the big public universities known of places of excellence, there are private universities of several levels in the country.

The companies and students favour an education and a research activity connected to a global university system, able to broad mind for wider linguistic possibilities all over the world.

Few universities have comprehended that the isolation concerning the social and productive system (industrial and financial systems) is disadvantageous and most activates a model of education that nowadays is not sustainable. To confront continually with these systems means to produce knowledge and contribute to innovate the system which takes part today, promoting a virtuous spiral of positive change in the country.

Through an international partnership with the POLI design, Consorzio del Politécnico di Milano, Unisinos, Universidade do Vale do Rio Sinos has chosen to open its offer of education also to the disciplinary sphere of design, developing a model of school of design based on a continuous innovation of the organizational model and of products offered. The model proposes:

- knowledge production, and not only knowledge distribution (model of research anglo-saxonic university);
- continuous innovation of professional profiles offered and of formatives typologies practiced;
- internationalization of curriculums (international professoriate and students engagement) and of the contacts of research;
- continual confrontation of the own contents with civil society and with the production system (continual education and production of applied research and specialize in companies, associations and local members).

For design we understand “culture of project” as:

- element of conjunction among science, management, creativity and know to do organized (between university and industry) in tunning with the concept of knowledge society.
- innovation process able to offer new responses and solutions to the necessities of the society, being the designer an agent able to introduce oneself in a cooperative and trans disciplinary way to produce, through strategies of innovation and creation of meaning to products and services, considering the environment and the availability unlimited of material and energetic resources;

The School integrates activities of education in graduation (Graduation in Design) and post graduation lato sensu (Specialization in Strategic Design), research activities (Master in Design) and activities in consultancy and continual education.

In the context, the professor and the students assume a role of centrality. Moreover, the academic activities are constantly articulated with the entrepreneur atmosphere from different processes, for instance:

- company study of case: in the courses of graduation and specialization, the organizations can be the object of study for the proposition of new products or services, considering the concepts of strategic design.
- comprehension of reality and project atmosphere: the companies can cause, in the research sphere, applied analysis considering the theoretical foundations of groups of research. In this way, metaprojectual researches, diagnosis of the sector, or even applied projects, can take place, always considering the areas integrations.

6. COZA Case

The innovation process involves generally 3 categories of actors in the contemporaneous production, that are: the producer, the company that invest a certain capital to making practical the Idea of the business identified, the consumer and an intermediate category that is commonly defined as of the mediators of the process (Celaschi 2007).

In general the innovation process is generated by this third category. There are many figures that operate in the territory of relation between productions and use/consume market.

This study of case highlights the sphere of activities of mediation, promoted by the School of Design UNISINOS together with the company COZA, domestic vanguard in objects of home use for classes A and B. The theme of the project invites the student for a reflection about the opposition between order and disorder to identify and to project new solutions of domestic use.

The general objectives of collaboration between school and company were basically:

- Activate a dialogue of project between the school and the innovative organizations in its ways of acting, able to enrich the processes of research and education generated in the school of design.
- Establish a real experience, giving form to the entailment of exercises and enriching the didactics experimentations of projections,
- Approximate to the job market potential future talents, starting a virtuous cycle in the relation knowledge-profession,
- At last, establish a link and a permanent way of culture diffusion of the project as a factor of value and competitiveness of industry and market and consequently as a factor of progress for the society.

In every Project developed, became evident the capacity that the students can reach good degrees of interpretations of a problem of a proposed design. Such interpretations made clear that the proposed solutions would be at least stimulations of innovation of new looks, much different than an approach focused in a mere formal-functional solution.

Two of the presented projects presented for the development and engineering relation were selected. Today the company has put the products in the production line and has opened position for the hiring of a trainee student.

The aim is to be ready for an industrial production in approximately six months, and can be launched in important events of the sector that takes place in the second semester in 2008, exposing in the products the companies and the school label associations, crowning, then, a rich approximation of two worlds.

At the same time, company and school, already in a mutual confidence relation, start to elaborate ordinary projects to be officially articulated and activated in the course next year.

7. Conclusion

The present work had as a goal present the existing structure in the School of Design UNISINOS, an answer to the challenges presented by the post modern society. One can realize the project alignment to social demands, considering as an element of fundamental importance the alignment and theoretical discussion.

For the comprehension of this process, the Coza case was described, where the fields of the School: Design Centre, Research and Graduation, took part and developed a considerable Project. It is important to reinforce that this work can be evaluated considering the quality of the projects presented.

However, the main acquisition is realized in the evaluation of the interfaces built, for the consolidation of the integration concept in the School. One proposes as unfolding of the present work a continual process of reflection about the existing interfaces between fields, considering as premises the academic excellence and the research with applied result adding value for the society.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Integration of Haptics into the Design

A designer-oriented tool for virtual clay modeling

Monica Bordegoni[1], Umberto Cugini[2]

Abstract

The paper presents a modeling system that allows stylists first to generate digital shapes in a natural and intuitive way by manipulating a haptic tool that closely resembles a physical rake, and then to evaluate the created shape with an additional haptic tool allowing the exploration of surfaces.

The system aims at providing more intuitive ways of working and more user-centred modeling tools based on “model making” approach. Stylists may conceive, represent and evaluate their design without depending on CAS expert designers and engineers. The evaluation of the conceptual shapes of new products is fully based on virtual models, therefore the number of physical prototypes required in the whole product development cycle would diminish, going towards a more economic, ecological and also social sustainable product development process.

1. Introduction

The design process of aesthetic products includes a typical iterative sequence of activities. The process starts from an initial idea or concept of the product and moves on to the representation of this idea through a modeling phase. Typically, the stylist translates his mental model of the product into 2D sketches, mainly based on synthetic and simplified representation of shapes based on characteristic lines. The sketches are given to a modeler who builds a coherent physical model, or to a CAS (Computer Aided Styling) designer who creates a digital model. If a digital model only is produced, the evaluation of the concept can be performed purely visually; anyway, a Physical Mock-Up (PMU) is always required for a complete evaluation of the design (Yamada 1997). In case, as it often happens, the shape is not fully satisfactory and must be refined, some modifications are performed on the model and the process cycles several times around this loop until a fully satisfied result is reached, or the time available is over (Figure 1 - a).

The correlation of the two product models -digital and physical- is not straightforward. The physical mock-up cannot be immediately derived from the digital model, but instead it requires a production phase that can be manual or consisting of a technological process including CAM (Computer Aided Manufacturing), milling and finishing activities, or through Rapid Prototyping. Conversely, the digital model can be created from a physical object through Reverse Engineering activities (Lee 1999).

Before reaching a final satisfactory shape of the product the various activities are performed several times; that means that several loops are carried out, and therefore several physical prototypes are built. Just to give an idea of the size of the problem we report some figures provided by Alessi (http://www.alessi.com) - a well-known Italian company operating in the sector of household design - related to the role of PMUs in their design process. Alessi produced about 1000 physical prototypes in year 2007, had about 300 open projects and 50 products finally developed, and plans to produce more than 1200 physical prototypes in year 2008.

Every time a PMU is needed for the evaluation of a new product the design process breaks up and the prototype is physically built. This activity requires long time that is at least an order of magnitude higher than the time required by the other phases of the product development process. Therefore, it is rather common that in order to meet time and cost constraints, the number of PMUs is dropped down. The direct consequence is that fewer solutions can be evaluated to the disadvantage of products quality and innovation.

An issue pursued by companies is to find a trade-off between obtaining the best result among the various identified solutions in the shortest time. We have seen that in the design process most of time is dedicated to build PMUs. Ideally, the number of PMUs should be diminished while maintaining high level of the quality of the product. Since PMUs are important to the aim of assessing the product design, the focus of the research is studying new tools that allow the reduction of the number of PMUs, while maintaining and possibly increasing the quality of the products, and exploiting the knowledge of the designers. Specifically in the industrial design domain, the technology is expected to support creativity and to enable the re-use and exploitation of designers' know-how, and also amplify the knowledge and acquired experience in a shorter time.

The paper presents the results of the research project *T'nD – Touch and Design* funded by the European Union (http://www.touch-and-design.eu), where we have developed a system that allows stylists first to generate digital shapes in a natural and intuitive way by manipulating a haptic tool that closely resembles the physical rake they are used to use in everyday activities, and then to evaluate the created shape with an additional haptic tool allowing the exploration of shapes (Bordegoni and Cugini 2006).

2. Towards a sustainable product development

The goal of the research work presented in this paper is to study tools for modeling and evaluating aesthetic products based on new designer-oriented interaction modalities. In order to design new interactive tools oriented to designers, it is necessary to better understand the various phases of the design process, the methods and tools currently used and their weak and strong aspects, and the profile and skills of the users of these tools.

Two main practices are used for representing concepts of new products: hand-made prototypes and full digital models. Handmade prototypes are created by skilled designers, stylists and model makers by means of modeling malleable materials using their hands and basic craft tools. These people are sort of artists who create products by modeling materials like resin, foam material, and clay using their hands and crafts tools. Some studies have demonstrated that visual, tactile and kinesthetic feedbacks are jointly important in the shape creation and evaluation process (Poitou 1974). Specifically, a craftsperson needs to touch his work; this touch is physical and continual, and provides control of the whole shape creation process. The process is creative, dynamic and evolving, where stylists give form to shapes by continuously interacting with them, thus in a continuous process of creation, perception and understanding. Modelers gather plenty of information by touching the physical mock-up, encompassing it, sliding hands around it, manipulating it and, of course, simulating its real usage. Modelers take benefit of these feedbacks to create shapes, to comprehend them, to check their adequacy to the initial or evolving idea and sometimes to the preliminary definition in form of drawings, and to evaluate the mock-up quality. By gestures done to physically explore the PMU, they enrich their mental representation of the shape, which helps to appreciate and criticize its features. This practice is expensive and requires long time of execution. Besides, some reverse engineering techniques are required for building the digital model of the physical prototype for subsequent manufacturing activities.

The other practice consists of CAS (Computer Aided Styling) or CAD (Computer Aided Design) tools used by designers for making digital models. In general, designers consider these tools too technical, and lacking intuitive user interfaces. The creation of a shape is usually done by handling surface control points, and the evaluation of the quality of the surface is performed using functions like reflection lines and porcupine diagrams. Although these modalities are useful, they are not completely satisfactory for designers who want anyway to touch the object shape in order to assess the design. Yet there is the necessity to physically build the prototype so that designers may evaluate the quality of the model through physical touch.

In the recent years CAS/CAD tools functionalities have been improved in order to offer more powerful and user-oriented functions, and user-centred interfaces. Very recently, haptic interfaces have been added to shape modeling tools (Cheshire at al. 2001; Dachille et al. 2001). This emerging technology allows users to interact with a virtual object through the sense of touch (Laycock at al. 2003; Hayward et al. 2004). Designers may use interaction devices that give touch feedback related to the shape they are creating. That aims at allowing faster and more natural shape design workflow than with traditional methods.

If we consider the evolution of the tools oriented to product design, we notice that they have been improved mainly in an incremental way by adding new functionalities (i.e., global shape modeling) and interaction modalities and devices (haptic interfaces), but without changing the basic paradigm related to processes and procedures of product design. In this application context, our research work aims at developing product design tools of new generation where the product shape creation and evaluation is based on a “manual making” approach, which is expected to have a strong impact on the product life cycle.

According to this new design paradigm, the stylist starts drawing the sketches of the new product, and then he himself may directly create the model from these sketches using in the developed system his sketch lines as rakes profiles if he likes, and afterwards he is able to evaluate the model by using the visual and touch modalities offered by the system, and eventually, when the design is mostly assessed, he may decide to send the model directly to

Rapid Prototyping or milling tools for physically building the product (Figure 1 – b). The major benefits of this new design paradigm are that the stylist can conceive, represent, model and evaluate its design without depending on CAS expert designers and engineers, and that the number of physical prototypes required in the whole product development cycle would diminish, going towards a more economic, ecological and also social sustainable product development process.

3. Haptic interfaces for virtual modeling

Haptic modeling is concerned with modeling of virtual shapes using haptic technologies. Haptic modeling systems allow users to touch, feel, manipulate and model objects in a 3D environment that is similar to a natural setting. The only shape modeling system commercially available is FreeForm by SensAble Technologies Inc. (FreeForm application), which is based on the Phantom haptic device (Phantom device). By using this application, the users work directly with the digital clay using the Phantom stylus as a modeling tool. Hardness and surface smoothness of the clay can be varied, and different modeling tools can be selected. The material can be removed using some carving operators, but the user can also work from inside out pulling and deforming the shape. The main problem designers have reported concerns the difficulty in getting used to the tool and to the forces required for removing material with a constant depth. In addition, the fact that the application uses a voxel model does not allow them to have a high quality surface in terms of smoothness and continuity that can be immediately re-used in the downstream activities of product development.

Within the context of the T'nD European project (http://www.touch-and-design.eu) we have studied new interaction modalities for shape modeling based on user-centered haptic tools. During the study and the design of these tools, great attention has been put on the usability and on intuitiveness aspects of the interaction modalities with virtual models. In fact, our tools are intended to provide ways of interaction that are easy, intuitive and pleasant to use for product designers so as to convince them to adopt the system as a daily working tool.

The target users of our system are stylists and model makers who are used to model physical prototypes of product by hands, and designers with some experience in using digital modeling tools. These users have motor and tactile capabilities that are well exploited during manual modeling of plastic materials. The skills they have in their hands allow them to intuitively create physical models from ideas, and to check surface quality just passing their hands over the newly created shape. The idea of this research work is providing a system that offers all the good features of CAS/CAD tools with improved user interface and interaction modalities that preserve and exploit designers' manual skills. Differently from other research works related to haptic modeling and virtual clay modeling (Cheshire et al. 2001; Dachille et al. 2001; Dewaele and Cani 2003) the aim of this work is to develop new haptic tools and modeling modalities which are effectively oriented to designers, and which are specified and evaluated by the designers themselves.

Designers have been observed while modeling physical prototypes of products in order to deriving some specifications for the new system user interface. Cognitive psychologists participating in the research project have observed and studied modelers while modeling physical prototypes using their hands and craft tools. Modelers of industrial partners of the project have been video recorded and interviewed while creating physical models of some selected objects (a vacuum cleaner and a car C-pillar) by working malleable materials (like clay, foam material, etc.) with their hands and tools like rakes, sandpaper, templates, cutters. Subsequently, the collected data have been quantitatively and qualitatively analyzed in order to understand the advantages derived from operating manually when creating shapes, and to understand the modelers' knowledge that is in their hands. The results of the analysis are reported in detail in (Giraudo and Bordegoni 2005). In synthesis, the analysis of hand gestures has highlighted the fact that visual, tactile and kinesthetic feedbacks are equally important in the shape creation and evaluation

process. The skilled hand motions performed by the modelers allow for a precise creation of the shape; the tactile interaction with the object helps in comparing adequacy of the physical prototype with the drawings, in providing early clues about shape features, and in improving the 3D mental representation of the shape.

The analysis of the acquired data has lead to the identification and classification of the tools used (manual tools, machines) and of the gestures and hand motions performed (for shaping the object, for feeling the surface quality, etc.). From this analysis we have pointed out the most recurrent, common and effective users' operations: *scraping, surface quality testing and finishing*. Scraping is usually performed using rakes, surface quality check using hands directly and surface finishing using sandpaper. The T'nD system offers tools and modalities for performing the same operations, in a digital environment.

4. T'nD system

This section describes in detail the T'nD haptic modelling system that we have developed (Cugini and Bordegoni 2007). The system has been designed considering the following three main requirements:

- the system should provide haptic tools and modeling operators for scraping, finishing a surface and for checking its quality;
- the system is oriented to the creation of industrial design models, therefore it should support the generation of high quality class-A surfaces;
- the system should render at real-time forces that simulate contact and force response with plastic materials like clay.

According to the first requirement, the system provides an interface that allows designers to interact haptically and graphically with virtual models of products including a true size car body. An extended version of the FCS-HapticMaster system (HapticMaster) is used since it is the most appropriate hardware solution for the project. In fact, the device provides an adequate workspace and rendered force (250 N). Within the context of the project, the FCS-HapticMaster is used as basic platform equipped with a strong and stiff 6 DOF device carrying simulated clay modeling tools.

For what concerns the mathematical model of shapes, approximated models do not satisfy the second requirement concerning high precision representation of the created shape. Therefore, a technique has been developed based on a tessellated model representation used during the material removal operations, and operators based on generic sweeping motions of profiles applied at the end of the removal operation in order to compute a precise high-quality surface (class-A surface).

Finally, the system is required to compute and render the geometric and haptic model of the sculptured object in real-time. Virtual objects must behave credibly, and interaction must take place in real-time. Therefore, the system is able to simulate properties and behaviors and at the same time satisfy the real-time constraints. The physics-based model computes and renders the forces in accordance to the type of plastic material simulated, on the basis of the well-known theory of chip removal (Merchant 1944).

The system is equipped with two haptic interfaces: a tool for shape modeling that resembles a rake and a tool for shape evaluation that resembles a piece of paper that adjusts to the object shape. The two tools are described in the following sections.

4.1 Tool for shape modeling

On the basis of the system specifications as previously described, a system prototype has been built. The setup of the prototype consists of the scraping haptic tool driven by two integrated FCS-HapticMaster systems (HapticMaster), and a monitor showing the object virtual model (Figure 2). The tool consists of a strip made of metal, which is typically handled by the user by gripping it between the thumb and fingers in two places, with both hands. Movement and force feedback on the tool is needed in at least all the 3 translational degrees of freedom that a body has: fore-aft, left-right, and up-down. The workspace provided is on the order of the reach of the human arm, or the size of a quarter of a 40% car model. Tool forces presented to the user when moving free of the virtual clay surface are as light as possible. The forces to feed back to the user are computed on the basis of the geometrical data provided by the detection of the collision between the object model and the virtual model of the rake. The resistance of the tool perceived by the user is the same as using the actual physical tool on real clay.

The user handles the haptic tool with two hands like in reality during the use of a scraping tool, and moves it for removing material. When the haptic tool gets in contact with the virtual object, it gives back the user a haptic feedback. The user can set the geometrical profile of the virtual rake and remove material from the virtual object just with one or a couple of strokes.

4.2 Tool for shape evaluation

The second tool allows the simulation of a piece of sandpaper, where its curvature actually follows the curvature of the virtual surface being explored (Figure 3). A piece of sandpaper, or rather the underlying surface of the work piece contacted, has curvature in addition to orientation. Our system is limited to the G2 curvature, which is the degree of "roundness" of the surface. In order to implement that, the device consists of a structure made of flexible spokes providing double curvature to the patch, which is covered with a piece of elastic material. If we consider that the user's hand relatively large in relation to the radii of curvature of the surface under exploration, and if the curvature of the surface is changing rapidly, then the users may well extract a cue about the nature of the surface, from the longitudinal changing of the curvature under the moving hand, i.e. by feeling the travelling bumps passing under the hand. The rotational workspace of the tool is the same as that of the human hand; it is usually limited to ± 30° in fore-aft tilt relative to the human arm, but the freedom in roll is at least 120°.

The tool is easily manipulated by the user who is free to move and rotate it around the three axes. During the haptic exploration, the system also renders the surface using the reflection lines modality. In this way, the user can better evaluate the quality of the surface by looking at the kinds of the reflection lines, and also by touching the surface. Using the system the quality of the surface can be checked, and the surface can be modified applying a sanding operator that removes very thin layers of material as the sandpaper does.

4.3 Users' evaluation

The idea of using a haptic tool for modeling shapes in the industrial design field is quite new. Therefore, it has been considered very important testing the concepts and interaction modalities proposed with designers.

Ten participants (designers, modelers and CAD engineers) took part in the evaluation sessions. None of the participants reported previous experience with haptic interfaces. After practicing with the system for about 10 minutes, they started modeling a given objects (a laptop cover) using the system. At the end of the sessions, that lasted about one hour each, the participants were asked to compile a questionnaire. The analysis of the testing sessions and the testers' answers to the questionnaire is hereafter reported:

- *general impression about the system.* All the testers where very positive about the concept and the system. They demonstrated a great interest in the haptic interface

and in its potential evolutions. In addition, they considered the proposed way of working very effective for creating new shapes. In conclusion, they think that the system introduces a new way for creating surfaces through sweep operations. This aspect is surely interesting and yet not existing as method for the generation of sweep surfaces in any CAD tool. From the users' point of view the generalised sweep approach fits very well with the concept of global shapes, which are thought of as an evolution of a curve along another line (trajectory) and can be realised through just one shot. More details about the evaluation results may be found on the project web site.

- *perceived usefulness of the system.* All the testers agree on the fact that the system is valuable for shape creation. At this stage, the system is suitable for rough shape creation more than for creating precise shapes. In general, all the testers have expressed the opinion that the system is a very helpful tool both for modelers and designers. They all seem quite positive about the possibility of integrating this new tool with other modeling tools within the design process.

- *effectiveness of the system.* All the testers agree in confirming the extreme intuitiveness of the scraping tool for creating shapes, also because of the intrinsic naturalness of the hand gesture. An important achievement to be noted is that all participants considered the motion they were making and the forces implied of extreme good quality, and fully similar to the ones occurring in physical clay model making. The testers reported some initial perception problems mainly due to parallax of the eye and hand working spaces. These problems have been solved in the new version of the system.

5. Discussion and Conclusions

The paper has presented a modeling system that allows stylists first to generate digital shapes in a natural and intuitive way by manipulating a haptic tool that closely resembles a physical rake, and then to evaluate the created shape with an additional haptic tool allowing the exploration of surfaces.

The research described aimed at providing stylists and designers a system that improves usability of current design systems and that also allows them to create and evaluate the conceptual models of their products not only through vision but also by means of touch. The system has been tested by a set of designers who have considered the interaction provided by the system and the way of working very effective and close to their real way of operating.

For what concerns the product design process, the obtained benefits are several. The global design cycle is shorten due to the fact that a high quality mathematical digital model is created directly and precisely by the stylist through few gestures, the quality of products is improved due to the fact that more variants may be designed and validated within the available time, and also the number of physical prototypes diminish towards a more economic, ecological and also social sustainable future, since physical mock-ups require material to be produced, and also tools for manufacturing them, as well as energy and the use of means of transportation, and in addition are not durable and seldom re-usable, and so need to be recycled or dismantled.

The limitation of the current implementation of the system, as reported by the users during the evaluation sessions, concerns ergonomics aspects of the system setup mainly related to parallax of eyes and hands working spaces. In fact, the space where the user sees the object and the space where he operates on the haptic interface for creating and exploring the shapes are not co-located. This problem has been addressed in a new research project named SATIN (http://www.satin-project.eu) where the system layout has been designed so as to offer a precise coincidence of the visual and hand operational working spaces so as to improve usability and ergonomics issues.

DESIGN VISIONS PROPOSALS AND TOOLS

Design for Social and Environmental Enterprise

Design at the Service of Social Businesses

Clare Brass[1], Flora Bowden[2]

Abstract

SEED Foundation undertakes academic and action research to develop new, innovative ways for design to most effectively contribute towards sustainable development. By aligning current political goals with cutting edge design thinking and good business sense, this paper presents our ideas on how more designers can profitably solve social and environmental problems through their work.

It specifically investigates how the still emerging discipline of service design, in dealing more with relationships and experiences than material objects, offers inherent social and environmental benefits and is naturally transferable to sectors broader than private business –where designers traditionally work. By working in public and third sectors, and especially with social businesses, this paper uncovers new roles and business models for comprehensively sustainable design practice.

Introduction

Design is about people and solving problems. Products, services and systems that are well designed are easier to use, more visible, more desirable and more sustainable. Since the industrial revolution began, design has been used as a tool to meet specific economic challenges for businesses, to increase growth, improve market share and boost financial gain. The UK Design Council came into existence at the end of WW2 to help get Britain back on its feet by promoting the value British made goods. The 1946 exhibition 'Britain Can Make It' was created to show 'the improvement of design in the products of British industry (Design Council 2007). This operation played an important part in driving post-war economic recovery and set the scene for the way the design profession would evolve.

But as the UK has shifted to a service-based economy, competitive advantage has moved away from product alone to incorporate brand and brand experience[3]. Businesses are now beginning to employ designers to improve the quality of their service offering and the way they connect with their customers. Service design is a growing phenomenon, which looks closely at the way people do things, reframing problems accordingly to fulfil people's needs through new, easier and more desirable experiences. In this new guise, designers are helping businesses devise strategies for customer interaction rather than just being brought in to design more 'stuff'.

This ability to deal with behaviours and relationships and to find attractive alternatives to physical objects has an added and largely unintended environmental benefit. Research on sustainable design identifies a shift to services as a potentially powerful tool for reducing the environmental impact of this industry. According to the sustainable design network, Sus-pro-net, "Companies should switch their focus to [offering] a mix of tangible products and intangible services, designed and combined to jointly fulfil a user's needs" (Suspronet 2004).

Aims

This paper aims to uncover how the current strengths and nascent trends in the design industry can be best employed to achieve the goals of sustinable development. It will

- investigate how and why service design is well-placed to drive innovation in public services, the third sector and particularly, social enterprise; and why it could therefore be an invaluable tool for sustainable development

- uncover the obstacles that prevent mainstream designers earning their living from solving social and environmental problems and identify the entrepreneurial skills and new ways of working required to overcome them

- and present SEED Foundation's new design-led social enterprise that will put the theses and methodologies discussed, into practice

[3] Green communication group Better Thinking describe a history of consumption in which competitive advantage used to be based on product, then on brand. 'The next step' says the company's director Mike Betts 'is that businesses will be valued on their behaviour and will have to provide transparency in order to maintain customer loyalty.

In our current economic model, businesses that sell products measure their success in turnover of units. A service model removes this dependency and can be equally if not more successful. In 2001 Electrolux piloted a project to test this thinking with a group of consumers in Gotland, Sweden: instead of selling washing machines (product), they supplied the machine free. Each wash was then paid for through the electricity bill, an action that required building a new relationship between these two disparate types of stakeholders. The problem was redefined as one of fulfilling a user need – that of getting clean clothes (service). Over the lifetime of the machine, this model generates a higher turnover than just selling products. Since Electrolux would retain ownership of the machine, they would also have greater incentive to design it to be easily repaired and to last longer. In addition, the company would this way be involved in the end-of-life of the machine and can remanufacture it or recycle its materials (UNEP 2005). There is an added benefit in user behaviour change, since paying per wash will likely make customers wash less, with a consequent saving of water and washing powder.

The United Nations Environment Programme believes that the integrated working of stakeholders is a great advantage of service design, the real key to unlocking environmental benefits (UNEP 2005). Britain, with its strong service industry, has pioneering service designers, putting it in an excellent position to generate new sustainable service models.

So although all projects that pass through the offices of a service designer do not necessarily have an environmental objective, this might be a suitable destination for that growing group of designers who are concerned about the impact of their professional practice.

Service designers are exploring the value of the Internet as a means to successfully accessing services. London-based design studio LiveWork developed the systems and interfaces of Streetcar, a flexible car-hire service. Subscribers to Streetcar can rent a car on an hourly or daily basis, finding the nearest available car through a simple online tool. With the potential to be cheaper and less bothersome than car ownership, it affords people the mobility of a private vehicle, ultimately reducing the number of cars on the road. The importance of design in this model is making an interface that is so simple and intuitive to use that this different means of private transportation can be as attractive and easy as owning your own car.

Designing Beyond the Private Sector

By designing for people’s experiences, interactions and behaviour, designers are developing skills and techniques that are not only well suited to the services of business, but that are also easily transferable to public services. By applying their service design skills to the public sector, designers are able to broach a new set of challenges and opportunities, applying strategic innovation to problems of systems, infrastructures and relationships that are rarely demanded of them in the private sector.

Through this methodology the former RED Unit at the UK Design Council was able to tackle a broad range of diverse problems relating to issues such as the prison service, domestic energy consumption and MP’s relation to their constituents. Hilary Cottam, who was awarded the Designer of the Year Prize in 2005 for this work, went on to form Participle, a multi-disciplinary design group further trialling the use of design in working with public services.

A new generation of young designers is experimenting with how they can support and improve public services. ThinkPublic, for example is using design to help the National Health Service build an emergency service that is better suited to the needs of today’s young people. Zest Innovation is working with Northumbria University to help them with their recruitment

strategies, exploring ways of promoting careers in design to school-age students. New communication tools are in development, that are more engaging for this target audience.

Further examples of design's reach into new realms came through the Dott07 initiative, funded by the North East of England, where social and environmental improvement was the key objective. Various projects explored how design can improve quality of life and wellbeing, involving local people in finding better and more sustainable solutions to their daily problems, such as how to get children in remote areas to school without dependency on a car (Move Me, Dott07 2007), or how to help low-income families cut carbon emissions through insulating their homes (Low Carb Lane, Dott07 2007).

The co-designed solutions that emerged were both innovative and unexpected: designers working with parents of children in remote schools came up with a spread sheet in the school entrance for more effective car sharing, as well as the re-design of the local bus timetables for easier use; the solution for people in low-income homes was a financial package, brokered between energy providers and banks, to enable insulating home improvements to be paid for through savings on fuel bills.

These projects illustrate that, when tackling the complex challenges of sustainable development, the designer can become a connector between multiple stakeholders, teasing out issues and finding common values. Here, where the re-design of systems and services become critical to making profound and lasting sustainable change, service design offers a number of valuable processes. Visual communication, mapping and user-centred design techniques make it possible to examine the journeys of different users through any given service, tapping into their needs, and understanding how their connected problems can turn into possible symbioses, reducing dependency on physical objects and finding new ways of effectively and enjoyably collaborating.

Recent research for the Design Council (Brass, Bowden & Moseley 2007) enabled us to overlay some of this burgeoning design thinking with some of the broader aims of the UK government's sustainable development strategy, Securing the Future, whose stated aims include the creation of "…sustainable communities that embody the principles of sustainable development at the local level. This will involve working to give communities more power and say in the decisions that affect them; and working in partnership at the right level to get things done" (Defra 2005, 17) We concluded that service design could make valuable contributions to these objectives, but it is still in its early stages. It exists predominantly in demonstration projects such as Dott07 or in academic research, whose operations are not conceived as businesses and therefore have no self-sufficiency, remaining inaccessible to mainstream design. In the face of the current environmental crisis, enabling designers to tackle the critical issues of behaviour, systems and infrastructure using the methodology described above, could have powerful results, but this will never be possible until it becomes a recognised path on which designers can forge their profession and their livelihoods.

Outside of design there is another area of business that is generating profit from social and environmental problems: social enterprises are profit-making businesses which trade in goods or services for a social or environmental purpose. Whereas conventional businesses distribute their profit among shareholders, in social enterprises the surplus goes towards one or more social aims of the business. Well known social enterprises include The Big Issue, Cafedirect and Welsh Water.

Three common characteristics of social enterprises as defined by Social Enterprise London are:

- Enterprise orientation: They are directly involved in producing goods or providing services to a market. They seek to be viable trading organisations, with an operating surplus.
- Social Aims: They have explicit social aims such as job creation, training or the provision of local services. They have ethical values including a commitment to

local capacity building, and they are accountable to their members and the wider community for their social environmental and economic impact.

- Social ownership: They are autonomous organisations with governance and ownership structures based on participation by stakeholder groups (users or clients, local community groups etc.) or by trustees. Profits are distributed as profit sharing to stakeholders or used for the benefit of the community.

Design Council research (Design Index 2008), which followed share prices of a group of more than 150 companies recognised as effective users of design between 1994 and 2003, proved that design can boost the success of private business: they out-performed the stock market by 200 per cent. We believe that if this power of design were applied to social and environmental enterprises, it would propel them to a new level. We can see a potential for social enterprises to compete with regular business services while actually resolving one or more social or environmental issues in the process. Our premise is that problems are opportunities, and equipping the design sector to think more entrepreneurially and across disciplines would unleash design's benefits on a whole range of social and environmental problems.

We think there are two principle ways for designers to engage in this field: to support existing social enterprises, or to use their entrepreneurial skills to build new partnerships and social enterprises themselves.

A new model is needed to open the doors to the growing number of designers who wish to apply their skills and time to resolving social and environmental challenges, one which enables them to make money out of working towards these goals. Helping designers to be more entrepreneurial about their practice and develop new skills to design systems and services along with strong supporting business models, could turn them from perpetuators of social and environmental problems, into key contributors to solving them.

We believe sustainability should be as much about creating communities and jobs to enhance life as it is about environmental stewardship. To test our ideas and to develop methodology we will build a series of design-led social enterprises over the coming years. These will be based on a set of principles, on which we believe the design profession needs to focus:

1. Infrastructure

Up to now, where design thinking has been applied to environmental and social problems, it has tended to be in the realm of product design and around the familiar refrain 'reduce, reuse, recycle'.

Design's role in sustainable development must not be just about the objects themselves, but about what surrounds them. While looking at products and the way they are designed is important, doing so without considering the infrastructure that supports them and the behaviour of the people who use them is meaningless.

To many people, infrastructure is the most unfamiliar territory for design activity because it moves furthest from design's traditional role of creating objects. It seems rather to be the preserve of disciplines such as finance, politics or engineering. Designers are now challenging this, showing that their skills can be of enormous practical value. This is not a matter of supplanting other areas of expertise, but co-ordinating discussion between them, visualising problems and possibilities, prototyping solutions and putting the focus on end users to ensure real needs are met. It is about design navigating and managing complex networks of interdependent factors quickly and cheaply. It is also about design promoting adoption of new behaviour by making it desirable.

‘To bring the issues of sustainable consumption alive…people need to see symbolic effective solutions in their everyday lives. The effects of these interventions ripple outwards by opening people’s minds to ways of doing things differently’ (Sustainable Development Commission 2005, 109)

Most of the effects of our use of infrastructure are invisible to us. Research has shown that making the effects of people’s actions visible can significantly change their behaviour (Abrams, 2006). Design can filter and visualise this information, present it clearly and immediately and put it where it will be most relevant and visible.

Without thought for the systems that deliver an object to us, power it through its life and dispose of it when it is no longer useful, the environmental credentials of the materials and production processes are more or less nullified. Simply making material adjustments does nothing to alter the human behaviour that is really at the heart of the issue. This is the new space in which designers must learn to operate.

2. Interconnectivity

It is not enough to deal with the problems of sustainable development at face value or in isolation. What we need are solutions that can visualise the context in its entirety and deal directly with the root of problems, ideally eliminating the risk of recurrence.

Sustainable development is a multi-layered, complex network of interrelated challenges and design solutions must approach it accordingly. Designers must appreciate this interconnectivity and tackle the problems holistically to avoid unwittingly shifting them elsewhere.

Plastic bags are the face of one such issue that has been much debated and tackled by designers, legislators and whole communities alike. Capping their free distribution or swapping plastic for more ‘environmentally friendly’ materials might create a new problem while worthily trying to solve the old one. The unforeseen consequence of taxing plastic bags in Ireland was a 300-500% increase in the sale of plastic refuse bags and bin liners (Carrier Bag Consortium). Through this we can understand that the problem of plastic bags is intrinsically linked to the problem of waste disposal at home – if the systems were in place to make it easier to correctly separate wet waste from dry, there would be no need to line the dustbin.

This kind of analysis also expands the realm of possible stakeholders (e.g. retailers, local waste and planning authorities, household goods manufacturers etc) to consider who else might contribute to the solution, leading us to the conclusion that emerging design disciplines must consider cross-disciplinary and cross-sector collaboration. The complex nature of sustainability means the different groups of society must be brought together in coordinated action in order to achieve accelerated change.

3. Business, government and people

Each of these three sectors of society recognises that they need to change but UK Government research describes a gridlock of inaction between them, showing that they are unwilling to act in isolation (Sustainable Development Commission 2005). Each is wary of the other and each is reluctant to make a move without the assurance that the others will follow. Sustainable development issues clearly hinge on all these groups in numerous ways and it is this complex system of relationships that a product-design focused approach misses.

Advanced design thinking increasingly recognises the need to address relationships rather than deal with isolated objects. It examines the connections between things, the

infrastructure that supports them and the people who use both. This will require implementing strategies and initiatives that touch the issues on many different levels. For projects to be successful they must work with all sectors together, to unlock the gridlock and facilitate change.

To return to the example of the supermarket plastic bag, its network of relationships takes in government waste targets, consumer behaviour beyond the shopping trip (since the bags are re-used), and the interests of a number of businesses. A creative design approach to the problem would co-ordinate the needs of all these groups to come up with really effective and, perhaps counter-intuitive solutions.

Sustainability is an overwhelmingly social problem and design's great strength in approaching it would be a focus on end users, whether from business, government, the general populace or all three. A user-centred approach engages all interest groups and encourages their active participation in the design process. For organisations of any sort whose primary objective is to engage communities, there can be few more effective methods of tackling the problem head-on.

Enterprise 1: HiRise Gardens

HiRise Gardens is a social enterprise that touches on issues of biodegradable waste, homelessness, locally grown food, community cohesion and biodiversity. It offers local authorities a turnkey system to deal with biodegradable waste, using the skills of a particular group of unemployed housing estate residents to manage a community composting system that will create a number of spin-off benefits.

The demand for HiRise Gardens stems from the increasing pressure on local councils to reduce the quantities of biodegradable municipal waste they send to landfill under the EU Landfill Directive. As of 2009/10, they will face heavy financial penalties for disposing of waste beyond their allocation. Local councils are developing new ways of dealing with biodegradable waste, such as differentiated or fortnightly collections. But such operations are largely written off in blocks of flats, where any kind of waste separation is logistically complicated and requires significant changes in behaviour.

Given the proportion of flat-dwellers in the UK's inner-city fabric and the failure to design infrastructure fitting to these demographic requirements, this represents a huge loss to local Councils. In fact, in the London borough where we intend to run a pilot for HiRise Gardens, flats constituted about half the properties – half the potential waste savings in this case are consequently lost.

Successfully removing biodegradable waste from blocks of flats is ultimately a connectivity issue that depends on the creation of systems that will help residents understand the issues and inspire them to deal with their waste differently. Former local councillor Stuart Singleton-White, talking about the problems of waste minimisation in Peterborough, indicates the current failings: '…the root of these problems lies in the disconnect between those local politicians and members of the community, coupled with very poor communications skills for both the politicians themselves and from the PR teams of the respective council: a clear lack of creativity here often results in exciting opportunities being lost and failing to excite: cases failing to be made and policies developed in isolation.' (Jonathan Porritt's blog, comment posted 1 June 2007)

By mapping out the common problems of dense urban environments, we were able to visualise the needs of different groups of individuals and find their complementary symbioses. A series of maps helped us identify the key players in private and public waste creation and management, the individual issues of each and how they might help each other. Finally

through these maps we were able to highlight the areas where design's intervention might be most effective. (See plates 1-4 annex)

One of the clearest links that emerged through the mapping process was the potential of joining up the problems relating to biodegradable waste with those of homelessness. When we contacted the London-based organisation, Thames Reach, whose mission is to reintegrate homeless people into work and society, we discovered they currently support 550 individuals already on the path to re-integration in our sample borough. These 'service users' are accommodated in the very Council estates that are the focus of our proposal for the borough's waste problem. In this environment they are often seen as something of a blight, largely unemployed and around 50% with alcohol-dependency issues (Rough Sleepers Unit 1999). In fact one of the biggest challenges that face these service users is gaining regular and dignified employment: when surveyed in 2007, about 79% said they would like to work, but currently only 10% are actually employed (Thames Reach 2007). This huge discrepancy seems to be partly caused by over-expectations of their working capabilities, as well as a prevailing situation where anything less than fulltime work (often difficult to cope with initially) could well leave them worse off than being on benefits.

This poses another problem for the Council, as the cost of having many economically inactive residents on estates can be substantial. It can lead to neighbourhoods becoming run down as people have little disposable income and a lot of time on their hands, sometimes leading to anti-social behaviour. Furthermore for central government they represent a cost in terms of benefits payments, and lost revenue in tax and rent. Therefore providing manageable and respectable jobs to the formerly homeless in a way that brings them closer to their communities while improving the local environment and providing a valuable service, offers multiple benefits.

Our first task was to build a business case to prove the social, environmental and economic advantages of joining up these problems.

The Business Case

The UK has one of the worst recycling rates in Europe. Only Greece sends more waste per capita to landfill (Eurostats 2005).

Furthermore, an estimated 68% of municipal waste is biodegradable (Defra 2007), and about a third of all food bought is thrown away (WRAP 2008). An estimated 2% of the UK's greenhouse gas emissions come from the production of methane from material biodegrading anaerobically in landfill (Let's Recycle).

Landfill, once an easy way to dispose of our increasing waste streams, is getting more scarce and expensive, with gate fees and government taxes increasing. Legislation is forcing private and public waste management bodies to look for alternative means of disposal. These include anaerobic digestion and EfW (Energy from Waste) plants, both of which require substantial capital investment and use existing models and infrastructure with some shifts in the way waste is collected and treated. Whatever the disposal system, there is still a need to address the way individual householders perceive and manage their waste streams.

Our business model is based on Councils' paying HiRise Gardens to reduce the amount of BMW tonnages to landfill. By putting systems in place now we are preparing Councils to not only save money on landfill tax and potential fines but to generate income from the sale of landfill allowance credits. On top of that, we expect to generate income from waste collection beyond the estate as well as substantial revenue from cultivating seedlings and selling mini-gardens for urban vegetable growing.

Waste Infrastructure

Like many other systems that we depend on, waste management is for most of us invisible. We play no part in it beyond our doorsteps, making it easy for us to forget about it and its consequences. But getting people to participate in recycling schemes can be challenging.

The system we are developing provides every household in a housing estate with a bin to separate food waste, and an on-site community composting machine that transforms it from waste into compost. The compost can then be used for localised landscaping of the estate's public spaces and for nurturing fruit and vegetable seedlings, some of which will be returned to the estate, the rest sold. In current world demographics, where for the first time, over half the global population is living in urban areas, with a consequential loss of contact with nature and natural cycles; we believe the introduction of edible plant life into Council estates is a powerful learning tool that will help people understand the loop in which food can grow from food waste.

The time is ripe for this kind of intervention: across the world there are numerous indications of urbanites' desire to reconnect with nature and improve the experience of food and eating. Political pressure led to the exploitation of Havana's urban landscapes for food production, which now provide over 60% of the city's food (Viljoen and Bohn 2005); in the UK, allotment space is increasingly in demand, and for the first time, last year the sale of edible seeds exceeded that of flowers (Horticultural Trades Association 2008). Communities are mobilising to improve their green spaces, such as shown by the underground Guerrilla Gardeners; and the cultivation of a vegetable garden in the Anderson Shelter in St. James' Park, right in front of Buckingham Palace (Dig for Victory: War on Waste 2008), is evidence of the food gardening renaissance reaching mainstream society.

The benefits to wellbeing of direct contact with soil and plants are proven in many areas of research; Thames Reach, our partner organisation for homelessness, already sends some service users to help out at a farm in Sussex as a therapeutic measure, leading to several users expressing a desire to relocate permanently.

The experiential learning of the residents close-up view of the transformation of their waste materials into a resource from which they can directly benefit, is more valuable than educational leaflets and fines, which offer no real understanding of the issues. We perceive the thousands of available linear acreages of housing estate balconies, walkways and communal spaces as prime locations to be exploited for the cultivation of food plants. This has the potential to be a multiple win situation: it would enhance the aesthetic quality of the spaces, giving residents daily experience of natural and growing cycles and hopefully providing some edible benefits too. We suspect that the constant presence of gardening and waste management staff on the walkways of the estates might have the added advantage of reducing delinquency.

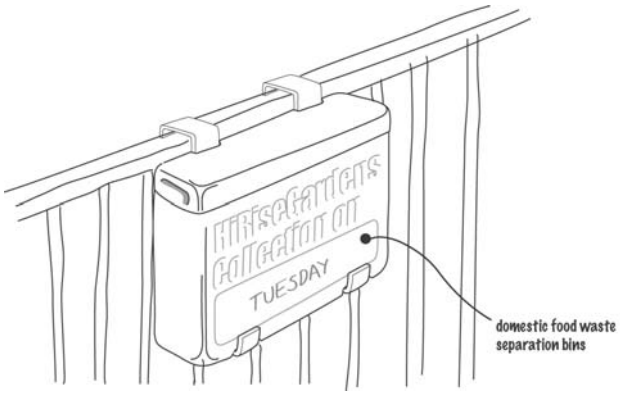
Beyond the estates, there are further business and social benefits to be had. Since commercial and public sector activities must pay extra for their waste collection, they could make savings if HiRise Gardens offered a more competitive rate than other waste companies for taking the biodegradable waste off their hands. Collection from these other sources, which might include hospitals, schools and restaurants, would also provide extra raw material for the composting machine and expand the staff's engagement with the wider community.

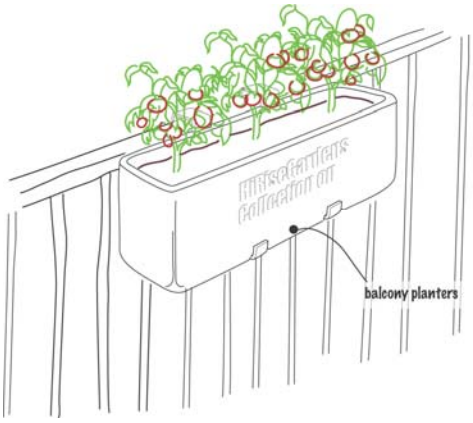
The Design Challenges

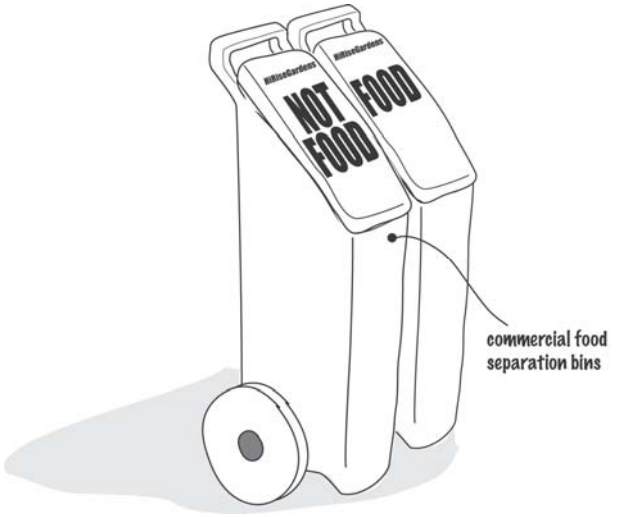
HiRise Gardens is a combination of products, services and systems that encompass a variety of design challenges for such issues as brand, product, service and communication. Our intention is to deliver HiRise Gardens with the maximum design capability at each step

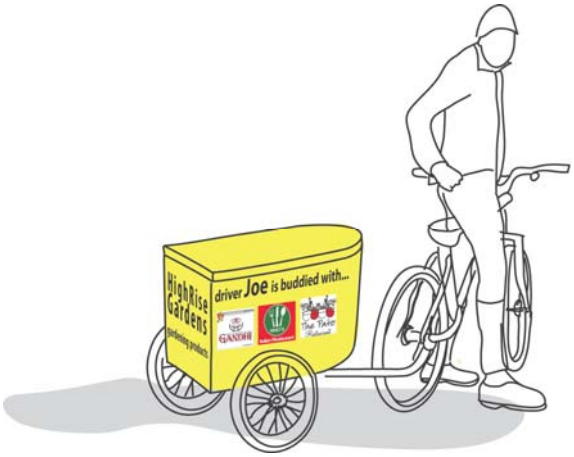
by tapping into the knowledge and expertise of other design professionals. We will be documenting our progress along the way to build cutting edge methodology to disseminate to the design industry.

For the creation of the physical products – which include domestic and commercial bins, window boxes and planter/propagators – we are working with gardening products manufacturer, Stewart Plastics, who will also be able to offer this range through its existing channels of distribution. We will also design a range of bikes and trailer accessories to allow employees to make easy and visible daily collections, of waste around the extended neighbourhood.





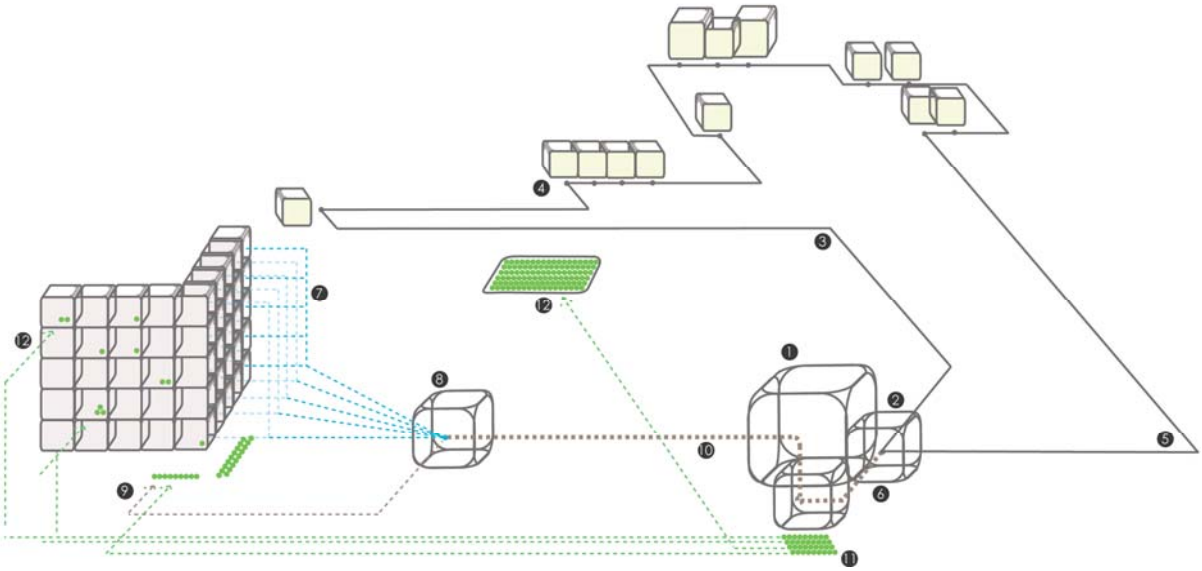




Brand expertise will be needed to build and maintain brand consistency throughout the organisation. This will ensure adhesion from within the organisation and without. There is a clear need to promote HiRise Garden's activities through excellent communication, which will also be important in selling the products and services that HiRise Gardens will offer.

System for External Collection

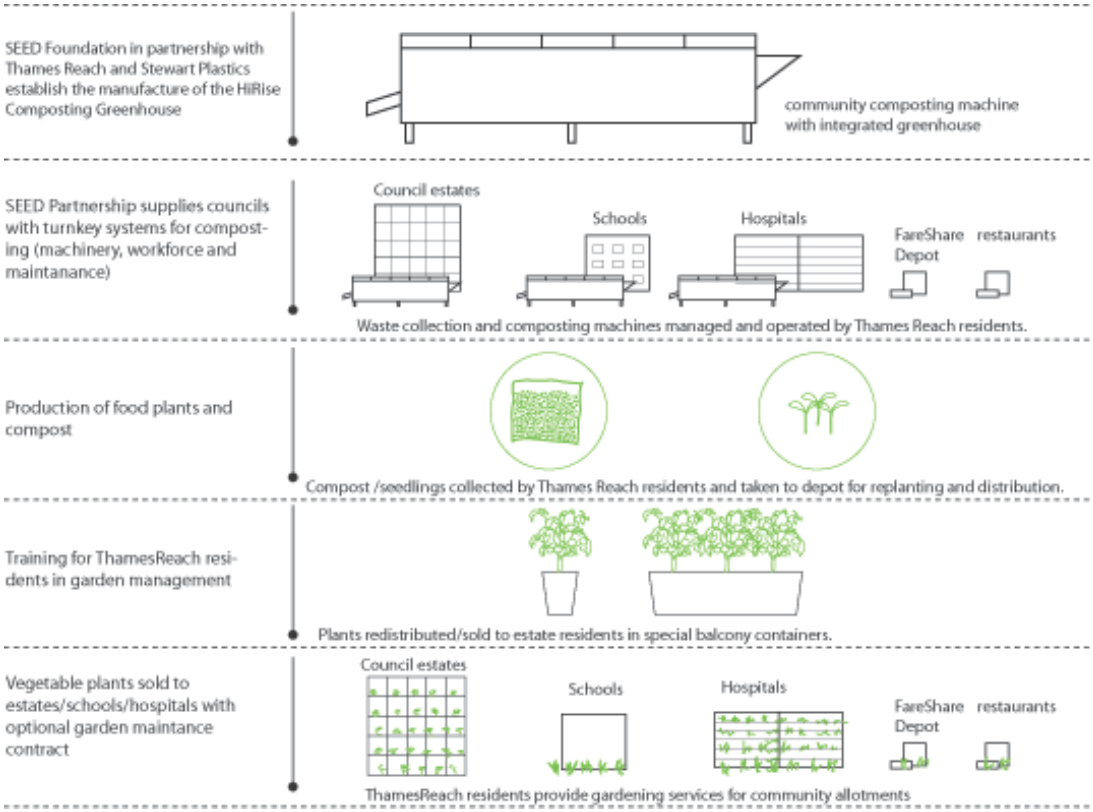
1. The shelter or day centre
2. Its on-site composting machine.
3. One of the members sets out on their route around a planned group of local restaurants or grocers etc.
4. All the food waste that they have separated out is collected.
5. With a full load, the rider returns to the day centre
6. where the food waste is processed and turned into rich compost.
7. At the same time, food waste from local flats is also collected.
8. It is then turned into compost in their on-site machine
9. Some of the compost is used in landscaping the building's grounds or is taken by residents if they want it.
10. The rest is collected by the shelter team.
11. The compost the shelter makes along with the excess compost it collects is bagged for sale or used to grow seedlings.
12. This can then be sold back to the community to green the tower blocks and public space.



Each of the various service aspects will need to be co-designed with the various stakeholder groups – Thames Reach service users, estate residents, external clients etc. We plan to run a number of workshops with each of these to get a better understanding of their various needs. For example, we currently have only an outsider's idea of what it means to have been homeless and to be striving to be once again a part of mainstream society. Working with Thames Reach users we hope to gain insights into what drives them, so that we are better equipped to gradually build up their working routine in a way that is both stimulating and satisfying without being over-demanding. Equally, the success of the operation will depend on striking a balance in the relationship between the service users and the other estate residents.

With them we must design a system that works according to each of their needs and desires, and also ensures their smooth interaction with each other. This co-design will influence the design of the tools for collecting and transporting food waste, the schedules for collections, the communication material and awareness-building aspects of the operation. An important design aspect will be in the building of the brand, which will hold the whole operation together and create an entity with which people will want to be associated, both from within the housing estate and beyond. It will be a means to communicate and build support for the operation in the wider community, important in the construction of a market for its gardening products and services.

The Collection System Diagram



Training

A well-designed training programme is another critical element of HiRise Gardens, which will bring with it further potential for public funding. As we have already mentioned, Thames Reach service users are at different levels of reintegration into mainstream society. Different levels of skills are required to make HiRise Gardens work. At the lowest level, employees must collect waste bins from outside each dwelling on a given day and transport the waste to the on-site machine. Basic training for operating the machine, which includes sifting through the food to filter out contaminants, controlling temperature and humidity and emptying and storing the compost produced, will be provided by the machine's manufacturer. The regular contact with the estate residents will be a valuable opportunity for the staff to interact with their neighbours, building relationships and potentially playing a key role in connecting the community. Beyond the estate, as the collection extends to local businesses, some staff will venture further and hopefully build similar relationships in the commercial sector, broadening their future employment opportunities.

As the enterprise develops and HiRise Gardens operates on multiple estates across numerous boroughs, it will require a structured hierarchy and management teams to oversee its smooth-running. We want to offer the opportunity for professional progression within HiRise Gardens and anticipate that staff will be able to progress from the collection team to management, perhaps training new staff themselves.

Aside from the waste management, the other critical function of the enterprise is in cultivating and marketing seedlings as well as offering gardening and landscaping services, on the estate and beyond. Building on our experience of developing training programmes (Designing Demand 2006), we plan to create a combination of classroom-style teaching with practical mentor/student modules in which new employees are initially teamed-up with a more experienced partner, leading to a learning method that is effective because it is both experiential and strongly supportive.

Conclusion

We are planning to pilot HiRise Gardens over the next few months on a London housing estate, with the support of Thames Reach and grant funding from various sources. The piloting period will provide an opportunity to refine our offering through continued testing and prototyping. We will also need to design evaluation methods that are appropriate to the long-term, soft benefits we anticipate HiRise Gardens will create.

Our intention is for this enterprise to become a blueprint for a proliferation of profitable, community-based waste management operations to be scaled-up and rolled out to create widespread change - an aggregation of the local that moves the national.

DESIGN VISIONS PROPOSALS AND TOOLS

The Hidden Value of Allotment Gardens in The Urban Context and The Opportunities for Design Intervention

Richard A. Brault[1]

Abstract

This paper shares observations of the author's 10-year involvement in a community allotment garden and its role in 'helping individuals live better, reduce their ecological footprint and regenerate the social fabric'.[2]

Community gardens (also referred to as urban allotment gardens) are about inter-connection: they connect people to food, people to living systems, and they connect people to each other. They address many relevant issues of our time, yet they are misunderstood by most, and generally ignored by the design profession.

The author suggests that urban allotment gardens deserve to be recognized as a relevant topic for design research and development. A challenge is made to design schools and several strategies are proposed.

[1] Studio Innova Inc. (CANADA) - Director, innova@bellnet.ca

1. Introduction

> *Jackie and Lorraine pose for the camera as they eat some soup. Today is our spring clean-up where members get together to work in the garden and prepare the soil for another growing season. The sun is shining, the weather has warmed and we are having a busy time. Three years ago, Jackie – homeless and in her early 20s, appeared at the garden like many others have. For several weeks, she slept on the ground at night and protected her 'adopted' plants by day, never saying a word to anyone. She was not a member but she was welcomed just the same. Nobody knew Jackie's story although it was clear that she was dealing with some difficult issues. And Lorraine, a founding member of the garden always made sure she was ok. Today Jackie is a regular member, who talks, asks questions, participates in the clean up and tends to her allotment. She has a home nearby and an email address to remain informed about garden events. We still don't know her story but we know that the garden has and continues to be an important part of her life. (Brault 2008)*

Designers appreciate working on interesting projects and I have had the good fortune of working on several during my career. One project in particular, although it has not generated a single dollar in income for my office has nevertheless provided worthwhile dividends year after year. It's a tiny community garden next to our studio in downtown Toronto where approximately 30-40 people from the neighbourhood grow food or flowers and maintain a small green space for the community.

For 10 years, I observed countless episodes like Jackie's story described above. I also had the opportunity to reflect upon what this garden represents, the lessons it teaches not only about gardening, but also about community, connection, sustainability, and ultimately about design.

If one was to describe the general characteristics of this garden in the manner one would describe a 'product' or 'building' the list could look like this:

- Operates on solar energy
- Made of natural and bio-degradable materials
- Requires little or no maintenance
- Becomes more beautiful with time
- Is impervious to all weather and seasonal conditions
- Is accessible 24 hours a day
- Costs little or nothing to use
- Fits in a small space

The list would continue with:

- Builds community in a neighbourhood
- Inspires strangers to randomly meet each other and spend time talking face to face in a relaxed and convivial manner
- Creates dignified connection between people from extreme socio-economic realities (i.e. a homeless person and a successful business person)
- Allows apartment dwellers without private land to grow their own food
- Raises awareness of living systems, organic agriculture, biodiversity, rain-water harvesting, composting
- Develops horticultural skills and knowledge
- Promotes healthy physical activity

It would conclude with:

- Creates oxygen and aborbs CO_2
- Produces food for people
- Provides food and habitat for insects, butterflies, birds and small animals
- Brings enjoyment, tranquil relaxation and beauty
- Motivates people to freely give their time and expertise

This is an impressive list of features. In fact, it would be challenging to find other man-made products that could make such claims. Yet these are actual outcomes of the Alex Wilson Community Garden and other similar 'products' called *urban allotment gardens*.

Urban allotment gardens exist in the heart of many large cities, often occupying vacant or abandoned lots and built from salvaged materials and rescued plants. They are cared for by city dwellers who live in high-density areas who don't' own land but who have a connection to gardening either through personal history, cultural background and/or economic necessity.

Onlookers and neighbouring residents sometimes complain of their messy appearance. Policy makers and planners in both developed and developing countries have at times described them as 'undesirable' and even '*anti-modern*', and they are often destroyed to allow room for new buildings or other forms of urban progress (Irvine et al. 1999, 35)

Yet it is clear that urban allotment gardens address many relevant social and ecological issues of our day. They are filled with hidden value. They connect people to food, ecology and living systems; they connect people to each other. They assist those with low incomes. They create a context where beauty or conviviality can happen at random. They link micro to macro, local to global. They bring joy, provide healing and offer quiet contemplation in the heart of a busy city. They do it all quietly, gracefully and inexpensively without much involvement from the design profession.

Urban allotment gardens fall between the cracks of landscape architecture, architecture and industrial design. They seem all but ignored by the design profession. They are invisible, buried in the shadows of our man-made technologically driven, fashion-conscious world, where thin plasma TVs and Louis Vuitton handbags seem sexier and more modern than a patch of land with food plants in a noisy city.

2. The Alex Wilson Community Garden – a brief history

The Alex Wilson Community Garden was created in memory of Alex Wilson, a Toronto author, landscape designer and activist. Wilson organized a community garden on a vacant lot next to his house in downtown Toronto where friends and neighbours gathered to grow vegetables, fruits and native plants. Shortly after his death in 1993, the landowner decided to sell the property. Wilson's friends attempted to buy the land to create a permanent garden in his memory but the land was instead sold to a developer and the garden was destroyed to make room for new construction.

Wilson's friends decided to search for another nearby site where a community garden could be built. At the time, my partner and I were looking to create a community garden on a tiny parcel of land (10 x 30 m) next to our studio located just a few streets from the original garden site.

Through fortunate circumstances, we were introduced to each other in April 1996 and met shortly thereafter to share intentions and ideas. Having already lost their original garden to development, Wilson's friends were hesitant to create a new one on land that could eventually become a construction site. They were looking for a permanent site. After reviewing several options we decided that the best solution was to donate our land to the City of Toronto with a conservation easement registered on title. The land would become a public space, protected from future development; the easement ensured it would remain a community garden in perpetuity.

There was enough creative talent within the committee to design the garden (Wilson's friends included an architect, a landscape designer, a horticulturist, a professor, a writer, a filmmaker several artists and neighbours; my partner and I were industrial designers). But instead it was decided that Wilson's legacy would be best served by holding a professional design competition and for the next months, the committee's energy turned toward the organization and logistics of the competition. Guidelines were prepared, announcements were distributed, a competition document was published and a site visit was organized.

Over 140 teams registered and when the deadline day arrived, 67 entries were submitted. Each entry consisted of a scale model with a 300 word written description. Submissions came from architects, landscape designers and artists, the majority from the greater Toronto area. Each model represented a design proposal for the tiny site and each was required to fit inside a larger context model that included the adjacent buildings. Participants were told that the winning entry would be constructed on the site so in order to win, their design had to satisfy the competition criteria within our specified budget.

In February 1997, a professional jury reviewed the entries with technical input from city staff and social agencies. Five finalists were selected and interviewed and ultimately one entry was chosen as the winning design.

The Design Exchange, Toronto's design museum offered to host a major exhibition the competition entries. A brilliant exhibit was created with a miniscule budget using corrugated cardboard podiums positioned against a hand-painted mural of the winning site plan. During its four-month showing, the exhibition attracted several thousand visitors. Toronto's mayor viewed the exhibit and commented that every single proposal deserved to be constructed.

The winning team consisted of two landscape architects and one architect. In addition to their prize, they were given a budget to prepare final working drawings. In June 1997 the committee organized a 'ground breaking' celebration and soon afterwards, the small parking lot was demolished to allow for the garden. A local company was hired to build the garden and many volunteers helped.

The design of the garden tells the story of our relationship with the southern Ontario landscape, from the shores of lake Ontario with its sand dunes and native grasses to the northern woodlands with white pine, shrubs and pink granite. A meandering boardwalk travels the length of the garden connecting Richmond to Queen Street creating a much-used route for many pedestrians who stop to enjoy a moment of tranquility in a busy city.

At the centre of the garden occupying most of the site are 40 small food-growing allotments rented each year by people in the neighbourhood. Rainwater is collected in large tanks, there are bicycle posts, tool sheds, compost bins and a central circle for gatherings. Walls from adjacent building provide massive vertical surfaces for vines on both east and west sides.

From the designer's perspective, a garden must be approached differently than a building. Whereas a building looks best when it is new (and often empty), gardens become more beautiful with time. In the first year, the trees, shrubs and plants are small and scattered but as the garden becomes established, the emptiness fills in with lush foliage as the trees and shrubs mature. It is constantly evolving. The end of construction is simply the beginning of a process that will ultimately lead to an intended aesthetic, years away. The designer's responsibility is to provide a framework where this process can happen gracefully over time.

The official opening took place on June 21, 1998, and the neighbourhood greeted the Alex Wilson Community Garden with expected enthusiasm. They welcomed this tiny green oasis on a busy artery where evening rush hour commuters raced home from their downtown towers to suburban homes, unaware that people actually lived here among these low-rise converted factories and parking lots. This was home to a rich mix of people from all socio-economic and cultural realities.

People rented the allotments and planted a variety of food crops or flowers. Members included professionals of all stripes, single mothers, homeless, couples, artists, and people recovering from mental health or substance abuse. They all rubbed elbows and got to know each other. One member commented that they lived in the area for 20 years and until they joined the garden, didn't know anyone in the neighbourhood – typical of our urban existence where we can't stop to chat because we are always rushing to get somewhere.

A retired university professor walked through the garden for eight years and one day started chatting with a member tending to her plants. He decided to rent an allotment. A widow moved into a nearby condo and was delighted to join the garden and keep her hands in the soil. A group of immigrant women came to grow herbs and learn English. Directly west of the garden is a non-profit social housing complex with 46 units where residents deal with a variety of difficult challenges. Many of them participate in the garden. For some, it is their first garden experience.

Mike, a 50 year-old homeless man arrived everyday at the garden pushing an old bicycle loaded with his possessions from under the expressway bridge where he camped each night. He helped during construction and for 5 years, he watched over the garden, watered the trees and shrubs, swept the boardwalk, built birdhouses from scrap lumber. He rescued abandoned plants from the neighbourhood and transplanted them in the garden. During the winter he would chip the ice from inside the frozen water tanks and place the large blocks at the base of the trees creating a spectacular landscape of crystal. He made sure his homemade birdfeeder was kept full until spring. Mike accepted odd jobs to earn some cash but never did he ask anything from anyone. A local merchant gave him a part time job and whenever he felt he had too much cash in his pocket, he'd knock at our studio door and ask if we'd keep it for him. We became his bank. Everyone knew Mike. He was the garden angel. Then one year, he didn't come back. We found out that he was working for a landscape company and after many years in the cold, was able to rent an apartment across town.

Each garden season begins with a clean up day in April when warmer temperatures arrive. Returning members meet new ones and they prepare the soil, prune the shrubs and lay fresh straw in the pathways. Everyone brings a vegetable for a large pot of soup that is cooked on-site and enjoyed after the work is done. Throughout the season, people tend to their allotment. Sometimes, they meet other members or chat with visitors on the boardwalk. Life in the garden is informal and convivial. In October members come together for the fall clean-up day and once again a big pot of soup is prepared and enjoyed. The winter months are quiet with daily visits from birds and squirrels tha stock up seeds and berries.

As the Alex Wilson Community Garden enters its 10th year, it is remarkable the extent to which the small site is respected. The fact that it is not gated, not lit at night, accessible 24 hours a day, surrounded by graffiti-filled alleys, nightclubs and considerable overnight activity, one would expect it to be an easy target for vandalism or undesirable activities.

There have been problems but these have been relatively infrequent and reasonably minor. When they arise, the gardeners restore the damage quickly. There's always some trash, bottles or cans to pick up. One particular morning after an oppressively hot summer night I found 30 used crack needles under the pine trees, left there by neighbourhood drug addicts. On another occasion, a double mattress was removed from the same spot.

Surprisingly there has been no graffiti considering the alley directly behind the garden is one of Toronto's most active paint zones. The infrequent 'tag' appears every now and then but it gets removed (recently by a graffiti artist who considers the garden to be a sacred space), or covered by a birdhouse that Mike built. The food-growing allotments are rarely affected but come harvest time, certain crops inevitably attract local poachers (four-legged and two legged ones).

Occasionally a homeless person finds a quiet spot under the shrubs to spend the night in relative safety. Drunks have passed out on the boardwalk in broad daylight. There have been numerous discussions about gating and locking the garden at night but some feel that more would be lost than gained. A community garden is as much about 'community' as it is about 'gardening'.

In 2003, the garden became entangled in a landmark battle with a developer who purchased the property on the south side of the street and wanted to build a 45m condo, twice the allowable height. The additional height of the building would block the midday sun and push the garden into a full shade condition for most of the year.

The members opposed the project and organized themselves to defend the garden's right to sunlight. The developer's application was rejected by the City of Toronto but they appealed the decision at the Ontario Municipal Board (OMB), a provincial body with a history of overturning planning decisions made by municipal councils in favour of development. At the OMB hearing the lawyers representing the developer and their 'expert witnesses' argued that the shadow impact on the garden from their 45 m building would be insignificant. The gardeners argued that the impacts were not only significant, but they also threatened the garden's very existence.

The developer's architects presented an 80-page document with computer generated shadow diagrams to support their argument. But upon careful scrutiny, it became evident that the document omitted the shadow diagrams where the impact on the

garden was most severe. The only option for the members was to prepare an equally competent shadow study that showed the true impacts. The process consumed weeks of preparation.

In their final decision, the OMB rejected the project application and ruled in favour of the garden's right to sunlight. The developers had to redesign and eventually build the condo to comply with the site's height limits. Today the sun continues to shine in the garden.

3. The Hidden Value of Urban Allotment Gardens

It's difficult to estimate the number of urban allotment gardens scattered across cities around the world. They are everywhere. Toronto has upwards of 70 gardens (Irvine et al. 1999, 34). Boston has close to 200 (Boston Natural Areas Network). They exist on vacant land, between buildings, or on rooftops in cities in all continents (Deelstra 1987).

There are networks and associations that connect, educate and advocate on behalf of allotment gardens at all levels. The Toronto Community Garden Network (www.tggn.ca) is a volunteer organization that promotes community gardening in Toronto, assists with implementation, organizes workshops, and publishes a monthly e newsletter. Other cites have similar organizations. The *American Community Garden Association* (www.communitygarden.org) and the *National Society of Allotment and Leisure Gardeners* (www.nsalg.org.uk) in the United Kingdom provide support at the national level. The *Office International du Coin de Terre et des Jardins Familiaux* (www.jardins-familiaux.org) represents 15 national federations across Europe with more than 3,000,000 gardeners.

Urban allotment gardens address similar issues today as when they first appeared in the early 19th century Europe at the dawn of industrialization: they provide a small piece of agricultural land to city dwellers as a means to grow their own food (Irvine et a. 1999, 36). At a fundamental level, they contribute to a family's survival during times of economic hardship. In Matalahib barrio in Quezon City within metropolitan Manila, a remarkable allotment garden was created on 1.5 hectares between two squatter communities in 1980. It was initiated by 2 police officers that felt the garden would reduce violence, bring the communities together and help feed families. With technical assistance from a local NGO and university, and volunteer help from off-duty police officers, people were able to grow nutritious crops that met 80 per cent of the needs of 400 families. The Matalahib garden was unfortunately destroyed within 2 years to allow for development (Wade, 1987).

Regardless of culture, economic stature or climate, gardens seem to share a common set of outcomes. In his book *Get A Life* (1995) Dr. Wayne Roberts provides an eloquent summary of the hidden values they offer, many of them validated in the Alex Wilson example. He writes:

> A small patch of land given over to community gardens packs more uses into a compact space than a Swiss Army knife. At one and the same time they:
>
> – Allow people who own no land to produce fresh food… at virtually no cost;
> – Provide healthy outdoor exercise, relaxation and even therapy;
> – Offer recreation the whole family can take part in;
> – Extend the constituency for city parks to 'passive' users often excluded from parks built around 'organized recreation' for [athletes];
> – Act as a neighbourhood crime watch, Jane Jacobs' "eyes on the street," over many hours of the day and evening;
> – Beautify derelict land on a pilot project basis, without the deeds required for permanent structure;
> – Add biomass that converts excess carbon dioxide into oxygen;
> – Create space for a "new commons," public space for hanging out that was lost when streets were taken over by cars;
> – Provide a natural fire barrier between buildings;
> – Add to green space that can absorb rainfall and divert it from sewers;
> – Provide common ground for community development in low-income areas such as Walnut Terrace, North Carolina, where, supporters say, "the community garden is a deterrent to destructive or apathetic behavior because its very existence is an expression of people's togetherness, productivity, hope, responsibility and caring for the whole environment, from flowers to neighbors and families;"
> – Provide fertile ground for transplanting immigrant food traditions
> – Provide a job-training center for at-risk youth, as pioneered in Boston
> – Creates spinoff jobs in commercial greenhouses and allied fields, as in San Francisco, where the homeless get top dollar for 26 varieties of salad greens sold to leading restaurants, because, as urban critic Terry Fowler describes one such project in the Bronx [New York City],"in the course of organizing themselves to grow food, the people also organized a project to generate their own power;"
> – Offer a site for innovative partnerships with governments and charitable foundations, which can match grants to community "sweat equity;"

- Work out the bugs in sustainable agriculture, including organic growing and, in dry climates, low-water xeriscaping;
- Encourage advances in intensive agriculture, since, in contrast to corporate farming, space is at more of a premium than time;
- Lower garbage disposal costs by providing nearby outlets for composting kitchen waste, the “twin sister” of community gardening;
- Reduce the costly highway infrastructure for food transportation, and encourage “urban villages” where key services are within walking distance;
- Teach respect for nature, farming, natural cycles and future orientation, as in Boston’s inner city where Dr. Arturo Cervantes, supported by Schweitzer Urban Fellows, finds the most important work he can do from his clinic is to teach children how to garden because it teaches them to gauge future results from actions taken today; that is, you plant now, you reap in six months (Roberts 1995, 95).

Roberts argues that community gardens are an elegant form of economic and social judo “ that turns the weight of a problem to advantage by flipping it into a solution” (Roberts 1995, 96). Allotment gardens not only optimize limited resources, they also leverage them. Every dollar invested seems to create several dollars in value, whether from volunteer efforts or “sweat equity” as Roberts describes, to material and plant donations, to crime reduction, increased health, to the teaching and sharing of knowledge.

The benefits extend beyond the food-growing needs of the urban poor. People living in big cities, regardless of their economic position, and particularly those living in crowded residential towers suffer from a general disconnection to the natural world and living systems. In ethnographic research conducted by environmental scientist Christopher Ferguson, city dwellers were asked what was missing to make their life more sustainable. One respondent who had moved from farm to city explained:

> When you live in the city it is easy to become disconnected with the natural world. The more you become disconnected the more you take advantage and abuse the things that supposedly make life easier- using the car all the time- buying food from all over the world- buying meat in Styrofoam containers- rather then understanding and connecting with what is around you (Ferguson 2008).

Ferguson found that people wanted ways to be live more sustainably and the opportunity to participate in activities like community gardens helped begin a process of connection that opened new perspectives and possibilities for all parts of their lives. Little by little people become aware of their consumption patterns, about the food they eat, the cars they drive, the products they buy (Ferguson 2008). Awareness is the first step toward meaningful change. If such opportunities are not readily available, or not within a 3-minute walk from home (Alexander et al. 1977,305), the connections are difficult to establish.

Design Opportunities

Urban allotment gardens must be recognized as a relevant topic for design research and development. At the very least, design intervention could improve their image from being perceived as ‘anti-modern’ to one where they are considered *visionary* in how they address a myriad of issues with elegance, economy and beauty. The Alex Wilson example demonstrates this clearly. With intelligent design intervention they can become an integral component of a healthy urban environment, and an important element to the built-form requirements of any city.

Presently urban allotment gardens get little attention from the design profession. Whether they seem unsavoury as a topic or are simply invisible because they fall between the cracks of our major disciplines, they deserve some serious consideration. They offer a rich opportunity for inter-disciplinary design collaboration between landscape, industrial, architectural, and graphic design. They invite input from the environmental sciences, horticulture, agriculture, ecology, horticultural therapy, and occupational therapy.

I challenge design schools to begin this process.

Many students would welcome the opportunity to ‘cut their teeth’ on projects like urban allotment gardens that help communities live better while reducing their ecological footprint. Within the core curriculum of an undergraduate program, students could gain considerable knowledge, technical skills and ‘hands-on’ experience in all aspects of urban allotment gardens. They would welcome the collaboration with other disciplines. Experimental gardens could be created in abandoned corners of campus property and also on building rooftops that are structurally adequate. The students would provide the design, construction and maintenance. Crops could be given to local shelters.

There could be exchanges between design schools from different cultures and climates where students gain an appreciation and respect for local traditions, crops and conditions while working side by side with local people. Such exchanges would create an equitable transfer of skills and knowledge where each culture learns from the other. Schools could form an international alliance or network to share information (e.g. Toronto – Milano - Sao Paolo - Nairobi – Bejing - Bangalore).

At the local context, the school or university could initiate collaborations with local clients or sponsors such as municipal governments, public housing authorities, hospitals, senior residences, elementary schools and private corporations whereby the students provide technical assistance and participate in the construction. Such outreach projects would bring the gardens into the community, similar to the way architect Samuel Mockbee and his students at Rural Studio delivered an ‘architecture of decency’ to clients in Hale County Alabama.

Design competitions present another viable strategy. The Alex Wilson competition attracted 67 submissions from teams of architects, landscape designers and artists in Toronto. The topic clearly mattered to the design community, given the creativity and

effort that went into the entries. In a recent article of Metropolis Magazine, Susan Szenasy explains, “[w]hen design competitions *reach for relevance* (author’s italics), they can lead to discussions that move our thinking forward” (Szenasy 2008). They contribute to an ongoing dialogue and body of knowledge.

Competitions also offer the opportunity to explore specific themes or technical challenges, for example extending the growing season in cold climates or water harvesting in dry climates. They could be organized locally or internationally. Competitions raise awareness through media and exhibitions and provide a vehicle to showcase the creative talents of a profession that is in tune with the times.

In his book *The Culture of Nature: North American landscape from Disney to the Exxon Valdez* (1991), Alex Wilson wrote:

> We must build landscapes that heal and empower, that make intelligible our relations with each other and the natural world: places that welcome and enclose, whose breaks and edges are never without meaning. Nature parks cannot do this work. We need urgently need people living on the land, caring for it, working out an idea of nature that includes culture and human livelihood. All of this calls for a new culture of nature, and it cannot come soon enough (Wilson 17).

Community gardens contain countless opportunities and rewards for forward thinking designers and educators seeking to bring their creative energies and talent to an area that demonstrates great relevance yet remains largely untouched. These gardens will never go away. They are like the little weeds that appear in the crack of a concrete sidewalk: they grow against all odds, reach for the sun, produce a flower, attract pollination and spread seeds. These seeds are falling on the doorstep of our profession. If we plant them, they will blossom.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

New configurations for networks

The case of the Virtual Institutes

Ivan BURSZTYN[1], Luiza Farnese de Paula LANA[2]

Abstract

It is permanently stressed that information technologies are a powerful tool to change our lives. The countless possibilities of use of the worldwide web can contribute to the formulation of new behavior paradigms in modern global society. This article aims at analyzing the idea of Virtual Institutes as a tool for exchanging experience and for establishing dialogic relationships among people interested in a given field of study. It examines the implementation of the Virtual Institute of Tourism. Its main theoretical references are Ivan Illich´s "tools for conviviality" (1975), Ezio Manzini´s "enabling systems" (2007) and Manuel Castells´s "network systems" (1999). After presenting the experience of the Virtual Institute of Tourism, the paper will discuss the creation of the Virtual Institute of Social Innovation.

1. Introduction

It is permanently stressed that information technologies are a powerful tool to change our lives. The designer, as a “bridge builder” between technology and society (Flusser 2007), has a new field to work on: translating, adapting and designing instruments that may realize the full potential of change of these new technologies. One of the contemporary challenges concerns the use of internet as a basis for new types of social relations. The countless possibilities of use of the worldwide web can contribute to the formulation of new behavior paradigms in modern global society.

This article aims at analyzing the idea of Virtual Institutes as a tool for exchanging experience and for establishing dialogic relationships among people interested in a given field of study. It examines the implementation of the Virtual Institute of Tourism. Its main theoretical references are Ivan Illich´s “tools for conviviality” (1975), Ezio Manzini´s “enabling systems” (2007) and Manuel Castells´s “network systems” (1999). After presenting the experience of the Virtual Institute of Tourism, the paper will discuss the creation of the Virtual Institute of Social Innovation.

The objective of the Virtual Institute of Tourism is to “*support the creation of research networks on relevant themes for society*”[3]. It was established in 1999 by the Laboratory of Technology and Social Development of the Production Engineering Graduate Program of the Federal University of Rio de Janeiro (LTDS). The Virtual Institute aims at facilitating the exchange of information, knowledge and services through a network involving researchers, experts, professors, students and institutions whose work deals on tourism. The Internet is its most important mean of diffusion, and the site which houses the Institute is found at <www.ivt-rj.net>.

Nine years after its foundation, the Virtual Institute of Tourism is a central locus for interaction and collaboration for its more than 2,000 participants, that include brazilians and foreigners. However, keeping this network active and productive is a continuous challenge. It has demanded several strategies of mobilization its participants. It has been necessary to overcome obstacles as physical distance and the daily duties of the participants, not to mention the common reluctance to make use of collaborative communication tools. Throughout the years the coordination team has noticed that the network participants are more apt to make contributions when demanded to perform specific activities. Therefore, the Institute restructured its activities so as to stimulate the participation of its members. As a result, we can mention the publication of the book “Turismo e Sustentabilidade no Estado do Rio de Janeiro”, the organization of the “Virtual Workshop: Tourism and Social Development” and the creation of the peer review board for the journal “Caderno Virtual de Turismo” (ISSN: 1676-6976).

As a consequence of the recent strengthening of the relations between the LTDS and the Politecnico di Milano, through professor Manzini, new possibilities of collaboration have emerged. One of them is the creation of a virtual institute dedicated to the subject of social innovation and design in Brazil. The interest on social innovation in the Brazilian context has arisen from the participation of the LTDS in the project Creative Communities for Sustainable Lifestyle (CCSL), coordinated by Prof. Manzini. There are already academics from 17 universities affiliated with VISI. Another theme of interest is the role of design in the formulation of strategies for mobilizing and enlivening networks.

The Virtual Institute of Social Innovation is still at an early stage, but the idea is to build on the experience of implementing Virtual Institute of Tourism. Besides supporting the academic debate about social innovation, it aims at stimulating the exchange of experience and information among socially innovative initiatives, including the stakeholders directly responsible for those activities.

2. The Information Society and Network Relationships

Great part of the transformations that the world faces today is a consequence of the great changes that occurred, mainly in the last few decades, consequences of the development of new technologies in information and communication. These advances have implemented a new relation in space-time, shortening the geographic distances and allowing that information to circulate around the globe in current time. Beyond these, many other transformations are consequences of the development of the new technologies of communication, which demand a deep reflection of how the society comes to act and react to the great changes.

Manuel Castells analyzes these changes in society having as reference the diffusion of the use of the new communication technologies. In his book, *The rise of the network society*, the author makes an analysis of the transformations in the way of producing and the relations between the people, companies and institutions from the mid 80's by what it calls "*the informational way of development*". This , in turn, is "*the action of knowledge on the proper knowledge as main source of productivity*" (Castells 1999, 35), what, according to the author, leads to a new technological paradigm, based on information technology .

When explaining what is understood of the *network society*, Castells indicates initially that the networks are "*structures capable to expand in limitless form, integrating a new us since we can obtain communication inside the network, that is, if we share the same codes of communication (for example, values or objectives of development)*" (Castells 1999, 499). The society in the network, in turn, is the society in the mid of these structures and in a certain form of way, it is guided by it.

It fits to distinguish that Castells when glimpsing this new middle scene for the networks - laces of flows of capitals and information - currently indicates that, "*the new economy is organized around global networks of capital, management and information*" (Castells 1999, 499) and that "*the synthesized processes of social transformation in the ideal type of society in the network exceed the sphere of social relations and techniques of production: they affect the culture and the power profoundly*" (Castells 1999, 504).

From the new existing communicational structure it is possible, and necessary, that we have to think beyond the circulation of capital, management and information dominated by a specific source. The space to fill the potentialities of the existing instruments is the one that provokes deeper changes, allowing the contribution of individuals and institutions of local scope in the construction and reflection of global transformations.

In this prism Virtual Institutes have been thought of as the primary tool. Taking into account the existence of an informal network already, however dispersed and with tenuous relations still marked by the distance geographic locations in Brazil, a virtual platform of contribution was created that served as one privileged locus of contribution between the diverse interested segments in theme of reference of these Institutes. Using the potential of the new information technologies, the virtual institutes represent the effort to congregate in one same space people and institutions that argue and consider action of global transformation and repercussion, from local experiences.

These networks of virtual contribution bring a new form of dialogue, exchange and collective construction that demand a bigger knowledge and reflection on its vulnerabilities and potentialities. It is in this direction that this article works, learning trough trial and error the experience of implementation of the Virtual Institute of Tourism and reflecting on the possible contributions of this network of virtual contribution in the development of a network about the theme of Social Innovation.

3. Conviviality and Enabling Solutions

As we saw, the global contemporary society lives in a moment of great possibilities for the cooperative and collaborative work. It was never so viable technically to surpass the geographic barriers and to shorten the distances that separate the people of the world. However, this favorable scene is contradictory to our more individualistic positions in our lives. The hegemonic way of relations in the capitalist society where we live has as one of its pillars maintenance and amplifying individualism. As Bauman (2001) told us modernity is the age where social life starts to have as center the idea of the existence of the individual and individualism, demarcated by an increasing autonomy in relation to communitarian and social life. In the words of the author, "*the presentation of the members as individuals is the registered mark of the modern society*" (Bauman 2001, 39).

In this context, an excellent question that deserve attention presents itself, the potential use of the new information technologies in favor of the new relational standards of this generation and its diffusion. Illich (1973) shows us that the *"produced tools"* in the industrial age has lead our society to adapt some aspects of our lives like models of production in production series. However, as the author points out, the hour has arrived to retake the reins of our lives, placing the "*tools*" created by the men in benefit of the creativity and freedom of action.

> *"I will suggest how this present trend can be reversed and how modern science and technology can be used to endow human activity with unprecedented effectiveness. This reversal would permit the evolution of a life style and of a political system which give priority to the protection, the maximum use, and the enjoyment of the one resource that is almost equally distributed among all people: personal energy under personal control. I will argue that we can no longer live and work effectively without public controls over tools and institutions that curtail or negate any person's right to the creative use of his or her energy. For this purpose we need procedures to ensure that controls over the tools of society are established and governed by political process rather than by decisions by experts"* (Illich 1973).

For Illich, the possible solution for a transition of the current society to "*a more convivial*" society is in the redefinition of available "*tools*" today or the creation of "*tools*", in order that they become "*tools for coviviality*". "*Tools*" that are in the service of creativity of humans and not defining them.

The search for the paradigm of "*conviviality*" implies a significant change of today's effective ethical and technical values. Of the ethical point of view, our society needs to rethink the limits of its action in order not to compromise its proper existence, retaking the essence of the relations between humans and the way they live. Of the technical point of view, to project tools that propitiate the establishment of these new social relations. And, as such, does not exist ready prescriptions, but the necessity to reaffirm the commitment every day (Illich 1973).

Convergent with the proposal of Illich, Manzini (2007, 2005) presents the concept of enabling systems, capable to support and to favor the sprouting of the new relational standards considered by Illich. The convergence pointed here does not imply to ignore diverse horizons of technical facts of the formularizations in question. The proposal of Illich remains in a previous horizon to the existence of the Internet. Its level is much less effective operational than that of Manzini, for who the enabling systems are organizations capable to transform the resources of its users into individual and social values, making of its participant part of the solutions.

However, Manzini alerts for the risks of trying to project all the elements of these solutions. When dealing with the relations between the people, it is not possible to predefine all the interaction forms, under the risk to destroy them. It is necessary to create favorable contexts so that such solutions develop in a bottom-up movement. Thus, the author detaches as possible enabling foundations instruments of government, infrastructures and public spaces of meeting conceived to facilitate and to consolidate base innovations (Manzini 2007).

Manzini points with respect to two possible types of planned interventions: the enabling platforms and solutions. Enabling platforms are combinations of products, services, knowledge and procedures that, in data context, qualify the people to have access to a set (different, but with

common characteristics) of results. Already the enabling solutions would be the combinations of products, services, knowledge and procedures that, in data context, qualify the people to reach a result.

In both the cases, the active role played by the participants gains prominence. According to the author:

> *"We must place new idea of service alongside the currently dominant one of services disabling systems. Idea If today the most widely held is one in which the service itself is designed considering users only an expression of problems (problems you solves requiring minimum of participation on to their part), the new idea of service must instead start with what to user knows how you, can, and wants you of. In to other words, the service must be conceived an enabling system, one that matches user's desired result, with an to offer of the means by which you achieve it using his own capabilities you the best advantage and, if appropriate, stimulating his desire you of and delight in taking part in the game"* (Manzini 2005, 4).

Certainly, participation is one of the great challenges of this process. The capacity to mobilize users and to promote its auto-organization demands of the designers creativity and sensitivity to develop "*tools for conviviality*" that is potential to the individual efforts.

As we will see, we believe that the Virtual Institutes can present a fertile way as qualifying solutions directed toward the academic research in specific thematic areas. Based in the establishment of collaborative and cooperative relations between researchers, the Virtual Institutes place the new information technologies to service of the public interest and the exchange to knowledge, in a peer-to-peer relation.

4. The Virtual Institutes

The Virtual Institutes program was launched in 1999 for the Research Foundation of the State of Rio de Janeiro (FAPERJ), with the intention to support the formation of networks of research on subjects for the society and the economy of the state of Rio de Janeiro. The program had as objective to identify and to register the academic-scientific, scientific-enterprise abilities, in a way to promote actions integrated in its respective areas of performance. Another goal of this program was to promote and to spread the available knowledge of the community in the state about each one of the areas by means of integrated actions, such as events, seminaries and courses. The program longs to attract complementary, national or foreign abilities, with the purpose of promoting strategically, definite actions as essential for the development of the areas of performance of Virtual Institutes.

The Virtual Institutes are part of the Program of Advanced Studies of the FAPERJ, whose objective is to support and to induce a already existing form of scientific cooperation from nuclei of excellence. The base of the program is the notable demography and installed capacity of the scientific community of the state, characterized for high qualification, creativity, variety to discipline institutional and international insertion and ability to generate results with strong public and social impact.

Initially six thematic fields for the performance of the Virtual Institutes had been chosen: The International of Global Changes; Logistics and Economy; Social state of the Nation; Tourism; Bio-information; and finally the ability of Democracy and Separation of the Three powers in Brazil. However, the lack of clarity in the definition of the concrete actions that would have to be played by each Institute after they were made, the coordination of the program extinguished five of the six after 2 years of performance. In this occasion, the only Virtual Institute that showed concrete results of operation was the Virtual Institute of Tourism.

In 2003, a new election was made so that the headquartered institutions of research in Rio de Janeiro received the proposal of six new Virtual Institutes in the following thematic areas:

Sport, Neurodegenerative Illnesses, Dengue, Nano-science and Nanotechnology, Pharmaceutics and Paleontology. The new Institutes have joined the Virtual Institute of Tourism in the effort to define more clearly its line of performance. Some have seized to exist, however, we can detach the performance of the Virtual Institute of Tourism as emblematic by the point of view that it joins the researchers of the area and it tied academic production.

The state of Rio de Janeiro is the state that receives the most tourists in Brazil. Its natural beauties and the affection of the Carioca people (people who born in the city of Rio de Janeiro) are known allover the world. However, up to 1999, there practically did not exist scientific research of quality in the academic environment on the subject and the ones that existed were dispersed. The courses of graduation in tourism installed in the state were all tied to particular institutions of education with its focus in the formation of human resources for the work market. As we will see ahead, the scene changed in last the nine years and the Virtual Institute of Tourism contributed at this change.

5. The Virtual Institute of Tourism

The tourist sector is pointed out by the World Organization of Tourism (OMT 2001) as the second biggest economic activity of the world in income generation and jobs, in 2006. It generated about 380 million work ranks. However, the economic potential of the tourist activity has not had only positive effect in the socio-cultural and environmental conditions of the societies and receiving communities.

With relation specifically to the Brazilian case, tourism activities in small communities supported by public politics had not brought the promise of potential benefits for the local populations. This verification implies the questioning of such practices and public politics that supports them (Bartholo et al 2008). Some successful experiences of communitarian tourism (Bursztyn 2005; CNPQ 2003; Oliveira 2004; Sansolo 2006; Saviolo 2003) bring important subsidies to this debate, pointing ways that can be fruitful for the promotion of taking tourist root activities in a local model of development, with more social justice and environmentally responsible (Zaoual, 2006).

According to the NGO WWF-International (2001), the communitarian tourism is defined as a eco-tourism modality where the local community has substantial control and involvement in its development and management and most of the benefits proceeding from the activity, remain in the community. In this perspective, it is imperative that tourist activity is, in its bigger part, developed and operated for the local population, guaranteeing the economic support and making the resources proceeding from the tourism revert in direct benefits for the community (Bursztyn 2005).

These reflections on tourism and social inclusion are the questions that have motivated the birth of the existence of the Virtual Institute of Tourism (VIT), entailed project to the Laboratory of Technology and Social Development of the Federal University of Rio de Janeiro, that congregates, in its virtual headquarters (www.ivt-rj.net) diverse information on tourism, such as: notices, courses, events, essays, interviews and news articles, in the social developmental perspective. Moreover, the VIT edits periodically the scientific electronic journal Caderno Virtual de Turismo, with the same focus. The information contained in the platform are published and are accessible by any person and can be nourished by the net of users registered in the cadastre of the VIT: researchers, professors, students, collaborators, institutions with performance in tourism, constituting a quantity and quality of information on the subject.

Since August 1999, the VIT takes care of to the lines of direction of the FAPERJ institution, financing its activities, support the formation of nets of researchers to deal with excellent subjects for the society and the economy of the state of Rio de Janeiro. Throughout this period, the VIT explicitated its institutional mission and consolidated its structure, providing the accomplishment of the objectives defined in its original proposal.

Amongst the main ideas glimpsed for the Institute, we detach the constitution of a vast net of associate researchers who come growing throughout the time in function of the promoted activities.

The academic text of the VIT is well-known and enriches the debate on the theme of tourism, promoting its inclusion and rooting in the public institutions of superior education of the State of Rio de Janeiro, as a reference for the studies in the area of the tourism. The VIT is developed from a platform in the Internet, wich is the virtual headquarters of the Institute. Its main actions and proposals are concentrated on virtual search over all, to dynamize the exchange of information, knowledge and services by means of the constitution of a network.

The lines of action of the VIT have prioritized the boarding of knowledge, analysis and comparison of experiences developed for other institutions and groups, that can result in significant teachings for the formularization of strategical lines of direction for the politics of tourism and the deepening of the referring studies to the "tourism and social development" theme. Actions that have detached the work of the IVT for the stimulation to the proposal of the tourism as a possible potential element of beneficial effect of developmental politics, defending the planning and the incentive to more tourist activity.

The maintenance of the activities of the VIT is justified by the increased access of users, of academic means, interested in the material available in its electronic placing. In this universe, the prominence is the significant contingent of professors, researchers and pupils of the institutions of education in tourism.

However, the active participation of the members of the network, as pointed previously, is a daily challenge. Since the beginning of its activities, the VIT is dedicating to mobilize and to add new researchers in action. However, the lack of cooperative culture and domain of the computational tools moved away some researchers from the network that was forming. With passing of the years, the technologies of the information have been totally inserted in our lives, making possible a significant increase in the number of users of the VIT. The biggest domain of the technological tools also contributed to the formation of a cooperative culture, but it was necessary to develop some specific actions that will be described.

With the lack of systemized academic production in the field of tourism in the state of Rio de Janeiro, one of the first actions of the VIT was to launch in 2000 a scientific eletronic journal dedicated to the subject. The Caderno Virtual de Turismo, CVT (www.ivt-rj.net/caderno), was conceived with the objective to base the theme of tourism in academic means. In 2006, the CVT inserted in the world-wide net of periodic of open content that uses Open Journal System (OJS), developed by the Canadian project of public knowledge (PKP, http://pkp.sfu.ca). In 2007, a peer reviewer board was formed, with 85 researchers with doctorates level, to evaluete all submitted articles for publication. These actions had contributed decisively for a jump of quality in the available computational content. Today, the periodic accounts a quantity of 161 scientific articles, more than 300 authors, published in 26 numbers.

Another proposal of the VIT that fortified the academic basing of the tourism theme and the contribution between the researchers was the launching, in 2005, of a book on tourism and sustainability in the state of Rio de Janeiro. Until then there was no exclusive dedicated publication to the debate of tourism in the state. Since the beginning it was clear that it was not only about the chance to create an inexistent academic product, but mainly to establish a process of dialogue and reflection to materialize the idea of a collaborative work. The first meetings happened in January of 2002. The first guests suggested other names and the group of participants in debate about the book was extending. Nor all remained throughout the construction of the book, but the contribution of each one enriched the debate.

The proposal was not simply to congregate articles; there were many concerns about the coherence of the theoretical references. The process included a series of meetings carried throughout the years of 2002 and 2003. Each one of the concepts and subject-key was discussed in the group, to form and establish affinity and complement between the different present visions, therefore, also between resulting articles. The clear identification of the blocks that would

constitute the book and the responsible of each segment was chosen during the reunions till reaching to the definitive proposal of the summary.

In the year of 2007, the VIT gave a basic step for the reinforcement of its network of researchers realizing the first virtual workshop on tourism and social development. This meeting congregated the associate researchers to the Institute in a form to promote academic reflections and to contribute for the diffusion of new ideas. Moreover, it deepened the questions to multidiscipline that involve the orienting subject of the project, betting in the use of information systems and virtual tools of collaborative communication for the production of knowledge in a shared form, configuring a research network.

The workshop was promoted by the VIT and organized by the courses of tourism of the Fluminense Federal University (UFF), Federal University of the State of Rio De Janeiro (UNIRIO), Agricultural Federal University of Rio de Janeiro (UFRRJ), course of Geography of the University of the State of Rio de Janeiro (UERJ) and the Masters Program of Hospitality of the University Anhembi Morumbi, beyond the Laboratory of Technology and Social Development of the UFRJ.

The idea of the workshop was the result of a series of meetings between these researchers, that, throughout five months had been debating the objectives of the workshop, its structure and organization, beyond the expected results. From these meeting five thematic axles prioritized for the workshop had been defined, respecting the interests of research of the institutions organizers, as well as the reflections and focus of the proper VIT. In this manner, each institution was responsible for coordinating, moderating and to define the activities developed in each one of the five thematic axles, namely: “Education, Research and Extension in Tourism”; “Tourism and Cultural Patrimony”; “Tourism and Environment”; “Management and Planning in Tourism”; and “Tourism and Hospitality”.

Its duration was projected for about one month, initiated with an opening meeting, carried through in 8 of August of 2007, and a closing meeting, carried through in 10 September of 2007, both in the audience of the UFRJ, in the Center of Technology of the Island of Fundão, in the city of Rio de Janeiro. The virtual period happened between 9 of August till 9 of September of the same year.

The experience of the first Virtual Workshop on Tourism and Social Development extended the integration and production of knowledge, where the bred relations and the gotten results were already promoted in 2007, an attempt of the collective project of research between the organizer entities, is the intend to make an effect in the year 2008. The perspectives of animation of the network by means of the virtual tools of collaborative communication had also stimulated the VIT to reorient its planning. To the foresights for the year 2008, wich are among others, a re-launching of the electronic animation and activities bulletin of the VIT for forums of debate in interesting subjects, connecting the network of VIT with other existing networks already active in the subject of community tourism.

The result of the workshop was available on the net, since the texts that had served as base for the debates, were passed for an audio-appearance apprehension of the lectures, until the results of the forums and chats, as well as the resultant thematic texts synthesis. The tool developed for the accomplishment of this workshop was incorporated in a permanent platform of the VIT, having made possible that the Institute carries through and houses similar events to the one above. The available bibliographical references in the media of the Internet had been available for the event and are being fed periodically in the VIT, with the contribution of the actors of the network.

6. Considerations and appointments for the Virtual Institute of Social Innovation

The Virtual Institute of Social Innovation (VISI) is a virtual space for debate and construction of proposals related to the social innovation in Brazil. One is about an initiative of researchers of different areas and universities of this country to connect by means of a virtual platform of collaborative communication. With this tool in hands the Institute considers arguing the role of design in this process by means of the formularization of a methodology compromised to situated and sustainable development (Zaoual 2006).

The VISI is fruit of debates that took place throughout the *Design, Social Innovation and Sustainable Development* Seminary, carried through by the Program of Production Engineering of UFRJ, with the support of the High Studies School of the brazilian government agency for post gratuate studies (CAPES), in September 2007. In this meeting there were diverse universities present that, where arguing the methodology presented by Professor Ezio Manzini on creative communities and sustainable lifestyles, it presented the interest in deepening this vision in the Brazilian perspective. From now on, the efforts for the creation of a virtual platform was beginning that allowed continued debates independent of actual meetings.

In this form, taking of the previous experience in the management of the Virtual Institute of Tourism, the Laboratory of Technology and Social Development of the Program of Production Engineering of UFRJ organized the necessary infrastructure so that initially the 17 institutions that had been part of the creation of the network collaborated permanently in the comprehension of social innovation in Brazil.

In November 2007 the group of researchers made a first virtual meeting of debate for the planning of activities for the VISI, involving the initial researchers of the formation of the network. From this meeting some priority fronts of action had been defined, as well as points to be considered in medium and long run periods. The first actions indicate the concern of the group in lining up a common understanding of what it is understood as social innovation in Brazil and, moreover, collect cases, to elaborate key criterion for the identification of socially innovative cases.

Defining these lines of immediate performance, the participants exchanged texts and opinions, making it possible to delineate a first theoretical reference on Social Innovation to guide the actions and debates of the VISI. This first version - that is in permanent construction by means of feedback with practicality - was divulged between the members by means of the “VISI Newsletter” – created to facilitate the circulation of qualified information between the members of the network - and comprehension of social innovation as a process of recombination of elements that implement, fortify or restore relational standards .

It fits to point out that, when making a link between social innovation and relational standard, the basic aim is on which type of relation is in debate. In this case, the relational standard is identified by its direct, approximate and accessible dialogical attributes.

The second line of immediate performance, is proposed as a parallel development to the first development, initiating the collection of considered cases as social innovation for the members of the network. The proposal is that the debates for the definition of criteria of identification of cases of social innovation are strategies of animation considered for the network, so that the movement feeds the constant survey of cases. Its fit to point out that the objective of the network is not to collect cases of Brazil exclusively, but to have a qualified analysis from this point of view and comprehension of social innovation in the brazilian context.

Still in embryonic process, the VISI intends, to go beyond the promotion of academic debate on the theme in question, to stimulate the exchange of experiences and the interchange of information between socially innovative initiatives, incorporating directly in the network involved social actors in the identified cases of social innovation.

From the reflections generated by practice the VIT makes it possible to conclude that the VISI did not only consist as a enabling solution – to make it possible to reach to results - but also as a enabling platform, promoting a space of sharing of effective practices (Manzini 2007). With this as base we consider the growth of VISI in two perspectives: the first one to the public of

researchers interested in the theme of social innovation in the most diverse areas of knowledge; next to the directly involved actors in the cases of social innovation.

This first perspective is important in fact for VISI to count on the researchers of the 17 institutions that have participated in the *Design, Social Innovation and Sustainable Development* Seminary and that in this form they have created a network. However, the social innovation theme needs to have a transversal character in diverse areas of knowledge wich is basic so that they can add to design other forms of comprehension and analyze this subject, enriching to the look and extending the reach and depth of the production of knowledge in this respect.

The second perspective, in turn, is the axe that will allow VISI the visualization of its transforming potential. This because, the force necessary to take in to account for this task is on a contract basis and has as focus the generation of a network of sharing of experiences, practices, challenges and solutions in a day-by-day life of the innovation cases. This action will not only contribute for the improvement of these practices, but also will allow the generation of a quantity of practical effective cases and a reference for new initiatives. Moreover, another quantity in permanent construction will be generated to divulge knowledge from reflection proceeding from this partnership between university and society.

Other actions already developed by the VIT can inspire the VISI in the mobilization, and dynamize the searching management of the network associates. To think about the structure of permanent animation of the network, about the models of virtual workshops promoted by the VIT, elaborating key subject and facilitating the debates using some collaborative tools of the platform, can represent an important means to ferment the conceptual debates around the theme of social innovation. Articulated in this proposal, is a vehicle of diffusion of this knowledge in a scientific periodic.

These are, for the time being, only some ideas of performance for the VISI. However a concrete action already is in course: the production of a book contending reflections of Brazilian researchers, generated from the seminaries lectured by professor Manzini. This publication will involve, the members of the network of associates researchers and the contribution of other Brazilian researchers with vast experience in the social innovation theme in more economic and technological boards.

The road of the VISI is fertile, but still we are initiating the passage. As an open process it is still in construction the participation of all is very welcome. Thus, we invite you, to read this article, and be part of this path. Please enter in contact with us and the associates of VISI. The address of our virtual site is <www.ivis.pep.ufrj.br>. We await your contact and contributions.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

DESIGN (x) DIASPORA

- implementing sustainable development in developing countries

Jan Capjon[1] and Håkan Edeholt[2]

Abstract

This paper attempts to raise some basic questions and indicate some possible resulting strategies. Inspired by migration studies it is suggested that emigrants' connections to locations of origin could form a basis for sustainable structures and development based in high/low-tech integration and design competence.

Through integrating Design and Diaspora, one can avoid merely transferring technologies from the west to 'developing' countries and instead: (i) leapfrog fundamentally unsustainable solutions of 'developed' countries', (ii) develop products that *either* are designed to be appropriate for the local context *or* designed in order to utilize the local context's comparative advantages, and (iii) at the same time approach a profound commitment grounded in the local social context.

Introduction

The term *sustainable development* stems from the Brundtland Commission of 1987.[3] The Our Common Future report proposed to approach development through holistic contexts; the fight against poverty, the implications of social and cultural factors and the ability of environments to meet present and future needs were all central.

Publications on the topic of design for developing countries has since then been rather modest, but have increased during the past few years. This may indicate a growing concern within the design field, that in a world with decreasing abilities of developing communities to meet future needs, the challenge of sustainable thinking is escalating. Current dissemination contains a lot of illustrative and potentially interesting approaches to design for development – both in terms of new products and new processes [Manzini and Jegou (2003), Wimmer, Züst and Lee (2004), Greffe and Pflieger (2005), Maase and Dorst (2006), Tukker (2006), Charter and Clark (2007), Vezzoli (2007), Meroni (2007)]. Such exemplification is in accordance with designerly ways of meeting challenges. But in addition, an intention of making new solutions durable more than anything seems to require that we focus discussions on what we apprehend as *fundamental* questions. In hoping to inspire needed discourse, we have attempted to suggest some root problems.

Victor Margolin (2006) approaches the problematic from a basic position. He presents the limited history of design for development, which can be characterized by a tension between a low-tech crafts approach on one side and a more high-tech impulse on the other. The low-tech impulse was originally suggested by Papanek (1986) and is based in local needs and on present local and traditional production structures. This approach is aimed at community survival more than at national development strategies. The high-tech impulse is based in the Ahmedabad Declaration on Industrial Design and Development (National Institute of Design 1979). The declaration emphasises the importance of design to a nation's economic development, and it proposes that 'developing' countries (as the term indicates) should adapt similar industrialisation strategies as 'developed' countries. Bonsiepe (1991) builds on this document when he emphasises the important role that design will have to play in industrial development of peripheral countries. Margolin argues that toady there is a need for design oriented theory which integrates multiple factors of trade, technology transfer and cultural expansion in the increasing complexity of globalised practices.

The low/high-tech dichotomy appears as a valid description of basic historical impulses in design for development. But Margolin and Bonsiepe refrain from addressing the problematic in framings that exceed the boundaries of traditional industrial design thinking, where complexity patterns of infrastructures and social preconditions for development are rarely included. How shall "integration of multiple factors" in design impulses for developing and developed countries be understood? The differentiation appears as clear-cut, but how should the gap *between* the polarities be seen and approached? Let us coin the missing link *the lo/hi-tech design challenge*.

In alignment with Margolin we suggest that the lo/hi-tech design challenge can serve as a platform for building sustainable design thinking. However, we propose to basically expand the scope of vision in search of some social and cultural understanding of how low and high technology can be integrated and how involved development actors can collaborate towards such integration. Three questions are at the forefront:

(a) can *socioeconomic structures* with potential for making development sustainable be identified?

---

[3] WCED-World Commission on Environment and Development (1987) *Our Common Future,* Oxford Univ. Press.

(b) can *principles for interaction* between 'developing' and 'developed' technologies be suggested?
(c) can practical obstacles be overcome through appropriate *development strategies*?

In order to extend our vision we have searched for correlates within other fields of inquiry and have eventually demarcated three tentative strategies:

(a) ***Migrant remittances*** – as an important source for transferring relevant knowledge and funding to developing countries in a sustainable manner
(b) ***Leapfrogging*** – as an efficient approach for developing countries to 'catch up' and become globally competitive based on their own merits
(c) ***Design-driven strategies*** – as a crucial complement in order to facilitate required communication and that both products and production are in tune with local conditions

We will briefly address these for identifying, strengthening and expanding practices of sustainable development.

(a) Migrant remittances

Internationally a central challenge is that the effects of development aid programs often collapse after donor funding has been spent. Indications are many that old ways of donating development aid need to be revised and that new strategies are called for.

A thought provoking example of a new approach to development can be found in Nobel Prize winner Mohammed Yunus and the highly successful Grameen Bank movement[4], which build durable enterprises from responsible credit schemes and shared ownership regimes. The Social Entrepeneurship (SE) movement[5] has similarly had a substantial world wide growth during the past few years based in the principles of defining a local problem and trying to solve it through establishment of a profit sharing firm (with network relationships) which fulfils a need. Kai Hockerts of Copenhagen Business School says: "with social entrepreneurs we face a radical change in the way we envision aid to developing countries".[6]

The basic principle which characterises these initiatives appears to be the establishment of *lasting responsibility structures*. Inspired by these movements, we have turned to a field of inquiry where the principle of lasting responsibility patterns may facilitate a relevant approach the lo/hi-tech design challenge: migration studies.

In research on the dynamics of migration and transnational practices the implications of emigrants' remittances (transfers of value) to their home countries are studied. Can such remittances and close family and community bonds to locations of origin represent a source for durable development structures?

Updated remittances research is funded by the Norwegian Agency for Development Cooperation (NORAD) and performed in cooperation with the International Peace Research Institute, Oslo.[7] The following statistics and elaborations are taken from Jørgen Carling (2004, 2005). The approach to these studies is "under what circumstances and through which mechanisms the development impact of remittances is *susceptible to policy interventions*".

Bold font indicates Norway's partner countries. The figures refer to workers remittances. Source: International Monetary Fund (2003).

In 2007, registered remittances to developing countries grew to 240 billion USD, which was more than two times official development assistance means.[8] A large unknown sum is additionally transferred through informal channels or to countries that do not report to statistics.

Emigrants' motivations for remittances vary: "when migrants do invest, their emotional attachment to their (often marginal) regions of origin can help compensate for the disadvantages of these regions in the eyes of purely profit-seeking investors". Motives for remitting have been suggested by development economists: *altruism;* meaning care for receivers, *self-interests;* referring to possibility of heritage or community resources, and *insurance;* involving sharing of parts of income. Remittances can be understood as "intra-family obligations being sustained despite the geographical separation of the family". Female migrants often earn less than males, but possibly remit a higher income proportion. Respect and status in an origin community is held to be a motivation factor. Generally it is believed that remittances of individual migrants tend to decline over time.

[8] Migration and remittances fact book 2008. World Bank.

The division of remittance expenditure between investment and consumption has been discussed in the literature on migration and development. Researchers and policy makers in the 1970s and early 1980s were concerned with the small proportion of remittances that were used to set up small businesses or for other forms of 'productive' investment. Recently 'consumption' items such as health and education have been seen as investment in human capital – and increased consumption by the poor has been seen as poverty alleviation, which is a goal in its own right. The view that remittances are hard-earned money that migrants and their families should be entitled to spend as they wish has eventually become widely accepted.

Carling distinguishes between four kinds of benefits from remittances. (i) Intra-family transfers have *immediate benefits* which contribute to daily basic subsistence needs, but may not have sustained effects. (ii) If the recipients manage to save or invest remittances, it may result in *future benefits*. (iii) Benefits may or may not extend to *secondary beneficiaries* in the community if remittances are spent on locally produced goods or services, e.g. construction works. (iv) Finally, remittances can contribute to *remittance-independent development*, like setting up local enterprises, which is the desirable form of investments because they sustain livelihood independent of future remittances.

Abbreviated resulting policy recommendations of how the Norwegian Ministry of Foreign Affairs (MFA) and Norad best can contribute to increasing the benefits of remittances to poor countries (in collaboration with government agencies, civil society, private sector, partner governments, international development agencies and multilateral agencies) are:

- support immigrant's opportunities for sending remittances and/or doing business in their countries of origin
- promote transnational entrepreneurship among immigrants
- create opportunities for reasonable and reliable transfer mechanisms and promote tax exemption for gifts to charitable organizations in developing countries
- promote development initiatives in migrants' countries of origin
- work with microfinance institutions in partner countries to promote linkages between remittances and microfinance
- collaborate towards formulating and implementing sound policies to increase the benefits of remittances
- promote the exchange of ideas and experiences of engagement with remittances and diasporas
- support the ongoing work on migration, remittances and development and cooperate on specific initiatives in partner countries.

In addition to these recommendations, in Norway it is presently being elaborated if migrant remittances allocated for local enterprise investments can be expanded through development aid means, for instance on a 50/50 basis.[9] Such arrangements could significantly motivate remittances, but convincing project propositions are needed.

The above policy recommendations and actions, according to our view, can represent a highly interesting socio-economic grounding for lasting responsibility structures – as a platform for making development sustainable. Their authors invite to interdisciplinary intervention. In accepting this invitation and building on above elaborations, some potential root-premises for design for development can be suggested:

- a new strategy for sustainable development should have its foundation in the principle of durable responsibility structures

[9] A 50/50 pilot project in Pakistan is prepared by the Ministry of Foreign Affairs.

- responsible new enterprises can be created from the principle of ownership which is shared between the central actors of a project
- a promising durable ownership source is migrants to western countries with close family and community bonds to locations of origin and a desire to remit means
- in well planned enterprise suggestions with ownerships structures involving immigrants to western countries investment motivation can be increased through additional development aid funding.

How, then, can enterprise suggestions become well planned and convince potential investors of how they could grow beyond consumption and self-interest? From the cited research it seems likely that big changes will take place within these sectors in the near future regardless of whether or not the design aspect of the challenges is acknowledged. But the challenges to design inquiry appear as obtrusive once they are seen in the referred light of contemporary policy making. What are the practical aspects of the challenges?

(b) Leapfrogging

The Oslo Manual: guidelines for collecting and interpreting innovation data (OECD/European Communities 2005) gives a realistic account of the highly complex practical obstacles for development intervention. Some abbreviated characteristics of innovative premises and processes in developing countries are:

Exogenous factors are characterised by:
- Macroeconomic uncertainty, instability, lack of infrastructure (electricity, communication), lack of innovative awareness, risk-averse enterprises, barriers to start-up, lack of public business support and a seemingly small local market for high-tech products
- Dominance of multinational corporations result in less local decision making and that the fundamental source of innovation typically is based on technology transfer
- Weak information flow and linkages between science and enterprises challenge the capacity of firms to overcome problems

Endogenous factors are characterised by:
- The sector of privately owned, informal and relatively small SMEs is significant. These companies typically lack resources for innovation
- The sector of state-owned or parastatal, formal and relatively big enterprises is also significant. These companies typically lack competition and are often bad innovators
- There are high barriers to accumulation of formal or tacit capacities in companies

As a result developing countries tend to compete with cheap labour rather than with efficiency or differentiation; and with incrementally changed (or copied) products rather than with radical innovations utilizing comparative advantages available.

These accounts illuminate different important challenges. Especially the need of local learning, production adopted for local conditions and establishment of new kinds of infrastructures for both technology transfer, in itself, but also for development of local more advanced markets.

Our assumption is that we today have a historical window of opportunity where new technologies can facilitate important leaps forward. We suggest that it is possible to make our future more sustainable in all dimensions of the Brundtland Commission report (WCED 1987) if we are able to reinforce *leapfrog technology*[10] tendencies already flourishing on the market today. However, such a move requires that we are able to change our mindsets regarding 'developing'

[10] Leapfrog technologies can 'over-leap' or sidestep technical solutions made for other preconditions than we have today.

countries, acknowledging that that is exactly what we all need to become, and that we actually both can learn from leapfrogging tendencies spearheaded by developing countries and reinforce their impact. Therefore we allow ourselves three summarily described examples of emerging leapfrogging possibilities where Norway both have useful competence and more short-sighted interests to defend:

Leapfrogging traditional electrical grids

In 1994 a cluster of Norwegian companies[11] with competences within silicon rectification and wafer production started an R&D initiative, which today has resulted in a world leading position as sun wafer producers. Hanson & Wicken (2008) describe how the global need for renewable energy resources has propelled this initiative and given high national support along the way. Sun cells for electricity production do not generate emission or sound, can be installed (decentralised) at the location of use, have no moving parts and have a minimum of service need and long durability. In 'developed' economic terms they cannot compete with traditional electricity sources, but their production price is expected to be halved by 2015. In 'developing' economies the calculation will appear differently, as the principle of decentralisation and elimination of infrastructure altogether present highly relevant leapfrog opportunities for design thinking, without initially interfering with 'developed' base component production principles. The application of wafer cells in local developing communities call for intervention and rethinking on the topic of basic user needs and can promote new kinds of high-tech applications that use less energy than the ones designed for 'developed' countries do.

Leapfrogging traditional sewage systems

2,6 billion people do not have access to adequate sanitation and a child dies every 15 seconds from water-borne diseases.[12] 2008 is the UN international year of sanitation proposing a millennium development goal of halving the proportion of people without basic toilets and hygiene facilities by 2015.[13] Can the extremely costly infrastructure-based sanitation solutions of 'developed' countries be leapfrogged? Scandinavia is pioneering sustainable solutions to wastewater treatment, and several appropriate technologies for low-cost decentralised systems have been developed. Jenssen, Vråle and Lindholm (2007) write: "A variety of watersaving and urine diverting toilets can nearly halve water consumption. Toilet waste (blackwater) or urine can be collected separately. Cotreatment of blackwater and organic household waste yield both energy and hygienic fertilizer and handle all organic waste from the household in one waste stream. Water from showers, sinks and kitchen (greywater) can be treated in a variety of systems. Treated greywater is suitable for irrigation, groundwater recharge or as a source of potable water production. Utilizing the latter, more than 90% water saving is possible. Source separation (blackwater/greywater) systems produce near zero emissions." New innovations of western universities represent powerful leapfrogging possibilities, but their introduction in developing contexts involve several social issues where methods for designing the 'user-technology-interface' will be crucial.

Leapfrogging traditional business models

An example which highlights the leapfrog problem from a social rather than technology perspective is the development of new hearing aid technology by SINTEF.[14] One aspect of advanced hearing aid technology is the infrastructure which has emerged in its wake in developed countries; the specialists needed to adapt and adjust the technology. New high-tech innovations have allowed automatic adjustment of the devices and eliminated the need for instruments and know-how. These innovations are obstructed by the specialits' organisations that

[11] Renewable Energy Corporation (REC), Orkla, Elkem, Hydro and Norwegian Silicon Refinery.
[12] Source: UNDP 2006.

[13] Sanitation now. 2008. A magazine on the global sanitation crisis. Stockholm Environment Institute.

[14] Reported in Teknisk Ukeblad, no. 31:12. Nov. 19th, 2004.

protect their craft interests. So effective has this obstruction been that it has blocked the introduction of the technology to the market. The end of the matter is that there is only one potential market where the technology has access: developing countries, where it is now being adapted according to its basic low-cost potential *because* there is no infrastructure to handle adjustments. However, just as in the previous example, in order to be successful without any person mediating the technology, the design of an appropriate interface making the use of the technology both evident and socially acceptable is crucial.

These few examples (among a multiplicity of other possibilities) are not meant as project propositions. They are illustrations of opportunities that could be realised through employment of a leapfrog principle with inherent capacities of mediating innovation in interaction between developed and developing countries. We have attempted to suggest root-problem approaches to responsibility structures and technology mediations. Can some similar approach finally be proposed as to how all the obstacles and challenges of practical projects could be met?

(c) Design-driven strategies

The Oslo Manual displays some of the preconditions for innovative development scenarios; only incremental change culture, minimal innovative awareness among actors or future users, minimal public knowledge and support of initiatives, small local markets, suffocation of local initiatives through multinational enterprise/capital domination, high barriers to formal or tacit knowledge regimes – in addition to serious infrastructure deficiencies. How can attempts to solve such severe problems be practically arranged and how can design thinking contribute?

Since Papanek and the Brundtland commission the sustainability focus has been on the local community and its ability to meet present and future needs. Local communities have their material context – and they are inhabited by potential contributors to their own development; the future *users* of that which is developed. Local development actors (or their emigrated representatives) basically know the local preconditions for development, but they lack the input factors characterising updated development processes. If such a process has an intention of being innovative (new product solutions and their commercialisation), local actors will need supplementary stakeholders of many specialised competences. We then arrive at collaborative scenarios that will involve development actors of diverging interests and competences. As an example a project can include representatives for socio-economic interests (e.g. emigrants), public authorities, technology competences (e.g. leapfrog), local interests – and (tentatively) design competence. Objectives of a project could be to develop innovative solutions to local design problems that will comply with sustainable claims – and that can be applied elsewhere if successful.

Regardless of the particular project, whenever collaborating it is important to see the participants as actors in an ‘ecological system’ having *different and complementary* qualities. Arguably, the kind of result we can expect from a certain project is to a high degree determined by the composition of the actors acting in the ‘system’ and what kind of qualities the system allows to flourish. When comparing design to other relevant disciplines within product development some typical characteristics will stand out particularly sharp:

(i) designers work in the interface in-between technology and the user, making sure that the product makes sense in his or her use-situation
(ii) designers are used to making the most out of the technology at hand and available production core competencies
(iii) the methods designers typically apply when ‘solving problems’ tend to be reversed

compared to other's by being solution- rather problem driven[15], and finally

(iv) designers are used to communicate through physical models easily understood in-between disciplinary and/or spatially dispersed cultures

In the context of sustainable product development in developing countries these qualities seem to be of utmost importance as they all appear to approach apparent problems within present development work. However, a profound conceptual understanding of the last two ones is perhaps giving the most fundamental urge for a change on a concrete, and more, instrumental level; i.e. how *solutions* seen from primarily a user perspective can feed into a system with experts driven by, primarily technical, *problems*, on one hand, (i.e. the engineers) and primarily economical *results* (i.e. economists) on the other (Edeholt 2006 a,b). And, finally, how this interaction can be facilitated by refinements of established 'design tools' (Capjon 2004).

A collaborative scenario example like the above one can be approached through multiple alternative processes.[16] Can some productive core principle be identified that can basically support them all? The scenario involves actors of diverging cultures, norms, values, preferences and *languages*, and a main objective of an innovative process will be to find a way to engage all actors regardless of background. There is interdisciplinary agreement on the importance of employing *material representations* of emerging ideas in collaborative processes. Physical models can have inherent abilities for enhancement of communication, support of ideation and development of shared meaning.[17] Jacucci and Wagner (2007) have studied the performative roles of materiality in collective creativity settings. Their inquiry reveals a distinct shift in focus from verbalised articulations, written words and intellectual meaning to the multi-sensory dimensions of human-made artefacts. They hold that "more and more studies draw attention to the performing body, to spatiality, and to the haptic qualities of physical artefacts as crucial for interaction, experience and understanding."

The principle of employment of material representations to engage and negotiate between mental differences can thereby be suggested as a fundamental approach to enhancement of innovative interaction in collaborative teams. This is a generalised conclusion – implying that it is applicable in 'developing' as well as in 'developed' contexts.

These general principles can be extended to a strategy for stimulation of sense-based communication[18]. In iteratively repeated physical experiments and following negotiations technological possibilities, functional properties and aesthetical approximations can be integrated. Diverging mentalities and preferences of the team actors can be gradually adjusted – and shared experiences can generate learning leading to unconventional solutions. Creative impulses can in such scenarios survive the meeting with complicating technological and functional realities, and focus and growing understanding of user aspects of many alternative solutions can be maximised. The designer's role is central for such collaboration, since (s)he is closest to the integrating and form-giving aspects of the solutions – or functional surfaces where oppositions tend to collide. A metaphorical process model has been developed to facilitate understanding. The central stage of a process is here called *Negotiotyping,* and the other stages are called *Visiotyping, Prototyping* and *Seriotyping.* The team stakeholders have individual mentalities (leaves) in formative and adaptive modes, but they share the physical models experienced in shared contexts (junctions in the plant's stem). Some branches lead to breakdowns, but one eventually gives a negotiated concept. If the extreme capacities of the Rapid Prototyping (RP) tool for production of material

[15] See e.g. Lawson (1997)
[16] Examples are plentiful in Changing-the-change proceedings.
[17] Such material representations, including drawing on paper, have been given many names: Star (1991); *boundary objects,* Henderson (1995); *net-organizing devices,* Perry & Sanderson (1998); *procedural artefacts,* Brandt (2001); *things-to-think-with,* Boujut & Laureillard (2002); *intermediary objects,* Bucciarelli (2002); *linguistic artefacts*. [Ref. Capjon (2004)]
[18] Capjon (2004).

representations are systematically employed in this regime, a highly engaging, efficient and time-saving process can result.

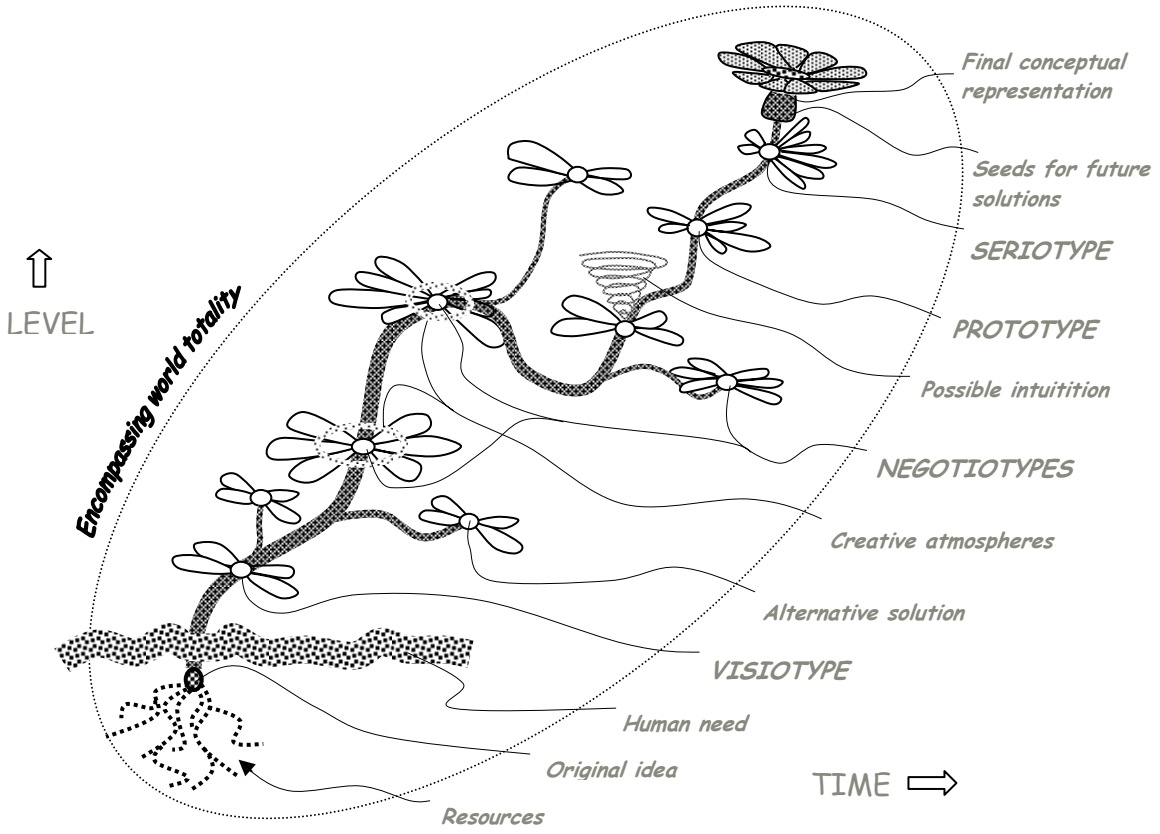

Fig. 1: PoEM – The Plant of Emerging Materiality model

Application of solution-driven principles and a materiality supported development strategy to 'developing' contexts may involve advantages compared to more traditional approaches.

- Idea generation and communication between actors of widely diverging cultures, values and languages can become highly effective through material stimulation
- Solution concepts emerging in the process should be tested and experimented with in their real-world environment and iteratively changed according to hands-on learning
- Acceptance barriers of new concepts with designs adapted to local (not 'developed') preconditions may be gradually overcome through shared sense-based experiences
- There are good possibilities of integrating local technologies (engaging local labour resources) and high-tech leapfrog technologies impossible to produce locally
- If RP facilities can be operated in or close to environments of use, great distances between development actors need not represent high obstacles
- High risk involved in innovative solutions can be substantially reduced through physical RP-based testing before acceptance or rejection

A possible scenario founded in a leapfrog philosophy can be envisioned. *Co-labs* can be fitted with all necessary equipment for material and digital facilitation of collaborative development processes including power supply, updated ICT technology and an RP aggregate. Inseminated through potential migrant partnership, containing a bank of leapfrog technology opportunities and successful local case-stories, and operated by trained development facilitators, such units could initiate and support locally adapted development projects. Labs can be located at universities or in central places, but if they were mobile (e.g. in appropriate trucks) they could cover large areas regardless of non-existing infrastructures. Connections to collaborating development actors in world-wide locations can be arranged through net-based services (physical Negotio- and Prototypes can be exchanged wirelessly). Such units could be equipped with the latest Selective Laser Sintering (SLS) technology, where different materials can be materialised, including steel. *Co-labs* could then additionally supply spare parts to broken down machinery, products, farming equipment or the like (a huge problem in locations without infrastructures). Such Rapid Manufacturing (RM) technology could represent a unique possibility of producing diverse components – through the air, from virtual sources and materialising at the location where they are needed.

Conclusions

Initially we posed three questions based on what we have coined the *lo/hi-tech design challenge* of developing countries. The issues were; sustainable social structures for development (i.e. a), underpinned by alternative modes of technological transfer (i.e. b) and adapted design methodologies (i.e. c).

Based on these questions we have tried to combine competencies, needs and ‘driving forces’ from different fields and/or disciplines. Through such an approach we believe that we can make development work more efficiently and sustainably. Additionally, we believe that we can utilize some comparative advantages inherent in ‘developing’ countries, based on the fact that we all need to develop in radically different ways compared to the blind alley ‘developed’ countries have eventually ended up in. As a consequence we, in fact, see the developing countries as a possible source of highly needed new solutions, and the ‘developed’ countries as the problem – not the other way around.

However, more research is required in order to know whether these rather speculative inputs actually can ‘change-the-present-change’ in a positive and more sustainable direction. Therefore, as a final request, we would like to use this conference as an opportunity to invite anyone interested to continue a discussion along these lines and see whether we can ‘change-the-change’ by joining forces.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

DESIGN DIRECTORY [ITALIA]

A strategic web-tool for the Italian design system

Giuliano Simonelli[1], Venanzio Arquilla[2], Marco Sammicheli[3], Antonella Castelli[4]

Abstract

Design Directory [Italia] is a research project promoted by Triennale di Milano and carried out by Dipartimento Indaco of Politecnico di Milano. It is also a tool to map the Italian design system (including companies, professionals, publishers, culture, schools and research), which, by visualizing information, allows to represent, interpret and share the system. It is a “mechanism”, a a simple service design tool which wants to become a winning action and a cultural activity aimed to stimulate the creation of social networks, the participation of all the actors and the co-creation of contents. All this by using the web 2.0 approach.

1. Design and system: an evolving process

Design represents one of the main characters of the Italian territory. Recently the design profession has seen some changes. The “heroic” phase of Italian design has ended (the years of the best Italian designers such as Magistretti, Munari, Castiglioni, etc.), and a more spreading one has started, in which the number of actors involved in the design system has significantly raised: design schools have proliferated, as well as associations, magazines, exhibitions, design-oriented companies, and Italy, especially Milan, has established relationships with the international capitals of the design culture production. At this moment in time, when a lot of changes are taking place, design can, once again, represent for the territory a sort of guidance to support the dialogue and competition among regions and their production and cultural systems. (Bonomi 2006)

Furthermore, design represents a strength for the Italian economy. It represents a production field comprising of design activities, education and publishing activities, cultural products, places, events, as well as a general orientation toward business. Italy, and especially Milan, represents in this sense a worldwide known and appreciated brand: for this very reason it needs to be acknowledged and leveraged. (Simonelli et al. 2002)

The design system is evolving and currently comprises, more then ever, new profiles which dialogue with the advanced design requirements, counting on a solid and significantly wider offer. The system of the design professions gained the current importance because it was initially supported by a production system, the Italian one, which largely experimented design in several successful collaborations. It is possible to affirm that the business system as a whole grew within a design “shared atmosphere”. Design is mainly inclined towards some sectors because of the historical relation with part of the Italian industry, as well as the repeated collaboration between designers and entrepreneurs. Furniture, lamps, objects and clothing, as well as machinery and transport, lead the Italian companies and the designers they collaborated with to the worldwide reputation. (Arquilla et al. 2005) On the contrary, it is currently difficult to have a clear picture of the design professions; for example, there isn’t a professional list to refer to like engineers and architects have, and the relations and professions sees many activities and specializations.

It used to be possible to talk about design structures, now it is possible to talk about design networks, comprising of small professional studios that deal with parts of the design process and collaborate with other small studios (Simonelli et al. 2002) and with other actors of the systems. The network of relations gets wider and becomes a mesh, a combination of links, and the designer can create design relations, gathering for each project the right skills to answer to the client’s need. This is one of the most interesting aspects of the Italian way of working. The system of professionals on a given geographical area has been internationally connected for quite a while, working for foreign companies and for Italian companies on foreign markets. Many talented young professionals come to Italy. The result of these exchanges is a fruitful dialogue which generates advanced innovations both in the products and ideas world. Schools, fairs, publishers, cultural institutions, and all the new aggregation places on the urban and national area activate those prolific exchanges, not only the companies. Italian design is characterized by a systemic and a sectorial coexisting aspect: from one side design resources, activities and competencies are tied to a set of different resources, activities and competencies which belong to different overlapping and interacting layers; from the other side the sectorial aspect is crucial to investigate, understand, interpret but most of all support the design phenomenon.

High priority is given to the investigation of the system’s structure, the definition, so to speak, of its form and the understanding of its functioning and relations among the actors. To this regard, the research allowed us to sense the more profound nature of the complex system comprising the Italian design and fhe fact that it is defined as a favorable habitat for the plurality

of the systems it comprises of. We believe it is important to carefully follow the dynamics that have recently led to the reorganization and change in the production system.

2. The ‘production room’ of the design system

The different systems that revolve around design are often represented by micro or macro design organization, production processes to which the designer belongs, often with a “direction” role. These “creativity processes” express the capability of a geographical area to become a privileged place for the design culture. The designer becomes the strategic point of the system. Thus, the professional isn’t a single unit any longer, but he represents a hub, the “production room”, in the network which builds relationships and collaborates with the other actors involved in the process. The actors of the process are the education system, the publishers, the companies, the suppliers, the manufacturers (prototypers, printers, etc), the associations, the cultural and exhibitions systems, the research. The system of relations of the Italian design is represented by the systematization of the resources and competencies. The designer is compared to a director which has a vision, an idea, and that is capable of translating this vision in an integrated and consistent project, while enabling the relation among several actors in the system. (Pacenti 1998) The Designer becomes a director especially thanks to his inborn capabilities, described as follows (Zurlo 1999):

- *organization and coordination skills*: the capability of coordinating, “orchestrate” and systematize the resources and the actors, being able to interpret and mediate the different specific languages of the several actors’ professional fields involved in the project development;
- *negotiating skills*: negotiation is needed in any creative process. The design culture, for its systemic vision and the multidimensional approach to problem solving presents a stronger negotiation skill than other professions;
- *connection and “translation” skills*: design becomes a tool to manage and integrate different resources to enhance the efficacy and effectiveness of the design solutions. The multidisciplinary education of the designer and of the design manager especially, the ability to understand and act as a “translator” and coordinator, the central position in the system, the ability to synthesize and visualize become the precious tools available for the whole design system;
- *communication skills*: the designer has the competencies and tools to visualize the processes and communicate the project potentials outside the system. The designer acts as an interface with the actors of the system;
- *innovation* skills: subversion isn’t intended as negative: it defines a specific ability in being able to eliminate cultural prejudices or inactivity in seeing things; it means to use a point of view which isn’t the conventional one, and to be able to foresee what’s new and useful (for the company, the society, the environment).

These skills were developed and transformed in time, thanks to the social, economic, market and technological changes which led to the definition, re-articulation and implementation of the designer’s new capabilities. The direct relation between designer and company changes, and there are several actors with more specific skills which take part into the design process. The designer becomes the activator and actuator of strategies to create shared agreements. Thanks to the evolution of the education system new disciplines find birth, which gather these thoughts together. Strategic design for example is a design activity focusing on the system of product, service and communication (the product system) with which an actor (company, territory, etc) gets on the market, is placed in society and shapes its strategy. Other disciplines are service design, design management (Triad Project 1990) and design coordination (Henrion and Parkin 1967), which define the designer as the director of the system.

3. The numbers of the design directory

To map the whole of the activities and professions ascribable to design wasn't easy, as many professions and activities non clearly codified, but still existing and rapidly growing, are linked to the word "design". Italy is extremely rich and fruitful as regards the design "production". Thus, the research had to define a method and some criteria to identify and select the actors belonging to the design system. The criteria have to be valid, and to validate the system. As there were no specific researches and references to associations, the numbers of the system were defined at a twofold level: both the "emerged" (acknowledged sources) and "submerged" (acknowledgeable sources) parts of the design system were identified. The emerged part is mainly and naturally investigated from above (who is o makes himself visible, who is or isn't subscribed to…,who is part of…., who has to complete certain paperwork…): it is a visible, represented and known world. The submerged part is investigated with a different modality, as it is not officially acknowledged; though, if well addresses and circulated even through policy actions, it represents the real novelty, where an incredible potential for system innovation lays.

The categories allowing to break down the "design" aggregate in consistent subsets have been defined, and 7 systems emerged: 1. Companies and trade associations; 2. Designers and design associations; 3. Schools; 4. Research centers; 5. Fairs and exhibitions; 6. Publishers; 7. The cultural system.

To find "design companies" was not easy, for two main reasons: the fact that an official inventory of the "design companies" doesn't exist, and the fact that all the companies of the made in Italy sectors (or even just the furniture/home related ones) seem to be somehow defined as design oriented companies, for the kind of products they produce. Actually, this is a partial and inaccurate result. The research aimed to define a method to identify companies that are part of the design system: through tests, collaborations with R&D centers within the companies, events promotion, competitions, awards, publications. The factors taken into consideration are: to be published on the ADI Design Index lists; to have been awarded a special mention or to have won an international design award among the long-lived one (Good Design Award, Compasso d'Oro, Red Dot Award, Observateur du Design A.P.C.I.), in a given period of time (1995-2007); to be exhibited in permanent design exhibitions at prestigious international museums (Ney York MoMA, Triennale di Milano, London Design Museum); to promote design competitions aimed to influence the company offer or to use design as a communication lever or as a proof of a precise market policy, or where design can be seen as a qualitative or communicative term; to take part in fairs and exhibitions such as "I Saloni", "Abitare il Tempo", "Macef", where a strong trade component is merged with a design oriented profile and a contribution to the design culture is given (exhibitions, installations, shows, etc…). Starting from the identified criteria a selection was made, to highlight companies the excellence of which could be measured by using design variables. Around 1500 companies were selected throughout Italy, through acknowledged sources, and around 1000 through acknowledgeable ones.

Several actors which, under different names, in an explicit and implicit form, act as designers collaborate with the companies. The phenomenon and its dynamics were investigated at two levels. From one side the visible and known world was analyzed, meaning the "emerged" part of the professionals, considering the lists of the main national trade associations (ADI - Disegno Industriale [Designers Department], SIE - Ergonomia, ASPRONADI - Nautica di diporto, ANFIA - Industrie automobilistiche [Professionals], APIL - Associazione professionisti dell'illuminazione, AILD - Associazione italiana Lighting design, AIDI - Associazione Italiana di illuminazione, Lighting Accademy, AIPI Promes, AIPI - Progettisti in architettura d'interni, AIAP - Progettazione per la comunicazione visiva, ADCI - Art Directors, UNICOM - Imprese di comunicazione, Assocomunicazione [Advertising and communication and Digital Sectors], Federpubblicità, TP – Associazione italiana professionisti pubblicitari, ADICOM – Associazione italiana pubblicitari e designer, Camera Nazionale della Moda Italiana [Professionals], ADOR - Designer Orafi). The "submerged" part includes about 5.500 professionals working in the different design application fields, such as industrial design, communication design, interior and fashion

design. The regions with the higher numbers are Lombardy, with 1800 designers, followed by Campania, Emilia Romagna, Piedmont, Lazio and Veneto which count between 400 and 500 professionals on average. The three main associations have ADI: 850, AIAP, 530, AIPI 30 designers. Around 15% of the professionals are part of more that one associations. The other observation modality for the "submerged" part is less codified, but equally important to get a clear picture of the current trend of the profession. From this observation the importance of the sector investigations emerges, especially the 74.87.5 – design and styling for the design of textiles, clothing, shoes, jewellery, furniture and other house goods – which best represents the design world, comprising almost 10.000 professionals. Other acknowledged sources are books, websites, exhibitions and events which gather together and suggest lists of professionals, such as the Guida Index of the magazine Interni, which publishes around 2.500 studios, or the national ad international websites such as Design Boom, CORE77, Italiandesign360.com etc… which have 100 to 800 subscribers on average. Last but not least exhibitions and researches highlighting the phenomenon, such as The New Italian Design (exhibition at Triennale di Milano with a selection of designers under 35) and Design Roma + (dedicated to the Design System Lazio), are also valuable sources.

The specializations that designers seek for in their profession are strictly tied to the educational offer of Italian universities and public and private institutions. The current offer is very articulated and comprises over 150 schools mainly located in the north and center of the country. Universities, Academia (Accademie di belle Arti e Accademie di belle Arti Legalmente Riconosciute) and ISIA (Istituto Superiore per le Industrie Artistiche) represent the main active majority of the schools that MIUR (Ministry for Education, University and Research) accredits. Though, beside these "official courses" there are many famous private design schools both undergraduate and post graduate. Over 150 design-related schools have been identified, among which 17 Universities, 44 Academies (20 Fine Arts academies and 24 legally accredited Fine Arts academies), 4 ISIA, 60 post high school schools and 29 professional institutes. At a graduate level, 3 Institutes provide a Design Faculty and all provide at least a bachelor in Design within a Faculty of Architecture or Engineering. In the academic year 2007/2008 10 are the 3 years bachelor courses, 11 the specialized degrees and 30 the master courses. The latest trend in the applications to the bachelor courses is increasing, and in the year 2005/2006 2500 have applied and 8500 have attended the 4 courses: Product Design, Interior Design, Visual Design and Fashion Design. The ISIA - Istituto Superiore per le Industrie Artistiche institutes are part of AFAM and are public institutions providing university level courses structured upon the same modality (3+2 years). They are located in 4 cities: Rome, Florence, Faenza, Urbino. The ISIA apply a strict selection process to select the limited amount of students they accept: between 25 and 50 per year depending on the institute. On average, 30 students per year get the I level degree and 15 per year get the II level one in each institute. Besides the university/academic educational system there are a lot of schools and institutes – often private – which provide many and very diversified 1 or 3 year courses, I, II level or non accredited masters, short courses (4-10 weeks, like Summer Sessions), intensive specialized courses (like1 to 3 week workshops or seminars). The first private schools offering design related education and training were founded in the early Seventies. Currently there are about 60 at high school and post high school level, and about 30 professional institutes. The main schools taken into consideration have, for the 2006/2007 year: IED 3500 students, Domus Academy 250, Scuola Politecnica di Design 200, Polimoda 350, Istituto Arte Applicata e Design in Turin 250, Istituto Marangoni 1200, Istituto Quasar Roma 400. Furthermore, the private schools have the highest number of foreigners: on average 60/70% of the students. (Gallico 2007)

On top of offering education, the design schools also carry out research projects in the design field, especially universities and faculties, departments, university consortia, observatories, university and interuniversity centers, spin-offs and start-ups, innovation and knowledge transfer centers, experimental centers, BICs, centers and agencies for local development and thematic and multidisciplinary centers, observatories, public research centers such as CNR and smaller centers. Private schools also invest in research, although on a smaller scale; the main ones are IED with the CRIED research center and Domus Academy with DARC. In the research field, it is

possible to see how design is recognized and has become a research topic for innovation. The sources used for the acknowledgement of the research centers were the RIDITT (Rete Italiana per la diffusione dell'innovazione e del Trasferimento Tecnologico alle imprese) network, where all the national public research centers are equally listed, and sources like the web sites of the main companies with internal research centers, of the schools' and associations' research centers. In total, 350 design research centers were listed.

To have a complete overview of the system of actors involved in the design world, it is important to analyze the cultural system and system of fairs and publishers. Fairs represent more and more, in Italy and abroad, events which attract the public's attention. Design has a strong link with the fairs as many of the market sectors, which take part into these events, use design as a distinguishing factor in their productions. The main source to list the national fairs, in which design is present in its multiple expressions, is the Guida Mondiale delle Fiere in its updated 2007 edition. Of all the fairs on the manual, those more related to design were selected (about 300): 90 fairs in the Living category [furniture, building], 62 in the Fashion category [clothing, fashion, accessories, jewellery], 40 in the Food and beverages category [food – local development] 30 in the Mechanics – Electronics category [production – innovation], 42 in the Tertiary and Services sector [hospitality – tourism], 34 in the Arts and Crafts category. Almost 40% of the fairs take place in Lombardy and 15% in Emilia Romagna, then in a lower percentage, Tuscany, Piedmont and Veneto. The organizations promoting the fairs are about 160.

The design cultural system includes about 200 among museums (40), archives and companies' museums (110), temporary locations (50) offering design exhibitions, performances and installations. The sources used to collect the data are dedicated websites such as ICOM (International Council of Museums), museionline.com, etc…under the design listing. Other sources were: the indication by associations belonging to the design directory; the presence, in the corporate name of the institution, of key words such as design, art, arts and crafts; the publication on accredited guides (Touring, Guida Index Interni); the museum and business archive website (*www.museimpresa.com*), the thematic website linked to the fairs such as fuorisalone.it and the lists of Italian regions and provinces published by the websites.

The design editorial system comprises magazines and related publishers committed to publish and communicate design related texts and images. This industry currently represents big worldwide famous publishers as well as small and medium publishers which work in specific market niches. The design publications include a large number of periodicals, magazines, dossiers, on line publications regarding design issues: internationally renown magazine, as well as specialized publications widely spread among economic and market operators, specialized publications, books and manuals about design and the design culture, publications related to design schools. Around 200 magazines and 60 publishers were listed. The majority of the publishers are located in Lombardy. As a direct source, which guarantees the scientific validity of the publications, the presence of ISSN code was taken into consideration. Indirect sources were used since there is a large publication of design related contents in more general types of magazines. The parameters allowed to consider all the publications (periodicals, dossiers, free press) which contributed to the communication of the design culture: the publication on the AIE (Associazione Italiana Editori) list; the acknowledged tradition related to design related disciplines; company house-organ; main websites, webzines and on line magazines with newsletters.

4. Building a system: methods and examples

The capability of building relations, "orchestrate" situation and "building systems" is a peculiarity of the Italian context, where for "system" it is meant an entity comprising of a plurality of elements. As regards Italian design though, the term can be used in its more correct meaning, thus system indicates "the whole of elements and the relations established among them". The

relations are those which determine the “form of the system” and finally make him recognizable as whole entity. (Manzini 2002)

In fact the *design system* comprises a series of actors with different skills, resources and specific competencies, but it also includes media, meaning communication channels dedicated to institutional promotion spaces, small research and technological testing labs. All professional associations, schools, courses and cultural events are part of the system. It includes all the activities that support design: from model to prototype makers, to mould producers to web masters, to graphic designers. The perception of the system is pretty immediate, while it is more complicated to focus on how the system functions, what elements “keep it together”, what allows it to be recognized as one entity, despite its internal and complex articulations. As regards this topic, the research allowed us to see the profound nature of the articulated totally of systems comprising the Italian design system; the way in which it self-defines as a favorable habitat for the plurality of systems it includes; its strength and potential weakness when changes are happening inside and outside the system. All this shows that the Italian design system is to be considered as an “evolved ecosystem”, as such quite resistant to the adversities of the environment. (Manzini 2002) In Italy to “design” currently means to act at a system level. Although Italy is internationally considered as the *design capital*, it doesn’t institutionally have any political or information support for the design field, thus there is no acknowledgement of the implicit or explicit design system. (Maffei et al. 2004)

The Italian design system has many strengths such as the solidity of structure’s base, but also many weaknesses: the system is hardly mapped, non shared and thus uninformed. The actors involved never had a guidance, a definite form, a codified structure.

The international experiences are of different natures, public or private or both, and their approach is to privilege actors relations of different scale. However, the shared aim is to combine an institutional policy with a tendency to share data in order to establish relations.

A first example is represented by the Design Directory Wales (Dylunio Cymru, Design Wales), managed by a public institution, Design Wales, and funded by the Welsh Assembly Government. The Design Directory Wales is periodically revised in order to guarantee the information update. One of its main objectives is to guarantee an independent consultancy service regarding specific design oriented topics. The main target is the Welsh industry, based on a creative and diversified industrial design. This kind of Directory allows to freely access the information on design competencies in the area.

In the United Kingdom there is another example of public institution, the Design Council, which uses applied research as a tool to publish annual reports on the actors of the English design system. (The business of design - Design industry research 2005) The English case, although without using a real directory, represents for its structure and experience one of the first institutions that answered the need to direct and manage such a complex system as that comprising the actors involved in a design project. (Arquilla 2004)

There are also private examples raised by the needs emerged in professional fields. One of these is the CORE77 directory, created with the collaboration of the magazine Business Week (DESIGNDIRECTORY).It is a detailed database published on the magazine homepage where other contents regarding the discussion on the strategic value of design in business opportunities are published. With about four million users, the directory has a large potential of being seen by a global and differentiated public. This directory, created in 1995, is used by international designers, both students and well-known designers. Furthermore, CORE77 publishes articles, forums, a calendar of events, conferences, parties and exhibitions. Coroflot is an appendix, the characteristic of which is to concentrate on portfolios and job postings.

Design Boom and Italiandesign360 are also private but represent a different typology in the representation of the design system. They use the interview and communication modalities close to journalism as tools to present thematic lists, privileging contents related to individual initiatives. Italiadesign360 was created in 2006 and has a very wide public of actors. Their access

and that of the companies is filtered by the site management and divided in categories and design disciplines, as it is dedicated to the Italian contexts.

Once the two possibilities are highlighted, the institutional and the private one, the Design Directory hereby presented represents a third possibility, original and experimental, which combines the models in one tool. The Directory is the result of a research project carried out by the Dipartimento Indaco of Politecnico di Milano and Triennale di Milano. The main characteristic of this tool is represented by the input that activates the system, where the single user, once registered, is the protagonist of a series of activities not only comprising the self-communication and promotion, but also the dynamic definition of a method to interact with the elements involved in the project. The process, once activated by the University as a public institution, is then extended to the other actors.

5. Shared platform: how to represent and recognize the system

To acknowledge design its value means to implicitly acknowledge the system around it. For this reason, the design system needs to be constantly monitored and analyzed, so that it is possible to see its endogenous and exogenous changes, and the elements which bring vitality versus those that lead to impoverishment. The centrality of the system involves the designers, the associations, the publishers, the education and cultural promotion, the fairs and exhibitions. At Politecnico di Milano an intervention idea was tested: to acknowledge the system and its evolution through a representation model, a platform shared among the actors of the system. It isn't a design center or a window for Italian design as there are in other Countries. The idea was to suggest from the bottom, sharing the concept, a self-representation method which involved since the very beginning (in the ideation and creation) all the actors of the system, trying to gather them together and giving them a shared identity, and most of all enabling the relation among them.

The strength of the system lies in this network of relations on the territory among the different actors involved: their competencies and skills are complementary for the development of design projects. The shared platform is called Design Directory, a "mechanism" that from a simple service design tool aims to become an intervention, a cultural action aimed to make the system explicit, a process of creation of a value that the actors share. The Design Directory becomes an action to found and represent the system, a list of the involved professions which is well represented by this claim: "count yourself to matter". The platform was defined through several steps. The first was at a local level: the Design Directory Lombardy was created for this, and presented at the "MilanoMadeInDesign" exhibition (organized by Design Focus – Observatory for design and promoted by Provincia di Milano and the Chamber of Commerce of Milano, in collaboration with Regione Lombardia). It represents the first step toward the creation of a wide information and service system aimed to enable the dialogue and the mutually advantageous exchange. The platform has two main values: from one side it gathers and visualizes the lists of all the professionals listed in Lombardy in the design systems, and from the other it visualizes the clustered data, emerged throughout the research, through maps and schemes which simplify concepts and current phenomena in the design system.

The second step, still in process, is that of creating a platform shared at a national level, Design Directory [Italy], which follows the dynamic of the regional one, but represents a tool to share and represent the design system, which could be used and updated by all the actors involved. The web was chosen to build and collect these data as it is currently a valid tool to share this kind of information, and it was the main tool from which the communication actions were activated. The online tool allows to get over the cultural boundaries and makes the system accessible to everyone.

The Design Directory is a “mechanism” that besides being a simple design tool, aims to become a winning cultural action using the “web 2.0” approach (Grivet Foiaia 2007) to stimulate the creation of social network, the participation of all the actors and the co-creation of contents (O'Reilly 2006). This new working method should make explicit the process of value creation, which participants can eventually share. Thus, Design Directory becomes a founding action to represent the system, a list of the involved professionals, well represented by the motto “count yourself to matter”. The Design Directory represents an example of mass collaboration, where new communication technologies are democratizing the creation of value. (Tapscott and Williams 2007).

This model wants to have a twofold aim: to aggregate actors in order to make them recognizable and communicating with each other on one side, and become a replicable example in different situations and territories both locally and globally from the other.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Fish Box in EPS

Zero Impact

C. Anna Catania[1]

Abstract

The object of the study is to demonstrate that an enterprise can be efficient also when it concerns the protection of the environment and that this is the key in order to obtain a sustainable development.

In order to obtain this, a company is held to reduce the impact of the products during the entire life cycle of the product (from production to disposal) and to use adequate strategies that aim to reduce the impacts on the environment.

The analysis will regard the field of packaging, considering a Sicilian company, that produces packaging made by Expanded Polystyrene (EPS) and in particular boxes for fish.

[1] University of Palermo, Department of Design, e-mail: a.catania@unipa.it

1. Introduction

Nowadays design has the limitations that the environment imposes on the current system of production and consumption. We live in a world of products with a minimal environmental attention: a world of disposable items. Producing minimal levels of quality and an enormous mass of waste will lead to an environmental disaster.

The urgency and relevance of the problems connected with the environment has lead to a new set of solution, based on new different research lines.

Different research lines for a production system and a consumption model respectful of the environment is an approach to the environmental management of products.

Indeed, today, the phase of the ecodesign assume a strategic role in the product process development and in the process of innovation of the enterprises.

The aim of this project is the development of a production system and consumption model environmental friendly and a novel approach to the environmental management of products.

Therefore, to ensure today that a product matches the environmental criteria waste management with product design, it should be removed from the waste stream, reprocessed, and reused.

Indeed, today an important objective is the protection of the environment, a new approach, that is fundamental for the processes production and the competitiveness of the enterprises.

In fact, the goal of this paper is to demonstrate that an enterprise can be efficient also when the production becomes concerned in the protection of the environment and that this is the key in order to obtain a sustainable development.

In order to obtain this, a company is held to reduce the impact of the products during the entire life cycle of the product (from production to disposal) and to use adequate strategies that aim in reducing the impacts on the environment.

2. The research methodology

The analysis will consider the field of packaging, considering a Sicilian company, that produces packaging made by Expanded Polystyrene (EPS) and in particular boxes for fish. The company sells the boxes in the entire Sicily and also to foreign countries.

The boxes in EPS destined to the transport and conservation of fish are safe from the hygienic point of view because mould does not develop.

In practice, the paper will be organized in two phases:

- In the first phase, the production and properties of Expanded Polystyrene boxes will be improved, designing boxes that will be put one on each other, stackable and with a lower weight. This will imply a better stacking, about forty percent in more than with normal boxes with a consequent saving of energy, resources and therefore a reduction of the environmental impact. In this phase the packaging will follow the parameters of ecodesign: redefining of packaging in weight, reuse of the product also for other functions, recycling of the material to introduce in the production cycles as second materials, and energy recovery.

- Then, the aim will be the recovery of the boxes to be reutilizes in a new production process in order obtaining zero impact. This phase will begin with the description of data related to the amount of the wastes and of the models of collection and reuse of disposal boxes.

After this study the recovery to the logistics and the reuse of the boxes will follow .

The new methodology will be based on the total recovery of the boxes in the Sicilian territory and the indications for a subsequent reuse.

It is a design methodology that does not consider the production process in terms of resources and wastes, but consider output as inputs of another processes

Therefore, an optimal use of the waste, through the employment of new technologies, will bring returns and benefits to the territory thanks to the zero impact.

3. Design and environment

Today, design is important for producing items with reduced environmental impact. Indeed, in the product process development and in the process of innovation of the enterprises the phase of the ecodesign assumes a strategic role . Environment requirements of a product defined at the design phase cause positive effects in the environment during the other phases of product development.

The aim of ecodesign is to minimize the environmental impact from products and processes with these strategies:

- selection of low impact mterials
- maximise energy and water efficiencies
- design for waste minimization
- choose cleaner production processes
- making products recyclable
- design for waste minimization

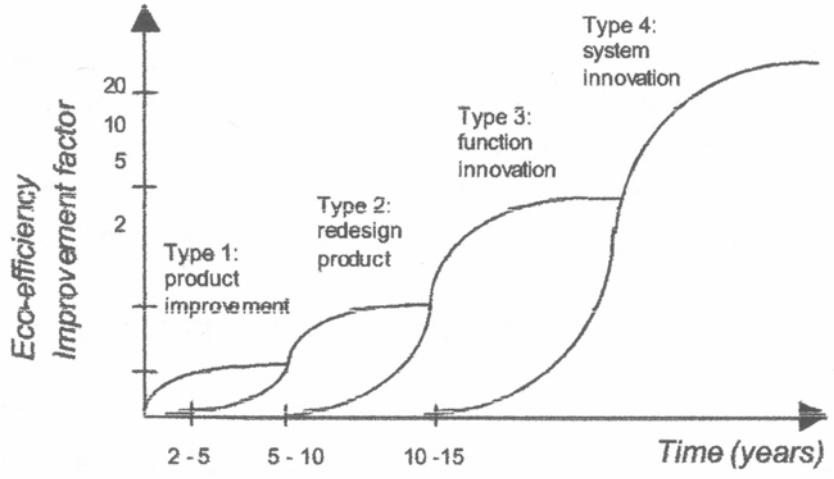

Fig. 1: Four steps model of ecodesign innovation

Environmental research in industry started in the 1960 and led to the ecodesign activities of the 1990, which refers in product development aimed at minimising a product's environmental impact during its entire product life phase.

Ecodesign model can be visualized using the four-step model as is illustred in fig.1

The four step model as described by Brezet (1997), Charter & Chick (1997), Stevels (1999), and Meinders & Meuffels (2001), from incremental improvements of products to new products that have a functionality wich completely fit into a sustainable society

These steps are further described in the following:

step 1, product improvement :The improvement of existing products consist s of decreasing the use of materials or with regards to pollution prevention and environmental care;

step2, product redesign: redesign a new product on the basis of an existing product; the aim is increased reuse of spare parts and raw materials, or minimising the energy use at several stages in the product life cycle ;

step 3, function innovation: changing the way the function is fulfilled. Example private cars to 'call-a-car' systems.

step 4, system innovation: new products and services arise requiring changes in the related infrastructure and organisations.

Ecodesign in step 3 e step 4 involve more companies in multifunctional systems to succeed. These steps will need new ways to: produce and distribute energy,communication, manage waste materials.

Furthermore in these steps work will need new values and attitudes, both in the companies, among consumers and in the society as a whole and the perspective of these steps solutions will be 10-50 years; while the perspective of step 1 and 2 solutions might be 1-5 years.

In recent years, environmental research has concerned with moving towards sustainability.

As Stevels states, "Applied EcoDesign has developed strongly in the last ten years and is now solidly on the business map. It has changed from a subject with a limited scope and an inward green-looking approach to a wide field, inspiring engineering, business, consumers, and society as a whole" (Stevels, 2001)

Thus in this work I will use ecodesign strategies to find solution more environment friendly. The parameters of ecodesign will describe:

- redefining of packaging in weight ;
- recycling of the material to introduce in the production cycles as second materials.

Finally the recovery and the reuse of the boxes will follow and so wastes of a process can become the resources of another one.

4. Expanded Polystyrene (EPS) and properties of EPS packaging

Expanded Polystyrene (EPS) is made from non renewable petroleum based chemicals.

EPS products are 98% air and only 2% PS It is made from expandable polystyrene that contains a small amount of pentane gas.

The gas expands under the action of heat, applied as steam. Thus EPS consist of a foam structure of closed cells containing air. These products are ultra lightweight, with excellent thermal insulation and shock absorbing properties. They do not contain any CFC or HCFC.

The insulating properties of EPS can be used to ensure that a product is kept at an temperature low. Thus it is the ideal material to use for any packaging where thermal insulation is important. Expanded Polystyrene can also help to protect against sudden temperature changes.

Expanded Polysryrene is light, hygienic and used for packaging food, medical supplies, electrical goods and insulation panels and it is also used to protect products used for distribution, storage and delivery.

Properties of Expanded Polystyrene (EPS) packaging are:

protection

The shock absorbency of expande polystyrene and compression resistance of expanded polystyrene packaging provides excellent protection properties.

durability

The durability of Expanded Polystyrene makes it a protective packaging for a wide range of goods. The material is moisture resistant, so hygiene requirements are met. EPS is also odourless and non-toxic.

lightness

EPS is made up of 98% air, making it a lightweight material. This means that fuel consumption emissions are lower than with heavier materials and ransport costs and fuel emissions are kept to a minimum

versatility

EPS can be moulded into any shape to protect the smallest electrical component or the largest fridge-freezer

termal Insulation

The thermal insulation properties of EPS is used to box fresh fish and for seed trays where it assists in the growth of the plants. It is also used in packages items that are temperature sensitive and that need to be transported

recyclability

Expanded polystyrene recycled is used used to make new EPS insulation or packaging, or items such as replacement hardwood furniture, CD and video cases.

5. Recovery and recycling of Expanded Polystyrene (EPS) Packaging

The production of packaging material is the largest segment of the plastics processing industry . Food industry constitutes the major slice followed by beverage industries and cosmetics.

Expanded Polystyrene for packaging is a way of protecting the goods, its light weight reduces shipping costs and its water resistance and insulating properties protects perishables products during transportation.

The insulating performance of Expanded Polystyrene is very high compared to conventional packaging materials.

In fact Expanded Polystyrene is the ideal material to use for any packaging where thermal insulation is important.

The insulating properties of Expanded Polystyrene can be used to ensure that a product is kept at a temperature and it can also help to protect against sudden temperature changes.

Hence Expanded Polystyrene is ideal material for fish box and seafood industry , but the disposal of used polystyrene fish boxes can be expensive and a difficult problem thus is very important an alternative to throwing boxes in the bin.

Actually there are two options for the disposal or recycling of used Expanded Polystyrene as energy recovery and recycling.

Energy recovery for Expanded Polystyrene (EPS) fish boxes or horticultural trays , generates value from used contaminated packaging material .

So the energy available from petroleum that is used to produce them then 'return' it when it is used as a fuel in the waste-to-energy conversion.

Moreover the calorific value of Expanded Polystyrene available for heat recovery is higher than that of oil and so Expanded Polistyrene provides a valuable source.

To recycling used Expanded Polystirene packaging, it must be segregated from other materials. So the collected material is compacted for easy, cost-effective transportation. Then recycler will send a lorry to collect the material.

In a second phase the Expanded Polystyrene will be granulated in smaller pieces. Then the material is passed into a blender for thorough mixing with similar granules.

At the end the material is fed into the extruder, the extruded material is then moulded into a new material such as hardwood replacement for making garden furniture, slate replacement for roofing tiles and new plastics items such as coat hangers, CD and video cases.

The landfill of Expanded Polystyrene packaging represents a missed opportunity to recover valuable resources. However, EPS is an ideal material for landfill because it remains inert, is non -toxic, odour-free.

Furthermore in 2005 borned an agreement between Aipe (Associazione Italiana Polistirolo Espanso) and Corepla (Consorzio Recupero Plastiche) with the intent of regularising and facilitating the procedures of conferment and recycling of polystyrene foams packaging waste.

Aipe (Associazione Italiana Polistirolo Espanso) and Corepla (Consorzio Recupero Plastiche) have signed an agreement to create a national structure to increase the system of collection and recycling of EPS packaging waste.

The agreement has born to favour Expanded Polysyrene recycling by a separate handling of waste packaging. The system, intends to favour the recycling of expanded polystyrene thanks to the creation of special EPS collection platforms (PEPS) spread throughout Italy.

The management of the platforms will be entrusted to a collection of companies . These companies will see to the recovery and the reinsertion of waste packaging into the production process.

6. New prospects for fish box in Expanded Polystyrene

This work shows the development of ideas for sustainable products through the utilization of the packaging. The packaging is an essential part of the industrial and commercial supply chain, it protects goods, allows efficient transport and the distribution.

The analysis will provide information needed to better understand the current environmental profiles of the product and in particulary implementation of ecodesign.

Ecodesign, which refers to actions taken in product development aimed at minimising a product's environmental impact during its whole life cycle,is as a means to preserve, besides the environment, the competitiveness and the image of the company.

As we said Expanded Polystyrene has many characteristics: it is a lightweight cellular plastic material. It is this closed cellular construction that gives EPS its remarkable characteristics.

Expanded Polystyrene offers the following benefits when used as a packaging material: shock absorption and protection against humidity, low density, thus lightweight packaging, low thermal conductivity protects contents against sudden temperature changes chemically inert and therefore can be safely used for food packaging.

In fact packaging sector continues to absorb considerable quantities of Expanded Polystyrene (24% of the demand of polystyrene foam in the packaging field) in the form of slabs, corner pieces,for the protection of goods during transportation.

Among the main segments boxes (29%), componentry (19%) and seed boxes (14%), followed by the furniture and food segments (9% and 5%).

A main shortcoming of the Expanded Polystyrene packages is that are too and they deemed a collection and recycling phase.

In fact, the environmental impact appears as one of the most important problems for the entire sector.

The companies have the need of a program for stimulating the environmental sustainability of Expanded Polystyrene , accompanied by appropriate phases of recovery and recycling.

To do this we analyzed a Sicilian company that produces packaging made by Expanded Polystyrene (EPS)

The analysis is started from the presente state, considering:

- analysis fish box
- analysis of the organization and disposal of fish box

The analysis has investigated on technical requirements and legislation for the suitability of Expanded Polystyrene uses for food.

From the investigation the Expanded Polystyrene fulfill the requirements of legislation the regulations about fish transportation and to food safety as reported down.

Packaging materials and products that are in contact with fishery products must comply with all the rules of hygiene, and in particular: they must not be such as to impair the organoleptic characteristics of the fishery product and they must not be capable of transmitting to the fishery products substances harmful to human health.

Containers used for the dispatch or storage of fresh fishery products must be designed in such a way as to ensure both their protection from contamination and their preservation in hygienic conditions and,they must provide adequate drainage of melt water.

Expanded Polystyrene packaging,with its outstanding thermal and protective properties, offers a reliable and cost effective packaging option for fish producers.

In addition, the fish box must be produced in compliance with the UNI regulations:

UNI 79 70/05 ensures that packages are needed to transport food;

UNI 70 35/00 confirms that packages are made with plastics for contact with food;

UNI 64 26/00 ensures that are pallettizzate cassettes for the transport of fish;

UNI 64 27/00 material was subjected to the tests planned for the plastic boxes for the transport of fish.

The production of the Expanded Polystyrene boxes have been improved designing boxes that are put one on each other , stackable and with a lower weigth than normal boxes used by company.

This will imply a better stacking, about forty percent in more than with normal boxes with a consequent saving of energy, resources and therefore a reduction of the environmental impact

In the analysis of the organization and disposal of fish box, the aim has been the recovery of the boxes to be reutilizes in a new production process.

The analysis shows that there is not recovery of post consumer polystyrene for recycling and therefore it is important to implement a 'Waste Strategy' which aims to explore new methods of waste management; looking at the ways in which we can achieve our environmental responsibilities.

In this way waste management programmes can be tailored to local circumstances, such as the infrastructures for collecting waste and demand for recycled products.

Recycling techniques must be chosen to maximise the value of the goods produced, whilst minimising the consumption of resources for transporting, sorting and cleaning the waste.

Part of waste strategy can to help develop new markets for recycled materials, in fact Expanded Polystyrene can be granulated and mixed in with virgin material to make new products and used to manufacture a container for colture hydroponic.

The mixture will be composed with 50% recycled Expanded Polystyrene and 50% virgin material.

The model of collection promote the recycling of Expanded Polystyrene box waste, from municipal segregated collection. The recovery will be organizing the systems of conferment so that the material can go from storage, from wholesaler and from point of sale to the recycler without intermediate phases.

The waste Expanded Polystyrene boxes will come back to company in a truck. In the company, they will be granulated to make new products or can also be mixed in with concrete.

These new materials make from recycling of Expanded Polystyrene box waste can be used in Sicily by company manufactured cement and concrete products and company manufactured hydroponic systems product .

6. Conclusion

Implement waste strategy can help develop new markets for recycled materials, and material to dispose, and it can guarantee the survive of another company, that can use it as raw material.

Therefore, the main objective of the new methodology is to employ the wastes in a new production thus to obtain an added value, an approach on the System Design: wastes (output) of a process can become the resources (input) of another one.

This new organization will be able to lead to: activate new production fields; new resources and new actors; to produce with zero impact.

These will become the starting points for the creation of an integrated system of local production that will bring returns and benefit to the territory .

DESIGN VISIONS PROPOSALS AND TOOLS

New Outputs policies and New connections

Reducing waste and adding value to outputs

Clara Ceppa[1], Cristian Campagnaro[2], Silvia Barbero[3], Franco Fassio[4]

Abstract

To solve the waste problem we could configure new networks among different companies in geographic proximity. This allows to establish relations that lead to zero emission by implementing a sustainable management of wastes.

If we have a design methodology that values the quality of the outputs, we need to make these potentialities concrete by providing a system with available resources and their possible users.

It deals with the design and establishment of a Database that can be consulted: this acquires and organizes the information about the outputs produced and the inputs required as resources, the manufacturers present in the community. The goal is to organize data into a system in order to create connections between outputs produced and inputs required.

1. Introduction

Industrial development has always been based on the intensive exploitation of natural resources; this violent aggression against nature has jeopardized precious resources that often are unrecoverable.

Water, air, soil, from which most of the indispensable resources for human survival derive, until not too long ago seemed to have no value and were exploited in the conviction and presumption that they would never be depleted. Now we must acknowledge the scarcity of these resources and plan ways to manage them more rationally.

In a similar context in the past few years two questions of social, economic and environmental significance have become ever more problematic: on the one hand we are witnessing the continuous rise in the price of raw materials and a strong demand on international markets for recyclable materials, while on the other hand we are producing more waste.

Though in daily life we make an effort to eliminate solid urban waste by differentiated collection, we are paying less attention to industrial waste. The latter is perceived as being far from our personal sphere, though the mass media reminds us of the growing importance of its impact and the proportions of the phenomena. And this does affect our daily life.

We could go so far as to consider waste an indicator of lifestyles or consumption habits of the society in which we live. It tells us what we consume, how much we consume, the way in which we consume it. This statement derives from a careful observation of the power of persuasion we are all subjected to everyday, through various media that exalt the equation according to which greater consumption favors a rise in one's well-being and social prestige.

Our attention to the real value of goods is clearly limited. We ignore its value when it is being used and after using it, even briefly, and we ignore its value after it is discarded.

We must wake up to the fact that the growing mass of waste generated by industrial activities is becoming increasing critical as much as it causes serious damage to human health and the environment.

Humans have recognized the problem too late and have tried to solve it downstream of the process of using the product. These actions that later proved to be inefficient.

This occurred because we have always thought of production processes as a sequence of actions, independent from one another, implemented to produce a commodity. Along with said commodity a huge amount of waste is produced. Said waste is considered an obvious result, along with the finished product, of the manufacturing process. And as such it is accepted.

In the current-day manufacturing model, the focus is exclusively on the product, though there is sometimes a targeted attempt to minimize the negative impacts of byproducts.

We must change this behavior. In a world that is ever more complex, like the world we inhabit today and will inhabit in the future, we must extend our gaze to the entire production process and see it in its entirety, i.e. not by single phases. We must deal with everything produced, products and waste, to start implementing targeted actions to achieve a substantial harmonization of the relationship between the environment and local communities.

This is one of the principles underlying systemic design: to think by connections allows us to see each anthropic process in a new light, and by viewing the entire system we can pursue the goal of zero emissions.

Production must be seen as a support to society and not as an end in itself. Therefore we need to seek out new ways of producing that guarantee remarkable results in social, ethical and environmental terms and lead to an improvement in the quality of life.

2. Aims

The purpose of this study, carried out by Disegno Industriale (Politecnico di Torino) in collaboration with ZERI (Zero Emission Research & Initiatives), Neosidea Group, Corep and eHORIZON s.p.a., is to propose an instrument for study and analysis based on the concept of an open system that would allow the configuration and realization of a new network of connections among different companies in geographic proximity. This would allow the establishment of relations for the purpose of achieving zero emission by implementing a sustainable management of the waste products of said companies. This would also earn them revenue from the sale of their outputs.

The goal is to build a network of know-how which, through true market mechanisms, would stimulate a reduction in all forms of waste and would help upgrade the remaining outputs by giving them a new economic and legislative value.

The new relations created between local companies in the community would minimize the use of external resources and provide more clarity in tracking the chains involved. This would help create strategies for potential additional instruments for territorial development.

This methodological principle totally changes the perspective for observing things: according to the first principle of systemic design the discards (OUTPUTS) of a process are used as resources (INPUT) for another manufacturing process.

The outputs are enriched with new value and become a resource available to be in the manufacture of new products closely associated with the local skills.

Therefore it becomes possible to create new manufacturing scenarios where the output of one company, a useless material to be eliminated incurring expenses only, can be reused to ensure the survival of another company related to the business category or physical location of the first company. The latter sees this output as a raw material to transform and add value to.

In order to avoid squandering and creating residues, even industrial activity must reflect on how way the Perfect System works: Nature. In Nature there is no such thing as waste because the substances eliminated by one species are used by other species for nourishment and even surpluses are metabolized by the System.

Nihil igitur fieri de nihilo posse. These are the words of Lucretius in “De Rerum Natura”, and express with artistic finesse the concept that nothing can be produced from nothing. Lucretius was ahead of his time because only several centuries later did humanity start understanding the concept summarized in the phrase “Nothing is created, nothing is destroyed”.

The balance that regulates systems and natural cycles has always respected this rule and has continuously “recycled” the outputs of natural processes to obtain a producing material from it. If Nature does not understand the concept of waste but only the concept of material transforming itself, humans can do the same with their processes of use and transformation of natural resources.

In this way the material continuously circulates and diversity ensures the capacity for recovery. In manufacturing this allows us to design open autopoietic systems that can sustain themselves.

New flows of material, which start as outputs, are valued as resources and create relationships for the first time between different companies that come together to reach a condition of reciprocal advantage by reusing the outputs of their production processes.

It comes natural to specify that we are facing not only an environmental issue but the unfolding of a new business model. Currently we are forced to spend huge amounts of money to treat and dispose of waste. The new methodology proposes that we add value to the discarded materials so we can eliminate waste disposal costs and create a network for marketing the outputs. This generates greater profits and creates jobs and wealth in the community by

spawning new entrepreneurial initiatives, developing businesses and improving the already existing businesses.

This process can be applied to any production sector. It is deliberately being proposed locally not only to appreciate local potentialities and specificities and reinforce the connection with tradition, but also to avoid transportation costs and the air pollution created by it.

By following these concepts of systemic design, the world of manufacturing, which today is truly lacking an environmentally mature culture, would succeed in achieving the goal of zero emissions.

3. Area of research

This study will focus not only on products but on production cycles with the intention to create a system that resembles Nature, where there is no concept of waste and even surpluses are metabolized by the system. Therefore the outputs of one production process can become the raw materials for other processes.

Enriched with new values the outputs become a resource and available to be used to produce goods and services, thereby favoring the birth of new local manufacturing activities.

In this sense all in industrial production must reduce the use of nonrenewable materials and evolve toward less energivorous processes, making uncontaminated outputs that can be reused for their qualities.

The availability of many new resources stimulates research to find new fields of application suited to the territory being examined.

In the case at hand the study area is Piedmont Region, and specifically each of its provinces where the major activities are associated with the sector of metalworking and textiles as well as agriculture and animal husbandry.

In this study area it was essential to determine which activities can be connected in an open production system with the goal of completely re-utilizing the outputs and achieve a zero emissions production system.

Along with this identification process, we also carefully analyzed the data on the MUD (Environmental Declaration Form) which reports the waste produced by economic activities, along with the waste collected by the municipalities and the waste treated and eliminated, sent to be recycled or transported during the year previous to the declaration. On this form the waste is divided according to industrial output, activity and category of waste, and the waste management activities conducted for each:

- waste management activities grouped by region;
- detailed data regarding the recycling activities of the aggregated waste by category;
- detailed data regarding waste treatment activities grouped by waste category.

The study of this information in relation to the activities for managing the waste produced by the major sectors on the Piedmontese territory shows that currently there is a large quantity (tens of thousands of tons per year) of material with abundant potentialities brought to the dump or destined to biological or chemical-physical treatments. Said treatments produce compounds or mixtures that are eliminated by scattering them on the soil or storing them in permanent storage locations. This not only prevents the possibility of exploiting the intrinsic richness of these materials more effectively but also squanders resources that can be used in other areas. Last but not least, this approach is potentially dangerous to the environment.

All of this is further demonstrated by the comparative data between the types of waste and the operations they undergo currently to recuperate material. The result is a huge amount of material, today seen as waste and not as a resource, used mainly as fuel or scattered on the soil

to benefit agriculture or the environment. However, this method fails to take into account that if the waste is contaminated it will contaminate the soil on which it is scattered.

Subsequently research is focusing on the study of the current use of manufacturing waste and in particular the different types of waste to identify which ones are already being recovered and which are being sent to the dump. This is being done to determine and categorize the different types of waste to be studied.

To prefigure the use of outputs as resources in a new process, the quantity and quality of the waste produced currently on the regional territory of Piedmont are carefully examined. Then they are categorized according to their chemical-physical and biological properties and their potential applications. This allows us to discover the optimal application of the ways, even through the use of available or innovative technologies, to bring revenue and benefits to the local economy.

As soon as we have a design methodology that realizes the potentialities associated with the quality of the outputs, we need to make these potentialities concrete by providing the system with the available resources and their possible users.

The results show the differences between the current production process having a linear structure and the new process that proposes an open industrial system based on a sequence: output quality> output reutilization> resources> profits. Moreover it indicates the significant advantages of the latter system.

Specifically we are dealing with the design and establishment of a Database that leads to the management of a databank that can be consulted. Initially the information about the outputs produced and the inputs required as resources is acquired and organized in terms of quantity, type, quality and geographical location on the territory. We also gather data regarding the manufacturers already present in the community. In the second phase we enter the processed data into a system for the purpose of creating new connections and relations between the outputs produced by certain companies and the inputs required by a production process.

In order to ensure maximum accessibility by all the entities involved, thereby favoring the creation of new relations, the system was designed and developed with Web 2.0 technologies and made available on an ad hoc web portal; graphic images about the type of local activities and type of waste products are elaborated and created in order to make easier the comprehension of the entire research.

The purpose is to create a new network of skills, know-how and relations amongst the various companies located on a given territory who can contact each other and establish a condition of reciprocal advantage by re-utilizing outputs.

All of this enables new resources to circulate continuously thanks to the creation of new local flows of material, generating positivity and profitability.

This research sets out to promote optimal forms of exploitation of the outputs which, after adding new values them, become available resources already present on the territory to other active local businesses.

Cleary this issue is not solely environmental but also affects economy. In fact enabling companies already active on the territory to reuse outputs, the relationship between local companies is reinforced, their earnings are increased and important new effects are engendered on the territory. This approach will weaken the current system of supplying resources that require procurement from sources outside the local territory and sometimes even from abroad.

It favors local development and provides new opportunities for feasible encounter, exchange and collaboration. This in turn establishes a direct and local relationship between the producers of outputs and the users of these outputs as inputs, i.e. as a resource in their own process.

To do this it is necessary to build short production chains that go beyond the common concept of “short chain”. These are better known as “direct sales”, which allow consumers to purchase foods directly from the producers, especially farm produce and meat products.

With the creation of a Database we are proposing that short chains be set up in the production sphere that allows operators to contact local companies to procure resources or set up operations to reuse outputs for the purpose of reinforcing the bond with the local territory.

According to this logic, the radius of action for the exchange of materials will not be greater than 45-50 km. This will reduce the time needed for procurement and the impacts of long-distance transportation.

The advantages of such an approach are both environmental and economic. Among them the most significant is the reduction of waste disposal costs and the consequent increase in profits a company earns from selling its own outputs. This also reduces environmental costs, i.e. energy consumption, pollution and traffic caused by the transportation of materials because it uses materials already existing locally and avoids exploiting virgin raw materials.

Nothing is lost because the reciprocal output>input process becomes evident and multiplies the business opportunities of the system which becomes ramified, dynamic and multi-polar. It values peculiarities, cultures and know-how and local resources minimize dependency on outside resources.

The Database would have three functions:

- producers of waste would be able to determine which local companies could use their outputs as resources in their production process;
- the Database could tell them which companies produce outputs that they can use as resources;
- the Database could also be an effective instrument for evaluating the entire production process and become an instrument for providing feedback.

This process can provide useful and effective information regarding the company's current production process. If you enter the type of waste produced by your company as a search criterion, and the Database gives no results for possible reutilization of your outputs, this means your current production process makes waste that cannot be reused or recycled. It means your company produces items by using inputs and processes that do not comply with the vision of an open system.

This sheds light on the need to make certain changes within the production chain and to reconsider the current inputs in favor of other ones that are more environmentally sustainable.

As regards the operative functions of the Database, in this document we would like to present two case studies. The first involves the identification of an output-input process in the cattle raising business; the second one involves a feedback process concerning the production of ball bearings. In both cases we show the differences and advantages (regarding the outputs and inputs, the reuse of the outputs, the new resources made available, the costs and profits) between the current process and the systemic process proposed. What is more important, we show the close relationship between the overhaul of flows entering and the possible construction of new relations aimed at the substantial limitation of harmful or unusable outputs.

We deliberately chose two sectors that are entirely different but which demonstrate that this method can be implemented in fields of application that are diametrically opposed: rural farming and the metalworking industry.

The first case study looks at the activities defined by the Ateco 2007 codes (classification of economic activities) in category A which includes agriculture, forestry and fishing. These are the most advantageous businesses for applying the systemic approach because these businesses annually produce approximately 68.000 tons of nonrecyclable waste on the Piedmontese territory alone.

In the preliminary phase, after establishing the business category of reference, we carefully analyzed the regional territory to create a detailed map of the entire Piedmontese area. Later we later concentrated specifically on each single province and municipality.

This allowed us to locate all the businesses present on a provincial and municipal scale and subdivide the territory into micro areas characterized by the type of production and type of waste products. Using this map we proposed the sustainable management of outputs by creating new networks of expertise in relationships among local companies.

Cattle: current situation

Taking into consideration a territorial setting with a radius of approximately 45-50 km including some municipalities of the Piedmontese provinces of Asti and Cuneo, we focused on the agribusiness sector of cattle raising, which uses intensive breeding. We analyzed the current phases of the chain, the incoming resources, the amounts and qualities of the waste products and final products.

Intensive breeding (factory farming) refers to a form of husbandry that uses industrial and scientific techniques to achieve the maximum quantity of product at the minimum cost by using minimum space for each single head of livestock. The study conducted on the various phases of the process, showed critical points in all the phases.

In the current situation the waste produced by this process is not reused and incurs disposal costs. In particular the water dirtied by milk is sent to a disposal plant which does not exploit its protein properties.

The same happens to the blood produced by the slaughtering phase, a substance that contains meat residues now stocked in dumps and not appreciated.

Moreover, though the cow manure is rich in nitrogen, and therefore harmful to the environment, it is spread on the soil as a fertilizer but it creates only negative effects.

Various critical point are therefore present at all levels of the chain and significant quantities of material are now sent to the dump or disposal operations which entail considerable economic loss and damage to the environment.

In conclusion, the final products of the current process are low-quality meat, milk and leather products.

Cattle: systemic vision application

Creating an open system means designing flows of material on the basis of which new companies relate with each other to achieve zero emissions production thanks to the sustainable management of their waste products.

Examining the chain and its complexity allowed us to find new opportunities which till now were unseen:

- the cow manure, as well as the sawdust of the stables, is exploited to produce biogas from which we obtain carbon dioxide, methane and sludge. The latter can be used as natural compost for local agriculture in both the Asti and Cuneo provinces. This brings benefits to a place where today the spread of livestock farming effluent is one of the main causes of soil pollution;
- the water containing milk residue (approximately 310.000 m^3 per year, of which 5% is milk), rich in nutritional properties, is not discarded but used as food for freshwater fish, e.g. tench, raised in companies located near the livestock farm of the case study;
- the slaughtering scraps and blood have protein and nitrogen properties that can be used as natural fertilizer for floriculture outdoors or in green houses. The meat residues (approximately 1.200 tons per year), after an appropriate treatment, can be used to raise the larva that are then used in the poultry raising business.

This renewed flow of products and materials shifts to focus to quality rather than quantity and it becomes vital to have an instrument for guidance and suggestions about the best forms of transfer.

To make waste “disappear” as a problem and cost we need to find, as shown in the case study above, users on the territory. Among the many users we need to choose the ones with the most compatible forms of production.

This way of thinking by connections also acts as a form of verification and activates retroactions on the process, sometimes concrete and radical turning points for production. In cases where a “natural” compatibility between output and input is not achieved, we are faced with the thing that humans call waste as well as the resulting economic, environmental and social costs incurred by such waste.

In this case the problem does not lie in the absence of “users”, but in the impossibility of finding them due to the nature of the raw material itself. The problem lies in the choice of the material and the lack of an overall vision of the process that goes beyond the central focus on the product and production. Unless we start by contemplating the raw materials, i.e. examining the nature of the inputs, the problem of waste will not be solvable except by artificial and costly actions.

To support this concept we would like to cite the case of NN Europe, a company of the American group NN Inc. which is a leader in the production of rolling ball bearings. Its production offers the market excellent quality ball bearings but entails significant problems essentially due to a linear vision of the process, closed to material exchanges with other manufacturers and opposed to technological innovations and transfers from other manufacturing sectors.

NN Europe

The most important issues found during manufacturing, and downstream of the manufacturing itself, involve the use of nonrenewable resources entering the company and production processes that are highly energivorous.

- The abrasive grinding wheels for the surface-finishing of ball bearings are produced with bakelite; in the production phase this thermo-hardening resin emits formaldehyde into the environment. Formaldehyde is a volatile substance that is carcinogenic if inhaled.
- Most manufacturing processes use nonrenewable mineral oils or solvents having a hydrocarbon base which cannot be accommodated by the environment. During the manufacturing process, these auxiliary liquids tend to emit vapors that are troublesome to workers and require specific (and costly!) air treatment processes.
- The traditional hardening processes are not very efficient; the ball bearings are heated in a furnace which involves the dispersion of energy and heat. In addition to this quenching process that occurs in vats of mineral oil which is nonrenewable and requires an additional washing processes.

The use of inputs from nonrenewable resources is a “premise” that is difficult to ignore and dramatically influences the outputs. They are nothing but an economic cost and an environmental problem because they are sent to be treated with special processes to “neutralize” them:

- the slimes with a solid base and water from the machining process are contaminated by mineral oil;
- the corn cobs used for drying the ball bearings are also contaminated by mineral oil and cannot be used as a resource;
- the kerosene, of hydrocarbon origin, is harmful and polluting;
- the same applies to the bakelite, which is equally harmful in the post-manufacturing phase.

Reduction to the point of total elimination of these waste products by conferring them as raw materials to specific manufacturers, in a sort of metabolization process, was not applicable because the nature of the raw materials did not allow it. The problem would not be solvable with

incremental improvements compatible with the current process but only through radical overhauls and a propensity for change.

With a systemic approach the research group discussed the product system as a whole, the inputs of materials and their flow, the techniques, the manufacturing phases and the energy consumption of each. All of this for NN Europe s.p.a. translated into its first goal: the challenge to produce in their own factory in Pinerolo (in the province of Turin) 16.000 tons of ball bearings without using auxiliary pollutant liquids.

We are talking about a significant reduction in the ecological impact of the company. The use of manufacturing inputs that are highly biodegradability, surface-active agents deriving from cornstarch and fatty acid from coconut, in a solution with water and sodium bicarbonate, perfectly replaced the hydrocarbon products that today are used in washing and lubricant-coolant processes.

“Sugar instead of oil” nicely sums up this suggestive innovation which is about to be launched into production. It is associated with the above-mentioned feedback operation enabled only through a systemic approach.

Observing natural phenomena, such as surface tension, allowed us to determine other forms of primary production, and use natural surface-acting agents to clean the ball bearings by surface tension. Later we used this method on other raw materials too.

We have looked at processes in Nature: their efficiency at ambient temperature and pressure, their capacity to induce the building of a system of symbiotic relations around them (mutuality, complementarity, subsidiary functions, etc.) by different species, their capacity to adapt their own “behaviors” to the specific context. Then we proceeded to search for natural alternatives to the other currently used raw materials that tend to further increase the environmental sustainability of the production process.

- The surface-finishing wheels can be produced with wood resins from the Ipe tree, a byproduct of the woodworking chain, just as strong and effective as bakelite but the resin does not pollute in the production phase and post-utilization treatment phases.
- The use of plant esters in the pressing phase will make it possible to eliminate the entirely mineral oil and prefigure new utilization phases downstream from their use in the company.
- “New” processes for induction hardening that are more efficient than the traditional furnace ones will use water for cooling instead of mineral oil; this leads to a reduction in the additional washing phases needed to eliminate the oil from the surface of the ball bearings.

Living systems in Nature are intimately connected to the environment by complex reciprocities that determine the continuous adaptation of one to the other. The systemic project, in conformity to this virtuous model, revitalizes the connections of the company with to own surroundings on the basis of the outputs it produces. Thinking by connections, which is typical of the systemic design approach, becomes the only feasible solution in the effort to solve the problem of waste.

In this sense raw materials, coming from nature, will facilitate their use as a resource even after they have become “waste” for the company that used them up to that moment. In Nature that which is damaging and not useful for some species is nourishment for other species. Thus the potentialities of nontoxic outputs become concrete in a value-adding “production chain”:

- the water used in manufacturing with a higher than average surface acting power will be treated through processes of phytopurification; precisely the characteristic which makes it unacceptable to be sent to the sewer allows the production of algae, water plants and the breeding of authoucthnous fish species;

- thanks to the elimination of the mineral oils, the corn cob for drying ball bearings will no longer be contaminated and can be used to cultivate certain mushroom species that are edible and have pharmaceutical uses. This method exploits the quantity of cellulose in the corn cob which today the company disposes of as waste;
- new and appropriate productive utilizations will be proposed for the high-quality steel scraps produced by machining surfaces, the elimination of which today is only a cost;
- grinding wheels made with wood resin have value added applications and have no negative effects on the environment.

4. Current legislation regarding waste

The scarcity of raw materials and the rising demand for recycled and recyclable materials trigger a process that tends to increasingly favor actions that upgrade the output materials. This necessarily surpasses the current best practices of waste treatment and recycling.

In this situation we have no choice but to find solutions to recycle waste in the most "profitable" way possible. In legislative terms there have been significant developments aiming to promote the complete recycling of waste.

The emergence of two new concepts, i.e. “sub product” and “secondary raw material”, reflects a clear effort to give legal autonomous dignity to the stuff that lies between "virgin" raw materials and actual waste.

In this sense Legislative Decree 16/01/08 No. 4 defines the term “sub-products” as the substances and materials which the manufacturer does not intend to get rid of, according to article 183, paragraph 1, letter a), and that:

- originate from a process not directly destined to their production;
- have a certain use, right from the production phase, that is integral and this usage occurs during the production or utilization process determined and defined a priori;
- meets the commodities and environmental quality requisites established to ensure that their usage does not cause emissions or environmental damage that is quantitatively or qualitatively different from that authorized for the plant where they are destined to be used;
- are not subjected to preliminary treatments or transformations to meet the commodities and environmental quality requisites mentioned under point 3, but have said requisites right from the production phase;
- have an economic market value.

“Secondary raw material” refers to all the substances and materials that meet the following criteria, requisites and conditions:

- they are produced by means of reutilization, recycling or salvaging operations;
- the origin, type and characteristics of the waste from which they can be produced is identified;
- the reutilization, recycling or salvaging operations that produce them are identified with particular reference to the procedures and conditions of those operations;
- there is a specification of the environmental quality criteria, commodities requisites and other conditions required for being put on the market, such as technical standards and regulations required for their use, taking into account the possible risk of damages to the environment or health deriving from the usage or transportation of the material, substance or secondary product;

- they have an actual economic trade value on the market.

However, in spite of the recent development in these terms, the current legislative scenario is not objectively favorable to concretizing open production systems for the total recycling of waste because the definition of waste provided by Legislative Decree No. 152 (2006), now replaced by Legislative Decree No. 16/01/08 no. 4, is “any substance falling under the categories listed in Appendix A which the holder gets rid of or has the intention or obligation to get rid of”. The aforementioned Appendix A is merely in an exemplification because the last category listed refers to “any substance, material or product that does not fall within the above categories”.

This definition is therefore based on the concept of disposal seen as an act of will or necessity that occurs when a company is unable to directly use that given ”thing” and therefore must eliminate it or sell it to another entity who can subject it to a treatment or recycling process.

Therefore we are putting forth an objective view of what defines waste, which will always be waste regardless of its final destination.

The principle of disposal has always given rise to a wide variety of opinions. The most natural has involved economics because the idea of waste is inevitably associated with the idea of its negative economic value.

How can we call “waste” an object that I get rid of if it has a market value, i.e. a positive value for which we can find persons and entities interested in purchasing it?

For years it has been said that the economic value is not important and that the definition should be taken to the letter, regardless of the contingent conditions.

In any event the problem of defining the concept of "waste" is finding an acceptable compromise between the two contrasting needs: the need for environmental protection which rightly makes us afraid that "disposal" without adequate regulations will lead to dispersion in the environment at the lowest possible cost; the need to not hinder the recovery and circulation of recyclable materials.

What is really lacking in the current legislation is precisely the "regulatory" acknowledgment of the existence or the possible realization of open systems or chains in which the flow of materials, understood as waste, would be considered holistic.

Each chain should be seen in its entirety and not as single phase independent of each other. From this perspective the so-called waste could move with a new sense of positivity and a certain dignity.

If each chain, as we are defining it here, and its components were registered and incentives were offered for their development it would become the interest of the chain operators to make the system work properly and productively.

5. Greatest innovations

The greatest innovation offered by this approach and the Database, besides its instrumental value, is its ability to open the minds of producers and make them aware that:

The problem of waste “disappears” if:

- complex relations are set up in which they can become the nodes of a network along which skills, know-how, well-being, matter (materials) and energy can transit;
- an overhaul is made of everything that occurs upstream of the waste without delegating responsibility to other operators;
- a remedy is brought to legislative terminology and instruments which are inadequate for building open production systems.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Designing transition paths for the diffusion of sustainable system innovations

A new potential role for design in transition management?

Carlo Vezzoli[1], Fabrizio Ceschin[2] and René Kemp[3] [4]

Abstract

It is a shared opinion that the transition towards sustainability will be a continuous and articulated learning process, which will require radical changes on multiple levels (social, cultural, institutional and technological). It is also shared that, given the nature and the dimension of those changes, a system discontinuity is needed, and that therefore it is necessary to act on a system innovation level. The challenge now is to understand how it is possible to facilitate and support the introduction and diffusion of such innovations.

Bringing together insights from both *Design for sustainability* and *Transition management* literatures, the paper puts forward a model, called *Transition model of evolutionary co-design for sustainable (product-service) system innovations*, aimed at facilitating and speed-up the process of designing, experimentation, niche introduction and branching of sustainable such innovations.

[4] The paper is the result of a collaboration between the three authors; nevertheless Vezzoli wrote chapter 3 and 5 and paragraphs “Objectives and background assumption of the model” and “Evolutionary stakeholder system maps: a new tool” in chapter 4; Ceschin wrote paragraph “Characteristics of the model”, “Phases in the evolutionary transition path” and “What the model aims at” in chapter 4; Kemp wrote chapters 1 and 2.

1. Introduction

It is a shared opinion that the transition towards sustainability will be a continuous and articulated learning process, which will require radical changes, on multiple levels: social, cultural, institutional and technological. It is also shared that, given the nature and the dimension of the required change, a system discontinuity is needed, and therefore it is necessary to act on a system innovation level.

Assumed that sustainability requires radical innovations in order to operate a system discontinuity, the problem is to understand how these innovations could have place and re-orient the dominant socio-technical regime. Therefore it is clear that it is fundamental not only to hypothesize and design promising system innovation concepts, but also to identify in a strategic way a transition path to facilitate the experimentation, niche introduction and scaling-up of such innovations.

In this paper we delineate a model of *evolutionary* co-design for product service system (PSS) innovations to fulfill needs in a more sustainable way. The paper discusses the potential contribution that System Design for Sustainability can have in creating sustainable system innovations. It outlines the key steps of a possible model of transition, describing how to involve the appropriate stakeholders (universities, public institutions, companies, NGO, user, etc.). how to set the basis for the development of a pilot project (to test and learn), and how to evolve this niche experiment in a self standing and replicable sustainable innovation.

From the discussion a new role for design emerges. A role that may potentially opens new fields of activity alongside the consolidated ones. A role in which design is not only aimed at designing a product sevice system but it is also aimed at promoting, facilitating and setting the conditions for the introduction of that product service system through the strategic definition of the key steps of the evolutionary transition path.

2. System innovation and transition management

Sustainable development is a complex concept, dealing with different temporal and spatial scales and with multiple stakeholders (Martens, 2006). It indicates a process of changes whereby the development goal is not clearly outlined and is subject to changes throughout the process. (van Zeijl et al. 2008). Reduced environmental impacts is one element. This may be achieved through green products and greener production processes. Reduced impacts may also be achieved by system innovations, i.e. transformations changes in systems of provision and behaviour (Weaver et al. 2000; Rotmans et al. 2000; Smith et al. 2004). Examples of system innovation are: the hydrogen economy, industrial ecology and customised mobility.

System innovation cannot be designed in a top-down fashion because system innovations are the outcome of co-evolution processes. New knowledge is being created, new institutions and associations emerge out of processes of sociotechnical aligment. Various designs are explored and get perfected, some of which are abandoned. We have problem sequences and response strategies. System innovations involve various elements and processes, each of which is feeding on the other. There is an element of self-organisation: structure emerges out of interaction. For managing transitions processes the model of transition management has been proposed (Rotmans et al. 2001; Kemp et al. 2007). Transition management is a form of process management against a set of goals set by society whose problem-solving capabilities are mobilized and translated into a transition programme, which is legitimized through the political process (Kemp et al. 2005). Transition management relies on the interaction between processes at three levels (Loorbach 2007):

- *Strategic level:* processes of vision development, strategic discussions, long term goal formulation, etc.

- *Tactical level:* processes of agenda-building, negotiating, networking, coalition building, etc.
- *Operational level:* processes of experimenting, project building, implementation, etc.

The processes and outputs of the processes differ at each level (visions, strategies, agenda's, projects) and 'co-evolve' throughout the process. Through a process of partisan mutual adaptation against collectively chosen goals new interaction patterns, policies and socio-technical trajectories emerge, in a self-organised manner rather than through steering from the top. Sustainability concerns are expressed as part of the process. It is used in the Netherlands for managing the transition to sustainable energy, sustainable mobility, sustainable agriculture, sustainable water use and the biodiversity and natural resource transition.

Transition management breaks with the old planning-and-implementation model aimed at achieving particular outcomes. It is based on a different, more process-oriented philosophy. This helps to deal with complexity and uncertainty in a constructive way.

It is a model for working towards comprehensive changes in society, in an adaptive, forward-looking way, relying on processes of variation-selection-retention. It is not a model for managers who want to successfully manage an innovation process. But as we will show, elements of the model can be used for managing sustainable product-service system innovations.

3. (Product-Service) System innovation and design: the new research challenge

It has been argued above that if we assume sustainability seriously, we need radical innovations in the consumption and production system, and so a system discontinuity is required. Therefore, in order to seriously tackle the transition towards sustainability, system innovations should take place.

Within the wide debate on the definition of system innovation, design researchers have usually referred to the so called Product-Service System. Among the several converging definitions the one given by the United Nations Environment Programme (UNEP 2002) says that a system innovation (referred to as Product-Service System, PSS), is "the result of an innovative strategy that shifts the centre of business from the design and sale of (physical) products alone, to the offer of product and service systems that are together able to satisfy a particular demand". Even though the definition might differ from author to author (or from discipline to discipline), we can agree that we are talking about something broader than just product innovation, and so that it is not only a matter of technological innovation, but socio-cultural and organisational one as well. So when we talk about (product-service) system innovation, it is meant an innovation that involves all the different socio-economic stakeholders in a "satisfaction system". In this sense we mean that it is adopted a satisfactory approach, where the focus is no longer the function delivered by a single product, but on the system of products and services (and related stakeholders) that together fulfill a given demand of needs and desires: in fact a given demand for satisfaction. In other words the design reference has no more to be the "functional" unit but the "satisfactional" unit[5].

About (product-service) system innovation and sustainability, it is a shared opinion that these innovations could potentially lead "to a system minimization of resources, as a consequence of

[5] The use of this terminology meets with other authors' interest. Meadows (Meadows, Meadows and Randers, 2006) uses satisfaction in a formula5 to evaluate the limits of growth, in a 30-year update of the previous book known worldwide, "Limits to Growth", modelling the consequences of a rapidly growing world population and finite resource supplies, commissioned by the *Club of Rome*. Marks et al. (Marks et al. 2006) argues that among various indicators measuring personal well-being in the framework of transition towards sustainability, satisfaction seems to be preferable.

innovative stakeholder interactions and related converging economic interests" (UNEP 2002). In other words the potential eco-efficiency of system innovations derives from a new convergence of interest between the different stakeholders: innovation not only at a product (or semi-finished) level, but above all as new forms of interaction/partnership between different stakeholders, belonging to a particular value chain, or "value constellation" (Normann and Ramirez 1995). In other terms, this innovation model can raise the system eco-efficiency through innovative stakeholders' interactions.

In this perspective by both design researchers and transition management theorists a significant ambit in which to act to promote radical changes for sustainable consumption and production, is the widening possibilities for innovation beyond the product, towards innovation of the system as an integrated mix of products and services (and related supporting stakeholders) that together lead to the satisfaction of a given demand for well-being (Goedkoop et al. 1999; Brezet 2001; Charter and Tischner 2001; Manzini and Vezzoli 2001; Bijma, Stuts and Silvester 2001).

In this framework, what role for design? The introduction of system innovation for eco-efficiency into design has led researchers to work on defining new skills of a more strategic nature, that aim at system eco-efficiency through the stakeholders' strategic convergence of interests, and are coherent with the "satisfaction-based", "multi-life-cycle" perspective. In synthesis, the main characteristics of the system design for eco-efficiency approach are: a satisfactory approach (demand-satisfaction design); a stakeholder interaction approach (stakeholder's configuration design); and a system eco-efficiency approach (ecoefficient-oriented design). In this perspective design activity should focus on (Vezzoli 2007):

- promoting and facilitating new configurations (partnership/interaction) between different stakeholders, to find innovative solutions able to lead to a convergence of economic, social and environmental interests;
- facilitating a participatory design process among all the stakeholders while developing environmentally sustainable products and services together;
- orientating the design process towards eco-efficient solutions.

It has to be underlined that not every (product service) system innovation is eco-efficient (Tukker and Tishner 2006), and therefore it is of key importance to adopt appropriate methods and tools when designing new systems (with the potentialities to be radically sustainable)[6].

At the present time it is possible to state that the concept of (product-service) system innovation has been deeply studied at the academical level, and in the last years knowledge has been produced, accumulated and shared on understanding system innovation's characteristics, potential benefits (for companies, government, society, users and environment), barriers to adopting it, possible rebound effects, etc. In particular, in relation with the design of (product-service) system innovations, we can say that, within the researchers community, different methodologies and tools have been developed (and tested) to orient and support the design process towards the definition of sustainable system innovation concepts.

But to all this knowledge developed at the academical level corresponds a limited application of sustainable (product-service) system innovations by companies. In this sense several barriers can be identified (UNEP 2002; Mont 2002): for the user the cultural shift necessary in accepting a ownerless consumption; for companies the difficult in implementing the substantial changes required in corporate culture and organisation to support a service-oriented business, the

[6] The first design methods and tools that have been recently developed as outcomes of some European projects of the 5th Framework Programme, are PROSECCO (Product & Service Co-Design process), HiCS - Highly Costumerized Solutions (Manzini, Collina and Evans 2004), and MEPSS - Method for PSS development (van Halen, Vezzoli and Wimmer 2005).

resistance in changing the traditional business concept, the lack of knowledge and experience in design methods and tools and service management systems, and the difficult in evaluating the environmental and social features of a (product-service) system innovation; for governamental institutions the difficult in defining and implementing policies to facilitate the companies' adoption of system innovations.

For these reasons it is possible to state that now the research challenge is to understand which could be the proper conditions to: foster the adoption and dissemination of sustainable (product-service) system innovations, foster the knowledge transfer from university research centres to companies, and foster the involvement of the other key stakeholders in supporting these processes.

In this perspective it seems promising to view PSS as the co-design of a radical innovation, but even as transition path to achieve it. Key point is to introduce a process-oriented design, rather than a traditional design-and-implementation approach.

Within this context universities could potentially play an important role. In particular for design universities a field of action could be the involvement of key stakeholders in order to facilitate the ideation of promising and sustainable system innovation concepts, and in order to define new strategies and modalities to accelerate the experimentation of such innovations and foster their introduction in the "real world". In this sense universities can represent the pivotal actor in starting out a transition process, facilitating the strategic conversation between the different socio-economical stakeholders and the community, and facilitating a continuous learning process between them. A model, in which university could become a "facilitator" in starting out and accelerating a partecipated process for the introduction and dissemination of sustainable system innovations, is presented below, integrating objectives and approach of the *Transition management* theory[7].

4. A transition path of evolutionary co-design for sustainable system innovations diffusion

Design and system Innovation for Sustainability (DIS) research unit (Politecnico di Milano – INDACO Department), is currently working on some research projects (for example the *VDS*[8] project and the *University chair for innovation*[9] project), in which the aim is to design a sustainable system innovation concept, together with the strategy for its introduction and subsequent scaling-up, or better still branching.

Within these project has emerged a draft model, called *Transition path of evolutionary co-design for sustainable system innovations diffusion*, aimed at facilitating the designing, experimentation, introduction and branching of sustainable system innovations. It is based on the *Transition management for sustainable consumption and production* model, and at the present time represents a first draft, a work in progress. Nevertheless it is currently tested in the previously mentioned projects, in order to understand its feasibility, strenghts and weaknesses.

We are aware that there is the need for further reaserch and the need to realize field tests; however it has been likewise decided to present the intermediate results to the scientific community, with the intention to start out and stimulate a constructive dialogue and discussion.

---

[7] We are talking of the *Transition management for sustainable consumption and production* model, developed in the Netherlands by Rotmans, Loorbach and Kemp (see Kemp et al. 1998, 2001, 2004, 2006)

[8] The Vehicle Design Summit (VDS) project, run by an international Consortium of Universities coordinated by the Massachusetts Institute of Technology (MIT) of Boston, aims at designing, prototyping and producing an eco-efficient vehicle as well as defining an innovative and sustainable business model to introduce and diffuse it into the market. It will be described later in the paper.

[9] Within this research project (run under the UNIDO's umbrella), the role of DIS research unit is to cooperate with some African universities (Universitè Polytechnique De Bobo-Dioulasso, University of Zambia and University of Lagos), in order to design and introduce sustainable mobility solutions for local low-income contexts (see Vezzoli and Ceschin 2008).

Objectives and backgroung assumptions of the model

The main objective of the model is to support, orient and facilitate the development of the conditions for the experimentation, niche introduction and branching of sustainable system innovation concepts, with university research context as starting point.

In other words the model aims at fostering a transition process towards the adoption, dissemination and continuous development of sustainable system innovations.

As it has been pointed out before, system innovations require changes on multiple levels (social, cultural, institutional and technological), and in this sense they can be considered radical innovations. For this reason, when talking about (product-service) system innovations, it is proposed to imagine such innovations not only as static outcome of a design and development process, but it is necessary (first background assumption), within a transition paths to be designed and managed, facilitate and support the introduction and subsequent branching of such innovations.

It is called evolutionary process because it aims at diffusing new “mutation” in the system as a result of the environmental feedbacks reinforcing them, to substitute existing un-sustainable system of production and consumption. The words design and management are added to emphasize that these are not casual mutations, but oriented by the sustainability goals. And these casual mutations are designed and managed in the sense that they draft possible paths to be pro-active, hence speeding up the evolutionary process (that in nature, we know, has its foundation in long time processes).

It is also assumed (second background assumption), that university may represent a possible pivotal actor within that transition process. In this sense they can potentially act facilitating the starting out of this process, orienting it towards sustainability, involving different socio-economical actors and favouring a continuos knowledge exchange. In this sense university could represent the promoter of innovative stakeholder arena (and their interactions), and the facilitator in starting-out and orienting a multi-stakeholders process aimed at designing, introducing and branching sustainale system innovations.

To be more clear university could assume a strong role in the first part of the process (starting-out and orienting), and then could “pass the baton” to the socio-economical actors which in future could become the providers and the users/beneficiaries of the (product-service) system innovation. And so a university that activates the other actors of the system in an increasing involvement: in the beginning they only give feed-backs; then their role become central with universities giving support; and later they become autonomous in realizing and scalin-ug the product-service system concepts.

Characteristics of the model

What are the characteristics of the elaborated model of evolutionary transition path? The model can be defined as a *strategic orientation* and *adaptation* of the steps that, starting from an university research context and through a continuos and iterative multi-stakeholder learning process, brings to the experimentation, niche introduction and scaling-up/branching of sustainable system innovation concepts.

To be more clear, first of all we can say that this is a transition path which is co-elaborated and adapted by a plurality of actors (universities, research centers, public and private companies, NGOs, governamental institutions, community, etc.), and in which university acts as “promoter” and “facilitator”, assuming a key role in the first part of the path, and passing the witness to other socio-economical stakeholders in the second part of it.

Secondly, it has to be remarked that we are dealing with a process of continued learning (for the involved actors), because the transition path is based on continuous experimentations and consequent feed-back processes.

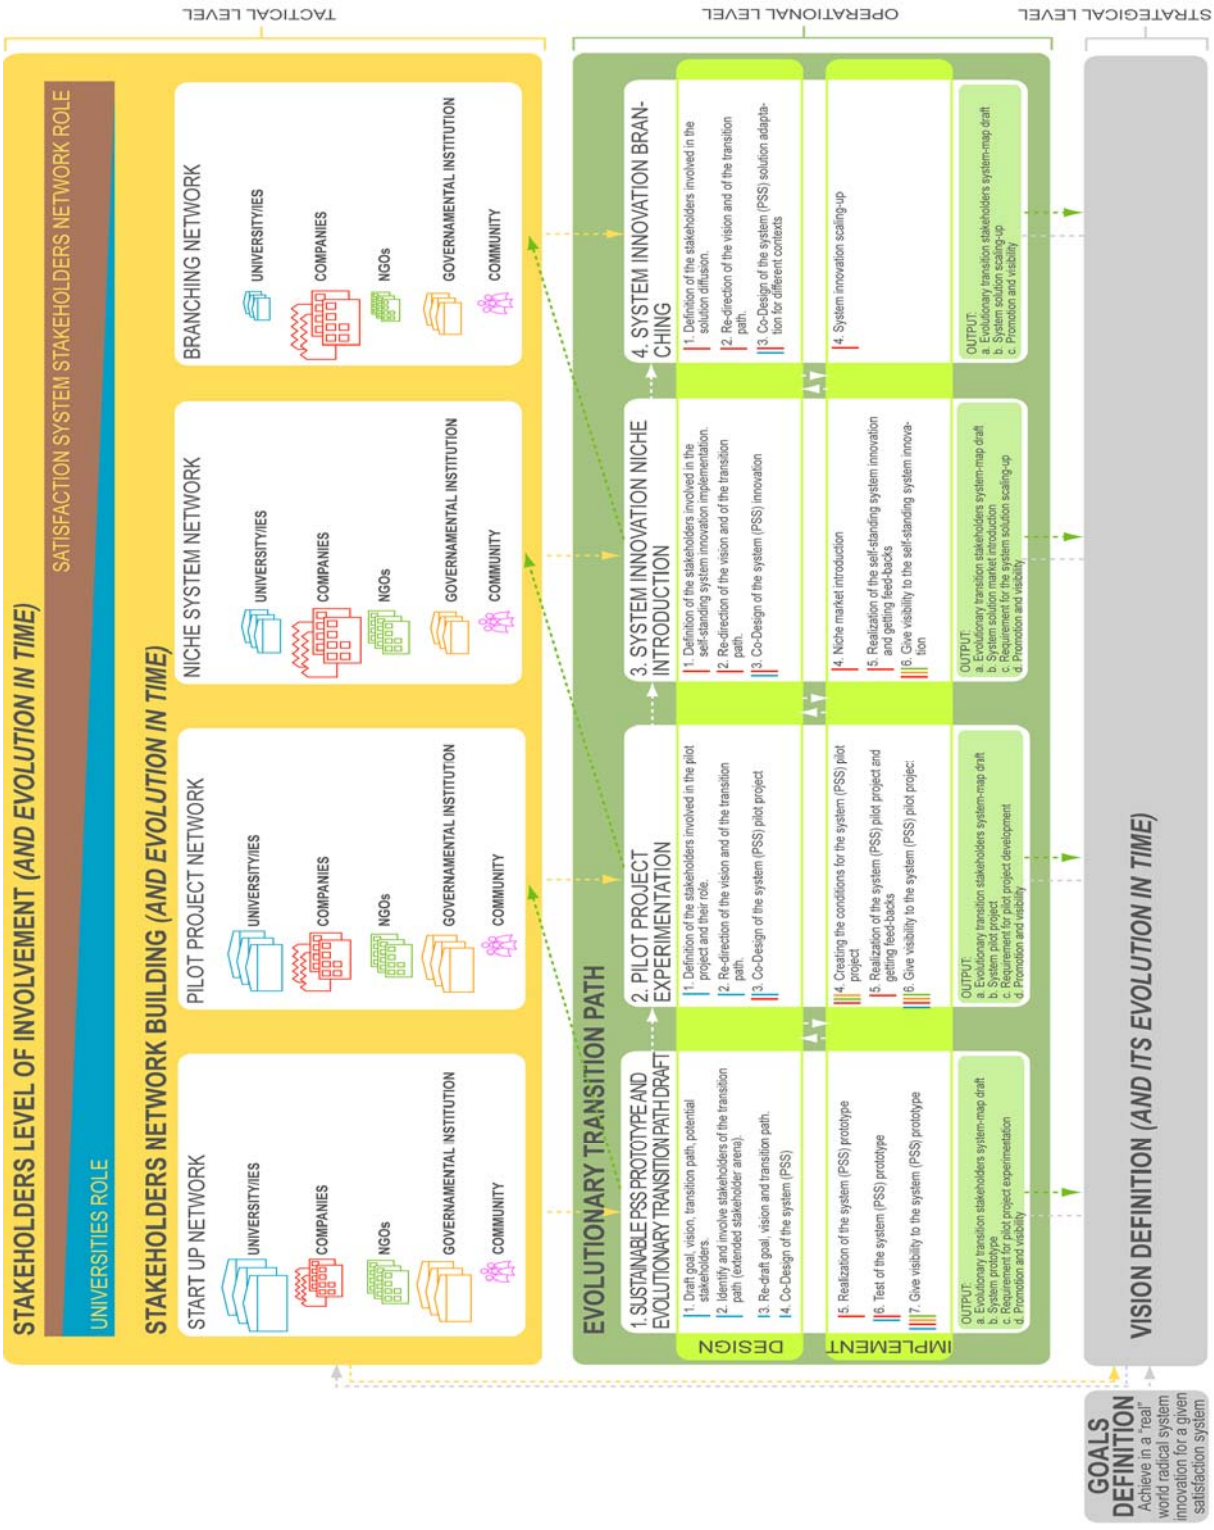

Fig. 1: the transition path of evolutionary co-design for sustainable product service system innovations, in which are illustrated the four transition phases and the stakeholders network evolution needed to carry out each single phase.

Moreover it is a process of *strategic orientation*, in the sense that the transition path is based on the definition of goals (to be achieved), and on the consequent building-up of a vision (of how to achieve these goals); this means that the steps of the transition path are oriented to the achievement of the defined goals, and are affected by the built vision.

Furthermore we are dealing with a process of *adaptation*, just because the transition path is based on a continuous learning; this implies that the vision can be adapted and modified in time (in relation to the context and/or stakeholders evolution), and consequently the same can happen for the single steps of the transition path. Moreover the entire transition path can be defined as a process of mutual-adaptation between the proposed system innovation and the context -or socio-technical regime- inside which such innovation has to be experimented and introduced; in fact both the context and the proposed system innovation evolve and affect each other.

For these reasons the transition model can be defined an “evolutionary” process, because it is characterized by a continuos evolution and adaptation of the transition path, but also of the proposed system innovation, and of the involved socio-economical actors. More precisely we are dealing with a *controlled* and *accelerated* “evolutionary” process, in the sense that the proper conditions to facilitate and speed-up this process are designed and created. And for proper conditions it is meant the conditions by which the involved actors can: collect in an effective way all the feed-backs coming from the experimentations; analyse these feed-backs; and use it for a system improvement. In this perspective it clearly becomes foundamental the setting-up and development of an appropriate stakeholders network, capable to adapt itself in time to better collect and analyse feedbacks (and in general to support the different steps of the transition path).

In synthesis, the model of “evolutionary” transition path (see fig. 1), is based on the definition of goals and the building-up of a vision, which includes the drafting of the stakeholders’ interactions evolution in time; the vision effects the steps of the transition and the stakeholders network configuration needed to carry out each single step; in turn the transition steps influence the vision definition and the stakeholders network building (in a continuous iterative process).

Phases in the “evolutionary” transition path

Seeking for clarity, in the model of “evolutionary” transition path it is possible to identify four main phases. It has to be remarked that the transition path, although being described as linear, in reality is an iterative process, with continued feedbacks; moreover the various steps are not distinctly separeted but overlaps each others. Nevertheless the four conceptualized phases are:

- *Sustainable system innovation prototype and evolutionary transition path draft.* As said before university plays a key role in this phase, representing the promoter and the facilitator. In fact, starting from a given satisfaction system (e.g. urban people mobility), university drafts goals, visions and transition path with relative potential stakeholders. Afterwards it fosters the building-up of a first stakeholders network (including research centers, companies, NGOs, institutions, media, the community etc.), which, in a partecipated process, develops and modifies the previously proposed visions and transition path. Starting from the implemented vision, a co-design process is carried out to define promising sustainable system innovations; the most promising ones are then prototyped and tested. At the same time the network acts in order to give visibility to the project and to the prototype.
- *Pilot project experimentations.* Starting from the results of the previous phase, the stakeholders network (which meanwhile has been adapted and/or integrated, and in which there is a lower university involvement), re-defines and re-directs the previously elaborated visions and transition path. Afterwards the network co-designs, realizes and controls one or more pilot projects, that are socio-technical experimentations to test the system innovation concept. The aim is to facilitate the learning of all the involved actors, in relation to the weaknesses, strenghts, barriers, cultural, political and economical acceptability, etc. of a possible market introduction of such innovation. These experimentations represent a continuous iterative learning process, involving with different roles all the stakeholders in: setting the conditions for the pilot project realization; analysing the pilot project experimentation results; and proposing modifies and integrations. In other words it is a process of feedbacks that may lead to the

adaptation and adjustment not only of the pilot projects characteristics but also of the vision. Moreover these pilot projects could represent an optimum “window” because of its potential to show sustainable innovations ideas to wider communities. In this sense they could be used not only for experiment ideas, but also for attracting new potential interested actors.

- *System innovation niche introduction.* What has been learnt during the experimentations should brought to the adjustment of the characteristics of the (product-service) system innovation, and to the definition of the modalities by which it can become economically sustainable and self-standing. In this sense the most promising pilot projects are selected, implemented and introduced into the market.
- *System innovation branching.* If the market introduction has been positive, it could become a model that can be replicated, imitated, adapted, developed and integrated. In other words it can be scaled-up and potentially contribute in destabilizing and re-orienting the dominant socio-technical regime. It has to be underlined that until the third phase the key actors could remain substantially the same (with an increasing role for companies and a lower university involvement); on the contrary in the fourth phase totally new actors could have a part in autonomously adopting, adapting, replicating and developing the system innovation concept.

As said before the transition path is described as it were linear, but it is important to underline that a cyclical and iterative process takes place. The cycical character of the transition is illustrated in fig. 2, in which are represented the continuous repetition of four main activities (Kemp 2006): establishing and further development of a transition arena (A); development of sustainability visions (B); initiation and execution of projects and transition-experiments (C); Evaluation and monitoring of the transition process (D).

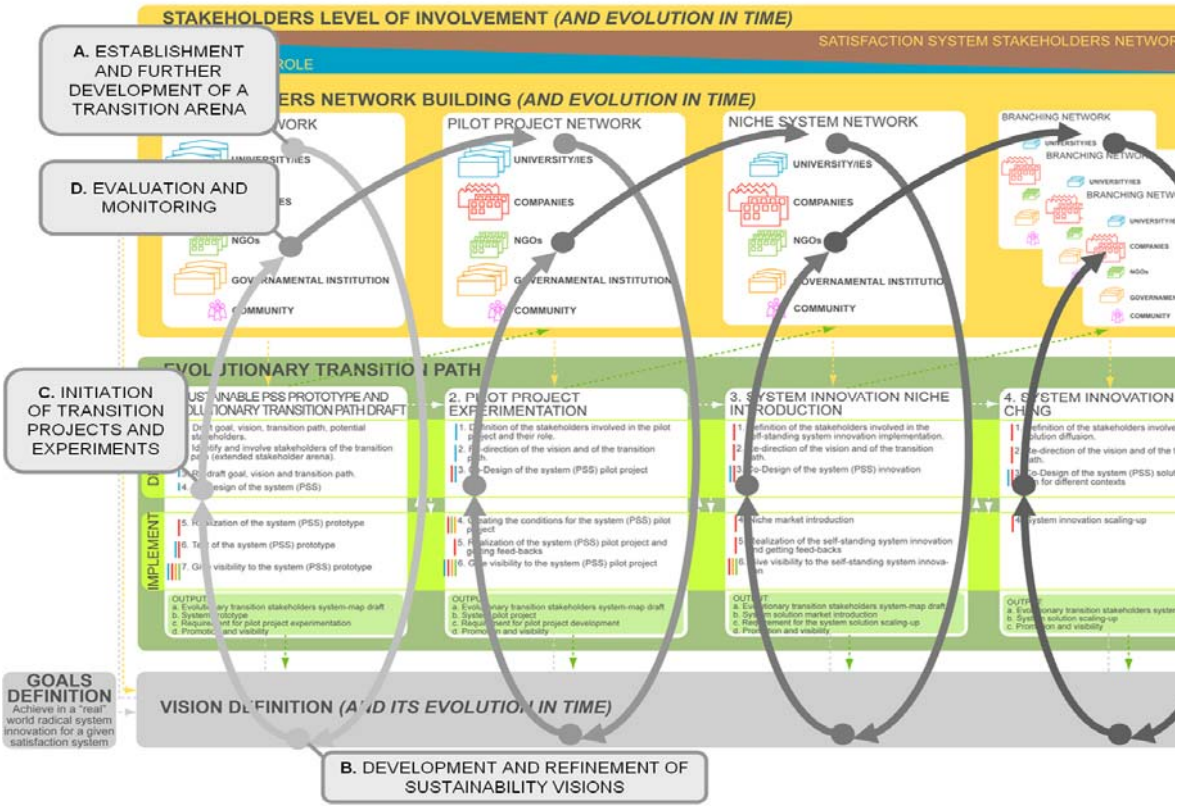

Fig. 2: the cyclical character of the transition path.

Moreover it is important to highlight that in the described transition model we took in consideration a process in which, besides universities, companies assume a key and foundamental role along the entire path. But this is not the only possible way. We can also imagine bottom-up innovations that start from self-managed groups of people –the so called creative communities (Meroni 2007)– and then are implemented, replicated and scaled up by other groups of people; or in alternative these innovations can likewise starts from a particular creative community, but then are developed, industrialised and branched by companies. However in any of these cases university can act as facilitator and promoter.

“Evolutionary” stakeholders system maps: a new tool

It is quite obviuos that, in the previously described transition process, it is very important a multi-stakeholder and multi-disciplinary approach. Therefore the identification of the stakeholders (and of their roles, motivation and mutual interactions), is a fundamental aspect in setting the proper conditions to support this process. In other words it is vital the creation of a network made up of different socio-economical stakeholders. In general terms we can have:

- *Universities,* because, as it has been explained before, they could represent the promoter and facilitator of the process.
- *Companies,* because they can provide technical feed-backs, competences and financial resources; they are interested in participating because there could be the opportunity of a new market, for a possible reputation comeback, or for acquiring new know-how.
- *Local Administrations and Institutions,* because they can provide financial resources or facilitations; they are interested in being part of the process if the system innovation concept is coherent with their objectives.
- *NGOs,* because they can support and create interests around the project; they are interested in participating if the system innovation concept is coherent with their values.
- *Media,* because they have to create interest around the project.
- *Users,* because of course they are fundamental in testing and experimenting the system innovation.

All these actors take part (with different roles and levels of involvement), in a process of co-production of knowledge and co-definition of the transition path. Nevertheless it is important to remark that the stakeholders involvement is not an action that starts and ends in the beginning of the process, but is a continuous and iterative activity along the entire transition process. This means that there is the need to define not only which actors include but also when involve them (in which phase of the transition process), and at what kind of level they have to be involved.

In other words we are dealing with a stakeholders network which is not static, but dynamic, because the actors and also the related interactions could deeply change along the path. A network that has to be capable to evolve in time in relation to the specific needs. And it has to be underlined that this evolution represents an important and fundamental element of the entire transition path. Element that represents itself a design activity.

If we can use a metaphor we can say that it is a sort of relay race in which we have several “baton passages” between different stakeholders networks. And to cross the finishing line more quickly (as the sustainability challenge requires), different actors/runners have to use their energies, each for its piece of path. A common path in which the first actors/runners have to know to which actors pass the baton, as well the second actors/runners have to know which are the third ones, and so on until the achievement of the goal. In this sense, in order to speed up the process, it becomes foundamental forsee which potential actors could be involved and have a part in each phase. And in this strategic anticipation a key role could be played by design.

In fact what is new here is the proposal to design, together with the draft of the transion path, the evolutionary stakeholders system map (ESSM), that is the potential stakeholders network, and its evolution in time, needed to carry out the transition path. And this ESSM represents itself a new tool to be used to forsee the appropriate stakeholders to be increasingly involved, and to facilitate the strategic conversation with them. In this sense the tool can be used in the beginning of the process by universities (that it is assumed to be the promoter of the process), to draft the transition steps and the potential stakeholders to be involved. In other words it is used to draft a first vision of how the transition path could be and which actors involve; and this vision could result fundamental in stimulating a first discussion with the potential stakeholders to be involved. In this sense the model is also a tool to start and facilitate the strategic conversation with other actors, and to build-up a shared vision.

What the model aims at

It has been already said that the main objective of the model is to orient and facilitate the development of the conditions for the experimentation, niche introduction and scaling-up of sustainable system innovation concepts, starting from a university research context. So, in general terms, the model aims at supporting a complex process by facilitating multi-stakehoders activities towards the achievement of a shared vision. In other words it is a methodological framework by which facilitate, foster and orient such transition processes.

In particular the model helps to define which key general actions have to be carried-out in the various transition phases, in relation to the system design activities and the system implementation activities (see fig. 1). It helps in defining the activities that have to be done but also the actors that potentially could manage each single activities. In other words the model facilitates the setting-up of a flexible stakeholders network to support the accomplishment of each single phase.

Before it has been underlined the importance of involving various socio-economical stakeholders, and that this can be considered a design activity. In this sense the model can facilitate the design process towards the definition, integration and adaptation in time of a system of multiple actors, identifying the proper stakeholders, understanding and converging together their motivations, defining their roles, mutual relationships and levels of involvement. In synthesis the model supports the stakeholder network definition and its continuous evolution in time.

Moreover the model fosters the adoption of an anticipative, cyclical and iterative approach (the previously mentioned cyclical character of the transition), based on continuous experimentations, feedbacks collection and analysis, and system improvements. In this sense it facilitates a continuous learning process and knowledge exchange between the various stakeholders involved.

Finally the model represents a methodological framework that allows the use of other design tools and method in a coordinated way. Tools such as the *Design Plan Tool-box* (Jégou, Manzini and Meroni 2004), to help different stakeholders in communicating and developing solutions together, and *the Sustainability Design Orienting (SDO) tool-kit* (Vezzoli and Tishner 2005), to orient the design process towards the definition of sustainable solutions; methods such as the *Scenario building* (Manzini and Jégou 2004), to facilitate the generation of shared visions. In this sense the model facilitates an integrated and coordinated use of these tools, supporting co-design processes aiming at accelerating the stakeholders adoption of new and sustainable production and consumption patterns.

As said in the beginning of the section we are aware that this model represents a first semplified version. Nevertheless it is currently tested in some research projects, for example the Vehicle Design Summit (VDS) one, run by an international Consortium of universities coordinated by the Massachusetts Institute of Technology (MIT) of Boston. The Consortium’s goal is to design and realize a low environmental impact vehicle as well as the definition of the conditions for its

introduction into the market (firstly the Indian one), through innovative and radical sustainable "mobility offers". The final aim is to influence and re-orient the whole automotive sector towards the adoption of radically more sustainable offer modalities and consequent production strategies. In this framework Politecnico di Milano work team[10] designed an innovative and eco-efficient business model[11], and delineated, using the previously mentioned model, a promising transition path to introduce and diffuse this model into the market. At the present time the produced results are now used by other work teams to select and involve the potential stakeholders to test and implement the proposed system innovation concept.

Of course the model needs to be developed and detailed, and in this sense it will be tested in further researches. At the same time we believe it was already worthwise to put it to the attention of the scientific community to open-up a debate, we hope, fruitfull of interesting results.

5. Conclusions: a new potential role for design in transition management?

At this point a proper question could be: which role could be played by design and design university in transition management?

Before it has been underlined the importance of adopting a general design attitude to pursuit (product-service) system innovation. In this sense design could result strategic not only in the definition of the system innovation characteristics, but also in drafting and adapting in time the stakeholders networks, in order to set the basis for the introduction and proliferation of that kind of innovations.

In other words design could play a key role not only in orienting and supporting the design process towards the definition of environmental and socio-ethical sustainable system innovation concepts, but also in designing the proper conditions to foster and speed-up the experimentation, niche introduction and branching of such innovations, through the design of innovative stakeholders' interactions, and their evolution in time. In this sense design could act as "promoter" and "facilitator" for the co-creation of the conditions to foster and speed up such kind of transition processes.

Moreover, as we have seen before, in such transition paths universities could result foundamental, representing the pivotal actor capable to involve, enable and guide other socio-economical actors in experimenting, introducing, adopting and developing system innovation concepts.

In conclusion the paper pones two main working hypothesis to be verified with further research and field tests:

- that design could result strategic in facilitating the setting-up of the conditions for the experimentation, introduction and scaling-up of sustainable system innovation concepts, through foreseeing the potential actors to be involved and facilitating the strategic converstation between them;
- that in this transition path university could act as key actor, promoting and facilitating the whole process.

[10] The work team is made up by the students Lorenzo Davoli, Francesca Fiocchi and Jun Lin, coordinated by Carlo Vezzoli and Fabrizio Ceschin (research unit Design and system Innovation for Sustainability, INDACO dept., Politecnico di Milano).

[11] In brief he alternative business model is characterized by: an approach to mobility as the scope of design; an innovative stakeholders network (including actors like energy supplier, insurance company etc, which usually work autonomously with the value chain); a shift from selling products (car, fuel, etc) to selling results (access to mobility); a change in product ownership; and a consequent change in vehicle design. For details see: Vezzoli and Ceschin 2008 (II).

The hypothesis seem worthy to be further investigated, that means new source of funding should be search and before institutions should understand the importance to assume these as one of the articulate research strategies and fund-raising.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

NON-DESIGNED DESIGN

A Study on Unprofessional and Non-productive Design in Shanghai

Yong Qun CHEN

Abstract

Design should not become a consumption behavior neither wasteful objects for rich people. Design can be brought to be a motive force for the changing of human society and its development. The research of the subject is to study the practice of the informal design in Shanghai, which indicates to those impromptu works for improving living condition made by common people. The way of solve problems represents a significant meaning for the real life. The conception and definition to this sort of creative practice can be called “Non-designed Design”, or unprofessional and non-productive design, and its spirit is in fact closer to the truth and genuine meaning of design.

College of Architecture and Urban Planning， *Tongji University, Shanghai*， Art and Design Department， *nuqqun@yahoo.com.cn*

Non-designed Design Definition

Non-designed Design refers to an “alternatives” practice without conscious of design. Most of practitioners are living at the bottom of urban pyramid. These Shanghai common people recreate their life necessities to improve the daily living conditions. Limited by the economic resources, they reuse those materials mostly are free of charge and easy to be accessed. Non-designed Design practice is a kind of unique creation, and it is a process of consciously learning, introducing and reinventing the subliminal invention. It is unconventional and distinguished from our “good” professional and productive design. This kind of informal design shows common people’s wisdom and adoption to living environment.

A Significance of Non-designed Design Practice

Non-designed Design is a central driving force pushing forward us to change our conception and perception on design. When we inspect current design practice and reviewing the value of Non-designed Design practice for life, the meaning on design would be adjusted.

The Background and Introduction of the Study

In this study, the method of the research is not based on a theoretical study on varied literatures, but the phenomena in the reality.

Non-designed Design practice makes a mockery of our formal design (professional design) and the role it has played in society. The study is to question the definition of design and practice we have conventionally. The composition of the study was aroused by my intuition to “mainstream” of design phenomenon in the world.

In China, out of instinct, the informal constructive practices for living environment are very common and constantly revised as the complex social reasons. At the same time, this sort of social behavior has never been interrupted in the history and got respect from the formal design practice and authorities. But its importance, extended scale, and the meaning in the changing of urbanization throughout of the country have been ignored.

Non-designed Design holds a gesture against the formal design out of the official campaign. In the context of constitutional roughness and partial out-of- control, Non-designed Design creator rebuilt their environment spontaneously through a bottom-up approach. Different from the formal design, the construction of the Non-designed Design is random, un-linear and self-organized. Consequently, it is more flexible and adaptive to the change of life. Today, the formal design emerges as the service consumed more and more by current elite Chinese and those from privileged classes who are capable to pay the fee. Therefore, the original significance of design practice has been totally forgotten.

The Shadows of Contemporary Design

In today’s changing world where human development is progressing, how does design play a significant role? What sort of creative spirit is properly approaching the essence of design and its origin? Our conception on design practice should be reviewed by answering the following questions and principles:

Question 1: Where could we see genuine meaningful design in our life today?

We could not see many, even some we can see but to have them applied in life, it would cost too much money and cannot be afforded by common people. In those called “formal” or “good” designs, they are mostly with chic shapes, forms, unique presentations or in a mass production. They are endless and new artificial objects, which could not be used for more than a few years. Because these “chic” stuffs are so easily out of fashion

that should be replaced by new designed things. Dose design only work for the ornaments of life, stylish artificial objects, novel ideal and goods?

Question 2: How could design play a real significant role in our society, while is rapid changing with wildly new techniques applied and global warming?

The objectives of design practice are basic and aimed at three targets: First, design should lead our living ways, furthermore, design should help to establish a healthy living system rather than turn off to good looking things only. Secondly, design certainly should solve our varied life problems to enhance our living condition and quality. Thirdly, design should turn unfavorable factors into favorable ones for our ways of life and living activities.

Question 3: How could design lead our life and human to a right direction in the future?

This is a very significant aspect for designer. In the design practice when a designer is considering the application of design in reality, and reviewing its meaning of the result to the human social development in a rational way, doubtlessly design in fact will be abused by profitable power.

What Changed and Changing What?

In recent years, our living environment have been changing and moving on, and it is unbreakable mixed with artificial designed objects and varied air made by human being. We cannot escape from the reality. It is always difficult for us to find and meet the interactive things in the souls, in the places where we have been and lived. Our bodies and mentalities cannot take in these artificial objects that we possess, see, touch and smell in our everyday life. To get those non-artificial and lofty things, we have to search for either at the bottom of our hearts, or from the ancient items in which have exited for several hundred years. What can we do next? How can we change the reality of the life?

Walking through this rapid changing city, Shanghai is on the way of urbanization and modernization with non-introspecting way of the changing. What is the most marvelous moment to see the changing? Certainly it is not the scene where those so called new “designed” environment and artificial objects.

Here is the moment when you could sense the real life: the extraordinary human strength and wisdom. In Non-designed Design practice, the creations are not recorded and the works are imperfect. But the adaptability and flexibility in which those common people evolve from their harsh living environment are astonishing. These mostly no-cost materials are fully utilized in very smart and amazing ways. We try to depict such ideas by our study: the basic impulse to **optionally and partially** change the realistic world is exact the essence of design practice. The spirit of design should be originated from an experience on the real life.

For the above questions on design practice and the significance, we can be inspired reexamine the right answers by a study on Non-designed Design, which made in the non-design trained people. From their unconscious designed items, we find the genuine human creation that deal with the harsh life. Here, the significance of the behaviors and practices are more profound than those formal design practices.

In this document, the recorded samples are from Shanghai in these years, which indicate how the masses change used and reused objects for living. The various spontaneous of Non-designed Design rooted in the self-care wishes of the masses. Not only having no representatives of common interest, they are even repressed and insulted by urban administrators and nation controllers. From these creative and imaginative things in the works of Non-designed Design, we hope we could objectively present the truth by these “masterpieces” that we have seen. To think about man, life, society, nature,

and the correlation with each other in Non-designed Design, will do help us realize the practices, and appreciate their unconventional aesthetics. In such reason, an understanding to the meaning of design might become closer or properly. In the end, a new strategic design working system would be studied and worked out further.

01 A sputum is reused as a flowerpot. 2007.07.07 North Xiangyang Rd.

Ready-found materials have been widely applied and existed in the thought of Non-designed Design. Ready-made products are worked as consumed and recycled materials. And collage is one of the best choices to present the ready-made products. The materials are re-organized in a new conception through the forced ability and the human knowledge.

02 A block is built in wasted bricks. 2006.07.08 Miyun Residential Neighborhood.

A wall can be understood as being divided into a series of unites next to each other, but not reacting to each other. It guarantees the co-existing of diversities.

03 A garden in the air, structured in a practical form. 2006.07.08 Miyun Residential Neighborhood.

Garden is a pleasant and enjoyable environment. Traditionally it is planed in a backyard. The uncertainty and illegibility of the context lead to the fundamental change of the content. The space nature is redefined.

04 A toilet paper box. 2006.07.09 Wenmiao Rd.

05 A functional frame for the mops drying. 2006.07.09 Duolun Rd, Culture Street.

06 A duty form for cleaning up the public. 2006.07.09 Wenmiao Rd.

07 A frame for clothes drying. 2006.07.09 Duolun Rd, Culture Street.

08 A free hand writing graphics for the repairing work. 2006.07.10 Lane 171, Tianshui Rd.

09 A chair made of wasted materials in a new combination. 2006.07.10 Lane 171, Tianshui Rd.

10 An advertising of bicycle repairing, made of wasted bicycle tyre. 2006.07.08

No.123 Bus, Miyun Rd Stop.

A defined object can be redefined as it is reformed or reorganized in a context of space.

11 An umbrella pavilion, fixed in a sack of rice. 2006.07.09 Duolun Rd, Culture Street.

12 The alternative cropland in a public corridor. 2006.07.09 Duolun Rd, Culture Street.

A site can be generated other content with its own particular context, moving away from being just a piece of land. The predefined function disappears when some factors are wrong, or go beyond the tolerance in either the context or the content. A site could be transformed as long as the content of function misused. It means that the meaning of object could be considered and used as an undefined function object.

13 The alternative farming land in a public corridor. 2006.07.12 Jixiang Lane 531, Middle Henan Rd.

14 The alternative farming land in a public corridor. 2006.07.12 Jixiang Lane 531, Middle Henan Rd.

15 A against regulations building. 2006.07.11 A house near Xin Tiandi area.

In the practices, the rigid and fixed structure is always ephemeral, whereas dynamic, adaptive and repeatable structure is every durable. For a certain purpose, the temporary structure attaches onto the unreliable major structure, engrafting into each other until flourishing the site.

16 A against regulations building. 2006.07.11 A house near Xin Tiandi area.

17 A used bamboo stick. 2006.07.12 Jixiang Lane 531, Middle Henan Rd.

18 A hand made post boxes. 2006.07.11 A house near Xin Tiandi area.

19 A lamp in a public kitchen. 2006.07.11 Lane 1299, Zhoujiazui Rd.

20 Locked a private tap water in a public. 2006.07.12 Jixiang Lane 531, Middle Henan Rd.

In order to prevent water from being stolen, each family has to give a lock to their respective tap. One of the most cheapest and easiest way is to use a pop can, abrading its mouth, burrowing along the jar mouth and perforating it with iron wires, covering to the top, locking through the iron wire buckle. In this way, the safety of using water for each family is guaranteed through the self-made way.

21 Locked a private tap water in a public. 2006.07.12 Lane 157, Tianshui Rd.

22 A combination of wasted chairs. 2006.07.12 Lane 157, Tianshui Rd.

23 A combination of wasted chairs. 2006.07.12 Jixiang Lane 531, Middle Henan Rd.

24 25 26 27 A method of space saving, an out of window-still is used. 2006.07.12 Lane 1200, made by Zhang Wen's father.

Interior is defined by the authorized boundary, the content determined by users, as well as the objects within. The interior is more controlled by instinct rather than self-discipline. The space functions are modularized the original boundary.

28 A stacking roof house, made of used windows. 2006.07.12 Lane 1200, Liyang Rd.

Originally roof acclaims the end of architecture at top. But here, it predicts a beginning of another construction, and another free site. In Non-designed Design, the structure is considered the practical function at the beginning. Then the energy is to be put into how to shape an ideal form. However, the ideal of Non-designed Design is usually the concocting of the advanced formal design. The form of Non-designed Design merges the either side of substance and spirit, a faked external skin with a practical core, which cares the harmony between neither different forms, nor the form and function.

29 The broken glass is used for the safety on the wall. 2006.07.12 Lane 1200, Liyang Rd.

30 The Pillows are dried on the roof, bamboo stick is used as a frame. 2006.07.12 Lane 157, Tianshui Rd.

31 The extended Balconies are used to receive sunshine, a floating land different from the enclosed interior. 2006.07.11 Lane 1299, Zhoujiazui Rd.

32 If we forget the regular conception on varied objects, a basin could be anything when it is reformed. 2006.07.11 Lane 1299, Zhoujiazui Rd.

33 The electric fan is changed to be item of whisking the flies off. 2006.07.30 Huangdu Rd (near East Jiangwan Rd).

34 A handcart made of used objects. The combination is functional and practical.

2006.07.12 Jixiang Lane (Lane 531, Middle Henan Rd).

35 In order to extend interior space, the stairs is built up in a yard. 2006.07.11 Lane 1299, Zhoujiazui Rd.

36 A suspending corridor. 2006.07.11 Lane 1299, Zhoujiazui Rd.

In Non-designed Design, the greed to grab more public space area, the expanding against each other among sites, the unexpected block at an exit, the chaotic occupancy in a corridor, and the stretching out of the illegal architecture, all of them force a crumpling path, which creates crinkled elevation, as well as intensively changing landscape along the way.

In these non-planed and designed residential areas of Shanghai, Non-designed Design is round us, and we can easily find the problems solved in different practical ways. The creators are not designers, and they even do not know basic knowledge on design, but the belief of improving life. They always try their best to resolve the difficulties without cost by exploring bravely, utilizing the wastes and applying their creation and intelligence. The reasons are due to realistic situation that “good design” costs lots money, and formal design in fact could not be intruded into their life. Although their works are mostly clumsy and simple, and the thoughts are glittering, such creative spirit is indeed approaching the essence of design and its origin.

Today, design has been being a tool or slave to stimulate users` visual and material consumption, the mission of design becomes a game of visual expression. The visual consumption does not mean only consuming the aspects of resource but hearts as well.

When design is getting involved only with designers` forms of expression, or to be the means of commercial dealings, then design is a cheat of profit for the powers, but nothing to do with the realization of humanity. The reasons are:

1. The endless of unique forms of expression in design means endless resource consumption.
2. The stylish or individual design practices do not mean could make the life happier or better.
3. The design with visual language orientation does not solve the social problems, especially for the crisis of our living environment.
4. The “good design” judged by the visual perception would encourage designers to pay attention on the considerations of surface, so that the essence of problems come to overlooked.

From the comparison with the formal “good design” and Non-designed Design practices, our realization and understanding on design therefore become clearly formed.

A Personal Perception

If I were a historian, I could find reasons and face the reality about our surroundings, by examining what have happened in our professional design fields. In the end, the time that now we have for design would become another tradition, which means it would be a part of the history as well. If I were an anthropologist, I could jump back to our real life to study the present human values of conception on material world, in order to insight the particular social reasons and related essence, with the traditional cultural spirit, value and content under the correlation in the context of the history.

Due to the correlated contrasted from a cut section of the history in an introspected gesture, I ask myself and try to search an objective word to precisely depict our social phenomena. A result comes in my mind, the valuable and meaningful things we believed should be reassessed. The assessment I make based on the feelings to the life;

by those visual artificial objects; samples of human materials and their thinking on the reality; and by the comparison with the history of previous human cultures. Beyond doubt, all the phenomena that I could see from the artificial designed objects to the peoples` consciousness, is truly the reflection of the souls, and the aspirations to living space.

I read the historical sediments of the culture yesterday; and today, I am watching the things surround me: From the changing direction of the social development to the details of mans` life; from the ways of peoples` thinking to their behaviors; from the general social value standards to the working systems of the society, I ask myself, how should I find the wisdom? Where could I reach an ideal world in my heart? Or should I have to have my ideal world buried?

Escaping?

By reviewing the world that we designed, I have finally read a mark that all human behaviors results represent human characters and instincts. The realistic world means we live in a complex life, and the life is full of different possibilities as well. As a negligible part of the procedure of human evolution, we are naturally formed in this age of the time, and laid at a certain geographic location. At the same time, we are involuntarily and baffled joined the variation of the cultural changing pattern of transmitting. The present situation of design patterns has annotated how the culture tradition evolved from one state to its opposite quality. It depicts a whole progress of the changing cycle. Now, from either internal or external contents, the beauties that people appreciated and understood for design are sorts of spurious **“surface” and “affected”** things. The meaningful and valuable aesthetic things are getting less and less.

When the value of surface presenting is regarded as a lofty and ideal beauty in design, the way of changing for the society is therefore more harmful than non-change. The belief of design practice “design makes life better” is in fact a lie. In China, an ideal cultural state is far and far away from the reality during the fast change of the development. At the same time, we have to come back to the space of the common life, just to enjoy ourselves in the games of the complex and unique social systems. Somehow, before we go to swim in the plays, we know we are already become a retarded men, but we have no place to escape.

Beyond the Vision of Design

By the realization on the cases of Non-designed Design, it helps us to think our definition on design and the meaning, as well as the affection to the change of the society. **A good design should not be assessed only by what we see, but the considerations of relationship built between human and material worlds and nature must be thought. It reminds us in which way to structure our artificial world.**

With China stepping into a process of rapid economic growth, commercial aims and profits naturally become the only measure of standard to most professions. It formed lopsided social values and mentalities. Could design face this sort of changing of the history in a new gesture, or initiatively participate the changing in the society? The answer is yes, the way of design practice need criticized.

Thousands years later, when future archaeologists and anthropologists studied the human society for our age, the way to approach the truth of design practice, they of course did not need to necessarily study the philosophy of design we had, but the samples of design objects were enough. Today, the attached danger under the fast development of human hi-techniques has started to strongly impact and overturn human values, exists and whole social systems. It is not easy to adopt us to a new social practice, when the individual and collective ideologies changed from the changing of life. The history of design itself could not tell us what we should do now for our future life. The context of the content on design is not an artificial written form, and to know the truth of

the reality for what we can trust still depending on our hearts, and the intuition of the spirits. However, the problem is that due to our beliefs have been changed and twisted, the valuable things therefore could not been seen in life. So it is not any more the matter of man, but the things we made and the things that we supplied in design practices.

If we accept and advocate with the spirit of Non-designed Design, we could reform a better or human world, and design practices could solve our social and life problems in new possibilities. In order to achieve the goal, there is two works should be formed: First, design genuinely intruded into conmen peoples` life. Second, to review our understanding on design and problems in design education, to have a new ideology intruded. Furthermore, a working system must be reformed in a practical and strategic way.

Chinese society is not another case when urbanization has been generally thought an efficient and quick mode for the economical development. When treasure becomes a common and only standard to assess ones value of life and happiness from individual to collective, by fair means or fouls to chase wealth spontaneously are fair and reasonable. The fast change of the society asked for formal design extensively in order to construct the country, but in the names of formal designs have widely produced “new items” with high recourse consumption. The design in fact becomes one of crimes to the changing of environment crisis under a “nice name” of life rebuilding. Beside the design practices have changed the scenery of the social changing, the formal design has also changed the scenery of Chinese culture context. In these changing years, people more and more believe that formal design could be a magic power to make life more beautiful and practical. The “good design” deals therefore appeared and run wild throughout the country, the material living environments are called “nice looking” forms. Obviously, the results of life are superficial and not happier.

The Value of Changing and the Value of Design

The value on changing to the world naturally formed a value on design practice. In fact, for the masses, Non-designed Design has been a fundamental philosophy and strategy of living experiments in Shanghai. In a city where established institution and market systems have never existed, and “good design” costs in a high expense, Non-designed Design is the only efficient possibility for commoner to express their creation and understanding on living environment. By both intellectual reflection and ethic solidarity, activities from different domains, or disciplines, should be regularly and systematically gathered and collaborate. Multi-disciplinary collaborations are an inevitable process open new spaces not only for more experimental design creation. Moreover, it urges the design practitioners to critically reflect at and redefine their own design activities.

Design is not a creative thing related with material worlds, it could effect our ways of life, living and the working systems. In this way, design practice can dynamically contribute its potential and power for the human society. More than being an approach for the surface changing of human world, design should design our values and thinking of living.

The reason for the problems of formal design is clear, when we do not know even about the meaning and value of life, or either the genuine meaning of design practices to human beings – these basic things, our endless and new forms of design objects or projects are of course dangerous to the human development. When GDP growing becomes governments’ main pursuing aims, and at the same time, materialism becomes what people admired, the practices of design are certainly used as the tools. This is what just happened in our current world.

What is a genuine and significant design for human? The answer seems came from what value of happiness that we chose for. We can simply divide the conception into

two choices: One choice is that we live in a high technical environment with varied advanced machines or artificial objects surrounded; another is that we live in a place with limited artificial items, we can see cherry blossom every day when we just open a window in a calm mood. The choice certainly presents our understanding and judgment for the meaning of life, means a happiness of life. As one of creatures on the earth, the second choice certainly would attract human. When we know what we chose means what design should practice.

The principle is simple, but in practice the practice of design is indeed very far away from the truth, and getting lost in a pure material consumed. The reasons are very complex in a social context, such as our social working systems, and the methods of human techniques inventions and applications. However, a root of the reason is indeed come from our consciousness and thinking.

Therefore, the basic fundamental objectives that design need intruded:

1. For the masses.

2. Ecological.

3. To guide a healthy life condition for both spiritual and material to human.

In this case, the practices of design should not work on mere in the visual perception.

Why Non-designed Design Intruded

From the realization on the practices of Non-designed Design, we could learn and review formal design in a right gesture. For example, how to have formal design introduced a methodology of inventing, which is more adaptable to the reality, more suitable to common people. By the study to the principles such as instinct, demand, handwork, low budget and context-orientation in the informal behaviors of the genuine life, formal design would not be lost in the changing the world.

For the sake of limiting natural resources wasting or consumption, a designed system for design practice seems more significant than design itself.

How can design play a proper role at the era? To have informal design intruded, Non-designed Design practice is a key to understand the shadows and problems of “good design”. The works that we should complete are:

1. To induce public discussion of the orientation on design. The main objective of this project is to evoke, in the design-field, re-evaluation and discussion on our designed-design surroundings, in order to recruit a great deal of power of design potential as major components of a rebuilding design culture. Discussion also brings about the self-examination in the current design reformation, moreover, eliminates the established language of the authorities on design.
2. To re-think design and everyday life, eliminates the grand narratives and myths in design creation and its application. It revolts against the control of authorities by actions, offering every different design activist more and better presenting opportunities.
3. To create a practical working system of design for the masses. The conception on design serves the society in China remains in a relatively low level, even though numerous art and design institutions of higher learning have already established, and contributed to making discussions and development for the public. Nevertheless, they have not yet been transformed into part of the design habits of community. As a responsible designer and sociologist, we feel obligated to contribute a variety of

design practice, to enrich the means of design, and to change the general conception on design.

Aims

By the realization on the cases of Non-designed Design, it helps us to think our definition on design and the meaning, as well as the affection to the change of the society. **A good design should not be assessed only by what we see, but the considerations of relationship built between human and material worlds and nature must be thought. It reminds us in which way to structure our artificial world.**

The objectives for Non-designed Design Studies

1. From September 2008, we will proceed to arranging and conducting in-depth research for Non-designed Design into design education. The research results will be sorted from object, space, motivation, function, media, etc. for exhibitions, publications later.
2. The literature of Non-designed Design will be archived and studied, being a part of philosophy of design in practice for design learning.
3. A system of the working platform will be studied to have design served for the masses and developing countries. A proposal of the system will be created.
4. To create a way of thinking theory about the combination between artificial objects and nature, between human techniques application and nature in design practice, and the work will be published.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Hybrid Ontologies

Design knowledge in a hyper-connected fluid society

Matteo Ciastellardi[1]

Abstract

All these years the proliferation of the World Wide Web and its constant growth have furthered the development of complex systems to control and manage information.

The hierarchical construction of classificatory systems has guarantee the first footsteps for a formalization of the online knowledge, notwithstanding have gone growing some popular taxonomies (folksonomy) without default relationships among the elements and without a precise point of departure.

This paper start from these shapes of widened ethnoclassification to explore which are sceneries and possibilities within design can improve on the construction of hybrid, bottom-up and collective ontologies, builded in itinere with the contribution of the users that trace definitions, associations and variations, in a kind of defective semantics, founded on the co-tagging, mash-up and syndication.

[1] Politecnico di Milano (ITALY) - INDACO department. Phd Candidate, matteo.ciastellardi@polimi.it

1. Introduction

Today we live in a society with a lot of relations between people, but too much bonds and links sometimes drive to a dimension of emptiness, instead of a shape of connectivity. This emptiness depends on a wide variety of social factors, like distance from people in communication, in cultural and behavioural elements, in information management, and many others (McLuhan and Fiore 1967, 12-14). The aspects we want to consider about this issue are specially focused on togetherness and sustainability between people when they decide to engage a common path toward new systems for knowledge management in the actual hyper-connected and fluid society.

The net represents today one of the most versatile, fast and economical instruments to manage and distribute information in every fields of knowledge. The Web has been transformed evolving itself from the end of the ’80s when the only perspective was to operate as if the immense archives of the net had to be consulted like a large file, in order to arrive today when complexes software are available in order to render the fruition and the construction of the information more flexible and dynamic.

Overcoming the challenges of these years, the net has changed not only its technological infrastructures, but it has redefined completely its economical and ecological system, transforming itself in the first and more efficient communication system ever used.

The merit is due to its social dimension, which has carried people to use the web in order to replace and to integrate relationships and rituals that belong to culture of the civilizations in a “second orality” (Ong 1982, 29-35)[2] .

To create a cognitive system free of an exclusively technological-driven growth, a series of disciplines and research fields have been alternated both to promote and construct new forms of knowledge management, and to optimize those existing.

A first observation underlines how orientation abilities to surf in Internet depend on experiences of information and on evocative force of the data retrieved by users from each kind of platforms (Stamou and Kollias 2005, 22-26). For this reason the involvement of two different layers in the creation of every knowledge-path online is inevitable: we can observe a human layer, deriving from the directed ability, formation and participation of the implied users, and a technological layer, codified and formal, related to the architecture of the used systems.

In order to conciliate the two layers, multiple attempts of structuring data have been made, according to different kind of criteria, logics and models. But till now, every attempt to facilitate the knowledge management has presupposed a preorganized architecture, a preordered and filtered database on which founding the successive steps of development.

2. Semantics and ontologies for a codified knowledge

Between the multiple perspectives of innovation and development, in order to codify in a flexible way and with great effectiveness the information of the net, at least two wide perspectives (correlated but with independent variables) have been advanced from various years. These perspectives are the semantic web (Berners-Lee 2002) and the creation of ontologies (Davies et al. 2003, 58); both these aspects have allowed to reach specific results in the field of knowledge management and in its indispensable declinations.

[2] Walter Ong highlights the passage happened from civilization at first orality (that knows only oral and phonetic forms to sharing knowledge) to civilization at secondary orality (that have also writing forms in order to communicate).

The semantic web represents a proposal that since the dawn of the net, for the merit of Tim Berners-Lee, has taken consistence, becoming then debatable and partially operating only in specific environments. The ontologies instead, that brings their name from philosophy, still today constitute one of the few framework codified for the management of the information.

Properly such structure would have to be reconsidered in order to mature a vision opened towards a future rich of elements based on a hyper-connected and fluid society: greater possibilities for interconnection between people, high speed of feedback on the actions and choices of the users and, above all, bottom-up[3] management for the data classification, granted by communities that complete an automatic selection and a cultural analysis of the information which they manipulate and with which they come in contact.

The semantic web, moving from evaluation dynamics of information like those indicated, becomes an environment in which all the present and traceable information (pages, files, images, links…) can be associated to specified metadata[4] able to individualize the context and to construct a network of multi-pertinence for each information.

Instead the ontologies are the structures able to maintain in perfect hierarchical relation all the entities found (Nirenburg and Raskin 2004, 353-8) and opportunely "tagged"[5], supplying also an exhaustive and rigorous conceptual schema with which manage specific relations, rules, dependencies, symmetries and differences. An ontology[6] is a descriptive, classificatory form, realized to open and delineate the schemes in which information will be incorporated and rearticulated.

Between the most widespread ontologies is possible to remember Cyc, a system already developed in 1985 that consists in a constitutive ontology and in various specific ontologies for each domain of pertinence; WordNet, a database designed like a semantic network and based upon psycolinguistic principles; SUMO (Suggested Upper Merged Ontology), a project of constitutive ontology that reserve some terms and their meaning for all the systems based on the same standard (P1600.1) in the same way in which a general ontology (in philosophical sense) defines "what exists", implying that a hierarchy can be accepted rather than a chosen base.

If it has been the hierarchical construction of such systems to guarantee the first steps for a formalization of the knowledge in the net, we can't forget that different modalities of information management are growing: they are popular taxonomies (folksonomies[7]) without predefined relations between the elements, and without a precise structure of departure. These taxonomies

[3] The word "*bottom-up*" indicates a model of production and construction of the knowledge "*from the low*", from the people; in a bottom-up construction the objectives and the organization of the contents are established from the same members of the community. This dimension is set against the "*top-down*" processes, in which the roles of the users are determined from an external authority and circumscribed from specific software mechanisms.

[4] Metadata are literally data about data, of any sort in any kind of media. Metadata are used to facilitate the understanding, characteristics, use and management of information; they are required for effective data management varies with the type of data and context of use. Each item of metadata could describe an individual element, or content item, or a collection of informational objects including multiple content items. See Baca, Murtha. 2000. *Introduction to Metadata: Pathways to Digital Information*, Los Angeles: Getty Trust Publications.

[5] A "tag" is literally a detailed label that can be attributed to a any element in order to characterize it: a tag describe the items and enable keyword-based classification and search of information. Tags are usually chosen informally and personally by item author/creator or by its consumer/viewers/community; they are typically used for resources such as computer files, web pages, digital images, and internet bookmarks, and for this reason, "tagging" has become associated with the Web 2.0.

[6] In philosophy the term ontology (lit. "study around the nature of being") represents the study on existence and forms the basic subject matter of metaphysics. In computer science and information science, an ontology is a representation of a set of concepts within a domain and the relationships between those concepts. It is used to create the domain scheme and its properties. See Taniar, David and Johanna W.Rahayu. 2006. *Web Semantics and Ontology*, London: Idea Group Publishing.

[7] The word folksonomy derive from the fusion of words folk (people) and taxonomy, and indicates a collaborative, popular modality (bottom-up) to classify the information in collective and collaborative ways (collaborative tagging, social classification, social indexing, social tagging). This method is a bottom-up perspective to apply tags to annotate and categorize content. See Tapscott, Don and Anthony D. Williams. 2007. *Wikinomics: La collaborazione di massa che sta cambiando il mondo*, Milano: ETAS.

have concurred to develop some spontaneous and collaborative forms of classification “bottom-up”, in a position to reflecting the conceptual model of the same users.

3. The defective semantics: unstable bonds and open ontologies

Starting from the definition of an innovation that based its effectiveness on the capability to foresee behaviours and on the dimension of user adaptation (semantic web), gradually begins a change of perspective that redefines the concept of knowledge management for as it has been constructed and for as it still comes formalized when it’s necessary to distribute information online.

The systemic hierarchies of information today begin to transform themselves into folksonomies, starting from a bottom-up perspective of common collaboration (Tapscot and Williams 2007, 41), to define and classify by tags different kind of data.

This perspective has started from a communication necessity and not from the matter of knowledge, in order to take advantage of the more suitable prostheses, of the more versatile instruments and of the more simpler technologies, just to define with these instruments what can enter in the grid of the shareable knowledge.

If we want to trace which are the consequences, or the forerunners of this phenomenon, we have to formulate some basic consideration regarding the scenario transition of the recent years:

- The people are “inside” the information and not only “in front”.
- The information do not have a relationship of pure fruition and distribution with users, but they have become active parts of the process of knowledge construction.
- Not only the messages (the contents) have been “tagged”, but also the objects (the media) that deliver contents, and all the entity involved in every process of information.
- The hierarchical schemas and the univocal classifications can’t describe any kind of scenarios in constant changing.

Considering these points the user becomes not only a passive receiver of data but an active propeller of the information in the net, exiting from every hierarchy and relational tie.

The information become a moment of proliferation of indefinite groups (Lévy 1996, 122), that aggregate and separate themselves according to complex and not measurable phases. The ties that are constructed among statement, terms, concepts and cluster of data born and die in the same time in which the attention of collectives focalize them, rearticulating the capacity, the content and the same labels (tags) that can classify it. Unstable links between the informations are developed, as a result of the “bottom-up tagging”, that is deriving from how online community accept and determine the attributable values.

The outcome of all these processes is a form of semantics that is declined on the attractions and the polarity of the involved users, and that rearticulates the same network, because no hierarchical structure can control a process that does not coincide with its own schemes of demarcation and classification.

We run into a sort of imperfect semantics, articulated on hybrid ontologies, in which no more models of heuristic and linguistic can be found, but it’s simple to discover processes of tag mash-up[8] and syndication[9], that characterize the collective mass actions, projective and unforeseeable, of the communities in the net.

[8] The term mash-up indicates a combination of data from more than one source into a single integrated tool (or environment). Mash-up adopts a more fundamental approach to content aggregation without regard to markup: individual content may be combined in any manner, resulting in arbitrarily structured hybrid content. The term could also be used

4. Changing perspective: from semantic web to hybrid ontologies

The passage that must happen is from “learned” ontologies, founded on information hierarchies, and flexible paradigms, within the limits of specific knowledge domains.

The change of perspective is founded properly on the imperfect nature of these links: to work these links must be founded constantly on the fluidity that a hierarchical system cannot guarantee; they must base their structure on the constantly in-definition shape of the social systems that share the information and rearticulate it into the web.

This way the knowledge management constructs itself on the connective dimension of users’ thought (De Kerckhove 1999, 16), still before on their presumable “collective intelligence” (Lévy 1996, 19), and it defines a kind of open-ontology form, in continuous alteration and semantically imperfect, that is without possibility of a linguistic or structural definition, because it’s impossible to determine when and where the knowledge domains could finish and how many (and which) entities could be involved before transforming all the environment in something completely different (Taniar and Rahayu 2006, 84-88).

The point of convergence between the connectedness of the information, and the social dimension of the net’s users, offers a perspective on how the knowledge is still organizing itself in the web dimension: which instruments, which challenges and which drivers are characterizing it and which forms of technology are growing in order to reach specific results on the various application fields.

As Nova Spivack[10] suggests, the actual net scenario is not characterized by the decline of the semantic web, but by perspectives still to pursue and to reach (figure 1).

as mesh-up, as it happens in some cases, in its meaning of “connection”, but it is preferable to use the most diffuse “mash-up” for the common sense it had assumed in the web.

[9] The word syndication indicate a way to made available a section of a website for other sites or applications. A syndication is based on web feed: a data format used for providing users with frequently updated content.

[10] Nova Spivack is one of the pioneers of the Web, one of the first businessman who creates a company related to Internet. Spivack currently is considered one of the maximum expert on the future technologies and evolution of Internet. For more information visit http://novaspivack.typepad.com.

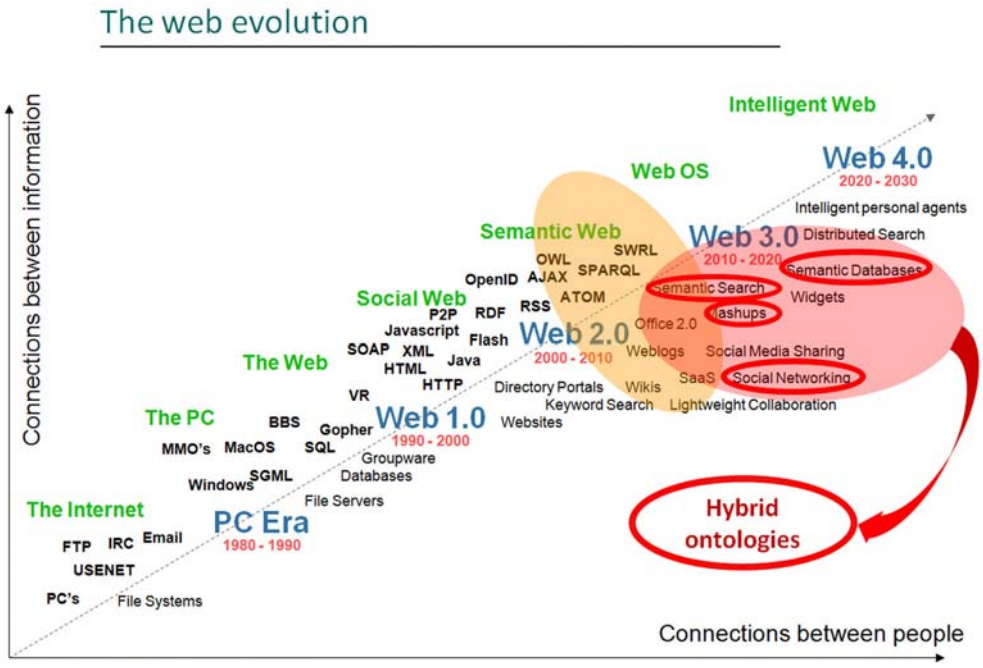

Fig. 1: The intelligence is in the connections, Radar Networks & Nova Spivack, 2007

The point of arrival is very difficult to localize, specially trying to following to realist path of implementation and development. But here is the challenge for design: finding a way to manage and organize the next steps of the online knowledge system, starting both from a point of view of conceptual planning and from technical implementation.

This way could coincide with the alignment of the actual hyerarchical structures with the bottom-up perspective of data classification, making changeable and classificable the same categories and relations used in traditional ontologies. This permits to arrive to an hybrid ontology, based on preconceived structure, but self-organizing and self-articulating in its constitutive schemes, constructing its recombinant structure on what online communities outline, vary, forget and reconstruct.

5. The design challenge in the web knowledge management

The user is a multi-dimensional figure in the world of the web. With the advent of the online communities, with specific software for social tagging and social bookmarking (Technorati, Del.icio.us, Flickr, Facebook…) and with wiki-like systems, the topography of the net has begun to model itself in a more realistic way, comply to the dispositions of the users whom classify and filter the information.

The translation of this classification resides, for example, in the tag-cloud[11] phenomenon: aggregates of terms with different font-size dimension that indicate the "popularity" of some words rather than others (some examples are present in figure 2).

[11] A tag cloud is a visual weighted list of user-generated tags used typically to describe the content of a website. Each relevant topic is represented by a tag, which is shown with different font size or color.

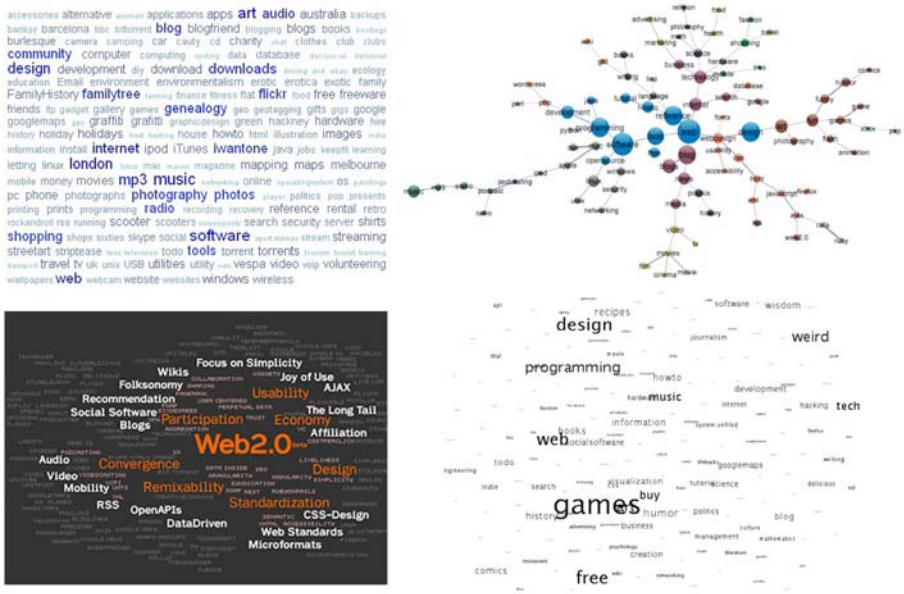

Fig. 2: Some examples of different online tag-clouds

The tag-cloud permits, just at first sight, to draft a scheme of what is relevant inside a specific informative domain. If in this system we embed the semantic dimension that characterize the users' choices, and we embed also a system to manage the flow of information traced, we can propose a new dimension for the online knowledge management. It's obviously indispensable that the bottom-up modification of the hierarchical structures is allowed to accord the emerging classification forms.

Such perspective creates the vision of a scenario in which hybrid ontologies, related to specific or general domains (and therefore developed based on narrow or broad folksonomy[12]) articulate the shapes of the knowledge that the same users determine and classify.

It's possible to criticize the system retrieval scientificity and the approximation of the data management processes (D'Alessandro 2002, 46-49), but a system based upon hybrid and bottom-up ontologies does not risk to become less scientific or less reliable than others that have only predefined rules in order to determine thresholds of quality information. It is instead a benefit relying on a system that avoid to leave in evidence only the result that already are in evidence: for example the most common crawlers offer a list of resources ordered by relevance criteria, and users usually choose between the first series of results, enhancing this relevance. This situation, such a closed circle, does not allow some significant changes until communities themselves start focusing on specific information which will gradually obtain preeminent visibility into the classification hierarchy.

The role of design emerges in this dimension of management and development of new strategies to codify knowledge. Particularly design has to become the interpreter of all the disciplines involved in the change of the web paradigm: sociology, philosophy, computer science, linguistic, semiotic and so on...

This role does not want to be a position to sew together distant activities: the first change which must be operated in the communication paradigm arises from the vision of a different role

[12] A broad folksonomy is defined as a lot of people are involved and describing same objects; a narrow folksonomy is about a small group of users tag particular items.

of the user, who is not a passive figure, but is the particle of a uniform and fluid mass which synthetizes schemes and produces variables and labels for the information to classify.

The goal is therefore to find a point of synthesis between the vision of a scenario where the information can rearticulate itself bottom-up, contaminating the whole system (redistributing itself and remapping its own schemes in every interrogation), and a framework of the information which is starting now to grant users the right role for the social-collaborative turning point they have made.

The design has the possibility to establish a rhetoric of the project in order to create a dialogue between the social and the technical tissue, and this means not only to produce a toolkit to support new scenarios with sustainable models, but also to suggest a vision of a different cultural apparatus, to offer a new way of online interaction, and a new points of access to the knowledge.

The real challenge is how to translate a common overview based on connected platforms, social systems and information in a framework of actions. A first answer is the creation of a different system to approach and retrieve information. This way proceeding the design role is to offer users the possibility to define and share different environments of knowledge. The modality could be the implementation of learning interfaces (example in figure 3) that are able to interconnect data, analyzing the browsing habits and the tagging classification of the users, and entrusting the new shape of knowledge management on:

- the consideration of three interconnected units: user, information and tag/labels;
- a modality to self-organize each information in a “hybrid” ontology;
- the dimension of the cooperative tagging: mash-up of the tags and self-classification (bottom-up) and deconstruction of the semantic links.

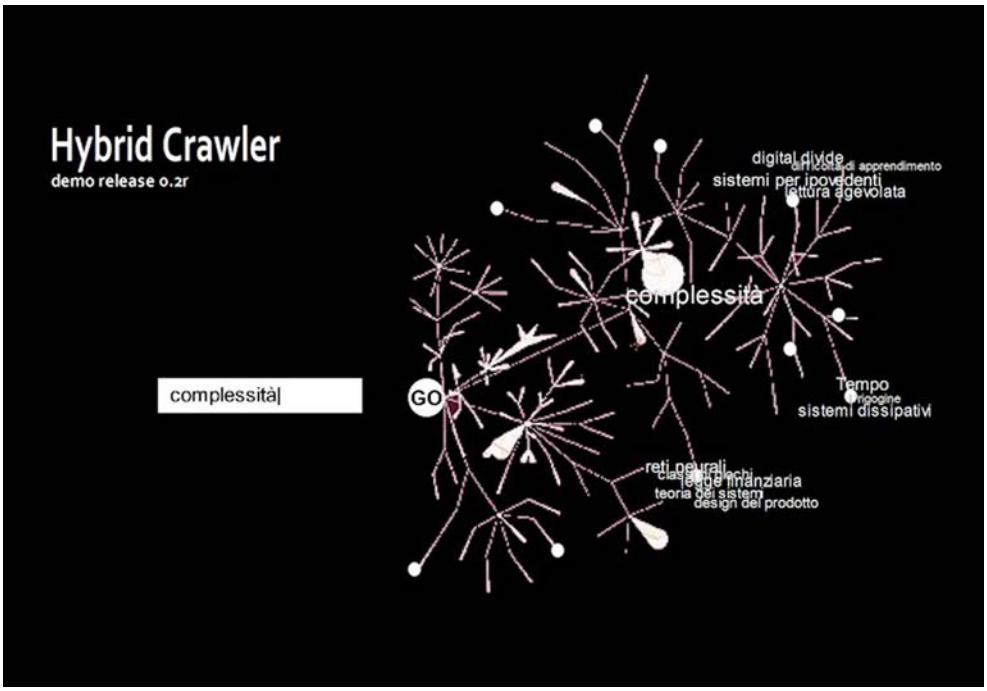

Fig. 3: A prototype of interface design for hybrid ontology: a simple bottom-up crawler for narrow folksonomies

Without enter in the merit of specific tools that design could try to develop, the hypothesis remains to plan the possible scenarios, to find out the focal points on which continue the research, without loosing the obtained progresses, and accepting the challenge to deconstruct the designing rules in order to create new project drivers, deriving from the contamination with a new system to build the knowledge.

6. A conclusion? A beginning

In conclusion the vision of a new sustainability for our hyper-connected and fluid society is based upon a common and collective approach to manage and develop knowledge, and actually could be realized with a new… beginning, in the sense of a redefinition of the constructs and modalities to articulate the knowledge in the web. Perhaps, if this vision can scare for its too much ambitious change of paradigm, it is important to mind that paradigms change without people notice something: only after the change we can discover the differences. Like italian novelist Italo Calvino suggests «we will be able to pass beside phenomena never seen without realizing anything, because our eyes and our minds are used to choose and catalogue only things just tested and classified» so, the real issue about changing the information, changing the approach to knowledge and, for instance, changing the change is: «if a new world would be discovered now, could we see it?» (Calvino 1994, 131)

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

HANDLING CHANGES THROUGH DIAGRAMS.

Scale and Grain in the Visual Representation of Complex System.

Paolo Ciuccarelli[1], Donato Ricci[2], Francesca Valsecchi[3]

Abstract

To change towards a more sustainable development could means to make decisions not only with a systemic approach, but also to be able to decide in the right time: the density. It seems that, when the discipline of Design integrate a systemic approach with the competences of designers in visualization, it can cope with dense situations, providing effective artefacts – diagrams – to improve the decision process and making profit from the richness of complexity. The prior findings of the Complexity Science are here assumed as a theoretical framework to have an interpretative model on how the knowledge about systems could be organized and depicted. Three tools to produce effective diagrams, framing, graining and scaling are here discussed though six case studies.

1. Introduction

Among the different approaches for sustainability and sustainable development, a common belief seems to arise: the economic, environmental and social dimensions are strongly interlinked. It is necessary to deal with them as a whole (Meppem 2000). This observation, endorsed by the major institutions committed in sustainability development policies (ie. WCED), finds a more general correspondence in the assumption that the world could be seen as networked and as a complex system (Capra 1996; Castells 1996). Over the past forty years complexity theory has become a broad field of study appreciated in a variety of ways and illustrated in books and papers among the others by Nicolis and Prigogine (1989), Anderson, Arrow, and Pines (1988), Jantsch (1980), Holland (1975), Gray and Rizzo (1973), where, older epistemological classifications and domains of expertise have become more permeable (Klein 2004). The increasing regard in system thinking and science of complexity showed - in different ways and times - by economic, environmental and social disciplines (Parker and Stacey 1994; Stacey 2000), and, more germane to our field of study, by planning in social systems (Byrne 1998) and decision-making, seem to reinforce the link between sustainability and Complexity.

Byrne (1998) argues that the disclosure of systemic approaches lies in the coherent integration of action and the understanding of phenomena, transcending the limits of analytical traditional modeling techniques. Even if a well-defined “toolbox” for sustainable changes based on the findings of system thinking and complexity science, has not yet been found, there is enough convergence on two pillars that can be used to shape new tools:

- **The need for trans-disciplinary sustainable development approach** based on a systemic perspective. This statement is supported by the relation established between trans-disciplinary and complexity (Max-Neef 2005);
- **The interpretation of sustainable development as a learning process.** Discussing the integration of the science of complexity, knowledge management and organizational learning disciplines, McElroy (2000) states that “complex systems are, by any other definition, learning organizations”, and adds, on the other side, that “knowledge is the product of natural innovation schemes inherent to all living systems”. If sustainable development means to drive change and to make it happening in complex systems, it has to take part to the learning processes underpinning complex systems behaviors.

It can be argued that sustainable changes need methodologies and tools able to support a learning process in a complex system with a trans-disciplinary approach. Moreover, this learning process should be collective (Manzini, Vezzoli, 1998). Holman says (2007): *“Effective, sustainable change are sessions in which people collectively explore each other’s assumptions, seek and expand common ground, shape a desired future, and jointly take ownership of the solutions to the issues at hand”*. Furthermore, Clark (1995) argues that traditional development models relating expert knowledge to social need with a top-down approach are increasingly unable to cope with the demands of a complex world.

Another point should be considered: time. In the past, changes happened slowly, in different regions at different times. Since 2001, in the “State of the World”, Gardner underlines the global scale and the speed of current changes, emphasizing the need to handle them responsibly and rapidly in order to keep the track of sustainability. The time issue is crucial. Quick reactions and decisions are asked, where, mostly local changes risk to be dampened out if communicated too quickly to the whole system (Prigogine). To stress the importance of time and complexity towards a sustainable perspective, we use the term *density*: density could be seen as the ratio between time and the amount of data, information and knowledge (interests, point of views…) to be considered in the decision processes that aims to a change. Again, Gardner underlines that, the dramatically fast pace of changes prevent societies from understanding the consequences of

their activities, also because the options for development, in a complex, networked system, have increased in number and complexity.

Considering the time constraints, handling changes in a sustainable perspective entails coping with a dense situation, or rather dealing with the complexity of a collaborative learning process that involves all the stakeholders. In the next pages, why and how design should be a discipline integrated in the changing process, in planning and decision-making, will be discussed.

2. Complexity Science and Design discipline

One of the most important challenges of complexity science researchers is to facilitate connections among knowledge domains apparently distinct and separated towards themselves, approaching system to be known in a systemic way. This basic idea is confirmed by Gell-Mann (1995), he describes a way about carrying on this approach: *"[...] some efforts just getting under way to carry out such a crude study of world problems, including all the relevant aspects, [...]. The object of the study is [...] to identify among the multiple possible future paths for the human race and the rest of the biosphere any reasonably probable ones that could lead to greater sustainability".* This, which seems to be more a challenge than an actual reality, has to recall disciplines by their own nature situated at the edge of different competences domains. Design discipline is one them. There is a need for integrating competencies, labelled by Gell-Mann as *"a crude look at the whole"*.

In this sense, the hypothesis that design may join those disciplines of *"looking at whole"* outlining a designer profile whose task is to select results from heterogeneous disciplinary fields activating a trans-disciplinary circulation of concepts (Pizzocaro 2000), is made. This means adopting and developing a new attitude based on a theoretical framework that overlaps systems science and complexity theory (Findeli 2001). Designers should use their skills to facilitate the emergence of the system; they should no longer focus on finding solutions to specific problems but on the ability to develop tools that can be self-adaptive, continuously modifiable and improvable (Scagnetti et al. 2007). It has been argued (Friedman 2003; Manzini 2004) that Design has gone through multiple phenomenons that have reshaped its meaning and its nature. Designing within Complexity, in fact, involves both substantive and contextual challenges, from the increasingly ambiguous boundaries between artefact, structure and process to the increasingly large-scale social, economic and industrial frames. This could be seen as the need to cope with a Complex environment in which many projects or products cross the boundaries of different organisations, stakeholder, producer, and user groups. Acting within complexity requires considering the impossibility to reach an exhaustive knowledge of the system in which one operates. It could be passed by developing a strategic stance that allows facing the system changes and evolution. Designer's key competences: **see**, **show**, **fore-see** (Zurlo 2007) could become also key instrument to define strategic changes in a system. More in details the skill of **showing** could be perceived as the detection and description of all the agents involved and of their relationship. It could be seen, also as the opportunity to visualize complex information referring not solely to the communication of quantitative information but also of intangible values and qualitative data.

3. Communication Design and social Complexity

We assume that design interventions could produce changes and transformations both in organizations that start them and in the complex systems in which they are performed. It is possible to state that evolution in organizations, here seen as social complex systems, and complex systems detract themselves from analytic logic rules and could not be leaded with simple actions (Lewin 1999; Lewin, Teresa Parker, and Regine 1998; Olson and Eoyang 2001). Stacey (2000) says that in complex environments the management task is coping with and even using unpredictability, dissents and inconsistency. The tasks of all managers are to deal with

instability, irregularity, difference and disorder. We can suggest that coping with unpredictability is a priority even for Design activities. This new approach leads to start questioning (Kurtz and Snowden 2003) the universality of three basic assumptions that had inspired for long time organizational and planning theories:

- **Assumption of order** – cause and effects in the human behaviour are linear;
- **Assumption of rational choice** – humans facing diverse alternatives will make a "rational" decision maximizing or minimizing some values;
- **Assumption of intentional capability** – the acquisition of a capability implies the use of the capability.

Even if in some contexts these assumptions could be true, new arising situations seem to countervail them, leading to guess that new tools and modes for managing complexity in human systems are required. Even though Complexity Sciences provides new paradigm for mathematical and computational system modelling, it could be also seen as a new approach to the human world. The comprehension of some of complex system structural features (Cilliers 1998) could be useful to outline new modes to act in planning, decision-making, strategy and design. A complex system, is dynamic, involves large number of non-linear interacting agents constrained with the environment. Furthermore, one the most important feature is the unpredictability of the system due to its sensitivity to external conditions. Based on the enlightened features a considerable amount of research projects have been carried on mainly using agent-based modelling to simulate phenomena and evolution of complex systems (Camazine et al. 2001; Weiss 1999), but there are at least three important issues limiting computational modelling application (Kurtz and Snowden 2003; Snowden and Boone 2007):

- **Identity** – humans bend and deform their identity both individually and collectively;
- **Rules** – nevertheless collective agreements and individual acts are under certain pressure or rules, the matter of intentionality plays a primary role in social complexity patterns (Juarrero 2002);
- **Local patterns** – the high capacity of interacting on large scale throughout abstract concepts on one hand, and, on the other hand, by using technological infrastructures is becoming more and more evident.

This does not mean detracting value to simulation in handling social issues but the use of simulations rather than being used as predictive tools, should be used as supportive ones.

Another force differentiating social complex systems from the complex ones could be identified by the fragmentation one and is directly linked to the identity issue. Fragmentation refers to the inhomogeneity (Chapman 2003; Stewart 2001) between social network actors (stakeholders, controllers, influencers, project teams and organizations) involved in system evolution, making effective communication very difficult. Social complexity requires new processes and tools fundamentally attuned to the social and conversational nature of decision making and design work. In this framework a new perspective seems to appear: to enable a more and more valuable interaction level and dialogue among the actors of a social system. It could be useful to shape linguistic tools and competences furthering changes rather than predicting and leading them. Focusing this new perspective on that side of Design discipline dealing with languages, the Communication Design could face the creation of visual languages affording representations of Complex systems, easing the spotting of awkward, creating shared visions within multi-actor contexts. The challenge lays on the use of communication artefacts utilized for the definition of common objectives in a project to create pivots so as to work in a resourceful manner. To act in such kind of domains, increasing the interaction and communication level becomes a fundamental action in order to manage and handle changes.

Diagramming and mapping, typical communication design artefacts, could facilitate to face the proposed challenge (Abrams and Hall 2006). Diagrams as devices for shared strategies and

evaluation of projects impact have an enormous potential to improve decision making processes thanks to their ability to involve all the actors, overcoming the possible hurdles created by specialized knowledge and languages. This definition of diagram includes all those artefacts (maps, scenarios, charts, storyboards, etc.) featured by a revealing capacity, a diagrammatic attitude finalized to the act of design (Scagnetti et al. 2007). Diagrams from this viewpoint could help designer to shape clearly complex problems, they are media between what is known about a system, and what it is; they could display not only quantitative data but also ideas, concepts, frames, schemes, viewpoints, perspectives and values of the system observer.

To sum up, extending and dropping some theoretical speculation about diagram reflections developed in architecture field of study (van Berkel and Bos 1998), four diagrams characteristics (Corbellini 2007), could be enlightened:

- **Condensation –** diagrams and the realm of tangible designed world, are related by their capacity to cope with the elaboration of huge amount of data and variables;
- **Bridging** – diagram could express relation between polychrome information often non homogeneous, suggesting unexpected description of phenomena;
- **Proliferation –** diagrams as dialogue enabler could generate diverse ways of thinking about problems being faced, becoming, also, story-telling devices;
- **An- exactitude -** The creation of a diagram is a partial and never exhaustive description of the environment. It is a narration in which inevitably a choice of what will be represented is made: it is a political stance, intentionally structured and thus arbitrary.

This feature shows the principle of responsibility designers should be aware of.

4. Designing diagram to design

In order to produce effective diagrams some preliminary operations have to be performed about information gathering and transformation. To design diagrams, information and data must be collected from different disciplines, with the aim of collecting not only an extensive knowledge about a Complex System, but also to synthesize its regularity (or irregularity) (Scagnetti et al. 2007) in a goal-oriented way, producing new knowledge about the system in which intervene.

Beyond diagrams differences in visualization and information management modes, they seem to be comparable in the way they treat information, or, to be more exact, in the way they allow us to treat information. This common feature might be an interesting approach for an effective modality to design them and to study how they are related to the described system. Assuming information as a key element to start visualizing complexity, it could be also seen as a parameter to "measure[4] complexity". An interesting way to quantify complexity is the *length* of a *message* to describe a certain feature of a system. It referring to a description could be nothing but a subjective property. Complexity, however defined, is not entirely an intrinsic property of the described entity; it also depends to some extent on whom or what is doing the description. The observer and the system are in a relationship. As a more general definition (Bar-Yam 1997) we could present that an observer is a social complex system, which through interactions retains a representation of another system (the observed system) within itself (Pizzocaro 2004). Obviously

4 The number of ways of measuring complexity has grown fast. This multiplication of measures has been taken by some to indicate confusion in the field of complex systems. In fact, the many measures of complexity represent variations on a few underlying themes. Here is an list of measures groups:

1. Difficulty of description.
2. Difficulty of creation.
3. Degree of organization:
   a) Effective Complexity. Difficulty of describing organizational structure, whether corporate, chemical, cellular, etc.
   b) Mutual Information. Amount of information shared between the parts of a system as the result of this organizational structure.

necessary condition to adopt this measure is to adopt a language intelligible to the actors involved in the representation of the complex system. Gell-Mann (1995), introducing this concept, says: "*The length of the shortest message that will describe a system [...] employing language, knowledge, and understanding that parties share".* This leads us to the consequence that defining complexity request to define and share, among other parameters, the thickness and extension adopted in describing the system. Furthermore, considering diagrams as picture shaping representation of complex systems, in order to design them it is required to provide conceptual and operative tools able to care and share these parameters. Using these tools increase designer consciousness in his condensation operations.

In this framework, we have defined project team and at the same time multi-actors organization, involved in handling changes in complex system, as the observer of the same system. Obviously, multi-actors organisations are here assumed as social complex system. The presented tools, which will be discussed throughout the paper are to be considered as a deepening of previous presented results during the international conference IASDR07. They refer to the first two steps: *analysing* e *representing*, belonging to a wider a methodology (Scagnetti et al. 2007).

The aim of this paper is defining three fundamental tools in generating diagrams, which define their features:

- **Framing** – the definition of the complex system extension domain being enquired and in which intervene;
- **Graining** – the definition of the threshold accuracy and deepness of the information whole, helpful to describe the system;
- **Scaling** – the definition of the viewpoint on the represented domain and related visualization.

The first two tools address knowledge objectives, whilst the third one dealt with communicative goals.

4.1. Framing.

The representation of a Complex system presents several difficulties arising from its structural features. In order to achieve an interpretative model on how the knowledge about systems could be organized and depicted is appropriate to define a key concept: Complex systems are usually open and interact with the environment they live in. This concept implies that it is difficult to clearly define the *space* where information should be gathered; therefore, it could be useful to define how *wide* the description will be, subsequently the system visualization, creating a *frame*. In design interventions *frames* are needed to narrow the number of information to make the system manageable and describable. It is important to notate it is more helpful to use the term *frame* rather than the word *boundary*. Boundary recalls a piece of land within a fixed limit, a frontier, and originally referred to the word *bound* meaning limits imposed or under obligation, and consequently could suggest something that inhibits actions. It has been argued that (Kurtz and Snowden 2003): *"the boundaries we consider are more like phase changes than physical boundaries (though they could be physical boundaries, if those boundaries coincide with phase changes)"*

On the base of this assumption, even if the space where a complex social system acts could be identified on a geographical or territorial base, a more faded term is required: *frame* could be this term. The etymology of the word frame[5] comes from the Greek KORONIS "something blended or curved" (Pianigiani 1990), so a process of framing could be described as a process of looking where the things start changing or blending in an environment that is obviously seamless.

5 We refer to the Italian term cornice.

A good framing action might be based on the system behaviour perception. In other words it answers to the question: **Where do we expect starting patterns of interactions change?**

Any frame is identified by who is attempting to describe the system for a particular purpose and therefore affected by biases, interests and vision. Cilliers (1998) explains this concept through the interrelation of the framing process to the position of the observer of the system. Moreover, framing is to be related to the temporal dimension of the system, not only they evolve through time, but past events are co-responsible of present behaviour. Ignoring the time dimension could produce inaccurate representations, synchronic snapshot of diachronic processes. Such kind of action is a very delicate one. There is a need to communicate and share how the framing process has been performed in order to discuss and to create consensus among all the actors involved in a specific design process. The action of framing ensures the system is defined in both relevant and manageable way, working on the domain extension field is wanted to be known.

4.2. Graining

In order to manage the description of the system, what information accuracy will be considered, have to be also decided. To set a resolution level, defining the systems structure, could be useful to arrange a process of *graining*. To *grain* information is a fundamental action considering the amount of sensible data much greater than the available, perceptible and intelligible one. Even if we assume the possibility of obtaining all the information about a complex system it will be almost impossible to use it, since it creates a situation of *information overload*[6]. Furthermore, analysing a complex system implies the acquisition also of noisy and incomplete data. Their huge amount, its noisiness and incompleteness if associated to a lack of selected and monitored data, constraints the system describer to a cumbersome filtering and sieving procedure.

The building of tools able to effectively parse data is required. Graining is the properly tool for doing that. It operates by making approximations, by ignoring details on finer scales, creating *grained observation* of the system at a resolution that shows the overall pattern of the system and the pattern of the elements in it. It is a crucial process for highlighting the *regularities* immersed in the observed system[7]. Adopting graining as conceptual tool, however able to transform the way we look and act in complex systems, it is possible to set two end points of a continuum where the various way where grained observations could fit in. On one hand are *fine-grained observations*, a near sighted way to perceive rendering detailed impressions, on the other hand *coarse-grained observation*, a far sighted observation rendering rough impressions. In other terms, if we make a coarse observation, the system describer can consider only large cluster of agents in the systems (i.e. institutions) obviously a lot of smaller detail will get lost in this process. On the contrary, a fine system examining, in *microscopic* details, the system observer has to keep track of each agent and of all patterns. Looking for regularities could be obscured *"by the buzzing activity at lower level"*[8] (Cilliers 1998).

Grain is a quite complicated concept, and requires more than a metaphor to clearly depict how it works. In addition, another example could be given (Gell-Mann 1995): envisioning taking a whole picture of a complex system in order to spot on a very small detail, the observer should zoom a lot the picture. Reaching a certain level he will only see the single grain of the picture film

6 The term was used by Toffler in 1970 and is often used to describe the simple notion of receiving too much information. It has led to various synonyms and related terms as for example cognitive overload, sensory overload , communication overload, knowledge overload, or information fatigue syndrome.

7 It is useful to remind that Complexity science mostly asks: What causes order and regularities? (Mainzer 1996).

8 A useful example is given by Chris Stephens: consider the number of degrees of freedom of the atoms composing a solid object (like a pen). This is enormous (≈ 1022). However, in order to describe the motion of a solid object, we just need 6 degrees of freedom. We have then a very much reduced "coarse-grained" description in terms of many fewer variables. So, we need to understand how more appropriate effective degrees of freedom, such as the translational and rotational ones of the rigid body, emerge and offer a more appropriate description of the dynamics. Of course, the coarse-grained description is not exact. How the resultant loss in precision affects the description depends on what one wants to know about the system.

and instead of distinguish the desired object, he will only perceive a group of stains. From this example follows that grain is a sort of *threshold* operator acting on the data gathering deepness. The process of graining narrows the amount of data should be managed by a representation, and then by a diagram. This means valuing the complexity of a system based on its description is function only of its resolution: the grain.

From a philosophical point of view should be asked that graining introduces an element of subjectivity into the theory. Furthermore, could be objected that the grain threshold is not decided upon unambiguous and rational choices but rather by the describer. As a general rule *common* sense should be used to distinguish between observable and unobservable quantities, manageable and unmanageable. As the coarse graining is subjective, so measurements are inherently subjective operations (Bais and Farmer 2007). Graining helps in addressing the following question: **At what deepness is it expected to find regularities or irregularities?**

Even if the term *grain* finds its roots in the photographic vocabulary and the Complexity Science uses it to explain some of its operations, in this framework it has to be considered as an effective parameter to be shared in reaching a common representation of the analysed space. Operatively, grain threshold process should be performed both on agents and on data about them. Information on complex system should be distinguished in flows (i.e. tangibles: goods or money; intangibles: information) and environmental ones (proximity, closeness, influence).

4.3. Notes on the adoption of framing and graining tools

The main idea is that the representation of a complex system is necessarily linked to the purpose of the representation itself and the disclosure of the purpose is a necessary condition of the same process. In other words one of the capabilities of complex system is to be able to acquire, compare, and store information concerning the environment for future use. Furthermore this process is related to the *meaning* conferred to the data and information in order to produce knowledge of the studied system. Meaning in this term could be seen as the result of a *dialectical* process. The aim and the meaning have to be made explicit in order to achieve a successful representation, and consequently a good visualization. The framing action as well the grain threshold level should be tuned on the purpose and the questioning wills about the system in which intervenes, avoiding senseless and uneconomical processes. For instance to trace an economic system is useless to know all about the movements of every penny or Euros even if all the economic system is a pattern of movements of penny or Euros clusters. The *cost* to trace every agents, data, information or relationship is higher than the profit it could generate, the cost should be seen here as a function of two main parameters:

- time and resources for data gathering;
- time and capacity for data processing.

In other words it is a function of the *density*.

A shared use, among design team, of framing, graining tools is necessary to avoid some difficulties of representation processes (Burkhard 2004; 2005):

- **Information overload** – Actors cannot identify the relevant information;
- **Information misinterpretation** – Actors cannot understand, evaluate and interpret the information;
- **Information misuse** – Actors cannot use or misuse the information.

Involving actors since early phases of representation and then visualizations helps to go over the different backgrounds (different ways to understand and interpret visualizations), and provide relevant information for design interventions.

Even if the two processes of framing and graining are not reversible, and exclude a part of the system to be understood and represented it has been stated that “harnessing complexity involves acting sensibly without fully knowing how the world works” (Axelrod and Cohen 1999). But design is a discipline that for its own nature has to cope with (Buchanan 1992; Cross 2001) open, ill-defined or wicked-problems (Conklin 2003; Rittel and Webber 1973), that happen in complex social systems. Moreover, what the system is depends on what is asked about it: different stakeholders have different views about what the system is and what constitutes an acceptable way to intervene in it – the problem. Since open problems have no stopping rule ending when “good enough” solution is reached (Simon 1996), it is also useful to say that even the framing action and the graining process could end only when it is found a good enough resolution satisfying all the actors involved in the system representation or in the design intervention.

4.4. Scaling

Operative instructions able to visualize phenomena could be mutated from a cartographic approach. Among the various tools provided by cartographic repertory, scale is a very useful tool in managing also visualization of Complex Systems. It chooses the *scene* and the viewpoint to be visualized. The scaling process does not affect the representation of the system, information gathered will be still available even thou they will not be depicted: like a movie-camera, trough the scale level setting only a part of a known reality is shown.

Far from being only a zoom of the map, it represents a fundamental step to depict information. The setting of the scale level consists in an operation that aligns the distance from the observed systems to the communicative goals pursued, as determined by the observer cognitive and perceptive capacity. Scale do not provide parameter to define how have to be know a system, instead it define how a system will be communicated; scale does not require an object to be know but a several object to be depicted.

Cartographic scale is becoming “visualization” scale (Montello 2001). The concept of scale is often confusing, even in the cartographic field of study having multiple referents:

- **Cartographic scale** – the object depicted size relative to its actual size in the world;
- **Analysis scale** – the size at which some problem is analysed[9];
- **Phenomena scale** – the size at object or processes exist, regardless of how they are studied or represented.

Although the three meanings are interrelated[10], we mostly refer to the first meaning. Scale setting level have enormous consequence for the degree to which information is generalized. Generalization refers to the amount of details included in a visual representation, in this term scale imply processes of simplification, selection and enhancement of some particularly interesting features in order to accomplish a communicative goal (Lam and Quattrochi 1992). It is useful to remarks that choosing appropriate scale level, again, can only be decided in empirical way. Starting by the same complex system, scale allows to explore in details system elements, or to read the overall characteristics on the base of communicative needs.

9 Analysis scale present some analogies with the graining tools, in fact terms such as resolution or granularity are often used as synonyms for analysis scale.

10 Choosing the map scale depends both on the scale at which measurement are made and on the scale at which an object of interest exists.

5. Case Studies

An empirical verification about the use and the application of the proposed tools has been performed in a didactic laboratory, the *Density Design Lab*[11]. Established in September 2004, the lab has been conceived as a platform for verifying the potential of communication artefacts in helping decision making. The course lasts six months, and usually forty students compose the class. Students are introduced to the concept of diagrams to support decision making processes. They generally work in groups of 6/8 members. To each group is assigned a system to work with and to verify the effective complexity. The whole group manage the data collection as well as the problem setting phase, under the supervision of an external advisor[12]. We choose topic coherently to students interests trying to explore relevant socio-political issues. In the last edition students explored:

- the Italian cinematographic system;
- the fashion system;
- the contemporary art system;
- the hospital - patient system;
- the Italian transportation infrastructure system;
- the Italian media landscape system.

The excepted output of the analysis and representation phase is a diagram able to identify some possible evolutions of the system student coping with, and a communication strategy to *activate* the evolution, the whole design experience is reported on the blog[13]. Even if we try to afford a fully understanding of the system and a relevant data gathering, the laboratory cannot provide a real decision making process albeit the decision table is simulate and the real actors often involved.

5.1. Frame setting discussion

All the six studied system were represented by real data, only the hospital system was represented abstracting it, creating an ideal model. In this case the framing has been set to the physical bound of the ideal hospital. Framing seems to be reasonably well defined, attuned to the purpose of the system description, namely to understand the relationship between the hospital structure and the patient emotions. In general, framing process has been determined by spatial limits: national extension for cinematographic, media and infrastructure ones, international framing for the fashion system.

Some consideration emerged about not appropriate framing choose: in cinematographic systems, the frame should be extended not only to the production chain (producers, distribution and directors of film) but considering hidden actors also, like political influence and religious interferences. It has to be admitted, the difficulty to grasp such kind of information hindered the possibility to consider, and then visualize, relevant connections within system. So the framing resulted too tight considering the initial cognitive objective: to discover how the financing process in the system is performed.

Contemporary art system suffered a similar situation: referring the representation only to the Italian territory without considering the international echo connected to their scope, it was almost impossible to pursue the intent to trace contemporary art market dynamic.

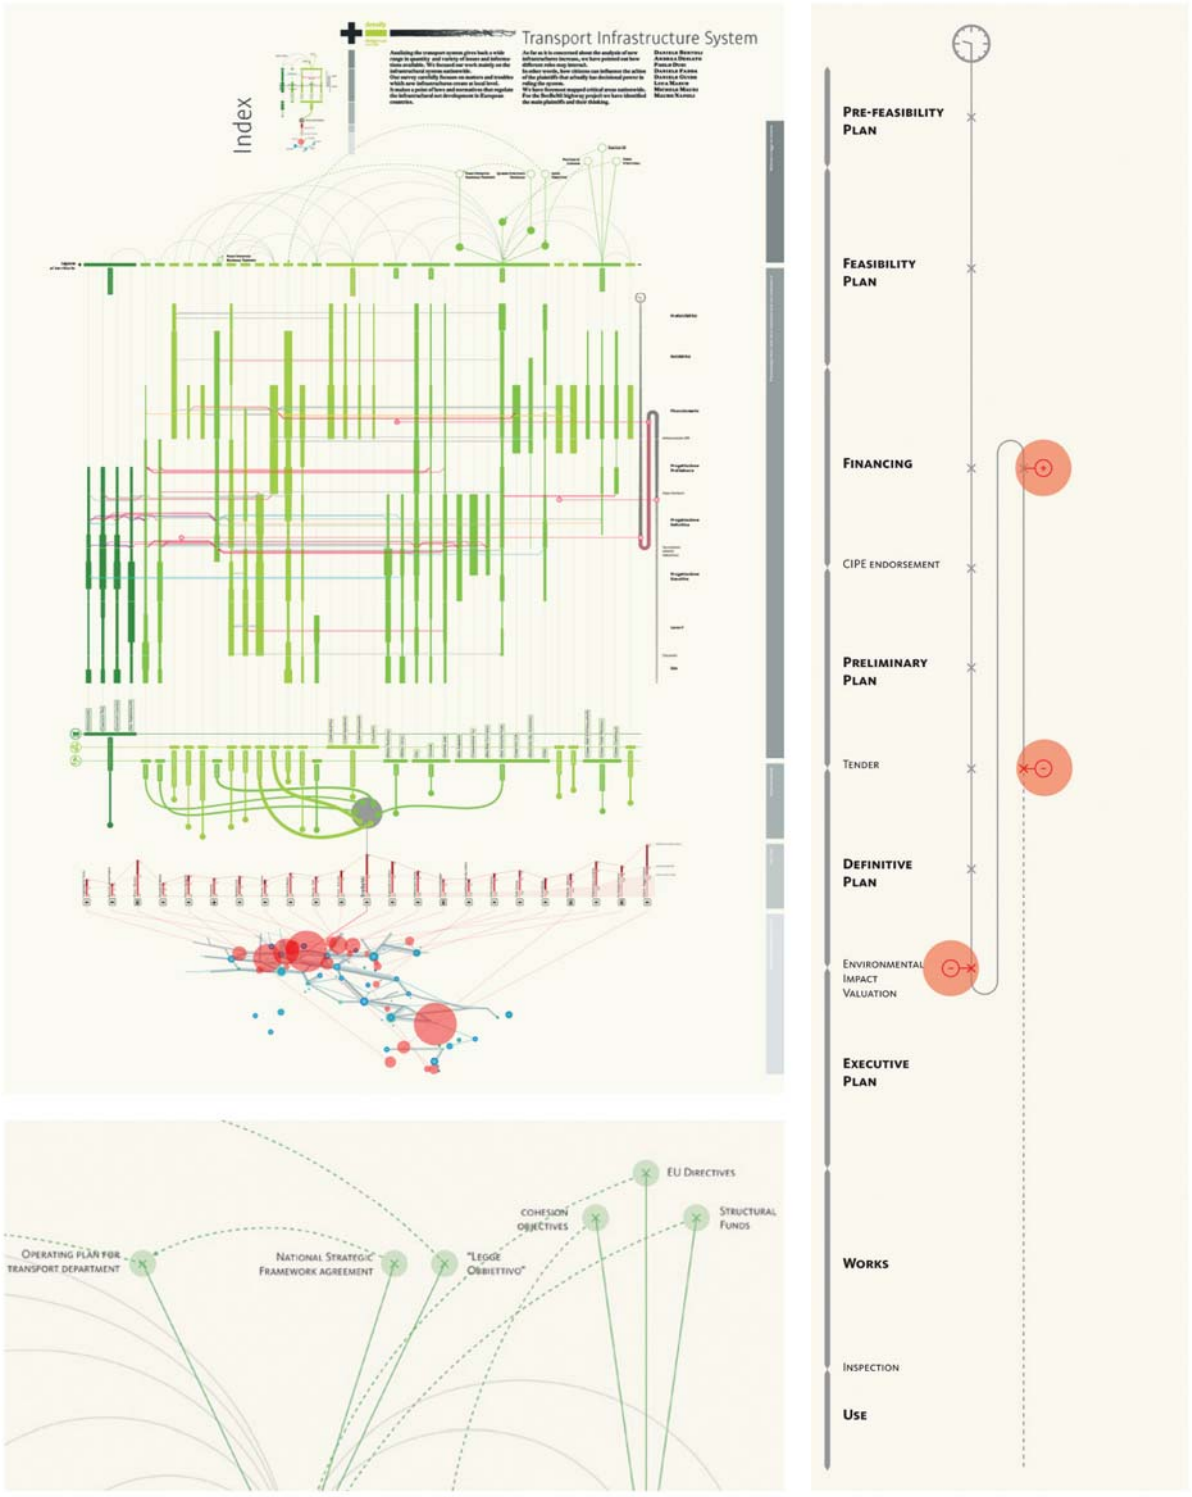
11 Density Design Lab is a research and experimental laboratory, born as a laboratory course in the final year of the Master Degree Course in Communication Design at the Politecnico di Milano.
12 The advisor is an expert of the system to be known and his task is to advise the group supporting them in the system exploration.
13 A fully detailed (pics, images, stories, knowledge base) description and explorations of the project is available at <http://densitydesign.org>

The fashion system case introduced time variable into framing process, limiting the representation to the last 5 years, which can be consider a relevant period in the fashion system evolution.

In the infrastructure system the frame seems to be well defined, focusing on the Italian controversies which new infrastructures planning and implementation create at local level. Students considered also the correlation between European laws and normative regulating the infrastructural network development.

	Purpose	**Framing**	**Graining**	**Scale**
Italian cinematographic system	Are the financings managed or influenced by subjects whose individual affairs are in conflict with the role that they dress again inside the system?	National extension, only focussed on production chain	Fine: single director and movie	Not provided
Fashion system	Do fashion capitals still make sense? Moreover are there new actors on the international scene?	Worldwide, 5 years	Coarse but “deformed”	Not provided
Contemporary art system	Which are the relations between influencers and the valorisation mechanism?	National extension	Medium	Not provided
Hospital system	Which is the relationship between the hospital structure and the patient emotions	Physical bound of the hospital	Very coarse: groups, hierarchies, protocols of the structure	Attuned to the communicative goals.
Italian media landscape	Are users reached only by few editorial groups? Is the same content provided in different ways giving a wrong idea of pluralism?	National extension	Fine: Editorial products	Not provided
Italian transportation infrastructure system	Which is the dynamic leading to controversies developing new infrastructures?	National extension, EU extension for laws and normative	Medium: Groups and institution, impact, % of project progress, cost	Some cluster of information were been depicted much in details than needed

Tab. 1 Resume of the system representation and visualization purpose and frame, grain setting parameters



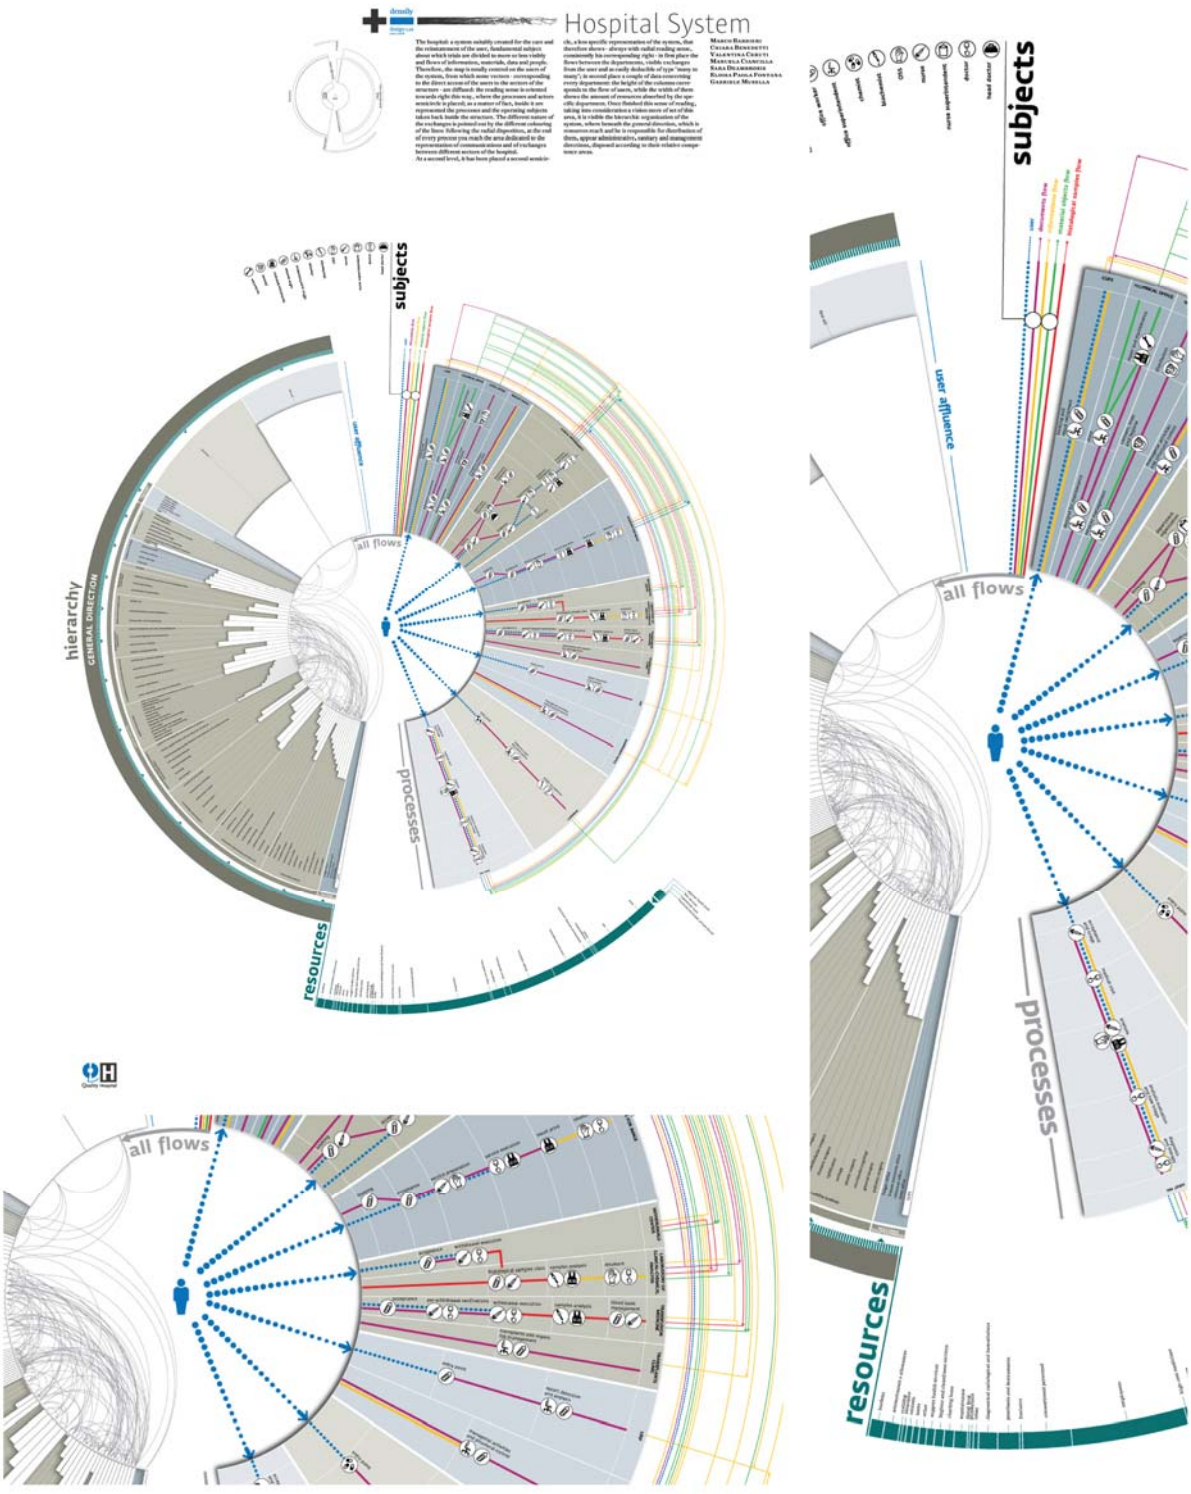
Img. 1. The Italian transportation infrastructure system diagram and some close up

5.2. Grain setting discussion

Not attuned to the purpose frames, easily affect graining process too, as it happened in the case of cinematographic system. Focusing on the production chain, fine grained filter has been applied detailing all the single film and director. The result is a huge quantity of single data not related each other; a coarser graining description of the system, investigating aggregations instead of single elements could better give sense to the influences affecting the production chain.

The approach to graining process has been different: sometimes very coarse (hospital system), sometime fine (contemporary art system). In other cases a middle level has been chosen: in infrastructure system grain, as in the fashion one, referring only to institutional agents and aggregate data. It has to be said, in the fashion system, due to unavailability of data the graining level has been “deformed”. Infrastructure system group sets the grain threshold starting by associations and local groups to ministries, departments and govern. Furthermore, in order to have a controllable parameter they selected data about infrastructure project on the base of project impact accounting the number of people involved, percentage of project progress and cost.

Often the relationship between framing and graining is very close as the case of the hospital system. The need to understand how an hospital works and which is the role of the patient, as stated in the investigation hypothesis, a very coarse level of grain has been required: representation concerned only the dynamics between different hierarchies and protocols of the structure. A finer graining level would have compromised the disclosure of the purpose, to understand the general mechanism of the hospital, and to trace every single individual agents would have masked the overall dynamic of the system.



Img. 2. The hospital system diagram and some close up

5.3. Scale setting discussion

In the six complex systems analysed the difficulties in choosing the degree of generalization of information, related to a specific communication goal, has been also faced.

It could be observed a general bias to visualize the system as it was known, too much details, not aligning the distance from the observed systems to the communicative goals pursued. Is the case of cinematographic system in which is not provided any kind of scaling, so the diagram do not shows the overall characteristics of the system itself. Instead, in the case of Hospital, scaling was coherently applied, and aligned. The diagram of the system describes the structure as well as the dynamics of the relations among the various agents constituting it. Furthermore to underline some of information has not been aggregate to clearly shown some of the analysis phase findings.

In the case of Transportation system in which framing and graining were well defined, some cluster of information were been depicted much in details than needed.

6. Conclusion

The tools described in this paper suggest paying a special attention to improve designer awareness in the use of diagrams; their use is proposed providing a theoretical framework. To sum up: the tools requires those who have to cope with complex issues to understand what is the purpose of system representation as well to stimulate a shared vision of it even through the use of framing, graining and scaling processes.

The framework proposed has been refined trough 4 years of didactic activities, leading to some limits, both logistic and related to the availability of only secondary resources. Thereby in the case studies, the use of time as a framing parameter has been affected by the lack of a real decision- making table and it has not been properly explored.

Overall, the experiments enlightened the effectiveness of the proposed tools, providing the students whit clear reference to approach complex systems. The processes proposed, negotiated with the teaching body and the experts, and emphasized the need of a recursive definition in order to share it. It has to be admitted that in some case the expected data availability affected too much the use of the tools, influencing both the effectiveness and the awareness in their use, they are the case in which parameters seems to be not tuned to the purpose of system enquiry.

The next step of this ongoing research would be a testing phase extended also to non academic contexts[14].

Some difficulties have to be noticed in the communication of the parameters setting to external actors to whom visualization have been presented, but in general term the diagrams effectiveness as facilitation tool has been well valued. Furthermore, it could be useful to design proper system to label visualization, developing new kind of legend. Information about how the framing, graining and scaling process have been performed, should be taken into account in this new kind of notation, in order to provide a clear explanation to all those who have to *work* with diagrams to help changes happen.

14 The tools and the processes here described will be adopted, in the Summer schools Workshop in the framework of Turin World Design Capital 2008. Further detail are available here:

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

How you define is how you design

Problematitic definitions in Design for Sustainability Education

Stephen Clune[1]

Abstract

This paper proposes that problematic definitions of sustainability, contribute to problematic Designs for Sustainability (DfS). Understandings of 'unsustainability' are embodied in realised design outcomes, or 'How you Define is How you Design'.

The proposal is explored through results of a three year action research project at the University of Western Sydney. The project aimed at improving the ability of undergraduate design students to Design for Sustainability. This was achieved by theoretical and pedagogical interventions within the sustainable design curricula to A. increase students understanding of unsustainability and B. assist in transforming this understanding into Designs for Sustainability.

Such interventions are required if we wish to influence the practice of our future generation of designers.

[1] University of Western Sydney (AUSTRALIA) – School of Engineering, PhD Candidate, s.clune@uws.edu.au

1. Introduction

This paper proposes that problematic definitions of sustainability, contribute to problematic Designs for Sustainability (DfS). Understandings of ‘unsustainability’ are embodied in realised design outcomes, or ‘How you Define is How you Design’.

The proposal draws on results from a three year action research study at the University of Western Sydney where theoretical and pedagogical interventions were implemented in the Sustainable Design curricula. The interventions attempted to A. increase students understanding of unsustainability, and B. transform the understanding of unsustainability into realised conceptual design solutions. This paper explores the process of how progressive DfS theories are transformed into conceptual design solutions in undergraduate industrial design education.

This paper is structured to provide a background to the framework of ‘How you Define is How you Design’ by a brief reading of the history of Ecodesign, illustrating that a poor understanding of unsustainability is embodied in design solutions and strategies. This is followed by a more appropriate definition of unsustainability. The methodology for the three year action research project at the University of Western Sydney is outlined, introducing the sample for the project in students participating in the sustainable design stream of the undergraduate bachelor Design / Industrial Design program. The theoretical and pedagogical interventions made in the sustainable design curricular in 2006 and 2007 are outlined. Finally the impact of these interventions is discussed in relation to students’ improved designs for sustainability, which were achieved through a more appropriate understanding of unsustainability.

2. Background

The historical reading of the progression of Ecodesign to Design for Sustainability also marks a progression in definitions of unsustainability. The framework of ‘How you Define is How you Design’ is used to explore this history of Ecodesign illustrating how definitions of unsustainability and design strategies are closely aligned.

The early focus of EcoDesign framed pollution as the problem, therefore cleaner production was the solution; waste was the problem therefore recycling was the solution; resource exploitation the problem, therefore LCA and design for efficiency (EcoDesign) were deemed solutions. These initial strategies represent a ’technical‘ school of thought behind which are the dominant forms of DfS engaged with to date by industry. The concern is that the dominant forms of DfS practice are based upon a narrow, non-relational and ill-defined notion of unsustainability.

A progression to more refined definitions of unsustainability offering a ’social‘ orientation for designers has been attempted, for example; Product Based Wellbeing was the problem therefore a service society via Product Service Systems is the solution. This marks a progression from the end of pipe solutions (waste and pollutions) to the front of pipe in acknowledging consumption. Schmidt-Bleek’s (1999) MIPS (material Intensity per unit of Service) presents a strategy that defines inefficient material consumption matched with poor service life as the problem, therefore more efficient material consumption and better service life are the solutions (MIPS).

Tischner’s progressive abstraction in defining problems can be applied to unsustainability as the definitions have progressively moved deeper and deeper to what would be the root causes of unsustainability (cited in Lewis and Gertsakis 2001). Moving from treating the symptoms of unsustainability to treating the cause introduces progressive theorists such as Manzini and Shove. Manzini defines unsustainability in social terms through a lack of commons and contemplative time, therefore he posits Design Orientated Scenarios that bring people together and the creation of contemplative time as possible solutions (2003). Finally Shove's work can be appropriated to define the problem of unsustainability in terms of Consumption, Cleanliness and Convenience in acknowledging inconspicuous consumption and the ontology of design as the problem, of which

to date there has been limited design response in interpreting the complex definition of unsustainability and transforming understanding into DfS outcomes. The hypothesis that a more informed definition of unsustainability will lead to more appropriate DfS is presented within this paper. The above overview of DfS strategies also marks a progression in the understanding of unsustainability.

Unfortunately the problem of poorly defined understanding of unsustainability is not isolated to industrial practice. Ramirez' (2006, 2007) studies of both Australian and International institutions teaching industrial design highlighted that the type of DfS taught is dominated by a technical approach focusing upon end of pipe strategies such as recycling and disposal. Educators defined 'sustainability as being identical with ecological design or green design, which focuses mostly on minimization of environmental impacts and usually not covering aspects of promoting equity' 2007 p3. This is problematic for Industrial Design education and indicates that an intervention is required to shift the understanding of unsustainability to a more holistic approach. Design education in the form outlined above may be contributing to broader problem of inadequately designing for sustainability.

The author's definition of unsustainability identifies embodied and inconspicuous consumption in our everyday worlds as the major contributor to the ecological crisis.

Drawing on discourse of embodied energy and ecological-rucksacks, embodied *consumption* shifts the focus to the demand side and refers to the energy, water and natural resources embodied within the products and services used within our everyday practices, a type of consumption which goes largely unnoticed by the consumer and thus leads to a 'disconnect' between the results these resources afford and the resources themselves. The concern of embodied consumption is best described by Frascara's observation of consumerist culture that 'ready-made products appear like magic' (1996 p 45). Lenzen illustrates that within Australia 48% of Co2 consumption occurs through goods and services purchased for the house (1998). The end-user only sees the tip of the iceberg in relation to what they actually consume.

Inconspicuous consumption refers to the inconspicuous (unnoticeable, unobtrusive, unostentatious) normality of our consuming (Shove 2003). Our default habitual daily behaviours consume a great amount of resources. Embodied consumption shows us only the tip of the iceberg in what we consume (the embodied consumption is hidden), where by inconspicuous consumption highlights that a large percentage of our consumption goes unnoticed as it is habitual, which suggests that the iceberg may not even be seen. Tonkinwise highlights that it is the 'throughput' of materials in the house are the core contributor to an unsustainable rate and scale of resource consumption (2005) and Manzini highlight that it is within the boring and mundane everyday where the drivers of consumption occur (2003).

Elizabeth Shove (2003) is influential in providing insight to inconspicuous consumption of the everyday; Shove presents our unsustainability by asserting that the normality of our everyday life is driven by comfort, cleanliness and convenience. Thermal 'comfort' has seen a shift from personal heating which most civilization developed as a means to maintain comfort of the individual through clothing, to space heating in the warming of a larger environment (home, workplace, car and shops) to maintain comfort. *'C*leanliness' identifies how shifts in bathing and laundering habits have occured, for example a major shift in practice has occurred from the weekly shower to the twice daily shower with obvious resource implications in water usage. Finally 'convenience' and social efficiency allowed products to be a dominant focus within the house; products designed to create or manage time dominate the aisles of our shopping centres i.e. 'fridges, freezers, vacuums, microwaves, recorders and packaged food all share the premise of convenience. Shove provides insight into the normality of the everyday practices that have contributed to the unsustainable behaviours of the present. Shove's perspective on inconspicuous consumption is critical to defining why we are unsustainable. In order to design for sustainability an understanding that acknowledges the drivers behind inconspicuous consumption is required, Tony Fry's philosophy of Defuturing does just that.

Tony Fry philosophy of Defuturing provides a process for understanding the drivers of unsustainability and strategically targeting interventions that may contribute to sustainability. Fry's philosophy suggests that our present is a construct of the past, therefore the future will be a construct of the present. Through deconstructing our past and why we are unsustainable, a road map to sustainability can be developed (1999). The philosophy is heavily drawn upon in encouraging students to create a holistic perspective on unsustainability prior to offering DfS solutions.

This paper illustrates how the University of Western Sydney has engaged in the shortcomings outlined above through an Action Research project over three years. The project developed interventions aimed at engaging industrial design students with A. a deep understanding of the drivers of unsustainability to form an appropriate definition and B. to transform the definitions into conceptual design scenarios.

3. Methodology

Action research was used to integrate the interventions through the three year project. Stenhouse (1975), Carr and Kemmis (1983) proposed the 'teacher as researcher' as a viable profession to contribute to knowledge, however Kemmis notes that today the 'teacher as researcher' has limited application due to national curricula and reduced teacher responsibility (Carr and Kemmis 2005). It is believed that Industrial Design education is still afforded this original position as industrial design is not governed by a national curriculum (like nursing and education) therefore the recommendations made have a direct route to impact within the curriculum of the design disciplines.

The project examined over 500 conceptual DfS scenarios which were the outcomes of student assessment tasks at the end of the compulsory sustainable design stream. The second year industrial design students had completed the formal sustainability stream therefore the results are indicative of their understanding of unsustainability at the particular time, the proposal 'how you define is how you design' forms the premise for this assessment. The assessment tasks were 'conceptual design scenarios' illustrating sustainable solutions to thematic areas i.e. water, transport and energy. The structure of the unit is modeled on Tony Fry's Defuturing in that 'the present is a construct of the past, therefore the future will be a construct of the present'. The unit offers three distinct periods in the past, present and the future. The past is explored by a tutorial exercise where by students identify why we are unsustainable and how design has contributed to this. The framework of Shove's Comfort, Cleanliness and Convenience (2003) is used to illustrate how inconspicuous consumption is attributable to design. The nucleus of the 'how you define' unsustainability is formed through this task. The present is explored through contemporary trends research where current trends are extrapolated for their potential impact on a sustainable future. The future scenarios are constructed in a series of day long intensive workshops utilizing a hybrid model of scenario planning (Lopes, Clune et al. 2007). Finally Designers respond to the scenarios with 'conceptual design scenarios' to contribute to a sustainable society.

Using content analysis the 'conceptual design scenarios' were examined against categories represented within the progressive DfS theory. The categories for analysis included the sustainable 'school of thought' that was represented by the design scenarios, be that 'technical', 'social' or 'socio-technical'. Brezet's (1997) four types of innovations in 'product improvement' offering incremental improvements to existing products, 'product redesigns' to existing products to offer resource saving, 'functional innovation' where by the function of the products is questioned and met in alternative ways and 'systems innovation', where systemic changes are offered as the solution. The potential resource reduction was also measured through a quick MIPS (Material Intensity per Service of Use) calculation which located the degree of resource reduction that the design's offered.

Content analysis was used to internally validate the results across the interventions that were made in the years ending 2005, 2006 and 2007. The interventions were both theoretical and

pedagogical, and focused on both sides of the framework ‘How you define is how you design’, to better our definition of sustainability ‘how you define’ by increasing students understanding of unsustainability, and second to transform the understanding into realised conceptual design solutions ‘how you design’.

4. 2005 Pilot; troublesome definitions of unsustainability

2005 was a pilot year for the study and highlighted that the students’ conceptual design scenarios struggled with two key elements; first the radical scale of achieving Factor 10 reductions and second, the proposed agency of design to effect change outside of technical product design. The problem lied in defining both ‘unsustainability’ and ‘what Industrial Design is’.

The majority of conceptual design scenarios offered designs with incremental ‘product improvements’. In relation to resource targets established such as factor ten and factor twenty only a fraction more than ten percent of solutions reduce resources greater than factor ten, with over sixty percent of solutions offering only incremental improvements. While resource reduction is not the only criterion, the designs did not engage with the social or social technical school of thought, which the author hypothesizes as contributing to low scale of resource reduction. The understanding of design’s agency to influence behaviours or to operate at a level outside of the product was largely absent. The problem in defining is not only located in defining unsustainability but in defining the scope of industrial design, viewing industrial Design as a purely product orientated occupation. This, it was hypothesized, severely curtailed students’ ability to contextualize design’s agency within society.

The road go-cart (see figure 1.) is a typical example of a student’s response to transport. The solution is purely focused on the car as the problem. The solution that is presented is more fuel efficient and uses less materials, and is well refined with regard to technical detail. However throughout the process the demand side of transport was never questioned. The complex social drivers underlying the need for the car are not acknowledged in how the student has defined the unsustainable problem to respond to,

The intervention planned for the following year focused on two areas; first to increase students understanding of unsustainability with regards to the scale of resource reduction required in relation to the demand-side drivers of unsustainability and design’s agency. And second the process for transforming the understanding of unsustainability into design solutions was developed.

A series of lectures, debates and tutorial discussion were implemented. The lectures quantifying the ‘scale of reduction’ were given explaining the underlying rationale for targets such as factor 20. Formal debates within class were held, for example ‘is the Tesla Roadster is an effective transport solution for Sydney?’ The opposing sides were briefed with alternative information, one pro evolving car technology one pro public transport, walking and biking. The examples of Curitiba's public transport system and the grand Lyon Velib bike share were pitted against the electric Tesla. The debate explored the limitation of electric cars to reduce congestion and more widespread issues of city planning, exposing the limitations of the technical solutions and the opportunity represented by public transport, walking and biking to contribute in a greater way to the transport mix. Tutorial discussions on Ezio Manzini’s criterion for the sustainable Everyday projects in light of the student’s project were also conducted. The criteria of ‘low material and energy intensity’ was easily understood, however the criteria to ’integrate and share’ and ‘bring people closer’ (Manzini, 2002, p.10) appeared to be an abstract criteria for students and a dimension of sustainability that has previously not been considered.

Particular attention was paid to the transformation of nascent understandings of unsustainability into design solutions. While it was identified by the researcher that the student design in 2005 were not representative of sound definitions of unsustainability, it was difficult to locate if the problem was simply a poor understanding of unsustainability, or that the designer’s lacked the skills to transform the broad definition of unsustainability into resolved design solutions To transform the understanding of unsustainability into design solutions, several mechanisms

were put in place which included articulating the polar opposite of sustainability, transforming the understanding into a brief for sustainability and applying creativity tools to the brief to refine DfS.

First the definitions of unsustainability were articulated, templates were developed to articulate why we are unsustainable. For example our transport is unsustainable because of A. dependency on oil, B. dependency on transport including conventional modes of satisfying this dependency At this stage, students were encouraged to address the root cause, to move beyond the obvious issues of cars being the problem to the underlying causes i.e. Urban sprawl and divided work and home locations. The polar opposite of unsustainability is then articulated to formulate criterion for sustainability. The criterion for sustainability is then transferred into a human-centered design brief. Once the design brief is identified the hypothesis is that students are now working with the familiar tools of design, just a slightly altered brief. The abstract notion of sustainability has been transferred into a straightforward design problem. The focus presented from the design brief allows creativity tools to be applied. Creativity tools require a well defined problem to enable them to succeed (Osborne 1963, Shneiderman and Fischer 2005) which the design brief affords. Even if students are adverse to sustainability all that is required is the appropriate application of design skills from this point forward.

> To assist ***your persona*** complete the daily activity of ***picking up the kids from school*** within the quadrant comprising of ***Urban Sprawl/Home Ownership*****,** whilst satisfying the design criteria of: A. low material intensity (less material removed from nature therefore having a smaller environmental impact); B low energy use in any form - electricity, fuels (solutions must be highly efficient across the life of the product); C. high regenerative potential (enhancing and if possible regenerating environmental and social resources); D. providing a positive experience in that completing the activities is fulfilling and E. ***reducing car dependency.***

A suite of creativity tools are then applied to design briefs in intensive day long workshops. Previously in 2005 the problems lacked focus; while we encouraged students to generate multiple solutions, when it came to the selection of solutions the lack of criteria curtailed students ability to make decisions.

The creativity tools drawn upon by staff included Osborne's checklist, morphological analysis and think back exercises. Morphological analysis charts are developed with students to expand the number of possible solutions they have to pursue. One creativity tool developed that proved successful is the 'Think Back' exercise (Lopes, Clune et al. 2007) which supports Fry's philosophy of defuturing. Students are asked to 'Think Back' to a time in history when society addressed its needs without electricity, air-conditioners; prepared food without fridges or coordinated social events without mobile phones? The exercise is successful as it forces students to acknowledge that there have been alternative practices in place in the past and that there is a great opportunity to draw on and re-invent such practices in the present.

5. 2006; Pedagogic interventions

The results of the first intervention saw an improvement in the student's conceptual design scenarios. The percentage of designs that addressed a higher level of resources reduction greater than factor 10 had increased by 12%, and there were 19% fewer designs that were classified as incremental improvements. The results were also encouraged by designs drawing upon higher types of 'functional' and 'systems' innovation.

The results indicate that positive ground had been made with regards to students' understanding of the problem of unsustainability. The solutions had addressed sustainability at a deeper level. Figure 2 'A suite of solutions to reduce demand for commuting' is typical of the design solutions presented in 2006. The solution progressed to the demand-side of transport, attempting to resolve the issue via reducing demand as opposed to making vehicle more efficient. Available technology was drawn upon to create a scenario that would significantly reduce the demand to commute for work and study. The solution is successful when judged against the metrics used in the study. The alternate criteria for sustainability, combined with a well thought

through design brief assisted to create alternate ‘conceptual design scenarios’ which supported the notion that ‘how you define is how you design’.

While progress had been made in student ability to design for deeper levels of sustainability, primarily through the generation of sustainability criteria and design briefs, Industrial design’s contribution to the process appeared to be poorly understood. The concern of the author was that the process developed had facilitated design responses that forced students to design solutions representative of the criteria, which was formed on a slightly more progressive understanding of unsustainability. The learning that occurred through the process was however, shallow. Students completed the process and generated concepts; however they had not located the solutions within the context of everyday life.

The apparent shallow understanding led the author from focusing on *what* to teach to focusing on *how* to teach, and the pedagogy used in education for Sustainability was engaged with. Multiple sources converged upon deep learning as the appropriate pedagogic approach to best facilitate Education for Sustainability (Ben 1999, Warburton 2003). The key to deep learning is on moving the delivery of the unit from being teacher-centered to student-centered.

Deep learning is closely aligned to the constructive approach to knowledge, in that the teacher cannot hand out know ledge; knowledge is created through the learner via the transformation of personal experience (Dewey 1963, Kolb 1984). Learning by doing to create understanding is closely associated with deep learning, while surface learning refers to more temporary learning (Williams, 1992, p45 cited in Beatie et al 1997) often associated with rote learning. Deep Learning is therefore assumed to be the appropriate pedagogic approach for DfS where understanding needs to be decisively linked to thinking and the planning and making so integral to design. Wanting students to be engaged, enthusiastic, understanding and appreciative of the subject matter is advocating a deep approach to learning (Lublin 2007). The hypothesis was that by employing the pedagogy of deep learning, greater engagement from the students with the problem of unsustainability would be afforded, which by default would lead to heightened DfS solutions through the framework ‘how you define is how you design’.

Industrial Design is in an advanced position with regards to deep learning as the constructivist approach of ‘learning by doing’ is a staple in design courses, Industrial Design almost teaches Deep Learning by default. Yet a comparison between the strategies for deep learning and the teaching of sustainable design highlighted that the unit could be delivered with a far more student-centered approach.

Engaging in the students’ perspective forms the core of Deep learning. The interventions that were implemented as a result of this engagement centered on removing the ambiguity from the unit structure and assessment tasks, while a student-centered focus was achieved through increased peer review and opportunities for personal reflection.

Previously the structure of the unit had phases of Fry’s defuturing operating concurrently, for example students were answering a tutorial question on the historical reasons to why we are unsustainable (focusing on the past) while at the same time collating contemporary trends research (focusing on the present). There was ambiguity in not having a clear focus to the task at hand from the student’s perspective, which reduced the capacity to fully engage with articulating an understanding of the problem (unsustainability). The unit was therefore divided into three distinct sections to provide a clear structure in the past, present and future. The assessment tasks were rescheduled to support this structure, and also reduce conflict with other units. A side effect of the rescheduled tasks was that the actual time spent designing was reduced; a greater period of time was spent deconstructing the problem so that when students were finally asked to design there was a clearer framework for what was required.

To encourage a student-centered approach peer review of assessment was implemented to enhance group cohesion and further progress an understanding of the objectives of the unit. To encourage personal engagement empirical data collated from previous subjects completed by students in LCA personal journals was used to generate current trend research and engage in the student’s experience. Using past assignments is also viewed to encourage personal reflection

throughout the course and build a holistic view of education. To further encourage student reflection tasks were scheduled to allow for development and reflection. Often reflection is asked for at the end of the session when there is liitle chance for change. Asking for reflection in action as advocated by Schon (1991) by asking reflective question intersession allows students to modify the conceptual design scenarios prior to submission of the final assessment.

The majority of interventions planned for 2007 were pedagogic and related to encouraging deep learning. The same theoretical content was presented within class as in 2006, with a slightly altered delivery in 2007. However two notable changes occurred in delivery. First between the creation of the design brief and creativity tools being applied, students were asked to provide utopian solutions that fitted the brief perfectly. From the solution students were then asked how the solutions could be implemented, drawing on Mckenzie-Mohr's (2000) community based social marketing, students identified barriers and benefits to the solutions were then transformed into further design briefs that the creativity tools are applied to. This step was missing in the previous cycle resulting in strategies being presented instead of design solutions.

The second was the presentation of the final concept in the form of a storyboard of the 'conceptual design solution' context. The process of story boarding assists students to think through how there solution is integrated within society. An example was developed and presented to students from previous year's work; this also assisted in setting expectations within the unit.

6. 2007; Reconciling Defining and Designing

The results of the pedagogic intervention appeared to significantly alter the results presented within the unit. The results from 2007 saw 'conceptual design scenarios' embodying Brezets 'System Innovation' increase by 18%, and for the first time saw the majority of solutions embody a 'social' school of thought. The higher achieving students reconciled a sound definition of unsustainability (how you define) with designed solutions (how you design). The solutions moved from strategies as the concept, to strategies with concrete technical designs to facilitate the concept. Instead of presenting sharing as the concept, designs to overcome the barriers of sharing were presented. CBSM potential to generate design concepts appeared successful.

The minor change in presenting story board and designing utopian visions also appeared to have a positive impact. The example (figure 3.) presented as a storyboard highlights how the sustainable strategy is proposed (sharing), but relies on technical design in order to bring the strategy to fruition suggesting a normalization of the role of design's social agency. The poster assisted students to think through the design solution in context.

The process of encouraging students to design utopian visions is one that Andrews (2007) and Fry (1999) argue as dangerous. The utopian visions created by the early industrial designers such as Bel Geddes' Futurama and Dreyfuss' Democracity were top down visions void of humanity, they assumed the god-eye perspective of planning from above as expert, visionary leaders, yet they were complete and detailed but devoid of humanity: people were absent in the visions, reflecting a failure to grasp future social relations (Nye 1994).

The dangers were managed by; A. having an excellent understanding of why we are unsustainable through a defuturing exercise B. forecasting a probable scenario narrative (persona based and therefore human centered) on trends research, making the utopian scenario very much a response to the probable future narrative, not a blank canvas and finally C, Checking the vision with regards to barriers, desirability, implications and normalising capacity of the design solutions. The utopian visions encouraged uncompromised scenarios as the starting point, which moved far beyond the incremental improvements seen in 2005 and 2006 and the majority of EcoDesign case studies presented in the design literature. The scenarios were then worked backwards; the barriers to implementation actually created opportunities for design .i.e exploring the barriers to communal living highlights points for design intervention.

While the minor pedagogic changes when looked at in isolation appear insignificant and trivial, the impact on education is significant, the results across the three years cycle highlighted that the pedagogy of design education has an equal importance to the theoretical content delivered. This should not be underestimated. The process is testament to how Action Research can be utilized within design education.

7. Conclusion

The combination of interventions lead to conceptual DfS scenarios that better embodied the progressive sustainability theories via a better problem definition of unsustainability. This was evidenced by higher instances of systemic social-technical design solutions presented by students.

If we are to re-orientate towards more sustainable directions, enabling designers the skills to seek and define why we are unsustainable, and transform that knowledge into resolved conceptual designs is critical. If designers cannot adequately visualise an appropriate response to unsustainability within the confines of academia, then there is little hope of implementing solutions with the additional pressures of professional practice. The argument presented in this paper highlights the key role education plays as a bridge between theory and practice, enabled by the teacher as researcher. In conclusion a greater emphasis on the problem definition of unsustainability in context leads to higher designed outcomes.

1. Introduction[3]

The approach to fashion design and system build around it must be faced in cross-sectional way; to work on fashion doesn't mean develop a dresses collection but it refers to the analysis of design processes that generate the project intention.

The research focuses on the territorial dimension of the project, which is meant to be a resource for the development and support of local economies, helping them to increase the value of their cultural identity and their design process as well as production's know how. While places and people are closely entwined and where modernity is liquid, the idea of an identity linked to "*what tradition is able to produce*" has a higher meaning, thanks to its relation to local culture, memory and spirit. The so called *Genius Loci*, i.e. what survives the unceasing changes of time, gives to the territory an indelible character and therefore makes it part of a unique and characteristic experience.

We are currently seeing the return and a new discovery of traditional techniques and manufacturing, which have re-appeared in the contemporary world with a new look and a new balance. The set of traditions, meant as material culture, can be identified with the craft manufacture, which becomes the founding element of a community's identity. As it is subject to changes in time, the set has to be interpreted as a variable heritage which should be preserved.

In some cases, the typical local "know how" has slowly been taken over by the industrial production system, which has been able to combine the craft's quality with the most advanced production techniques. This is the case of Italian industrial districts, which historically rise from a set of inherited skills concentrated on a specific territory, and are a perfect expression of an aggregative model of the most edgy Italy. Up to recent times, handicraft has been identified as something hostile to modernity, due to its dislike for standardization. Nowadays instead, it represents a model for the post-industrial production, thanks to its unique characters, its intolerance to "similarities among all products" and its exaltation of the product's personalization.

Considering such observations, we can identify a new trend aiming to recover settled in time values, through the strong relationship that connects an individual to a community and manual arts to history and local identity. The nostalgic memory of the past spreads out, together with the desire to recover objects and memories which belong to the past. If in historical evolution of Design we assist, at first time, to research and experimentation for the realization of an object, and then to research and technical evolution of the product, today we can assert of be observer and responsible in a phase of " Design Experience" where there's the new and innovative concept of design for customer. The new tendency of Design research try to emphasize all the elements that it's necessary to communicate.

Fashion and design, with Art, represent the expression of a society wish, able to understand the changes, rejecting, to the same identity need, the Zeitgeist in a precise historical moment. Continuing technological research, permanent experimentation and discovery of new declination of Design make Design able to become communicators of emotions. Today the object of market and consumption is not only the simple possession of a specific product but it is the experience, as enrichment of the subject, that the customer can live inside new worlds, according to values of the brand that create add value to the existence.

2. Situation of the Italian Textile System[4]

"The fascination of hand-crafted objects derives from an object having passed through the hands of someone, the marks of whose labour are still inscribed upon its surface; we are intrigued by what has been created; it is unique, because that moment of creation cannot be reproduced" (Baudrillard 1968)

In recent years, the Italian Textile/Fashion industry has been facing a crisis. This is due to market globalization and to delocalization processes, which shift production to countries where labor cost is lower. In turn, this makes it necessary for companies to rethink their creative, productive and distribution activities.

The Italian textile sector, with its historical traditions, is characterized by a system of small-medium independent businesses, highly specialized in different stages of the same production process. Italian companies were able to introduce into the market a remarkable variety of products with innovative design and technical content. Moreover, the particular attention placed on style and aesthetics has been the key to the success of *Made in Italy*.

This particular business organization model, i.e. the *industrial district*[5], is a local system strongly based on one, primary production activity. In order to increase production, the companies belonging to this system tend to develop synergies.

The industrial district model has two strong points. The first is its tight connection to the territory it belongs to, based not only on shared technical/productive know-how, but also on a common entrepreneurial culture and shared values. The second is its systemic approach in developing connections between companies working within the same production chain. Such systemic approach improves the district's overall efficiency according to the *flexible specialization* model, that is, the system's ability to react to internal and external changes. For instance, we can talk of "product flexibility" when companies produce a new product or radically change their product, or we can talk of "process flexibility" when companies are able to modify the production processes employed for the realization of their product.

Thus, Italian textile industry is characterized by a high fragmentation of the production chain among different companies. Virtually all of them are small or very small companies specialized in different stages of the textile-fiber and yarn manufacturing. They are unable to compete on the market with bigger companies that can delocalize their production in more competitive and remote countries. The progressive loss of the district's expertise and specialized personnel can be an important consequence of this mechanism. In addition, its productive know-how could be transferred to emerging countries, which would become even more dangerous competitors.

Due to their difficult market situation, companies need to find new strategies and new products, as well as achieving better quality, flexibility and product personalization. This is how they will be able to enhance the value of their specific production.

The crisis of the textile sector is to be faced with a well-defined entrepreneurial policy; priority must be given to continuing research and product innovation, as these are crucial steps towards the reconfiguration of the textile/ fashion system within today's overstocked market.

[4] By Federica Vacca, Politecnico di Milano (ITALY) - INDACO department.

[5] In Italy the status of *"industrial district*" has been acknowledged by Law 317, 1991 (Interventions for the innovation and development of small businesses). According to this law, districts are local areas characterized by a high concentration of small businesses, and by the productive specialization of all the activities involved.

3. The recovery of tradition[6]

Today there is a renewed interest in traditional techniques and productions, which return to the contemporary world with a new aspect and new functions.

From the etymological point of view, tradition is "*the transmission of past generations' cultural heritage (i.e., laws, habits, memories, historical facts, etc.) by means of written documents or verbal communication".* It can also be defined as *"cultural content transmitted by past generations that can contribute to the preservation of identity*"[7].

The cluster of traditions intended as *material culture* is identifiable with crafts production. This kind of production, therefore, becomes a founding element of the identity of a community. As it changes throughout time, it can be defined as variable heritage that must be preserved.

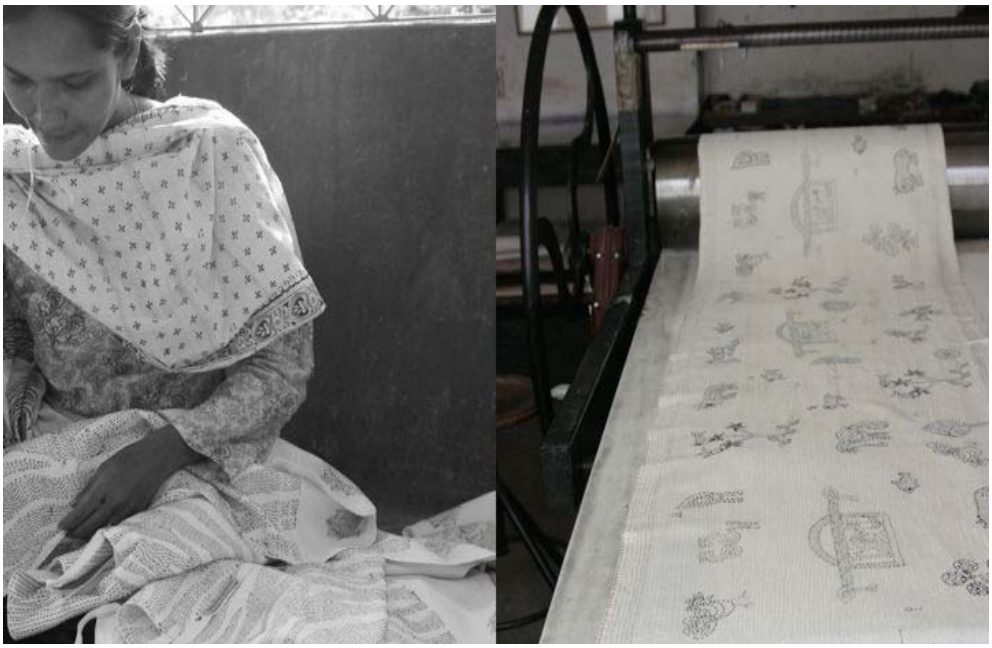

Fig. 1: Craftswomen at work on the Yooj collection.

In some cases, local *know-how* has been absorbed by industrial production, by combining crafts quality with the most advanced industrial systems. This is the case for industrial districts. Historically, they originate from a locally-concentrated heritage of skills, and represent today a successful aggregation model within Italy's most advanced region.

In the recent past, due to its open rejection of standardization, crafts activities were viewed as hostile to modernity. Today, on the contrary, craftsmanship has become a model for post-industrial production thanks to its unique character and personalized production, which rejects today's "everything is the same" mentality. Crafts help defining the cultural identity of production through their ties to culture, memory and tradition, and by doing so, they potentially become an element of innovation.

While cultural elements are often neglected by the industrial production system, they hold a crucial role in local crafts productions. Indeed, the value of the product depends less on its material quality than on the symbolic, emotional and identification meaning that consumers see in it. Therefore, craftsmanship in all its forms can be seen as "memory of habits" and "*transmission*

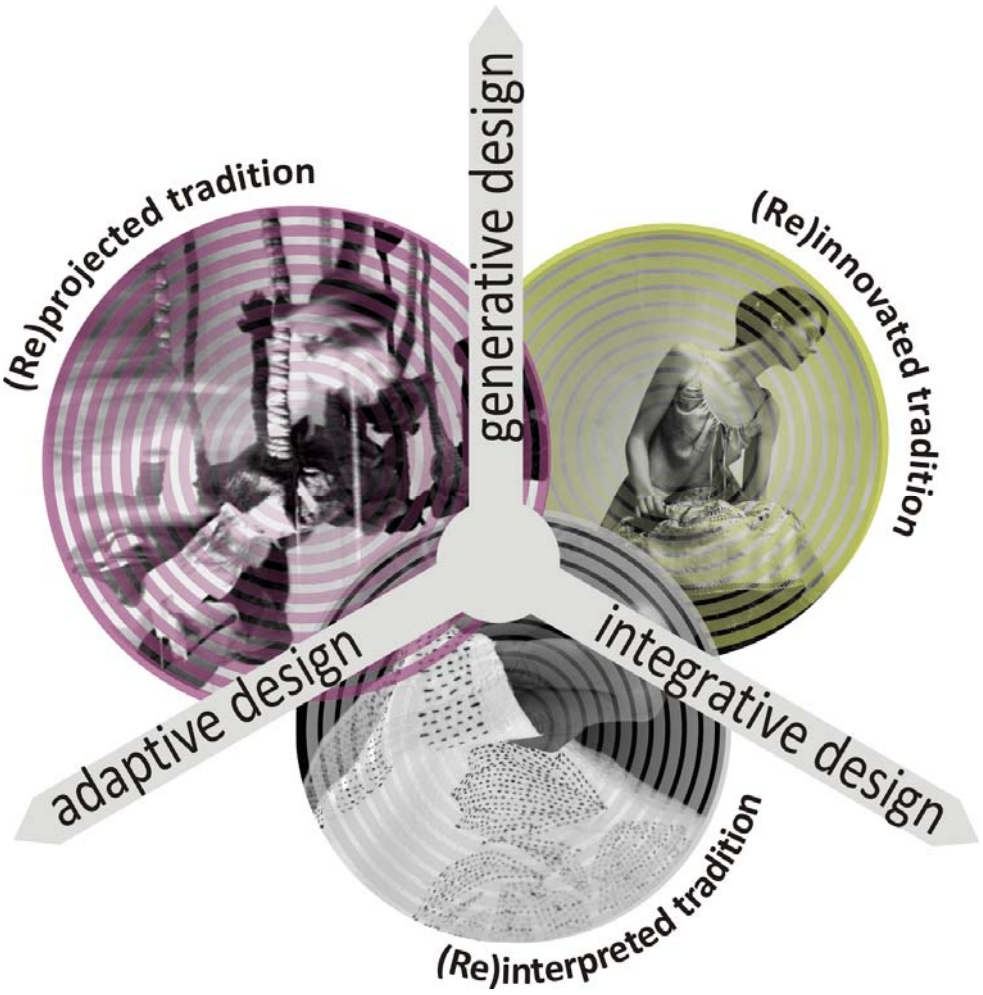
[6] By Federica Vacca, Politecnico di Milano (ITALY) - INDACO department.
[7] Definition from "Il Grande Dizionario Garzanti di Italiano", updated edition, 2007.

of meanings". It embodies the complexity and variety of a dimension which, when unable to transform itself, tends to inevitably disappear. The preservation of identity as a positive inheritance of crafts culture, as well as the transformation of planning and productive processes, means the creation of new languages that re-interpret crafts techniques with a contemporary taste, and avoid the passive reproduction of style and form. In other words, this process no longer produces traditional goods, but it produces value.

For manual arts in the textile sector, the relationship between tradition and modernity is crucial. We can talk of product innovation when a product is perceived as "new" by the market due to the way it looks, its characteristics, performance or meaning. On the other hand, we can talk "process innovation" when its aim is to cut costs, and add value to traditional processes connected to local identities, and to be more sustainable, flexible and fast in answering market needs. The analysis of planning and production processes leads to the identifications of different actions that can be performed in order to innovate the textile sector and recover local know-how by focusing on the development of high added-value market niches.

In terms of process, there are three possible interventions that can be performed:

- **adaptive** actions, that is, the adaptation of external know-how. Production is given a new meaning through the transformation of existing processes.
- **integrative** actions, that is, the integration of pre-existing know-how belonging to different sectors of production.
- **generative** actions, which tend to develop new know-how and competences.



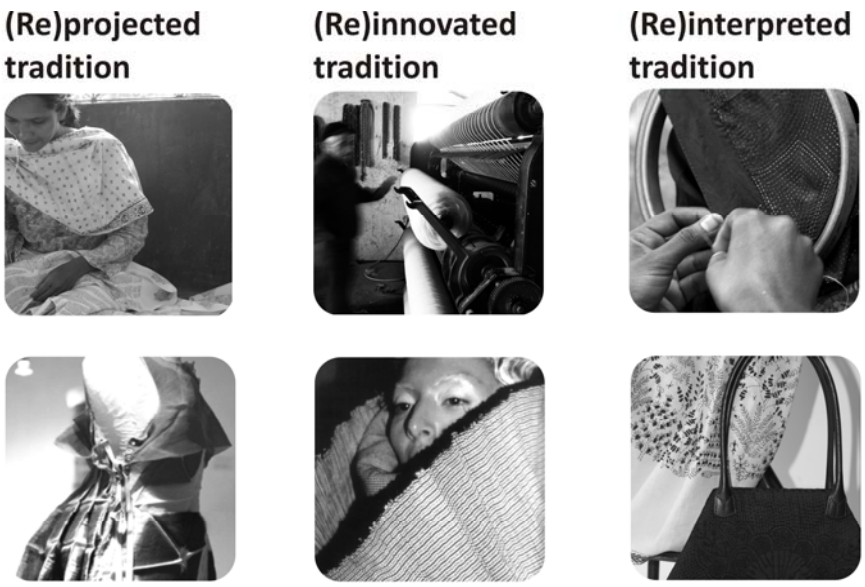


Fig. 2: Combination of interventions in terms of processes, as interpreted by the author.

Possible kinds of innovation connected to the *material culture* of craftsmanship can be obtained with a combination of these actions:

_**(Re)projected tradition:** production processes and textile techniques – from spinning to dye- are de-contextualized and transferred from the place of origin to new contexts with new codes. This is an *adaptive*/*generative* action because, on the one hand, existing crafts techniques are *adapted* to different needs, re-projected and removed from their original context; on the other hand, this transforming action can also *generate* new languages and new meanings according to market needs. As a consequence of this action, the original identity of the process is inevitably lost. The cluster of traditions and memories that informed the process identity are dissolved. Indeed, the process is no longer performed by expert craftsmen that inherited the know-how from past generations, but it is performed by new craftsmen who learned these techniques and re-interpreted them by revisiting their concept and meaning. If techniques with specific identities are passively reproduced, the importance and meaning of crafts tradition is at risk. On the other hand, this action can provide new, vital energy to techniques that would otherwise be lost due to the sector crisis, by combining them with new and more market-oriented know-how.

_**(Re)interpreted tradition:** manual traditions are recovered by partially removing them from their context. While the productive know-how continues to have its roots in the local territory, the planning process is performed beforehand by an external figure that projects the local know-how towards new results and different markets. This is an *adaptive*/*integrative* action because, on the one hand, it *adapts* handicraft productions to planning strategies different from those that traditionally belonged to the territory, thus producing innovation. On the other hand, it also *integrates* the know-how connected to these different planning strategies. In this case, techniques do not lose their identity; rather, the final product is improved by the addition of new meaning belonging to different contexts. If not supported by strong planning strategies, these techniques and the cultural heritage they come from are at risk of becoming copies of themselves. This approach is strongly oriented to the quality of the final product, which must be improved in its aesthetical form and in the codes and meanings it conveys.

_**(Re)innovated tradition:** traditional processes remain strongly tied to their original territory, therefore become an innovation tool for local communities. This is an *integrative*/*generative* action because, on the one hand, it *integrates* different processes which, in turn, generate a new process, with renovated projects and products. On the other hand, it

generates a new language that adds value to the final product. It is crucial to define a specific strategy that can combine memory and innovation according to new codes of expression. At the same time, it is important to activate processes and cultural changes that can produce innovation and development, and that have positive consequences for the local territory. Indeed, the greatest advantage of this action is precisely the involvement of local communities with shared identity. This action is highly process-oriented; that is, the process is the starting point to obtain an innovative product, both in its material aspect, improved by a specific planning, and in its immaterial aspect by adding new languages and meaning.

4. Emotional&Experience design. Designing objects or designing values?[8]

"*User's Experience is a specific reflection tool for many disciplines and activities connected to entertainment, consumption and design*"[9].

In the last few years, some aspects of consumption and entertainment have changed into dimensions where "*subject-consumers are surrounded by fluxes and inputs that make them experience something*"[10]. The continuing technological research, the constant experimentation and the discover of new dimensions for Design, lead Design itself to convey emotions.

The object of consumption is no longer identified with the mere possession of a given product; rather, the object of consumption is the *experience*, meant as the self-enhancement that the subject-user can experiment within new environments. These dimensions are coherent with the brand values and experience of a certain brand, created to add vital elements to existence.

"*Emotions modify the way in which human mind solves problems*", claims Donald A. Norman in his book *Emotional Design*[11]. "*The emotional system modifies the operative modes of the cognitive system*". Emotions are defined as vibrations that slip into the body and provoke curiosity, which, in turn, facilitates learning.

"*Emotions are the organism's answer to a change within us or outside us. They arise when something is not like it used to be a moment before, thus modifying the subject's status and provoking a feeling of uneasiness (negative emotion), or a feeling of well-being (positive emotion). Emotions arise from changes, and each change entails movements; in this case, inner movements that are then expressed outward. […]*"[12].

Emotion is therefore traced back to memory. In fact, emotion is not merely a factor influencing mystic functions, but emotion itself becomes a kind of memory. Senses are the starting point for the formation of emotions; external inputs reach the brain, which in turn responds to complex interactions. The brain's answers can be physical reactions, such as the increased heartbeat and perspiration, or behavioural reactions such as fear, rejection, joy. Emotions make us act and react according to the inputs received. Emotions interact with other systems within the organism, such as the cognitive system, the immune system and the perceptive system.

In time, the emotional component gained a very important role, especially for consumption activities. The sensorial approach has been universalized. Shops have become the place of cultural suggestion, while the *open museum* combines products sale with art, cinema and theatre. The new concept of *Experience shopping* defines an experience lived by consumers through the definition of 5 mental macro-areas: thought, feelings, action, relationship, sense. Recent studies analysing the relationship between men and the environment underline that space is not neutral

[12] S. Giambelli

but generates mental states. In other words, different ways of organizing space have a specific effect upon our nervous system. This new paradigm provokes new experiences and interdisciplinary encounters, like between architecture and medicine, or between fashion and crafts.

5. Emotional experience[13]

"*Design will help people to live better lives by offering an emotional and functional sense to their experience. Design will help marketing companies in planning an innovative future. […]*"[14]

Pleasant objects contribute to a sense of psychological well-being, because in stressful situations our mind tends to move on to the idea of the problem. Our brain is sensitive to certain situations and reacts in a positive or negative way. Senses contribute to the brain's elaboration of emotional states. The holistic attention to sense stimulation is today one of the most interesting approaches to design. Senses as a stimulus for memory; memory as the re-discovery of inner values; senses and memory as the essence of emotions.

Emotions reflect experiences, associations and personal memories. In their book *The meaning of Things*[15], Mihaly Csikszentmihalyi and Eugene Rochberg Halton interviewed a number of people in their homes, hoping to grasp their relation with the objects that surrounded them. In particular, they asked each interviewee to show them objects they considered special. It emerged that such special objects were objects connected to particular memories or associations. In other words, "special" were those objects that evoked a special feeling in their owner, and that brought to mind stories from the past. Rarely did interviewees attribute value to the object in itself.

We tend to feel close to object if they bear meaningful, personal connections. Even deeper is our relationship with places: our favorite corners of the house, our favorite places, our favorite landscapes. "*I'm sure that buildings last in time just because they manage to absorb the emotions of their inhabitants, weather happy or sad*"[16]. What we really connect with is not the object itself but the relations, meanings and feelings that object represents. In the design field, traditional crafts and techniques change their meaning. They are no longer connected to functionality, but they embody the history and the intrinsic narrative of those who invested the object with their time, love and passion. Objects are no longer constructive elements but experiential *cultural objects*.

5.1 Experience design: visceral, behavioural and reflexive

Human reactions before an object are complex and determined by different factors. Some of them come from within the individual, from his or her personal experiences.

Every design object is destined to prompt in its user a certain behaviour, therefore an experience. Achille Castiglioni used to say that we don't build objects but behaviours. More than a given kind of design, the expression "experience design[17]" evokes a design philosophy. It is a way to think and look at design from a relational and complex point of view. Experience Design is a way of conceiving the product beyond its aesthetical characteristics. It designs emotions and behaviours for the user. It has an emotional, functional and cultural impact. This approach has its roots in the work of J. Gilmore and J. Pine. They described how, in an "Experience Economy", the relation between products, places and experiences change in its form and modalities. There are

three levels of design: *visceral design, behavioural design and reflexive design*, each of them with a distinct role in the shaping of individual experience.

Visceral design concerns immediate reactions linked to human nature. It is fully based on the immediate emotional impact. *Behavioural* design is based on use. Appearance is not very important, what counts is performance. Tactile and sensorial perceptions are crucial elements for a behavioural judgment of products. Men are biological beings provided with body, arms and legs. A great part of their brain is occupied by sensorial systems that are constantly engaged in exploring and interacting with the surrounding environment. Finally, differently from the other two kinds of design, *reflexive* design is linked to the message, culture and meaning of the objects, and to the personal memories they evoke. Reflexive value goes beyond behavioural factors, because products can be more than the sum of their functions. Their true value consists in answering people's emotional needs.

Attraction is a visceral phenomenon; beauty comes from a reflexive dimension and from conscious experience. Therefore, it can be claimed that every object has a soul, no matter if it's real or not. Every object has a value attributed to it by those who use it and by those who created it. The latter, in particular, leave on the object a permeating, unique expertise. This is the soul that makes the object "live".

But as Pino Mantovani claims[18], "*the thing is 'other', that is, we define 'otherness' as the 'thing'. Even when we cross them or they cross us, things have different life rhythms and consistency levels. This is why sometimes things intangibly float away, and sometimes they hit us and undermine our proud intangibility. Things do not belong to us, actually the contrary may be true, that is, things may own us. If we accept this, we can imagine that a path keeps tracks of all those that walked on it, far beyond the actual life-span of the last footprints…*"[19].

If we consider Industrial Design as a cultural activity which, in fields dominated by creativity and taste, can convey technological, economical and production knowledge, then Industrial Design will have a specific task. Namely that of "*not only recovering some of art's essential roles, like making the world 'beautiful', or having a role similar to critical thinking, but it could also improve the entire organization of society.*"[20].

Today, innovation is a transformation in the way problems are thought of. If in the past innovation could have been a change in color or in shape, nowadays innovation means researching and experimenting on new materials. This can be done through new technologies or by recovering sartorial techniques specific of a given sector or industrial district. Therefore, the contents of a project are not limited to material products.

A project is a primary activity with capillary ramifications in all human activities. As a consequence, it does not belong to any specific profession. This is why we talk of *cross fertilization*, that is, transfers of knowledge between complex know-how, operative methods and planning approaches. This entails interdisciplinary cooperation between different fields of human knowledge, to the aim of creating innovation.

By introducing objects into the world, design partecipates in the planning of culture. Therefore, the history of designed objects becomes the history of culture. A functional object is, by its own nature, multifaceted, elusive and full of meanings. Throughout time, every object has had different meanings connected to its origin. Regarding the world of objects, the most urgent question concerns objects' future, or the future of design and its social role. In the introduction to Maurizio Vitta's book Il Disegno delle Cose, Mario Antonio Arnaboldi describes the future of design with these words: "*Objects' evolution does not lie in the repetition imposed by mass*

[18] Pino Mantovani in *Valeria Scuteri. Canto di donna. Canto di telaio*, Celid, Torino, July 2004 (Catalogue of the Exhibition, Chieri, Palazzo Opesso, 11th September – 10th October 2004)

[20] VanSevenant A., *FILOSOFIA DEL DESIGN, in IL FASCINO DELLE MERCI* ágalma, Castelvecchi, N°1, Roma 06/2000, p. 64

production, but in their originality. Such originality must be capable of grasping and answering society's real needs"[21].

6. Possible new visions: Antonio Marras[22]

"*Tradition is not a model to be copied, but the support upon which ideas take shape. There is no modernity without tradition*". This is Antonio Marras' philosophy, an artist/craftsman/fashion designer who pioneered the recovering of Sardinian handicrafts. Marras was born in Sardinia and there is where he decided to live and work, getting away from big fashion centers like Milan and Paris, where Marras presents his *prêt-à-porter* collection and *Haute Couture* collection for the Maison Kenzo. Marras style is very attractive and based on a distinctive creativity, connected to tradition but also linked to other cultures and epochs.

Marras' style is dominated by manual skills and knowledge, and is characterized by layers of fabrics, embroideries and decorations. Therefore, the piece of clothing is often unique as the creations of ancients dress-makers.

Fig. 3: Antonio Marras. On the left, a detail of a jacket with visible seams. On the right, a detail of a *Haute Couture* dress of the fall/winter collection *Adelaisa di Torres*. Made with Sardinian traditional pleating technique.

In Marras' collections, details and decorations are so many that poorest materials become rich through intersections, additions and overlaps. Free seams and tangled threads, inspired by

[21] Maurizio Vitta, *Il disegno delle cose, Storia degli oggetti e teoria del design*, Liguori Editore, Napoli, 1996
[22] By Federica Vacca, Politecnico di Milano (ITALY) - INDACO department.

Maria Lai's work[23], are some of the elements that define the essence of *Marras' style*: incompleteness, irregularity and hand-made quality.

As a consequence, techniques are fundamental. It is important to consider the very nature of textiles as an element that supports the collection narrative. Materials lead into a kind of sensorial process based on coherent elements: the tactile and chromatic aspects of fabrics, their relation to light and their material and sensorial value in relation to objects.

Serial production cannot guarantee the attention to details sought by Marras, nor can it reproduce the infinite decoration motifs that he applies to each model. Therefore, Marras needs the handicrafts skills he finds in the women-tailors from Ittiri, a small village near Alghero, heirs of the Sardinian art of embroidery. Marras entrusted them with the manufacturing of a limited collection called *Laboratorio*. With this line Marras conveyed the most creative and experimental side of his research. Each piece of clothing is almost a unique work of art due to the exceptionality of traditional embroidery.

With his catwalks, Marras tells us about a journey through time, and about an encounter of memories; he tells us insights from his own life and that of people around him, mixed with quotations from art and theatre. Together with Sardinian culture and the recover of manual skills, these are the founding elements of Marras' unique creative language.

Marras is the narrator of his own land, of abandoned and unguarded traditions. His attitude towards the past is that of recovering forgotten elements and bringing authentic stories back to life, with strong roots in their place of origin (Mancinelli 2006).

Narration is a fundamental elements in Marras' collections. Behind them there is always a narrative cue that inspires visual connections and original encounters. The narrative potential of clothes and ornaments is enhanced by the catwalk setting, a stage that introduces the public to an emotional narrative told with truly spectacular performances.

"*When I prepare a collection, I always start from the desire of telling a story. I choose the fabrics I like and I gather ideas that are turned into what I would like to tell, as if they were a script*." (Marras in Mancinelli 2006).

7. Conclusions[24]

In this context, design becomes a necessary interface between tradition and modernity. The role of design is important in order to make crafts production more contemporary.

Two possible interventions can be outlined. In the first scenario, craftsmen are cut out from the intellectual planning process, which is under the exclusive responsibility of the designer. The design/crafts/company relation is univocal because there is no exchange nor transfer of knowledge between the parts. The contribution of design is merely formal as it recovers and re-interpret classic codes and traditional materials, while crafts are viewed as a know-how tank to be exploited. If craftsmen do not fully understand nor feel part of the process, they will not comprehend the tools, processes and skills provided by design to answer market needs. This scenario could therefore remain an extemporary experience limited in time.

The second possible intervention requires that from the very start of the planning process craftsmen are considered equal partners within the project. Thus, the design/crafts/company relation is bi-univocal because there is a connection between designers' planning process and craftsmen's skills. They therefore cooperate in the planning and development of the product.

[23] Maria Lai. Sardinian artist who studied sculpture with Arturo Martini. In the core period of her career in Rome, she pursued a very personal search for community ethics and the myth of narrative. Her interest towards feminine manual skills and towards popular culture inspired some of her fascinating works such as *Geographies*, maps embroidered on fabrics and velvet, and *Sewn Books*: at first undecipherable writings, they then become fairy-tales told through sequences of images and patchwork.

[24] By Federica Vacca, Politecnico di Milano (ITALY) - INDACO department.

Such bi-univocal relation ensures that this experience can be repeated in time, and becomes an important innovation element for crafts production. Indeed, design activates an exchange of knowledge and expertise between the parts, thus transforming the traditional production process.

In the light of what has been claimed so far, it is possible to outline a new trend that aims at recovering cultural values accumulated in time through the strong connection between individuals and their community, and between crafts and local history and identity. There is an increased nostalgia for the past and wish to recover objects and memories from remote epochs. The encounter between different approaches, such as design and crafts, produces new ideas for products with different and unique codes. Due to these intrinsic characteristics, local products are *highly differentiated* goods (Sassu, 2003), and become "*cultural objects*" because they belong to a specific local identity. (Lai, 2007). Emotion is the key to unique experiences. Crafts and design can both re-elaborate tradition in a personal and unique way. Handicrafts convey the value of quality by evoking collective memories and the nostalgia for a remote culture charged with symbols and meanings.

Experience becomes representation, a scenario created by the *director* to arise emotions in the *client*[25]. This cannot happen in the world of crafts activities, because here the scenario is a fixed element provided by the territory in which they originate. There is a sort of *Emotional Geography*[26] in which space is emotionally experienced through memory and a the desire of experience. "*An internal and external landscape, made of people, things, imagination and intelligence, is always part of narrative developments. And it is precisely this landscape that gives meaning and sense to events and characters*" (Bruno, in Brogli, 2005).

Objects become icons that testify each culture's origin. Their power is conveyed through memory. Indeed, its narrative can combine archetypical images and future suggestions within a fascinating present. *Emotional Design*[27], as intended by Donald Norman (2004), defines a specific viewpoint within the context of design, by taking into consideration the emotional aspect of the man/object relation.

"*We tend to feel close to objects if we have a meaningful, personal connection with them, if they evoke pleasant and comforting moments. Perhaps even deeper is our relationship with places: our favorite corners of the house, our favorite places, our favorite landscapes. Actually we are not attached to the thing itself, rather to the relation, meanings and feelings it represents*" (Donald 2004). Thus, traditions are not an obstacle to innovation and creativity. From traditons arise knowledge and experiences that can be the starting point for new forms of expression. "*Tradition does not oppose progress, on the contrary it is the basis for any new challenge*" (Balfet, 1981).

[25] ibidem

[26] *"Emotional Geography"* is a theory by Giuliana Bruno, philosopher and professor at Harvard University. In her *"Atlas of Emotions",* Bruno analyses the universe of our emotional experiences. *"When I talk about Emotional Geography I am thinking of different perspective about daily life, of journeys inspired by a novel, of childhood smells. Or perhaps just imagination and memory. Itineraries that generate atmospheres, feelings, emotions that can arise by walking along familiar roads or in unusual places. Perhaps not exotic places, but places whose soul we can perceive"* (Bruno in Brogli, 2005).

[27] The expression "Emotional Design" has been defined by Donald Norman in "*Emotional Design*" (2004). His analysis underlines three aspects that need to be correctly balanced:

_**Visceral Design** *"is what nature does"* (p. 64). It is a simple kind of design, connected to the *visceral,* immediate impact before an object, which we perceive as pleasant because we find it close to our own nature.

_**Behavioural Design** *"is fully based on use"* (p. 68). This aspect of design normally coincides with usability. Norman defines four characteristics: function, comprehensibility, usability and physical perception. This kind of design is analyzed in Norman's "The Design of Everyday Things".

_**Reflexive Design** *"is connected to message, culture, meaning"* (p. 82). It takes into account the personal and social meaning held by design.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Sustainable Design r&d - Geneva

Bringing University and training design towards Sustainability

Yves Corminboeuf[1], Guido Styger[2]

Abstract

How to introduce the visions of the sustainable development in alls missions of the university of art and design? This was the main interrogation to make this project. What should be analyse and why? What are the methods, and tools should be implement? Which roles the university of art and design to promote sustainable development can play? Finally, how to inform, to training and to integrate directs and indirects actors of the university into the process?

Teaching Sustainable issues in design professions embody a huge potential for accelerating the change towards sustainability development. New transversally action platforms are necessary. Bringing a common understanding of the sustainable development is a key condition for a successful integration of good sustainable practices.

1 Geneva University of Art and Design (Switzerland) - Domain Design. Professor, yves.corminboeuf@hesge.ch
2 Geneva University of Art and Design (Switzerland) - Design Institute of Research. Scientific Collaborator, guido.styger@hesge.ch

1. Introduction

"How can we introduce sustainability knowledge and practices in the University of Art and Design?" This was the very beginning question that the members of the research team asked themselves independently in 2004. What began with a simple aim, became an important platform that is already interacting with hundred of actors and decisions makers in the heart of the international City of Geneva in Switzerland.

The scientific goal of Sustainable-Design R&D is to search and develop specific methods, which should help integrating sustainability in education and strategic missions of the Universities of Art and Design with their specific departments and teaching fields.

This research project is financed by the strategic research and development funds of the University of Applied Sciences in Western Switzerland (HES-SO) and takes part of the competence Network in Design (RCD). The project is further co-financed by the research and development funds of the Geneva University of Art and Design (HEAD) with their strategic investment funds, and the University of Applied Engineering (EIL). An additionally contribution in form of working participation, was offered from the seven project partners.

This paper presents the research program Sustainable-Design R&D with their scientific methods, questions and results, but also to show experiences in retro perspective point of view from the research team. Those experiences can give answers to the conference aim, which is focused in changing the change.

The research team of the project was built from three distinct researchers, with the task to insure the function and management of the research and their related investigations and analysis. The punctual collaboration with partners and people receiving benefits, allowed validating and reflecting their work. The partners covered the essential competences needed in the field of study, and was chosen in the aim to have a preference for local resources. Some independent consultants in very specifics topics like history of sustainable design, teaching or eco-design, gave a supplementary support.

Context

The research activity in the faculty of Design in Switzerland started in 1995 with the promotion of Applied Art schools into Universities of Art and Design. The first Swiss research and development project in Design was published in 2001. In the field of sustainable development, the Swiss research began around two decades ago. Education as the best-known field in the investigation of the project Sustainable Design R&D, started his research activity already centuries ago.

In the last twenty years, the notions of Sustainable Development entered gradually in the society and became already popular. The preamble of the new Swiss federal constitution included its principles since 1999. This legal situation in Switzerland is found in all political levels: country, states, municipalities and public establishments. Even the University of Applied Sciences of Switzerland (HES) included the Sustainable Development in its fundamental texts.

During the last few years, the sustainability movement started to transit from the founding texts to praxis. This research project emerged in this political context and was since the beginning supported by the actors of federal and states offices. At the same time, the United Nation Organisation launches a decade (2005-2014) in education for a Sustainable Development, which was ratified in 2005 by the Swiss Confederation. This decade started with a national conference in Geneva, what is certainly not a coincidence. Indeed, the city of Calvin looks back to several movements for the improvement of human conditions and environmental issues, and developed around these topics a dynamic framework of actors and institutions.

Geneva has more than one active institution in design training. The Geneva University of Art and Design (HEAD) as a part of the University of Applied Sciences in Western Switzerland (HES-SO), is the only one in Geneva, where Design can be studied at the higher level. The

HEAD experienced important changes during the time, where the research took place. Implementations of the Bologna principals, restructure of the departments are only a few selections of their changes.

Only some 70 km away from Geneva the Lausanne University of Arts and Design – also part of the HES-SO – have the same faculty on the same level. But their missions roughly like: Geneva as a pole of Design and Art, and Lausanne as a pole of design and technologies.

2. Research programme

To manage efficiently the interdisciplinary competence network connected to the project, the research team chooses a project management witch enabled them to consult – according to the needs – their partners and the actors. In the selected structure, each part preserved its own investigation methods. Information were collected by the research team, formatted and validated by the members of the working group.

Methods

A series of different, quantitative and qualitative methods, were used to collect the necessary information. The investigation field of the case study moves around Sustainable Development, University (Missions and Structure), Education and Design. To analyse the state-of-the-art, the research team worked with the academic and Agenda21 methodologies.

The first step consisted to collect the necessary information to analyze correctly the fields of the case study, which includes administrative structures, contents of the courses, material conditions and professional practices.

According to this task, the research team built thirst his knowledge framework trough the analysis of theoretical documents, books and studies on the various topics around the field of this case study. These documents and topics were chosen within different networks and institutions active in this field but also within actors that already had some experiences in other universities. This preliminary work enable the research team to develop a series of questionnaires, which were used to collect the necessary information for analyse of the state-of-the-art. These questionnaires related to the missions of University and Departments, to the design profession, to a regular study project, to the practices of teaching, and finally to the users habits. The outcome was compared with sustainable practices and measurements and allowed by side to learn more about the actor's values and their knowledge about sustainability.

The second part of the research has to confront the actors with the sustainability process, and help them to support and apply the Sustainable Development principals.

The research team organised round tables – according to the missions of the University, the infrastructure and the teaching – gathering the specific partners in the objective to select the priority elements of the obtained investigation results. These meetings allowed to reflect the results of the investigation of different point of view and to make an appropriated selection of tool and methods, which enabled the research team to address them afterwards to the actors through Focus groups.

These focus groups integrated the actors of the University to let them participate in the outcome of the proposals. The research team organised this Focus groups in two different levels. First level: The management board of the University formed by the director, the administrative managers, the education managers and the research institutes leaders. On the second level: The department, formed by the professors and persons in charge of the department. For each Department a specifics focus group was held.

The results out of the full investigation – questionnaires, talks, round tables and focus groups – allowed finally generating and developing recommendations with the support of the partners.

Investigation field

The state-of-the-art of the different fields of study leads us to the following observations.

The Sustainable Development has already become a common notion in Switzerland. The fourth Assessment Report of the Intergovernmental Panel on Climate Change, which proved that human activity is heavily responsible for global climate change, put the sustainability in the centre of medias and discussions. That's probably also the reason why a lot of people understand Sustainability like an environmental concern. Many tools for environmental improvements are in fact arising during the last ten years, but only few concepts care about the social issue of the sustainability concept. The lake of a common understands of the sustainable principles in connection to the current issue, don't allow people to see the real challenge of this concept.

The construction of the University of applied science in Switzerland provoked a huge structural change of existing academic structures during the last ten years. These changes were accompanied by a general growth of Universities. The quick change and a complex administration structure seem to break the potential to shift quickly towards sustainability. More and more Universities in Switzerland integrate the aim to go in the Sustainable Development but only few of them have already done something concrete. In general the first faculties they started to care about sustainability are situated in the environmental fields. The new teaching program (Bologna) and the still ongoing transformation process into the new University of applied science in Switzerland, with their financing and administration, make it possible to imagine the integration of the Sustainable Development on all levels of the institution.

Since the United Nation Organisation decade in education for a Sustainable Development in 2005, some Swiss school and university had engaged them self to integrate Sustainability in all levels of education. Non-governmental and student organisations contributed a lot to accelerate the change by making programs of pedagogical to shift education towards Sustainability. Methods and research experiments in this field presents several solutions according to the Sustainability principals, where can be introduced in the design training. However, the abridged duration of the design studies can braked with a successful integration of teaching the complexity issue as a part of the Sustainable Development.

Environmental issues and some social critical approaches exist in design practices since 1960 but are still criticised or minimised from a majority of the design community. The training in design doesn't focus until yet on environmental and social issues. The difficulty of the design community to put themselves behind a common definition of their practice, make it difficult to share the goals and visions.

A sustainable University of Art and Design

The principles stated previously are those included here in the objective of defining what means concretely the application of the concept within the framework of the design, the higher education, and finally within the framework of a University of Art and Design. The application of the principles of Sustainable Development can be at two different levels:

1. Strategic level (strategic positioning, interdisciplinary, pedagogic methods, etc.)
2. Management level of the University (infrastructures, personnel management, prevention, participation, transparency, etc.)

The research team identified a certain number of points that can be used, as general principles relating to sustainability and that can be the base for a "Sustainable University of Art and Design"

Positioning of the University

- Integrate the principles of the Sustainable Development in all missions
- To use the sustainable development like a strategy for the positioning of the university

Quality

- To set up processes, management and evaluation tools
- To valorise the existing sustainable experiments

Pedagogy, didactic and contents of teaching and search

- To train all teachers in the Sustainable Development
- To integrate the Sustainable Development in the training of the students
- To promote a transversely work practices

Service with the thirds

- To integrate the Sustainable Development in the strategy of search and mandates

Participation, communication, information, transparency

- To support and promote the exchanges, the communication and the participation

Working conditions

- The infrastructure must be exemplary
- To sensitize the actors in Sustainable Development

Policies of equality

- To support legality in gender
- To support the multi culturality

Promotion of health and prevention

- To support the wellbeing and the security of students

Question of research and hypothesis

This theoretical base of a "Sustainable University of Art and Design" enables us to put the following mains questions of search:

- Does the HEAD take position to the Sustainable Development?
- Is the HEAD currently in phase with the identified principles of the Sustainable Development?
- Do the managers of the University understand the Sustainable Development concept?
- Is the Sustainable Development trained at the University?
- The university is it exemplary in terms of infrastructures and management?

Following the development of the model of a "Sustainable University of Art and Design" and with the analysis of the state-of-the-art for the grounds of investigation, the research team estimates that search must be validate or cancel on the following hypothesis:

- The university currently doesn't have a position on the principle of Sustainable Development
- There is a different between the concept of the Sustainable Development generally accepted and what make the persons in charge within the framework for their respective courses
- The stakes and opportunities related to the application of the Sustainability principles within a University are not known by the direction
- The Sustainable Development is perceived like an additional constraint and not like an appropriated development

- The management of the infrastructure is not based on the principles of the Sustainable Development
- There is no policy of purchase integrating the notions of the Sustainable Development
- The communication of the good practices is lacunars
- Impacts of flow and consumption is perceived little
- The importance of the role of the education for the Sustainable Development is not perceived
- Complexity is taken little into account in teaching
- The Sustainable Development is perceived like already trained in certain department
- The transdisciplinarity is perceived as a waste of time in glance of other courses

3. Results and experiences

The research team analyzed the validity of the hypothesis with the investigation results and experience. This provided the basis for the specific recommendations in view of a sustainable University.

Institution

Positioning of the University – The University does not have a specific positioning with respect to Sustainable Development; it intends to integrate Sustainable Development, yet without marking it out as a priority.

- To clearly define the positioning of the University.

Prejudice of Sustainable Development – People of the University have very variable levels of knowledge in terms of Sustainable Development. During the focus groups, the majority of the professors requested access to education on Sustainable Development.

- To offer training in Sustainable Development

Opportunity offered by Sustainable Development – It was noted that the lack of information on concrete actions decreases the perception of Sustainable Development. The University does not wish to put Sustainable Development at the centre of its concerns, but there is sensitivity to it.

- To communicate the actions in favour of Sustainable Development

Education of Sustainable Development – There exist no cross vision of the practice in art and design links to sustainability.

- To create a dialogue and research platform to stimulate new visions for sustainable, art and design practices

Sustainable Development, an additional constraint – Because of the short duration of the studies, the majority of actors perceives Sustainable Development as an additional constraint. Sustainable Development is not appreciated as a vision rather than a method or a technique.

- To inform on the concept of Sustainable Development

Management of the infrastructure – It was recorded that the complexity of management is induced by the sharing of competences between two State departments. The university management require a charter, which provide a clear framework in terms of management

- To define a precise charter

Policy of purchase – Cost is the only element currently taken into account for the purchases. The university management also intends to establish a clear policy on this subject.

– To define a precise protocol

Good practice – The use of good practices is already well integrated in the university. The university is not aware of this fact.

– To communicate the actions already in force and to develop them

Management of flows – The device of departments among several buildings dilutes the opportunities. The University is aware that efforts can be carried out in the economy of flows.

– To sensitize the users on the use of flows

Department

Role of teaching – Teaching can be an element in the promotion of Sustainable Development, this concept is not perceived in the university.

– To train the professors in Sustainable Development

Perception of Sustainable Development – The actors of the university do not perceive the complexity and the impact of Sustainable Development. Several people have a false idea of Sustainable Development.

– To promote common knowledge in Sustainable Development

Transversal practice – Transversal courses exist, but their utility is strongly questioned and criticised. The professors do not see the link with the complexity of the society and the need to answer it in a transversely manner.

– To reinforce the programs in progress and to develop acquired knowledge

Work process analyze

The project experience, up from the starting aim to this present final result of the research program, gives a better understanding about the challenge of introducing sustainability in an University of Art and Design.

Sustainable Design R&D is from a bottom up initiative crossed by two different personal engagements on the same place with a similar aim. The meet of this two engagements, create the initial potential for the present project.

The experience exchange with other universities allow to see, that the creation of new places in existing structures – like this research program – is a good opportunity for introducing Sustainability knowledge in a University. Without such a place, ideas and aims would keep silent or isolated and probably never reach a wider public.

The work process of the researchers was conditioned by the moving situation of the university during that time and the quick progression of the sustainability movement. This continues change was a difficult challenge for the researcher, but open them also new opportunities to improve the project. The project took one year longer as previewed – because of the number of participant and timeline casual – but it was the opportunity to helps in the same time actors to familiarizing better with the subject it self.

4. Conclusion

The project Sustainable-Design R&D enlarged the sustainability process, to the different departments and teaching fields of the Design faculty of the Geneva University of Art and Design. The project used a transversally work approach that help to recognize new potentials between the different investigation fields.

The extremely different practices, visions and approaches existing in design, don’t allow sharing properly the project experience with other design departments. That’s why the following

part of the text separates the project experience in university (mission, infrastructure and pedagogic) and education & design.

University – mission, infrastructure & pedagogic

The experience of the research shows, that the most important elements on the way to a sustainable University turns around “human values”, “knowledge” and “pedagogic” and less around technical progression and tools. The role of Universities as an example for good practices in social, economical and environmental responsibility is one of the key recommendations of the research.

A general sighting of the research allows pointing out, that there is no “best practice” in sustainable development, but only good or failed sustainable practices. In competitive systems, best practices are important rhetorical tools to convince actors. The change toward sustainability need to introduce actors in the complexity of their situation, what often faces a rhetorical difficulty.

The analyse shows that all involved actors don’t know what kind of impact they produce through their everyday activities. It is in general difficult to do something better, what we don’t know yet. The sustainable development seeks a balanced contribution to the social, economics and environmental capitals, but the actors don’t know clearly how to split their activities between these three capitals. Those problems also relate to the different sustainability knowledge of each actor, what is largely based on their values and own information sources.

Introducing personal values and ethics in professional or educational activities is not an easy task yet. Most of dialogues with actors show that their values have a secondary place in professional activities in order to protect themselves and their economical income either than a negative social or environmental impact. Convince some one to shift values and ethics refers unfortunately to religion practice or moralistic arguments what is clearly a personal concern. The researcher share the aim to let the transformation take his time in offering an example in good sustainable practice either than convincing actors with Laws and rules.

Knowledge and information can be a powerful ambassador to touch people and provide them new possibilities to act. But today in open information gates like Internet and mass medias, a new learn approach is needed to share the quantity of information. Providing and developing tools and methods to share the complexity and the quick changes we face in a sustainable everyday, is one of the key tasks for a university.

Departments – education & design

The teaching fields in design were the second investigation place of the research project. The experience and results are more specific and don’t allow easily to compare with similar teaching fields in other universities of art and design. In fact the practice in design is extremely large and depends of the actors with their local culture and historical background. The experience shows that the most important elements on the way towards a sustainable teaching and working practice in design, turns around “knowledge”, “project management” and “sustainable solutions”.

Design is probably one of the most open work field in the beginning century. The interdisciplinary work approach of designers embodies a huge potential to develop new sustainable methods and solutions. Many other professions and faculty suffer under high clustered work dogmas, and are prisoner behind their own boundaries. The risk of open boundaries in design practice are the lost of clear professional visions and missions. Especially Design departments with their specialized training should more care about the future of design and their professional integration and contribution.

Many new tools and methods appeared around the design practice during the last 10 years. Especially out of engineering and management fields in connection to life cycles and material stock management. Design departments have to evaluate their potential to give them the right place in the training of design. Especially new management tools have a huge potential to enable Designer to create sustainable products and services in a local scale.

Design history shows that the understanding and interaction of industrial or handcraft production was until thirty years ago an important part of the design project. Today this knowledge could see an important revival on a local scale. In fact local products and services become not only ethical or ecologically desirable, but allows by side the local community to create employments and new local values.

It appears clearly that technologic progression doesn't solve the current development issue. Design professions have a long tradition to refer to new technologies in way to introduce them in the everyday life through products and services. Today where technologies shift progressively to bio and nanotechnologies, designer should definitely put his capacities of planner forward and take a critical distance to emerging technologies to find the right application and scale of them.

More and more universities wish to bring their campus towards sustainability and engaging themselves in signing new network charters to share their aim in networks. Depending the size of University campus, they have specialists or Sustainability task forces to organize and guide the sustainability process. They mostly focus on environmental issues and don't have access to the different faculties. Share work experiences become an increasing need for all sustainability task forces or specialists in Universities all over the world to improve their work process.

Perspective

The general results of the research allows to see that sustainability can become an important ambassador of innovation in design professions and teaching practices in order to set new visions of the possible. Step by step, actor-by-actor, the change needs time to enter in the minds and behaviours of people. Many things can be done to stimulate and accelerate the change of actors in Universities and projects.

The introduction of sustainability in Universities and Faculties depends of new places in existing structures that can act as transversally sustainability platforms. Everywhere where are motivated people, there is a potential to change. Connecting them together independently of their position and accesses to start a movement of change or a process of learning by doing. Experiences from others actors are important references in this change and can bring a better understanding to change managers.

It's not clear yet how the experience of Sustainable Design R&D enters in the practice of the Geneva University of art and design and shows clearly the failing of the research while a temporary and optional platform in the university. The aim of the researchers is about stimulating change toward sustainability, in presenting a multitude of possibilities, ideas and solutions.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

SYSTEMS DESIGN BECOMES EASY LIKE A GAME

A travelling exhibition as a tool to communicate sustainable society

Alessandro Balbo[1], Sergio Corsaro[2]

Abstract

Systems design is a methodology that does not consider production as a linear process, but redraw a map of matter and energy flows representing inputs and outputs of the system.

The characteristics of this method can be transferred to communication process, for spreading a deep ecological thought, intended as Man's consciousness of being part of the net of Nature, not above it.

A systemic communication has been put on trial with the exhibition Innovazione&Design. By activating a system of answers and contributions from the young visitors, this operation wants to put in discussion the current materialistic social paradigm, moving the attention on relations and on the role that every single person has with respect to society and its context.

[1] Politecnico di Torino (ITALY) - Dispea department. Phd student, alessandro.balbo@polito.it
[2] Politecnico di Torino (ITALY) – DISPEA department. Phd Student, Sergio corsaro@polito.it

Introduction

We are witnessing the growing fragmentation of daily experience and behaviour; we are assailed and overloaded by messages. Our natural tendency to simplify and save energy leads us to deal with this barrage of stimuli and experiences that bombards our lives by schematically grouping and dividing issues into discrete compartments. Our minds activate “short-cuts” in recognising and cataloguing tangible stimuli: these expedients take the name of heuristics, or methods of thought. This mechanism allows us to archive uncritically stimuli by analogy, with similar concepts that we have experienced in the past. Much of commercial advertising builds on these mental references, strengthening the direct connection between stimulus and response. This is why references to technology bring to mind almost exclusively electronic goods and sophisticated instruments, and why we think of fashion and the world of art when mention is made of aesthetics. The stronger these ties are, the more difficult it is to break them, which is why it is so difficult to recognise a butterfly's wings as technological, or the movement of a pendulum as beautiful.

There is an infinity of ways to establish a relationship between two elements. The most immediate way is determined by experience and habit, though alternative ways also exist, which are all the more fascinating, as they question conventional logics by establishing a connection between remote associates, or apparently distant or conflictual elements. This experience of novelty can be found in the creative and design fields, though it can also be observed in everyday life, when we laugh, for instance, at a joke: retracing the mental pathway that led to the final punch-line, we see a perfectly logical pattern which we previously would never have followed.

Looking at issues from a different perspective, and picking out unconventional logical pathways, is the real meaning of innovation, which unfortunately though is often confused and reduced merely to the technological sphere.

Individual existence, just like our collective and global existence, manifests itself as a web of relationships, in which interconnection and interdependence predominate. The question is how we can translate this intrinsic diversity into a methodology for communication.

Communication and learning

The mechanisms of traditional classroom learning are based on the linear transmission of the message. The model involves a source who encodes the message – that is, who transforms thought into a form of communication; the message is then received by a receiver who decodes the message – that is, who transforms meaning into thought.

The model has evolved over time with the introduction of contextual aspects and the defining characteristics of the three elements (source > message >receiver). A return loop may be added to this otherwise one-way transmission of information, which we call feedback.

A recent development in the mechanisms of traditional classroom learning has come from the introduction of distance learning tools (e-learning). With the physical absence of the teacher, teaching methods that exploit multimedia, interaction and the Web have had to be developed. Multimedia teaching standards are based on a block-by-block structure of "learning objects,” in which lessons are structured into chapters, with assessment tests proposed at the end of each chapter. One of the research projects at the Politecnico di Torino is aimed at strengthening the learning object. Through a systemic approach, the principles of sharing and autopoiesis are explored, giving students the opportunity to contribute to enriching lesson content, while the relationship between the issues addressed in different chapters are stressed, opening up the possibility of building a learning programme which is not tied to the linear organisation of chapters,

by exploiting the programming languages intrinsic to the Web 2.0, such as podcasts, wikies, and share tools.

Whether the tools used are virtual or real, it is not hard to gather that the most effective way to learn a concept is to put it into practice. The designer Enzo Mari describes learning as the alternation of two moments, which he calls HARD and SOFT phases. The HARD phase represents the cognitive, or knowledge process, in which information codified by others is acquired: for example, when you learn to play a musical instrument through solfeggio. The SOFT phase is the experience of know-how, that is, putting knowledge into practice: following our musical analogy, it means practising the instrument.

Schools traditionally privilege the HARD phase of learning over the SOFT phase. Recently, however, even in Italy, school gardens have begun to be planted, where SOFT phase learning consists of students directly experimenting with and managing natural plant cycles, so as to understand the concepts of growth and development.

Multidisciplinarity as a tool

Alongside communication and learning techniques, the systemic methodology builds on concepts from more remote disciplines, such as complexity theory and psychology.

IT is interesting to see how scientific method approaches reality in an abstract, numeric way, but the rules and characteristics that emerge can be described perfectly in concrete and qualitative terms, which are applicable even to design and communication projects. Indeed, complexity theory in physics and mathematics does not aim to find a solution to problems that cannot be explained through other methods; rather, it describes an approach through which problems can be addressed. While classical physics and linear mathematics describe models that can be reproduced and formulae that produce a single result, the complexity approach provides as its outcome structures, trends, and cycles, whose numerical values cannot be measured because they depend on factors that are not measurable.

A brief description is necessary of the levels of complexity which scientific research comes up against, as is an understanding of why they deserve our attention. Numerous degrees of complexity exist: simple, unorganised complexity can be found in many physical and chemical phenomena, such as in boiling water and atmospheric agents; organised complexity is typical of living systems, such as cells, where each individual component influences the whole system.

A higher degree of complexity can be found in socio-cultural systems. When humans become components of such a system, they bring with them a baggage of rules and behaviours that cannot even be represented, as the capacity for judgement, self-consciousness, and the free will of people influence the broader system in a highly non-linear way. Complexity thus becomes organised and teleological.

IT is also curious to see how humans, the most complex organisms in nature, find it so difficult to understand complexity, as we tend to reduce phenomena to a simple cause and effect mechanism. In this way, the characteristics of complex systems become a very useful tool for understanding and addressing socio-cultural issues. One of these characteristics is dynamic equilibrium. Just as fixedness and the absence of change are symptoms of death in nature, human social activity unfolds in a non-constant way, characterised by fluctuations and cycles which repeat themselves, while overall development remains in equilibrium. Another characteristic of human social activity is interdependence: each of the parts of a system stands in relationship to the others, and hence is capable of both influencing, and being influence by, the context. The properties of self-organisation emerge from this characteristic, placing open complex systems in a position to control and regulate themselves. Self-regulation is also made possible by feedback mechanisms, or loops. Such feedback loops began to be understood and developed with the advent of cybernetics, in particular by Norbert Wiener, who observed how the elements of a system form a loop, in which an initial cause is propagated and acts on each of the individual

elements in a cyclical way. The consequence of such an arrangement is that the original input is affected by the final output, resulting in the self-regulation of the entire system as the initial effect is modified each time it completes a full cycle (Capra 1996, 65).

Psychology is another discipline that can lend much useful insight into motivation and emotional involvement during communication phases. Attention levels rise when certain factors are brought into play, such as personal relevance, values, needs, abilities, and the opportunities perceived by the receiver. In short, planning any sort of communication effectively requires an in-depth understanding of the target audience, and the context in which the message will be set.

The broken windows theory can help us understand how behavioural choices by the target audience do not come solely from personal will, but are strongly influenced by context.

“Broken Windows was the brainchild of the criminologists James Q. Wilson and George Kelling. Wilson and Kelling argued that crime is the inevitable result of disorder. If a window is broken and left unrepaired, people walking by will conclude that no one cares and no one is in charge. Soon, more windows will be broken, and the sense of anarchy will spread from the building to the street on which it faces, sending a signal that anything goes. In a city, relatively minor problems like graffiti, public disorder, and aggressive panhandling, they write, are all the equivalent of broken windows, invitations to more serious crimes” (M. Gladwell, 2006).

This epidemic theory of crime can be compared positively to awareness of environmental issues, in which we do not act regularly but a line of behaviour is established.

Systemic Communication

The aim is not to question academic methods and education in a classical sense, but rather to ease the implementation of the difficult role taken on by those who wish to address issues concerning everyday behaviour and habits, through the introduction of a new tool.

The goal of systemic communication is to identify an approach in which the message conveyed is not only received and understood by the receiver, but in which the receiver is sufficiently involved, so as to become a vehicle of communication for others. This can happen where the communication project takes into overriding consideration the public being addressed, offering stimuli and concepts which do not have a closed meaning, but rather can be interpreted, discussed, reworked and questioned. In this way, communication targets participate in the formulation of the message, widening the discussion beyond the strict context in which the message was launched.

The Innovazione&Design Exibition

Open communication emerged from the need to build a tool to compare the research experiences of the Department of Architectural and Industrial Design (DIPRADI) and the Industrial Design Course at the Politecnico di Torino in the field of environmental sustainability, with those of other entities external to the university, in an effort to “test the waters” and gauge general attitudes towards environmental issues. Backed by experience gained through the application of systems design to industry, and the theoretical context outlined above, we decided to address the issue through a travelling show & workshop called Innovation & Design, promoted by Regione Piemonte, visiting primary, junior-high, and senior-high schools.

It is well known that our minds are most sensitive to external conditioning during our schooling years. It is then that we go through the process of developing sensible perception, before developing the personality that accompanies each and every one of us throughout our lives. At schooling age, we are particularly susceptible to the mentality dominating the environment in which we grow up, and we are inevitably conditioned by it.

Thanks to a capacity to understand abstract issues and a certain elasticity of thought, kids are the best audience when it comes to talking about innovation issues – without forgetting that it will be the choices of our young people today that will shape society tomorrow.

More importantly than how a topic should be presented, it is fundamental to plan what to go and say.

The issue of sustainability today has been addressed from a number of different points of view. The majority of these points of view focus on the environmental awareness of receivers. Such a strategy, however, is not always effective, as quite paradoxically, ecological issues are not always perceived as a problem that concerns us.

Raising sensitivity towards the problem is one of the goals that the show aims to achieve, because attitudes towards an issue which we know exists are very different to attitudes towards a problem which we feel affects us.

As such, understanding and interpreting the show is something left up to the kids themselves. They are presented with two scenarios which draw out aspects of behaviour, lifestyle and design from two different perspectives: one focuses on the Product, the other on Human being.

Concepts are then extrapolated from each of these two starting points, expressed as keywords which draw out a map of values, with each word placed closer to or further from the centre on the basis of its importance.

A Comparison of Two Paradigms of Thought

Each scenario is contained within an aluminium structure, four metres high by three metres wide. The map of values is represented on the ground, with posters positioned in correspondence to the keywords, presenting images to clarify the concepts.

The first difference between the two structures is in their colour. The Product scenario is yellow: a bright colour evoking vivacity and euphoria, but which can also be annoying or ambiguous, or as in the words of the film director and writer Derek Jarman, “a vision of evil, it is the sign of Judas. When yellow seeks to seduce, it becomes gold.” The Human being scenario, on the other hand, is blue, a calming, thoughtful, spiritual colour, or in the words of Derek Jarman, “I present you with the universal Blue/Blue and open door to soul/An infinite possibility/Becoming tangible.”

Near its centre, the Product scenario has keywords such as 'raw material', upon which the very existence of a product depends, 'economic value', 'ownership', 'status symbol', 'marketing', 'visual packaging' and 'communication'. These aspects refer to the commercial sphere of design, highlighting how seduction and product appeal are fundamental elements of the system. The Product must, first and foremost, enter the mind. One step down we have values which refer to the product process, in particular 'engineering', 'production' and 'logistics'. Further away we have the phase concerning the use of the product, identified by the keywords 'use function' and 'components', which acquire importance when the problem of maintenance arises. Finally, the keywords on the outskirts of the map represent the needs to be addressed once all the previous requirements are met, and when a product loses its seductive and functional value, such as 'life cycle', 'ecology', 'pollution', and 'environment'.

This scenario can be understood as a contemporary snapshot of our society, not only from the point of view of designers, bearing in mind that the manufacturing of products both influences, and is influenced by, the social context.

What would happen though if the central paradigm of our society shifted from the Product to Human being?

The change in point of view means changing our value system, restoring importance to notions such as 'biological, social and ethical life', 'respect', 'relationships', and 'real existence'. Alongside these keywords we have tangible aspects such as 'perception', 'ergonomics', and 'functionality'. Only on the outskirts of the map do we have concepts tied to 'production', 'the economy', and 'economic value'. There is, of course, no denying the presence of the product, and the associated concepts of 'logistics' and 'engineering', however they are considered of lesser importance than the rest.

One might wonder why references to ecology, recycling and sustainability are absent in the Human being perspective. At a first glance, we might expect that these marginal concepts from the Product point of view should become central when we shift perspective. If this were so, however, we would not have moved very far from our current focus on goods, as solutions for the disposal, recycling, and incineration of waste are downstream measures which are costly commitments for companies, just as project guidelines for the reduction of materials use and energy efficiency represent limitations. Furthermore, it has been seen that these solutions do not actually change consumption habits. When problems arise in the management of solid urban waste, local administrations generally choose to build new dumps, incinerators and compost plants, forgetting the importance of encouraging the community and business to reduce waste production itself.

In formulating the Human being paradigm, reference was made to a world view that does not separate human society from the natural world. If we consider the planet as an infinite mine of resources at the disposal of humans, and at the same time a waste dump without end, we remained locked in the Product paradigm, in which raw materials have central importance. Alternatively, if we consider the planet a web of open systems in which life conditions, and is conditioned by, the context, the emphasis is no longer on raw materials and waste, but rather on inputs and outputs. From this point of view, the waste output by the system can become the input of another system, promoting a virtuous productive and economic cycle.

Hence, it is not true that the aspects of environmental sustainability disappear; instead, they become implicit to the paradigm when Human beings are considered an integral part of nature.

We have always put ourselves in a privileged position when it comes to the reality that surrounds us, imposing our rules and shaping the territory to our pleasure. The evolutionary success of the human race has arguably arrived at a turning point, as we begin to feel threatened by the very lifestyle and well-being that our forebears so tirelessly worked towards. We need to act to change our habits and shift our perspective, without, however, turning back; the evolutionary process has to continue.

Perhaps in future years, the attitudes that we consider 'natural' today might come to be seen as abominable, not only those concerning our planet, but also our attitudes towards the weak and disadvantaged. Radical changes in paradigm have already occurred in the past, as Aldo Schiavone points out happened with slavery: a practice that we have unanimously judged to be degrading for less than two centuries had, until yesterday, a long, noble history in thought – from Aristotle to the Confederate publicist during the American Civil War, slavery was considered a typically “natural” institution, with no objections ever raised by the Christian churches. [...] IT happened with the condition of women, branded “naturally” inferior to men by a tradition of no less importance, and which remained by and large unchallenged until the first half of the twentieth century.

What are the prevailing labour conditions today in developing countries, and above all, who has benefited from development?

The keywords 'ethical life', 'respect', and 'real existence' seek to focus attention on these contradictions, and on how our everyday choices can influence apparently remote systems.

This arrangement of keywords and their meaning is not made directly explicit in the show, as otherwise visitors would not become fully involved, limiting themselves to either sharing or rejecting an interpretation given by others. Rather, visitors are left to freely interpret the panels and the relationship between them. The exhibition needs to be explored and lived in order to be understood: indeed, from the outside, the most evident images are the keywords on the outskirts of the maps, giving a superficial view of the issue. For instance, the concepts of 'ecology' and 'environment' are highly visible as one approaches the Product paradigm, though upon entering and moving closer to the centre, the visitor understands that real importance is held by other factors.

Placing Humans at the centre of the project is by no means a new or revolutionary concept – indeed it is quite natural to take it for granted, or even as anachronistic. In reality, for almost two hundred years now, human activity has become so focused on industrial production that it has absorbed its rules and rhythms. In his book *The Third Wave*, Alvin Toffler highlights the five principles that make industry efficient, which have been transferred to society as a whole. These principles are: standardisation; specialisation; synchronisation; maximisation; and centralisation. Without going into each principle individually, it might be said that an assembly line organisation and cyclical rhythms have transformed daily existence into a continuous race against time. Creativity, time spent with the family, and gratifying work are values which we have yet to recover fully from the end of the industrial wave, which, as we know, was strongly product-oriented.

A Network of Knowledge

The show was inaugurated in September 2007, and will be hosted in primary, junior-high and senior-high schools throughout Piemonte until the end of the academic year.

The physical structures are just the starting point for discussion with the kids. The show represents an example of applied systemic communication, as it is able to make use of a multitude of expressive forms, technologies, and communities, which broaden the network of information and opinions.

The images collected come from various different sources. Some of the photographs were taken by researchers from the Department involved in the project, while others were found on web sites dedicated to photography. In this way, specific situations experienced first hand along with choices made by others have been documented, reflecting very precisely the concepts expressed on the various panels.

Photographs from the Web were taken through the system of Creative Commons licences. This represents an example of how the difficult question of copyright can be managed, placing Humans at the centre of the project. Creative Commons are a collection of licences that set forth the rights reserved by authors over their works. The works can be freely distributed providing that they are acknowledged using the terms selected by the author and other restrictions, such as the non-commercial use of the works, the ban on modifying the works, and other specific indications that can be found on the website www.creativecommons.it.

The show's colophon lists the names of the authors whose works are used. This solution enabled us to make use of high quality photographs with a view to establishing reciprocal respect and relationships – two central values from the Human point of view.

While the kids are free to roam among the structures, the show also involves a presentation of the issues at schools and direct exchange with lecturers, researchers and students from the university. The aim of the presentation is to introduce the issues addressed by the show, through metaphors and analogies which shed light on this critical turning point in history that we are living through, namely the energy and commodity crisis, with the help of images, cartoons and suggestions. Of course the depth of the discussion is adapted to the age of the audience.

After the kick off presentation and a visit to the show, the kids are invited to express and work out their views, and give their impressions as feedback. A number of different tools are used to encourage feedback, though the kids are left free to express themselves as they wish.

One way to give comments is through Post-it notes, which can be left directly on the images displayed on the panels. These brief thoughts are a useful way to break the ice, as they are informal in nature, often quite out of place or ironic, and they can be read by everybody.

Other forms of interaction are established through a written questionnaire and a video box. The questions asked concern the kids' daily habits with regard to diet, travel, and sense of involvement in the issue. The kids are always questioned in an informal way so as to encourage sincerity.

For primary school pupils, the map of the two scenarios has been printed on paper, with a description of a pathway to follow through the panels, and a brief description, involving questions, of the meaning of the keywords.

Under the guidance of teachers, or independently, as the case may be, in the days following the presentation, kids are encouraged to produce reflective material, which can be represented in any way, and on any sort of support, from MP3 files to printed T-shirts.

A web portal at the address http.innovazionedesign.top-ix.it is also available, where the kids can upload electronic material, images, and videos, revisit the show, and share their observations with pupils from all the schools involved in the project.

The time the kids dedicate to the show is very different from the time they spend in the classroom, as they do not have to interact necessarily with teachers, and they have the opportunity of using tools and techniques similar to those used in entertainment. This encourages the spontaneous creation of networks which extend well beyond the classroom, to involve parents and friends.

The communication project is further enriched by the feedback that emerges every week when meeting the class groups, so it might be said that the project is a process of development, continuously updated, and perhaps soon it will be able to continue independently.

An exhibition to be held the Natural Science Museum in Torino, from 22nd September to 21st October, will represent an initial opportunity to organise all the material produced by the school pupils and present it to an audience beyond the schooling system. The exhibition will be an occasion to see the pathway followed, though as was the case for the pupils, visitors will be expected to participate in the event in a critical way.

Obviously, if the project does manage to shift our social paradigm, its effects will only be seen in the medium-to-long term.

The first results to have emerged from work with the pupils and the discussions held paint a rather worrying picture, as although it would seem they are aware of and sensitive to environmental issues, few of the individuals seem willing to question or change their lifestyles. It would appear that a change in paradigm cannot happen immediately, but needs time to become widespread, shared and metabolised. The somewhat disappointing reaction of the kids can only confirm the need for change.

In December 1987, the UN World Commission on Environment and Development spoke of sustainable development as “meeting the needs of the present without compromising the ability of future generations to meet their own needs.” This definition, which over the years has been modified, does not offer solutions but urges us to put Humans at the centre of attention. Nevertheless, responsibility has not been shared and put into practice by everybody, as the road to sustainability involves bans, obligations, regulations and additional costs, for both companies and individuals.

The systemic approach has already provided examples of how to apply the principles of sustainability by promoting economy and culture. Systemic communication is the key tool in disseminating this culture, and encouraging future generations to take greater responsibility in an effective and spontaneous way.

DESIGN VISIONS PROPOSALS AND TOOLS

The emergence of shamanic wisdom in the culture of the modern Brazilian project

The perspective of a new rationality for design

Rosane Costa Badan[1]

Abstract

The Brazilian contemporary designers develop their projects within a rationality that is magic. This thought does not have the same parameters that define the logic of Western scientific thought. By a vision that comes from above, they work in a dimension that transcends the rational and sensory exploring the world through free associations of elements.

The aim of this paper consists in bringing to light one of the logics that does not belong to the West. The shamanic logic of Amazon indigenous tribes plays the role of this rationality.

The main goal is to provide a new reading key to the contemporary designer, which could help him to overcome the limits of materiality, giving him the possibility to renew the energies of the current design.

[1] Politecnico di Milano (ITALY) - INDACO department, Ph.D in Industrial Design and Multimedia Communication, rosane.badan@polimi.it

1. Introduction

Contemporaneousness as a whole finds itself systematized within a peculiar dynamics and is therefore subject to continuous renovation. It tends to fluidify diverse logics of thought and creates hybrid and intermediary typologies among the various projectual scales. Designers are conscious of such a dynamics and thus move transversally among the many areas of knowledge. This offers them the advantage of appreciating a wide range of known realities and at the same time favors the exploration of other intellectualities that are structured differently from that of the West. Given the fact that there are various logics which rule the different languages responsible for the dichotomies in the world, the aim of this paper consists in bringing to light one of the logics that does not belong to the West in order to renew the energies of present-day design.

The shamanic logic of Amazon indigenous tribes plays the role of this relatively unexplored intellectuality. It is a mentality inherent in the way of thinking of Brazilian contemporary designers. The latter develop their projects within a rationality which is interpreted as magic. This rationality lacks the parameters that define the logic of Western scientific thought because it is developed on deep levels of perception and sensation.[2] In order to understand its parameters, the most adequate measure consisted in making present-day humanity look towards and follow the rising trajectory of a parabolic curve whose climax was the magic within shamanic traditions.

Within an indigenous society, shamanic logic suggests means, broadens the virtues of things, predicts effects, and fully satisfies the common wishes of an entire generation. Shamanic wisdom[3] transcends the limits of the Western worldview - which is ordered, stable, fixed - and provides resources for man to reach complex immaterial, expressive, and communicative horizons that make up an essential panorama of his survival.[4] Although shamanic and Western views differ, it cannot be denied that humanity also admits this type of rationality which is capable of overcoming the limitations of materialist science. It is, indeed, a decontaminated body of knowledge that is apt to reconcile man with Nature. A new reading key such as this may aid the contemporary designer to surpass the limits imposed by habitual materiality directions.

2. The shamanic perspective

Shamanism is not a primitive stage of religion, but a highly elaborate state of conscience and a key that human beings developed in order to comprehend the environment and to live in harmony with it (Drouot 2001, 23). Western civilization has longed to live harmonically with Nature, a return which valorizes the instinctive feature of man and gives him the possibility of integration with the whole. Certainly such a feeling of unity with existence may be reached, but it is necessary to renounce the illusion that Western thought occupies a central or preeminent place in the world. Once this perspective is kept in mind, the starting point consists in turning away from the West and penetrating the wisdom of shamanic traditions. Studying shamanism is the same as recovering the roots of human knowledge: it is the most ancient spiritual and cognitive tradition on record, one which is still present among the indigenous populations of all five continents.

Shamanic wisdom is disinterested and is structured within an intellectual way of thinking.[5] Such thought is integrated in an indivisible whole and is based on the principle which states that if one fails to understand all, nothing can be explained. This totalitarian ambition of wild mentality

[2] Sensation is the answer given by sensorial receptors and sense organs to environmental stimuli, whereas perception includes the recognition and interpretation of sensorial information (Rookes 2002, 17).
[3] The secret of shamanic wisdom resides in its access to non-ordinary states of conscience.
[4] If in the past man's proximity to Nature served as a standard to all of his actions, nowadays reestablishing closer ties between Nature and Humanity is the ensurance of human existence (Papanek 1995, 11).
[5] An intellectual way of thinking does not equate to a scientific way of thinking (Lévi-Strauss 2007, 22).

constitutes an immense challenge to the system of beliefs of modern science.[6] Whereas scientific knowledge is characterized by a rational logic that demands integral transparency to reality, wild knowledge possesses a magic mentality that intends to be incorporated to reality, a certain human density.

Magical mentality attributes great importance to knowledge and is dedicated to knowing Nature. According to indigenous shamanism, magic is essentially an art of doing which is capable of producing anything non-conventional. However, only that which was in fact believed in by an entire society is regarded as magical, not that which was defined as such by a fraction of this given society. Acts which are not repeated would not be magical; acts whose efficacy is not believed in by the entire group would not be magical; strictly individual acts cannot be called magical. The collective prevails over the individual despite the fact that magic is an isolated practice, mysterious and fortuitous, dispersed and fragmentary, arbitrary and facultative.[7] In fact, magic does nothing or almost nothing, but it makes one believe in everything, so much so that it puts collective forces and ideas at the service of individual imagination. As a complexion, magic is made up of acts, representatives, and agents: magical rites are known as acts;[8] ideas and beliefs that correspond to magical acts are known as magical representations; agents are known as shamans, the individuals who execute magical acts.

Shamans are distinguished in tribal societies as doctors, musicians and dancers, poets and story-tellers, painters and craftsmen, guardians of myths and mediators of conflicts within the community. They are also sophisticated experts in minerals, vegetables, and animals, as well as experienced travelers of the paths of the material and spiritual worlds. This communication between both worlds occurs thanks to the disposition of the universe which is generally conceived in three or four layers. A shaman seeks to be in communion with nature, not in control of it.

3. The shamanic universe and the cosmology of Brazilian design

I researched the Amazonian[9] indigenous cosmology and confronted it with the roots of the modern project in Brazil. My aim consisted in identifying the influence of shamanic thought over the mentality of the contemporary designer or in finding out whether any relation existed between shamanism and design.[10] I became aware of a correspondence between these two contexts by

[6] Contemporary science heads in the direction of overcoming this schasm. In 1986, during a summit in Venice, a written declaration stated that science and spiritual traditions are complementary, not contradictory. According to the Venice declaration there exists a new rationalism capable of overcoming the limitations imposed by materialist science and by institutionalized spirituality and of reconciling humanity with nature. It is possible to recover the link between spirit and matter which is embodied in traditional bodies of knowledge (Arantes 2005, 15-7).

[7] A magical ceremony does not occur inside a temple or on domestic altars; normally it is performed in woods – away from houses – at night and in the shadows. It is hidden even when it is licit. Even when it is forced to act in front of an audicence the magician seeks refuge; his gesture is fortuitous, his word indistinct (Mauss 2000, 18).

[8] A magical rite is normally irregular, abnormal, and dictated by necessity, not by moral obligation. Mauss named 'magical rite' each rite that is not part of an organized cult: it is private, secret, mysterious, and tends to the limit and the forbidden. Magic was not defined by the form of rites but by the conditions in which these are produced and by the place they occupy in society (Mauss 2000,19).

[9] Shamanic cosmology reveals that the universe is made up of three levels – the sky, the earth, and the subterranean world – which are linked by a central axis (Eliade 2002, 287). Below the earth's layers are the aquatic and the subterranean worlds: the former is related to aspects of creation and transformation and the latter is related to cannibalism; earth is the place of hunting whereas the sky is the world of the sun, the moon, and the stars. Each of these worlds has an ancestral anaconda which rules and represents them: the anaconda in the water, the jaguar on earth, and the harpy eagle in the sky. Shamanic wisdom and technique concern the ways of dislocating from one world to the other. The passage is represented by an opening or a hole through which sublime creatures or guardian animals of these worlds pass.

[10] The origin of Brazilian design can be traced back to European and indigenous cultures. As regards the European culture, aesthetic axioms originated from rationalist vanguard currents. As regards the indigenous culture, the principle of primitivism tended to an aesthetics of balance thanks to a system of assimilation between native culture, intellectual culture, and technology. Such elements were articulated within a syncretic cultural concept in which formal innovations promoted by "native originality" were conciliated with the universal demands of the modern spirit. Therefore some theoretical models elaborated in Europe influenced the culture of the

establishing a reading based on an artistic-intuitive reflection. This reflection produced conclusive considerations regarding the evolutionary process of Brazilian design. They indicated that this relation had a symbiotic aspect and involved a universe which was structured within European and autochthonous parameters as well as another universe structured on cosmological parameters perceived by the shamans of Amazon tribes (Badan 2007).

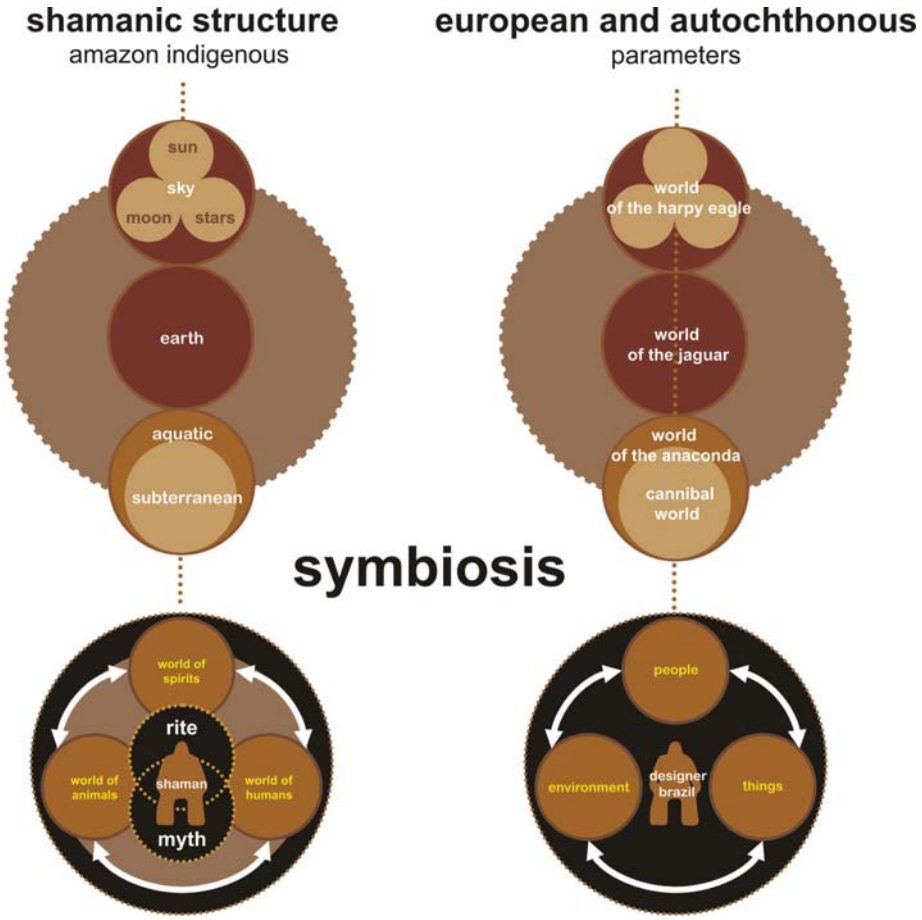

Fig. 1: The evolutionary process of Brazilian design reveals a symbiosis between the universe that was created from these two parameters – European and autochthonous – and the structure of the universe perceived by the shamans of Amazon indigenous tribes.

In order to understand this symbiosis, the structure of the universe of Brazilian design was aligned in a scheme made up of four specific worlds (Fig. 1). In the proposed scheme, the ideas congregated in each of these worlds failed to come together in terms of chronological aspects. What did bring them together were the aspects of identity and affinities which were verified, first of all, in the process of intellectual development of designers. The identity inherent to each world presupposed the persistence of a single knot, be it in the project, in the methodological coherence, or even as an acknowledgement of certain symbolic characterizing attributes.

Meanwhile, of the four worlds identified, the one to which I referred as the world of the harpy eagle revealed an intense correlation with magical or supernatural manifestations originating from the Amazonian shamanic cosmology. The designers of this world employ intuitivity and experimentation in order to carry out three basic actions within the projectual process: to recycle the things of nature, to reuse already used materials, and to recontextualize low-cost industrialized products.

Brazilian project in the same way that the image of tropical nature became the scenario and background of many modern design projects (De Moraes 2006, 6).

Eventually, in order to carry out their activities, shamans and designers decompose and recompose the world they know by exploring it through free associations of elements. By regarding experience as a direct perceptual contact with that which presents itself to mental faculties such as perception, memory, imagination, and introspection, both shamans and designers work within a dimension that transcends the rational and the sensorial[11]. By means of a top-down vision they juxtapose explored fragments and create new structures with new meanings.[12]

Having observed the development of these actions, I assumed that there were two elementary principles which established an interdependence between both universes: experimentation and contiguity (Badan 2008). The former is a principle which indicates a means of creation and makes explicit a risk of failure that allows one to recreate new things. As for contiguity, it is a principle that functions as a link between differences, allowing new relations to be created and new meanings to be produced, both for things and for beings (Gonçalves 2001, 33-4). According to shamanic theories regarding the Cosmos – all of which reveal that all things must be linked as parts of a unified universe – contiguity materializes through experimentation. Once I examined the phenomenon in greater detail, I concluded that there existed a dynamic confusion involving powers and competences within the regular state of this system (which is, in fact, magical). Each experimented thing was done so in a singular manner and each of these experiences differed in their descriptions.[13]

With the insertion of these principles in indigenous culture as well as in the culture of the Brazilian modern project, if the indigenous culture is to be valued first and foremost, several are the reports of anthropologists indicating that experimentation and contiguity support the existence of a fundamental interconnection that reunites all the parts of the unity. In this case, to experiment is the concept that reveals the possibility of transformation and continuous creation of elements that make up the Cosmos. Such a transformation is regarded from peculiar indigenous ways of producing transformation.[14] Native theories are concentrated around actions responsible for the metamorphosis that allows the transmutation to another body. If the same principles are subsequently transferred to design they may be interpreted as projectual phases of a non-conventional process constituted by the fusion of trivial elements and technological components, in other words, as phases of a top-down elaboration of products. Here the transformation does not equate to transmutation but to subversion:[15] fragments had their original function subverted so they could be used in a different context.

As a result of such dynamics, a few of the elements that were previously set in the material scenario of the two cultures "apparently" disappear without modifying the character of the final result. If such an analysis is correct, in essence, then shamans and designers – despite originating from different cultures – have developed an analogous way to arrange their universes and to act upon their worlds. Under a feature regarded as magical, both benefit from the same creative ability: more than simply perceiving connections between things and beings, they are capable of modifying the original context by recontextualizing it.

4. The aesthetic redimensioning of design in Brazil

The perspective of recontextualization has led the contemporary designer towards a vision that goes beyond the rationalist notions developed in the Western world. This new vision is based

[11] In a primary sense experience is linked to sensations and perception; sometimes illusions and hallucination are also regarded as experiences. In a tertiary sense experiences reveal a mystical basis.

[12] Intellectual assemblage results from concepts which originated in the European vanguard of the early 20th century, such as the pure vision of Cubism (synthesis, montage, and technical finish), the wireless imagination of Futurism, the irrationalism of Dadaism, and the free association of Surrealism (Teles 2002, 81-3).

[13] Experience is a mental state of an individual and reveals its own nature and way of being.

[14] The indigenous transformational tradition derives from appropriation. This means that the opening is not produced by autochthonous innovation but by exogenous appropriation – the innovation is allopoietic (Gordon 2006, 29).

[15] Subversion is here interpreted in its aesthetic sense (novelty, innovation), not in its dialectic sense.

on a juxtaposition of fragments which in turn is correlated with a reality of design mainly manifested in Brazil from the 1990s onwards. At this time, accelerated globalization contributed to the formation of a large group of professionals who acted in the Brazilian market at their own account by practising a deterritorialized production. Many of them did not have sufficient money to afford complex tools or to create their products. Such technical precariety caused these designers to carry out studies on language whose parameters surpassed functional requisites and to appeal to the use of preexisting objects. By taking advantage of their forms and colours they performed operations that would transform objects in components. Consequently, these difficulties propelled the formation of forces that innovated Brazilian design (Leon 2005, 16).

Fig. 2: Once the original matter is transferred from its natural habitat the spectral character of the world of objects is dismantled in an experimental kaleidoscope; after its reassembly, it is reverted into an allegory within a context of revalorization.

However, the act of transforming objects in components did not signify the construction of a unique language; on the contrary, the intellectual approach of superposition of elements redimensioned the aesthetic and conceptual structure of design in Brazil. The latter was no longer interpreted as a result of simple European influences or as an adaptation of preexisting codes or styles. In fact, such redimensioning was a result of a process based on shamanic principles which, by inscribing and reinscribing imagetic or cultural meanings that are non-contaminated by other languages, have promoted a new reading to objects and raw materials of daily life.

As previously indicated, these features are easily verified when various elements from a given culture are juxtaposed. This juxtaposition alters the meaning of the matter by removing it from its natural habitat and placing it in a context that doesn't belong to it (Fig. 2). By assuming

different values to those related to the preceding context the limits of comprehension linked to the new materiality emerge and are immediately surpassed, whereas the values of its fragments assume a secondary position. As expected, the recontextualization does not cancel or hide anything; it leads to the emergence of a new structure, one which is ambiguously organized by reverting the values of fragments into allegory within a context of revalorization.

If my aim consists in understanding this context more deeply, then it is necessary to extract the essence of the recontextualized object and to examine it in terms of its insertion in the cultural and social matrix in which it was developed. As far as the indigenous matrix is concerned, for instance, it is important to highlight that all magical experiences are integrated and form a real whole. The unity of the whole is more concrete than any of the isolated parts. It is not difficult to imagine that, if this same analysis had been produced within the western matrix only, each portion of this whole would have the tendency to be abstracted. However, in the context of recontextualization, the parts lose the ability to communicate their truths if analyzed on their own because, within this context, they only make sense and become necessary if essentially united. In the process of juxtaposition of fragments, the individual identification of each of the parts tends to disappear in order to reveal a visual condensation of the whole. When the whole is examined in its entirety one perceives that this object is loaded with an immateriality in its complexity, with a spiritual value that is completely different from that which formerly belonged only to its parts. It is important to point out that, as regards subversion, the original matter – in the role of components - is still easily identified in the recontextualized product; however, because of the fact that this product is submitted to diverse cultural channels, it is open to the manifestation of different emotional impacts. In fact, the transgression of the original matter incites the spectator to carry out a new reading of the object which, in turn, will lead him to express an unexpected emotion translated as mystical or magical.

For the Amazonian cosmology - whose thought is participative, mythical, symbolic, and above all emotional – emotion is a sensation analogous to all objects. Such objects reveal that Indians live in a world rich with sensations. Each object represents an integrated reality with which affectionate relations are established, therefore it is loaded with potentialities that arouse emotion. Nevertheless, in design, these are sensations which do not occur with any object, utensile, or created artefact. The energies of the designer are often turned solely to visual qualities, leaving other sensorial components out of the final project. For this reason the spectator's reaction is strictly limited to the contemplation of the present materiality. It is true that the spiritual value of a product depends on the intention of the professional who created it and on the respective use to which it is assigned. However, few objects are able to attain a projectual intentionality capable of uniting all sensorial qualities and which may imply a sacrality, in other words, an intentionality capable of involving the spectator's mental and muscular effort in the "reading" of its structure.

Synesthesic reactions serve to manipulate perception and emotion. However, emotional reactions rely on several other factors. It is clear that the designer's intention is important, but not less so than the components used. Similarly, the components are as important as the final product just as the final product is as important as the context to which it is assigned. To allow all these elements to contradict each other – failing to work in harmony - in all their extension with the aim of creating an ambiguous though permutational game may release unexpected emotions, transcendental sensations, and suggestions of the sacred in people. This ambiguous game allows the development of ludic behaviours in the minds of spectators. Ambiguity[16] is the place where the expression of thought, language, and image meet, as well as the place where art, design, and sciences converse with each other.[17] From this point of view the aesthetic

[16] Even though ambiguity may be regarded as the coexistence or confluence of two incompatible aspects of a single reality, the presence of a double meaning for things is not a negative aspect; on the contrary, it enables a total understanding of this reality.
[17] The man-artist and the man-scientist employ their own language when manifesting their peculiar thought: the language of the artist is normally synthetic, smoky, instinctive, and understandable, whereas the language of the scientist is more analytical, precise, rational, and obscure. However, in the dimension where science and arts meet, language becomes at once analytical and synthetic, precise and smoky, rational and instinctive, understandable and obscure (Caglioti 1986, 151).

redimensioning of design in Brazil is outlined within an ambiguous magical structure that has produced pleasing and original aesthetic results, with the production of authentic objects of a Brazilian matrix albeit of a universal expression.[18]

5. Intuition: from materiality to magic

The Brazilian designer reveals shamanic behavior. He creates original pieces with great expressive force and strong emotional appeal. Once disengaged from past burdens, this professional is intuitive and does not rely on theoretical models in order to develop his projects. He seeks inspiration in more ethereal worlds and reveals a natural spirit of observation, an attitude of a personal and subjective character. The starting point for the creation of his product does not follow paradigms: he thinks of things which may stimulate people's senses even before thinking of an image that will determine the object's form. Such a paradigmatic rupture finds certain correspondence in the way the shaman narrates the mythological tale. The narration of the myth does not follow the natural course of events. It must be understood in its totality because the basic meaning of the myth is linked to groups of events (Lévi-Strauss 2007, 60). In both situations – that of design or that of the myth – the perception of its meaning does not follow a horizontal path because it is more than what is revealed. The perception of the meaning goes along a vertical route: it happens simultaneously, it is integral, and it concerns all senses.

This means that the elaboration of the object is not restricted to a bottom-up approach, in other words, that of "appearance", an elaboration linked to a first glance. It considers a "beyond", a top-down approach which requires an interpretation of thought and criteria of judgement.[19] To perceive the form, colour, material, and texture is one of design's most important aspects, but the aesthetic results are not always able to account for imagination as a process. Perception does not only come down to this because there is something more. This "something more" does not refer to questions concerning the way of creating but the way of making someone feel something: it is an attitude that highlights how things may be perceived by the senses. Only through interaction of all senses would it be indeed possible to begin to see, to experiment.

As a consequence of such shamanic behaviour, the object has been conceived in Brazil as a "quasi-corpus", in other words, as a being whose reality is not exhausted in the exterior relations of its elements. This product does not only occupy a place in objective space but transcends it by establishing in it a new significance, in which objective notions of time, space, and form cannot fully account for its reality (Fig. 3). This object is not conceived to be solely captured by the eye: it includes all the senses because it is the bearer of a multimedia message.

Whenever a message to be decodified is of this sort the spectator's perceptive process clearly becomes more complex. All senses are interconnected in humans in such a way that an object's visual appearances are crossed with those of the mind. The latter establish a dispute with representations linked to experiences and to the intellect's imaginative capacities, thus instituting a dynamics that alludes to mythical and poetic allegories. At this moment a great number of sensations interact with the spectator and make him feel the object fully; in other words, the spectator perceives the object with the eyes, touch, smell, taste, and hearing. It does not stop there: this plurality of sensorial components may still be surpassed. By emphazising the details related to these sensations, what is important to state is that if intuitive creation were to be abstracted from the product, if the product were to be reduced to a mere objective body situated in an objective space, then the designer should seek only a reaction of stimulus and reflex from

[18] Aesthetic pleasure and emotion are only perceived if an infraction occurs within a preestablished harmony. This rupture is also known as originality.

[19] Top-down and bottom-up approaches have been applied in several cognitive areas, including the field of perception. A bottom-up elaboration begins with an analysis of sensorial inputs. Information derived from such inputs are transformed and combined towards the constitution of the perceptive object, in other words, information travel from the lowest to the highest levels towards the most cognitive ones, those which determine perception. A top-down elaboration performs the inverse: it is used to describe higher factors, the most cognitive factors of perception. Such higher-order information operates from the top towards the bottom and influence the way sensorial input is interpreted (Rookes 2002, 20).

himself and the user-spectator. As a result, communication would be limited to the eye as an instrument, not as a human means to see the world.[20]

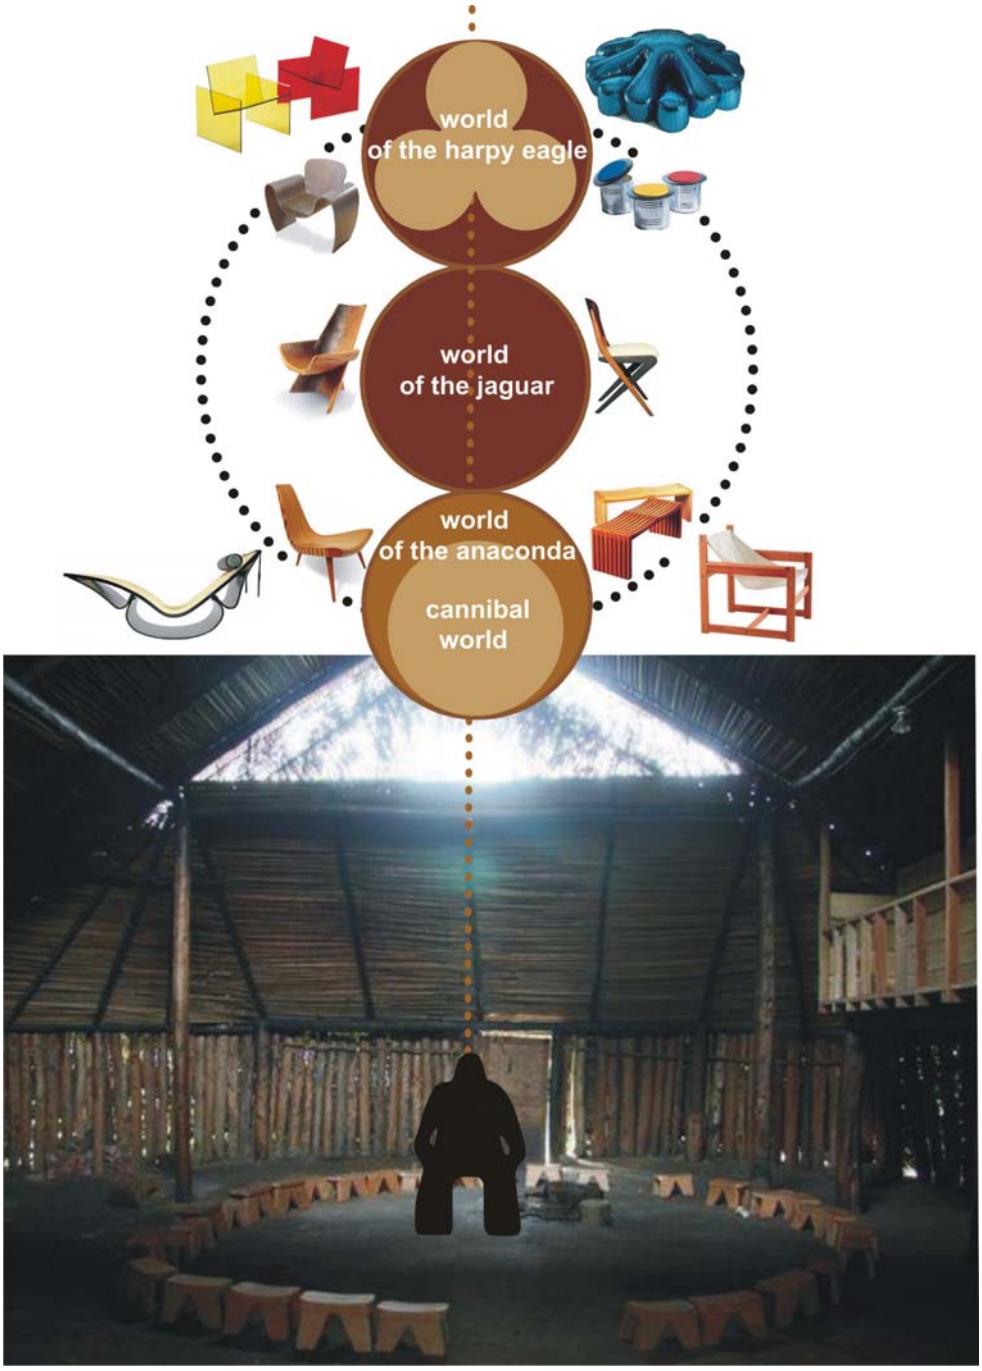

Fig. 3: The Brazilian designer conceives the object as a “quasi-corpus”, a being whose reality is not worn out in the exterior relations of its elements. In the same manner as the shamans or "pajés", Brazilian designers assume an attitude of pajés of industrial design.

Such process of interaction and integration among sensorial components remains at an unconscious level of organization in the majority of people. Only in a few individuals is there a conscious union between information that derives from the various senses (Riccò 1999, 61). According to the indigenous phenomenology of the myth of the world, this was an ability of

[20] The parallel course of further sensorial records requires the formation of phenomena in which the action of a meaning interacts with other modalities, thus modifying perception (Riccò 1999, 3).

communication which was taken away from humans, except from shamans and from those who chose to carry out works of a physical, spiritual, and psychological nature.[21] The adaptation of myth to reality enables one to state that this situation is pertinent to the designer of the world of the harpy eagle and to the shaman of indigenous tribes. Both are capable of perceiving and communicating other models of thought because they embody intuitive rituals. Whereas intuition makes them defend values that are rich in meaning and act on a more human creative scale, communicating with Nature and with materials instead of wanting to dominate them, synesthesia integrates and juxtaposes all the senses in favour of this intuition.[22]

Intuition promotes creativity by taking into account a multiplicity of points of view. As this is a prism which opens itself up in search of the new, the logic of shamanic thought – which has intuition incorporated to its conduct – appears to relate to creative thought in the strictest possible sense. Shamanic thought possesses a logic of values which allows it to communicate with the outside world. Its mechanisms encompass magic and rely on knowledge and experience, not on valid models. Substantially speaking, the parts of a given thing which are normally organized and interpreted successively in the West are provided by magic in a simultaneous way. What differs between both logics is that the Western rational mechanism guides thought whereas its shamanic counterpart serves it. Understanding the structure of this mechanism does not make one learn supernatural formulae; such understanding helps one to perceive the existence of other routes which a designer may follow in order to employ his own intellect. Therefore, once intuition has been used by designers in the search for new results and languages, the addition of the mechanisms of shamanic thought to those of rational thought might provide design with new perspectives in the present situation.

The shamanic perspective does not intend to focus only on isolated problems; it also aims to find new ideas and interpretations of reality regardless of their type. What basically characterizes this thought is the control exercised over its own proceedings. If this thought chooses magic as a system, for instance, it is because it wishes to use magic as a method, not because it refuses to adopt any other method.

Shamanic magic is not absurdly complex nor is the systematics adopted by the shaman too complicated. The monotony of its acts, the scarse variety of its representations, and its uniformity are all part of a relatively simple system (Mauss 2000, 91). In order to create new, valid, and practical ideas shamanic magic seeks simplified solutions that reveal unusual aspects of a thing or situation. Quite often the components are already available in the environment itself and all that is needed is to regroup them in a new structure. When shamanic magic relates beings and things it changes their forms and inverts their roles; it creates and recreates a world that is never complete. To produce something new from the very start is surely creative, but to make something known become unknown is also an act of creation. One way or the other, this process reveals a principle that considers things from the perspective of their totality, not from their separate parts.[23] It is the prime act of doing, a simple gesture that weaves new surfaces and realities.

In summary, shamanic thought is a kind of attitude that is materialized within Brazilian design as magic, a practice that reveals reality fecundated by imagination. Such practice of materialist inspiration highlights the complexity imposed by contemporaneousness by turning to a popular quotidian that desires a return to Nature, an integration with the whole. This practice does not aim

[21] In conformity with this myth, the sky was permanently occupied by a large luminous object towards which human devotion and admiration were turned. The planet was linked to this luminous entity by means of an access bridge whose course was changed by history at a given moment in time; this generated cataclysms and evoked a catastrophic end to this golden age. Such cataclysms allegedly shattered collective consciousness to such an extent that the spirit of man no longer had access to the thoughts of other individuals, at least not under normal circumstances. This catastrophe led man to isolation and made him lose all sense of communion with Nature, with the planet, and with the gods (Drouot 2001, 162-3). Shamanic myths speak of a time in which Nature and man lived in complete harmony.

[22] To observe nature, to produce results from senses, and to direct them towards the process of how to do things and how to communicate is an attitude which reveals a new field that unites design, science, and senses (Hara 2007, 71).

[23] Nature - when observed in its infinite details and peculiarities - reveals that elements placed in its interior are confounded among themselves instead of highlighted (Borges 2003, 148).

at reality as an undifferentiated totality but at objects and desires reduced to the status of things. The process consists of a succession of images born of the juxtaposition of material elements. This results in a panorama that mixes the unindividualized quotidian and subversion and imbricates them in each other. Here the occult forces of objects are set free by magic and, by following the simplicity of the shamanic system, they harmonize with reality by surpassing logical causality. Whereas shamanic magic seeks simple and flexible answers for things, logical causality aims to answer the complexity of contemporary society by becoming even more complex.[24]

One should warn that the risk of the process which encompasses both shamanic thought and design consists in transforming this cultural relation in a fashion event or in an elitist phenomenon. It should be pointed out that shamanic behaviour in design is more a mental form than a combination of techniques used to disassemble and reassemble physical components. The function of this mechanism consists in seeking icons, in finding new correlations, and in transforming the various elements dispersed in the world into creative expression. All this is intended to help man achieve a less materialist human condition and thus integrate him with the universal whole.

6. Conclusion

It was not the aim of this paper to discuss the functional or stylistic elements which involve the shamanic universe and Brazilian design, but to show that non-Western civilizations reveal logics that are rich in interesting energies and that are able to provide a renewing feature to current projects. For this reason, the ethnical-existential implications related to the shamanic aesthetics of Amazonian Indians and to the aesthetic mysticism of contemporary Brazilian design were frugally focused on the observation of figurative and symbolic codes during this research's analytical process. What really mattered to the analysis was the verification of the context that has outlined the new human condition of contemporary societies.

For Western societies it is difficult to comprehend that native practices of transmission of knowledge are based on that which exists, on the mechanism of copy, not on the idea of innovation (Gordon 2006, 29). This allocentric and mimetic feature of indigenous innovation promotes a sense of unauthenticity when submitted to Western concepts of originality. Parallel to this, verifying that rational thought does not seek to interpret reality in general is indeed odd. Therefore the West has failed to work in favour of true invention; instead it has worked in favour of a successive elaboration of inventions of the past. Through both situations the concept of creation in the West assumes an almost contrary connotation when confronted with the meaning of creation adopted by indigenous cultures. Originality has always been overestimated in Western societies and underestimated in other cultures because mechanisms employed by other intellectualitites have been unknown. However, the following statement must be considered: in order for a given culture to be unique and to be apt to produce something original, the culture itself and its members must be assured regarding their originality and superiority over other groups (Lévi-Strauss 2007, 31).

Situations such as this end up restricting the view of Western man and limiting his capacity to perceive the universe only within the boundaries of rational logic. The scenario that constitutes the panorama of global reality includes other possibilities. In the world we live in there are various intellectual procedures which radically differ from the logical method and which are, maybe for this reason, fecund with new ideas. In fact one logic does not exclude the other; both are complementing procedures because they are open to different perspectives, all of which are equally valid. The consideration of other intellectualities is equivalent to increasing sensitivity in

[24] This is the opinion of Wolf Prix, of Studio Coop Rimmel, regarding the "decostruzione" of architecture. According to his assertions, architecture should become more complex at the turn of the millennium in order to respond to and to express the complexity of society (Bottero 2004, 41).

favour of several points of view which originate from a certain situation; such points of view enable one to see the multiplicity of routes which may lead the designer to more interesting solutions. This means that procedures related to other logics do not cease to be satisfactory alternatives at the moment in which a logical procedure shows difficulties in finding the solution to a given problem or when it requires innovative ideas.

The 21st century is an era of discovery. Certainly one of this century's design tendencies is the attempt to understand Nature and to interact with other logics of thought that are capable of assisting man in the development of projects and of bringing him closer to a less materialist human condition. It is true that contemporary designers benefit from the same laws that regulate natural processes in order to create their products. However, by taking into account the complex phenomena of constant transformation observed in present times, designers are not too interested in carrying out definitive projects: their expectation refers to experimenting with the unknown towards suggesting systems of various kinds, imperfect and incomplete systems that must be adapted to a context interconnected with numerous logics that are responsible for the configuration of the world of today.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Is change as good as a holiday?

Using metaphysical bonds to design enduring change

Ian Coxon[1]

Abstract

Two things are necessary to recognise in a condition of everyday change. The first is to become aware of what it is about the everydayness that by contrast allows us to recognise that change has occurred. The second is the ability to determine what it is about the change that brings about a positive reaction to the perceived differential (the change).

This paper describes a new Taxonomy of Experience (*ToE*) useful for structuring and bringing to consciousness, aspects of everyday experiences which are commonly overlooked. It also presents a *SEEing* process for distilling and making visible the deepest (metaphysical) layers of meaning within these experiences. This metaphysical understanding is useful to designers as a primary change agent and for promoting stronger bonds to change. The design research methods (tools) presented in this paper are immediately useful in sustainable design activities such as design for longevity, design for social equity, universal design and many decisions affecting various stages of the product/service lifecycle.

[1] University of Technology Sydney, University of Applied Sciences Cologne. Lecturer, bluearth@optusnet.com.au

Prologue

Why use ‘metaphysical’ bonds and why refer to change as good as a holiday? My reference to metaphysicality is strong throughout this paper mostly due to a chance encounter with Singanapalli Balarams (1989) thought provoking paper about the power that Gandhian metaphors had in effecting change. Change being the key word in this context, not the metaphors or their metaphysicality. The metaphors Gandhi employed were not particularly striking in their physical form (his home spun white cloth, sandals, spinning wheel) but they contained powerful mythological and metaphysical qualities which the ordinary Indian people related to very strongly[2]. This has a similar resonance to the many things we are attracted to that have no great material value but which we treasure for their metaphysical value anyway (Grandmas teapot, my high school year book, a Stark lemon squeezer)

The holiday analogy is only important in establishing a different contextual perspective on how we react to change. It is as good as any other in so far as it is one which most of us are familiar with. In my holiday analogy for instance, I work and go about my everyday life then suddenly find myself (on holidays) in a different, strange and sometimes exotic place inhabited by strangers with strange habits; possibly a companion or two who I have hardly spoken to in months and now must spend every waking moment with. This mind-space is suddenly very different to my ‘every-day’ or normal life.

Over the following week or so (of the holiday) I slowly sink into ‘holiday mode’ and before I know it I am again wrenched away from my wildly exotic poolside lethargy and must return to what now appears strangely and disappointingly familiar – the grind of normal life. Is this why so many people experience depression and anxiety on return from holidays? What is it about this time away from our everyday life that fosters a positive condition, the cessation of which causes such negative withdrawals?

What is it about the holiday that offers a lesson about change?

and what does this have to do with metaphysicality?

If change (like a holiday) is to be considered a good thing, then what is it about a holiday that is good and by association[3], makes change a good thing? A holiday takes us away from the ordinary and everyday. It is the degree of difference (change) between our everyday experiences and those experienced on the holiday that make the change so recognisable and usually, pleasurable. A weekend away in the mountains or at a friends house in the country is nice but doesn’t shake our world (read perspective on life) half as much as two weeks in the snow fields or rafting down the Amazon.

Two things are necessary to recognise in this condition of change. The first is to become aware of what it is about our everydayness that by contrast allows us to recognise the change. The second is the ability to determine what it is about the holiday experience (aka. change) that brings about such a positive reaction to the perceived differential to the everyday. It is this positive experiential component that I keep referring to in this paper as the metaphysical[4] aspects of change.

---

[2] Gandhi came from a privileged background and did not initially understand these metaphysical qualities. He intentionally went out amongst the people he wished to help in order to study them closely and come to understand what was meaningful to them. This same process of developing understanding through immersion and using this understanding to effect change is a fundamental premise in this paper. (Balaram, 1989)

[3] A reference to the saying ‘A change is as good as a holiday’

[4] In this paper, the terms Metaphysical and meta-physicality are used in their broadest sense without ascribing any particular disciplinary or philosophical connotations. They are used to convey spirituality (without the religious component), ephemerality, intensely emotional and cerebral responses beyond the everyday physical plane.

1. Introduction

What is the meta-question, this paper addresses?

If the degree of change in sustainability required in the foreseeable future is so great that the concept of design itself is redefined, where do we start? The broader design community[5] has been aware for a considerable time that greater acceptance and commitment to sustainable products, patterns of behaviour and modes of thinking are needed to achieve the level and direction of change required for a sustainable future. (Fuad-Luke, 2006; Heiskanen & Pantzar, 1997; Manzini, 1992; Shove & Ward, 1997). In this paper I propose that a starting point for the required degree of change lies in re-valuing the role that a fundamentally more human-focused perspective has in the design (read sustainable design) task. This proposition goes far beyond the current trend of 'greenwashing' and further than the partial amelioration offered by popular user-centred and anthropologically focused studies. A revaluing of the human perspective is beginning to gain momentum with relatively recent interest in human-centred design (AIGA, 2006; Norman, 2004). This is a turn in the right direction however, the practical reality is that in order to understand humans better especially for design purposes, we need a lot more methods and knowledge about ways of going about it.

In this paper I am proposing two new ways to help to begin this process of valuing the human dimension as a starting point (not endpoint) for designing. I contend that by understanding the complexity of an everyday experience and the strongest metaphysical (spiritual) layers within it, that designers and decision makers will understand the bonds that create the strongest attachments to the experience. This is the first step in achieving the dual holy grails of sustainable design. To provide more satisfying (sustaining) customer experiences whilst delivering this in a more sustainable manner.

How is this question answered in this paper?

Quite enough has been written that defines our current situation in terms of sustainability and designs role in leading us to this point (Fuad-Luke, 2006). And socio-technical discourse abounds with reasoning for why we are in the position that we are in (Wiebe E Bijker & Hughes, 1990; Haraway, 1991; Latour, 1994; Michael, 2000). It appears that we know what we have to do. We know we have to do it now. We are just not sure of how to go about it. The tools presented in this paper can help in real and tangible ways to achieve these goals. This paper offers two new methods[6] that enable designers (and decision makers) to understand deeper layers of everyday human experience. The first will help designers to more clearly structure and see what is there to be seen within a given experience or event (the data) . The second probes more deeply into the hidden layers of meaning contained within the available 'data'; teasing out the deepest, intrinsically motivating forces within the experience. These are the, beyond-the-form-and-function, 'metaphysical' forces, which if understood and applied back into the sustainable design process (assuming the materials and energy intensity questions have been addressed), help to create stronger bonds and commitment to the kind of change intended in the design (either product, service or product-service system).

---

[5] Alludes to a broad range of sustainability and 'design' related perspectives presented by engineers, architects, sociologists, anthropologists; disciplines from both sides of the natural / human sciences spectrum. (McDonough & Braungart, 2002; Sofoulis, 2002; Stegall, 2006).

. [6] These methods while they are specific, structured and have defined outcomes are not limited to a *techne* interpretation. They should be taken as a methodological representation of a human centred philosophy suggesting ways to explore how we (as designers) can better understand what is important to all of us as human beings and so design more humanly-satisfying things (read sustainable attachment and ownership). Approaching these methods in this way opens them up to adaptation, extension and exploration – strangely, all laudable human traits.

2. In what ways can sustainable design begin to change?

Earlier I proposed that a starting point for change could be based on re-valuing the role of more human perspectives in design. Understanding a human-oriented perspective requires an understanding of what humans find meaningful and of course this raises the obvious question 'what do we mean by meaning?' This seemingly circular logic goes beyond the linguistic argument[7] so that we can address what is meaningful in the metaphysical sense. I contend that this human metaphysics is a missing ingredient in the intentionality presented in all things designed (Margolin, 2000). The meta-physicality of human experiences involving designed products/services is not the same thing as the cyborgised, socio-technically normalised relationship outcomes that are essentially unintentional by-products of design (Buchanan, 1989; Shove, 2007). Axiomatic suggestions that 'material objects configure their users' coupled with socio-technical theory (Wiebe. E. Bijker, Hughes, & Pinch, 1987) suggesting that this is a two-way relationship confuses the efficacy of current design practices wherein little is contributed from the user side other than from research after the fact. This imbalance might be addressed by designing objects that incorporate at a foundational level the metaphysical qualities valued by real-life, everyday, ordinary people.

The environmental imperative to design more for the metaphysical 'reality' of experience than the physical unreality of consumerism is well understood. (Heiskanen & Pantzar, 1997; Manzini, 2003; Shove, 2007). And the superficial and transitory un-gratification of unsustainable consumerism is at least partially due to a lack of metaphysical fulfillment (Hamilton, 2003, 2005).

I propose that this condition comes from a lack of understanding about and an undervaluing of the metaphysical aspects of experience. Until recently these aspects of experience have largely been inaccessible for lack of knowledge about how to study them and subsequently under-pursued in user-research (Green, 2001). For this reason it is important for designers to know how to understand the metaphysical so as to intentionally design stronger more satisfying, meaningful and lasting relationships (bonds) between customers and their purchases.

Stegall (2006) in recognising a lack of this type of understanding, proposes a set of four, ecologically oriented design philosophies which support 'intentional design'. The first two philosophies are very familiar and relate to Resources (materials and energy intensity) along with Form-and-Function (a 'post industrial' design approach). Further to these he advocates two design philosophies referred to as philosophies of 'purpose' and 'spirit'. One of *Purpose* promoting "a set of values, attitudes, and characteristics that designers wish to promote" and one of *Spirit* supporting a "feeling of kinship – spiritual [metaphysical] connection and sense of stewardship with the natural world" (Stegall, 2006,59-60). In order to successful employ these philosophies in sustainable designing, a designer must develop what Orr refers to as 'ecological literacy'. The methods described and presented in the next section of this paper satisfy Orr's call for methods that help to achieve this form of literacy; but they also take us beyond Orr's observational limitations, to a metaphysical level of understanding of the people we wish to design for.

> *"Overcoming this obstacle requires designers who can enter a local environment, observe and understand how its people relate to each other and to the natural world, and develop methods for improving those interactions... the fundamental skill of designing for sustainability is ecological literacy" (Stegall, 2006,63)*

[7] Refers to linguistic explorations of meaning such as I.A. Richards *The meaning of meaning* - (Griffen, 1997)

3. Tools for understanding the metaphysical aspects of events

The tools described in this section (the *ToE* and *SEEing* methods) relate to understandings of the kind described by Orr (1992) when referring to ecological literacy. They are intended for a designer to become immersed in the experience to be understood and with that perspective to analyse the data collected in such a way as to develop deep personal understandings of the metaphysical essence of the experience.

3.1 Taxonomy of Experience (ToE) : A model of experience

This hierarchical model is useful to researchers and decision makers as a general method or tool for guiding the collection, processing and categorisation of field data about an everyday experience. During trials, participants using this model, referred to the process as 'doing a ToE'

The *ToE* is a tool or model for understanding the ordinary, inauthentic[8], un-real, unconscious aspects of an everyday event. This method is useful for building a picture of the everyday and its fundamental 'everyday-ness' that by contrast allows us to recognise when something special (change) occurs. It is a method for structuring and bringing to consciousness those aspects of the everyday which are easily and commonly overlooked. In the two pronged approach to understanding the metaphysical aspects of an experience presented in this paper, the purpose of the *ToE* phase is to establish a clear understanding of the foundations on which any change might be based.

Both of these methods have been developed out of primary field research and analysis which explored phenomenological and hermeneutical methodologies to gather material and explore ways in which everyday lived experience might be probed for the deeper layers of meaning it contained (Coxon, 2007)

Findings from the initial data analysis in this research were compared to existing knowledge streams on the structure of experience from design theory as well as with disciplines outside design in psychology, neuro-physiology, sociology and marketing. These comparisons suggested that information gathered about an experience might be usefully explored if structured in the form of a taxonomy. The structure or 'Taxonomy of Experience' (*ToE*) that we have used with considerable success in university trials is shown below in its simplest (skeletal) form.

Insert figure 1 here

[8] Refers to Heideggers term for the everyday aspects of life experience "Modal undifferentiatedness, or indifference, between authenticity and inauthenticity is what Heidegger calls Dasein's 'average everydayness" (Carmen, 2003,2; Heidegger, 1962)

1. THE GUT - Somatic experience
    - Sensorial
    - Sight
    - Touch
    - Smell
    - Taste
    - Sound
    - Ergonomic
    - Aesthetic
2. THE HEART - Affective experience
    - Positively valenced affect 1 - 7
    - Negatively valenced affect 7 - 1
3. THE HEAD - Cognitive experience
    - Connation – reflective experience
    - Cognition – reflexive experience
4. OUT THERE - Contextual factors
    - Environmental factors
    - Regulatory factors
    - Social factors
    - Existential factors
    - Corporate, Economic, Political
    - Other – as determined by the situation

I will briefly explain how each of these sections in intended to be understood.

Somatic experience

Somatic aspects of an experience stimulate or directly impact on the physical body including sensorial stimuli, comfort (ergonomics) and appearance (aesthetics). These are what Donald Norman (2004) refers to as the 'visceral' level but whose descriptors often contain more complexity than simple physical references are able to convey; such as richness of colour, tactile appeal, comforting sounds.

Affective experience

In the *ToE*, Affect is treated as principally focusing on 'emotions' that is the mostly short duration, intense affective responses to experiential situations. Affective experience is sub-themed in terms of its positive and negative valance[9].

Cognitive experience

The cognitive section of the *ToE*, refers to the way in which a person 'thinks' about both internal (reflexive) and external (reflective) aspects of experiences. Cognition or 'Internal' aspects describe the way in which a person thinks about themselves (self talk), for example, "I am an industrial designer ...where am I going with this paragraph" Externalised cognitive thinking (Conation), relates to the way in which a person thinks about things that lie outside themselves, that may or may not lead to action or behavior, for example, "I must remember to email Larry the specs for that…what is that clown doing in that car? … that shirt should go nicely with that tie…"

[9] Valence - psychological value of the experience denoted in a positive Vs negative way (Reber, 1985).

The context of the experience

The somatic, affective and cognitive meta-themes described above, are all integrally situated with a contextual space (See Figure 1 above). This part of the *ToE* describes aspects of the context (the everyday life-world) in which the experiential event takes place, but only aspects that are considered immediately relevant to the people directly experiencing the event.

Summarising the Taxonomy of Experience (ToE)

The Taxonomy described above constitutes a framework for gathering and compiling data about an event in such a way that it provides the researcher with a preliminary picture of the experience through familiarity with its parts (constituted by small fragments of the experience which are essentially individual cause and effect stimuli). Through the experience of compiling and formatting data into the *ToE*, the designer (researcher) gains an initial understanding of the experience as a whole (*ToE*). This stage is similar to the data coding / analysis methods employed in ethnography but utilises the *ToE* as a flexible nodal structure instead of using predefined or *in vivo* methods (Creswell, 2007). Setting up a *ToE* of an event is a valuable establishing process in itself, which generates in the researcher a useful, be it broad grasp of the experience. This is the stage at which most ethnographic and phenomenological analysis tends to conclude. The *SEEing* method that follows, describes an entirely new approach to deeper analysis of the data contained in the *ToE*. This method takes phenomenological and ethnographic data analysis to a deeper level where the metaphysical side of an individual or group experience can be understood.

3.2 SEEing: Exploring the metaphysical essences of an experience

SEEing is a qualitative data analysis method which employs nine sequential steps through which information about an experience being studied, is gathered and reduced in a process that allows a researcher to *see* the metaphysical or spiritual 'essence' of the experience. The *SEEing* processes distil and make visible the deepest layers of meaning that uniquely define[10] the experience for what it is. The goal of the *SEEing* method is therefore to understand the metaphysical, the differential, the primary change agent, the authentic and the real.

What it is about the holiday experience (aka. change) that brings about such a positive reaction to the perceived differential to the everyday?

The moments when we are most in touch with ourselves and events in our lives are the moments when we become truly aware of being alive (Heidegger, 1962). It is this kind of alive-ness, this awareness of our being that we are confronted with in moments when we are confronted with change. On my holiday, change takes the shape of something requiring me to cope with something new, a situation that is unfamiliar or that forces me to reconsider my ability to adapt. It is in a way, mildly threatening, but it is precisely this difference to the normalness of the everyday that tells me that I am not at home, I am on holiday. Indeed, I would argue that it is the degree of differentiated-ness that I experience that defines the attachment I develop or the value I ascribe to the experience. Thus my visit to the local beach does not hold the same metaphysical value as my holiday in the Bahamas. This type of argument drives the kind of thinking that follows.

…and back to the ToE

[10] The use of the term 'define' is not to suggest any form of formula, codification, categorisation or fixed notion of the essences derived. They are and always remain fluid and metaphorically indicative of the understanding that these metaphysical essences generate in the designer-researcher

In the first (*ToE*) phase described above, the researcher establishes a basis for understanding an everyday experience (using the *ToE*) and develops a deep familiarity with the complexity of its everyday-ness through the gathering and coding of data into the *ToE*. The next, *SEEing* phase, begins to explore within the experience for the extra-ordinary, the aspects that are differentiated from the everyday base level of the experience, the ones that begin to emerge from the deeper metaphysical layers. This is the process which leads to understanding the aspects of the event which create the richest, most positive and lasting relationships to it.

The *SEEing* process like most qualitative analysis methods can not be done in five minutes. It takes considerable time to sit with the data, shifting and sifting in an iterative conversational process where data is interrogated and interpreted repeatedly. For space reasons it is presented here not as a detailed how-to, but as a summary of each of the steps in a quite simplified form so that a general sense of the process can be gained.

Step 1: The researcher learns the language of the experience through immersion in the experience. This step sets up the knowledge base which the researcher will later rely on to interrogate and interpret experiential data.

Step 2: The data captured about the experience is turned into rich text. Detailed experiential descriptions of the field data (interviews, observations, context studies) are written and used as a normalised data source.

Step 3: The text is thematically separated into its multiple general meanings by interpreting alternative (causes or effect) meanings out of the text using the researchers understanding of the language of the experience. It is placed (stored) in the *ToE* framework at this stage.

Step 4: Multiple hidden meanings are explicated out of these cause and effect meanings. Each fragment of data is further interrogated for the multiple alternate meanings that they contain. These become ‘see-able’ using the researchers’ earlier auto-ethnographic experience as an experiencer.

Step 5: The most essential (experience defining) meanings are filtered off. Meaning data that is essential or that ‘make the experience what it is’ are separated out from that which is ancillary or superfluous to the experience.

Step 6: The *extra-ordinary* metaphysical meanings within the experience are filtered off. Meanings describing basic, everyday, form and functional aspects of the experience are filtered out leaving the spiritual, metaphysical meanings.

Step 7: The researcher ranks the most intense meanings. The metaphysical meanings are not all as intense as each other. A ranking is applied so as to determine which are most important in defining the experience.

Step 8: Metaphysical meanings are grouped into themes and ranked by intensity. The most intense of the metaphysical meanings are interrogated and grouped into like themes. This clusters the more powerful metaphysics together into 4-5 key themes.

Step 9: The most intense metaphysical themes are re-expanded by describing them in terms of the essential meanings from which they came. These themes were derived out of the most essential elements of the experience and it is helpful for further communication[11] of the metaphysical essence of the experience to be able to describe them in some detail.

Student experiences and outcomes from using the two tools …so far

[11] Methods for communicating the metaphysical essence of experience have included the use of abstract manifestations, personas, storyboards and scenarios. Future research might explore the communication of this essence with virtual persona avatars acting out design interactions in 2nd life scenarios.

University trials with students in Australia and Germany have provided interesting and encouraging results using this type of development of everyday and metaphysical meaning. The Australian students' overall reaction to the trial was positive with a significant number experiencing very positive outcomes. The project succeeded in providing an experiential learning vehicle from which most gained a rewarding learning experience. The *ToE - SEEing* methods succeeded in being teachable, testable and provided a deeper understanding of the experience in most instances where due diligence was applied. The German trials of the *ToE* and *SEEing* design research methods were also very successful. Students achieved varying degrees of public recognition for their exhibited thinking, but overall there was agreement from academic staff and the greater student body who attended the final exhibition that the results were positive, unexpected and rich. While many students laboured under the existing interface and the volume of data-processing required, there was universal agreement that the process yielded surprising information from which to base their designs.

4 Conclusion

How do these methods help designers to make the desired change?

The methods briefly described above help designers to deeply understand the metaphysical layers within an experience so as to better match with human expectations of what is being designed to fulfill these expectations. They will help designers to design from more human-centred, (metaphysical) perspectives; enabling them to give primacy to these perspectives in the artifacts they are designing. It can be seen in my holiday analogy that metaphysical layers of meaning create stronger more lasting relationships (bonds) to exceptional as well as everyday experiences. Metaphysical bonds are stronger than the physical bonds offered in designs based on form, function and fashion. These types of physical (read superficial) bonds are easily broken by the 'next big thing' (the fundamental flaw in consumerism), while metaphysical bonds are longer lasting, more satisfying and culturally sustainable.

…and this can be useful to sustainability how?

It is largely our bond with the metaphysical that underwrites our attachment to things, events and even to change itself. It is the nature and strength of this bond that will help determine the direction and strength of our commitment to any changes proposed. If design is to provide the seeds for sustainable change in terms of new products, services, service systems or lifestyle changes then it must understand the metaphysical bonding agents that people will respond to and also the new bonds these new socio-technical systems are likely create within their recipients. Designers need to design experiences (incorporating the everyday and the metaphysical) which consumers want to own and value. This requires a deeper level of understanding of the conditions underpinning the change being induced and whether they are likely to create an effective and lasting bond with their recipients.

Where to from here – how can these tools be improved and more widely applied?

This paper is a first step in the process of dissemination and use of these methods. With continued use I expect they will be refined and evolve into more useful tools for advancing sustainable design. More interesting and productive ways will be found to reify the metaphysical. New media such as virtual avatars and 2nd world scenarios might be employed in future efforts to give voice to the metaphysical. The designing of products and services containing the full richness of metaphysical meaning have yet to be fully explored.

With all of these possible developments, the core purpose of these methods will remain the same – to aid the process of valuing, understanding and applying human metaphysical values to strengthen the bond between designed objects and services in the lives of people. Of course these methods are immediately useful in sustainable design activities such as design for longevity, social equity, lifestyle change, shared use and universal design however, the

understanding generated in designers using these methods is also useful in design decisions affecting many stages of the product/service lifecycle.

There is now a need for industry exemplars to show the way. Commercial industrial trials are required to showcase the benefits to sustainable innovation that these kinds of methods bring to a diversity of industries so that a general platform for change can be established. Without bridging the gap between design pedagogy and design practice these types of methods remain impotent. This will be a difficult process in a manufacturing world committed to sales volume and an economic model based on growth, but industrial early adopters and trend leaders, must be found and fostered. The concept of using metaphysical values to create stronger bonds and longer lasting relationships will not engage the imaginations or esoteric values of shareholders intent on higher economic return. However with the burgeoning shift away from monetary based fiscal accounting to triple bottom line reporting and carbon-based economic modeling, these values will very soon have a important role to play in changing the change.

It is time to discover the meaningfulness of man rather than searching for meaning in things.

If we must have things, then let them mean what is meaningful to man and not the meaningless shallowness evoked in him by things, without his knowing. Anon

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Macrocomponents

An alternative proposal for the production of home integrated systems

Brunella Cozzo[1]

Abstract

Due to the current crisis of the macroeconomic scenario, the production type approval of competing firms, but first of all the new environmental urgent needs, is rising the need of reconsider new production scenarios.

The methodological approach of the Design by components (Luigi Bistagnino, 2008), appears as one of the possible open paths to successfully face the on-going change; thanks to this approach we can redesign new typology of products/production chains as well as the system they are introduced in.

In order to improve the performance of objects we need to consider each of them as a system-object, in other words a system where components are in tight and complex relation.

[1] Politecnico di Torino (ITALY) – 1 Facoltà di Architettura, DIPRADI department (Dipartimento di Progettazione Architettonica e Disegno Industriale), Lecturer and Fellowship Researcher, brunella.cozzo@polito.it

1. Actual situation

Recent European researches revealed that, during the last 15 years, the industrial production in the field of home appliances, has been dedicating special attention and investments to the reduction of consumption, conscious use of materials and performance improvement.

Data presented by the organization *CECED Italia*[2] in Strasbourg confirms an improvement in the energetic efficiency of home appliances. Representing 60-70% of national energy consumption, the improved efficiency of these appliances has contributed to a reduction of 10% in total consumption.

Unfortunately, these initiatives allowed a limited improvement of the environmental fallout: in fact, the continuous technological evolutions cannot ensure anymore an effective reduction in the consumption and in the emissions that commodities produce. Although nowadays we think we are quite advanced, we actually handle objects that could be greatly improved as far as concept and use are concerned, and above all they are often foreign and even hostile to the environment around them. Advertising tries to convince potential users with emotions, diverting them from a reality which is in actual fact full of limitations, improper uses or even deliberately misleading descriptions. As a result we can have a use/non-use, a disappointment that leads to the abandonment of the appliance which will remain undestroyed and maybe indestructible, foreign to the natural environment[3].

Due to the current crisis of the macroeconomic scenario, the production type approval of competing firms, but first of all the new environmental urgent needs, is rising the need of reconsider new production scenarios.

During a recent meeting titled *"Cambiare le regole – il settore degli elettrodomestici: un sistema integrato"* (*"Changing the rules – the household electric appliances sector: an integrated system"*), organized in collaboration with *Politecnico di Torino*, Antonio Guerrini, general manager of *CECED Italia*, underlined the need for changes in the area of white goods; research is these companies' driving force, and for this reason it needs to be continually nourished by collaboration and the exchange of ideas. In Mr. Antonio Guerrini's speech he underlined the necessity of prioritising environmental issues when considering design/production parameters, and that these issues "should not be considered a sword of Damocles, but rather an opportunity to be exploited" in order to comply with the final user's needs and with new legislation, and in order to be more competitive in the market.

2. Possible solution: an interrelated components system

The methodological approach of the **Design by Components**[4] (Luigi Bistagnino, 2008), **appears as one of the possible open paths to successfully face the on-going change**; thanks to this approach, that critically analyses all the parts of a current industrial product, we can **redesign new typology of products/production chains** as well as the **system** they are introduced in.

---

[2] *CECED Italia*: association representing the household appliance industry in Italy. It is part of the European network *CECED* (Conseil Européen de la Construction d'appareils Domestiques, namely the European Committee of Domestic Equipment Manufacturers). *CECED Italia* supports the development of the sector by activating the more effective measures in order to strengthen the positioning of Italy – which is one of the world-wide leaders in this line of business – within the international market. The association actively promotes the dialogue among all the Italian interlocutors as well as, together with *CECED*, between these latter and the national manufacturers and the rest of the European/international Institutions.

[3] Abstract from Flaviano Celaschi's speech, at the meeting titled *"Changing the rules"*, organized by the *Politecnico di Torino* in collaboration with *CECED Italia*.

[4] For more details about the "Design by Components" methodology, please see the following papers:
Virano, Andrea. *DESIGN BY COMPONENTS. An operative methodological tool for the ecocompatible industrial design.*
Marino, Gian Paolo. THE SECTOR OF HOUSEHOLD ELECTRICAL APPLIANCES*. An integrated system.*

This approach that also includes the realization of charming containers where components are often located by force, was abandoned in favour of the relations existing between the internal and external elements of the industrial object.

The designer, therefore, is no longer creating a mass-produced object, and innovation does not restrict itself to act in watertight compartments, where problems are faced individually. In order **to improve the performance of objects we need to consider each of them as a system-object**, in other words a system where components are in tight and complex relation. Each system-object is, in turn, considered to be an integral element (that is a component again) of a more complex system.

The final system-object is the addition of every constituent subsystem and it may be regarded as complete (i.e. no longer an element that can be integrated and expanded) when all existing interrelationships will accomplish the performances they have been planned for.

The designer is central to this **new vision** of **design** which cannot focus solely on each single appliance, but which **has to look at the whole home environment in different terms**, using a very **systemic approach**[5]. A home which is completely redesigned according to the standards of the new millennium, where ergonomics, functionality, energy saving and ecocompatibility are all elements of a puzzle to be put together. The kitchen is the environment which requires the greatest amount of rethinking, because it is the most technological and complicated environment in the house, where a huge range of organic substances are treated every day, using fire, air and water to make them fit for consumption and for our physiology. Food culture is universally known as an Italian asset, as are the methods and the means of producing our national delicacies. The refinement of both Italian cuisine and Italian kitchens is very much appreciated abroad, and this is a solid foundation on which to build an enjoyable project which can belong to all of us. Another important factor which is an essential part of our everyday lives is that of cleanliness: personal hygiene, but also the cleanliness of our clothes and of our living environment, to name but a few. Essentially what we need to do is to exploit and promote the attractions of the Italian lifestyle, an age-old culture which is well-known and much imitated. We need to design technological appliances based around this lifestyle and on making our existence more comfortable and natural.

The path proposed by **Design by Components in a systemic vision** implies a design where the **external shape** of the object **is determined by the internal placement of its own components**. This type of design starts from the analysis of disassembled objects belonging to the same semantic category (so as to be able to understand all their constituent parts: materials and components), considering the relationships and connections between components, production technologies and physical-mechanical laws that characterize the product. It is important to consider the approach users could have to the analysed product, taking into account the different levels of accessibility the user, maintenance technician and manufacturer will have.

Each component must be considered as a final product with its own independent life cycle, and must be considered in relation to the other components.

It is subsequently analysed according to a functional scheme, where its composition is revealed by aid of follow-up abstractions, firstly in accordance with an operating scheme, and afterwards with an essential one, allowing for the isolation of the necessary and sufficient functional groups.

Acting on the basis of this criterion, it is possible to comprehend the complexity of the relationships which exist between functional groups and the system as a whole, and to recognize the various different types of problems which need solving.

[5] For more details about the “Systemic Design” vision, please see the following paper: Bistagnino, Luigi. *SYSTEMS DESIGN APPROACH*.

On the basis of the complexity of these relationships we can affirm that Design by Components intends to focus primarily on the system of which it is a part, and to which it belongs.

Design by Components is, to all intents and purposes, the up and downstream conception/planning existing behind and throughout a more complex process that looks at the finished product as the concrete exemplification of ideas, thoughts and the more diverse strategies, all entangled and interrelated into one with the others, in strict connection with the life cycle of the designed item.

Last but not least, is the concept of shared responsibility, also promoted by the 2002/96/EC *WEEE-Waste Electrical and Electronic Equipment* directive. The protagonists who contribute to the ideation, design and manufacture are designers, industrialists, law-makers, economists and final users. They will be asked to collaborate responsibly.

New products created thanks to this mental path represent the execution of relations and functions of the appliances.

Being aware that all household electrical appliances are part of an integrated system (with the territory, the society, the environment, the residential units, …) and not only of the individual production chain, will entail a new product design conception. From this perspective, research is always present inside of the home-system with the following tasks: in the analysis of the most frequently carried out activities, as well as those with the highest impact and of the toughest nature in the domestic field. The three categories which emerged were: washing, food preparation and food conservation. All these categories could be put together to create an integrated functional system.

For instance:

- the fridge will need to be placed within a “food nourishing and preserving system”;
- the washing machine will not only have to be conceived exclusively to wash clothes, but designed as part of the “washing system”;
- the dishwasher will need to be integrated in the “food cooking and eating system”.

Based on the principles thus far expressed, analysis of the washing machine, dishwasher and sink category begins with the disassembly of the products in order to understand what hides under the “external skin”; this activity shows how the different components work and what their role is in the cycles (water and power).

The next step was to define the general scheme, which is composed of indispensable components and the fundamental scheme, which is composed of ineliminable components (Fig 1).

Both schemes consider the treated object as a combination of components and functions of varying importance, an approach which breaks away from the classic aesthetic profile our culture and conditioning consider as fundamental to design development, and which puts the functional role in second place.

Thanks to these new frameworks, the design is free to express itself without formal and cultural constraints, so that the connections between the different components and their external shape can finally be seen as not as a purely aesthetic issue but as something justified by functional, ergonomic and ecocompatible issues.

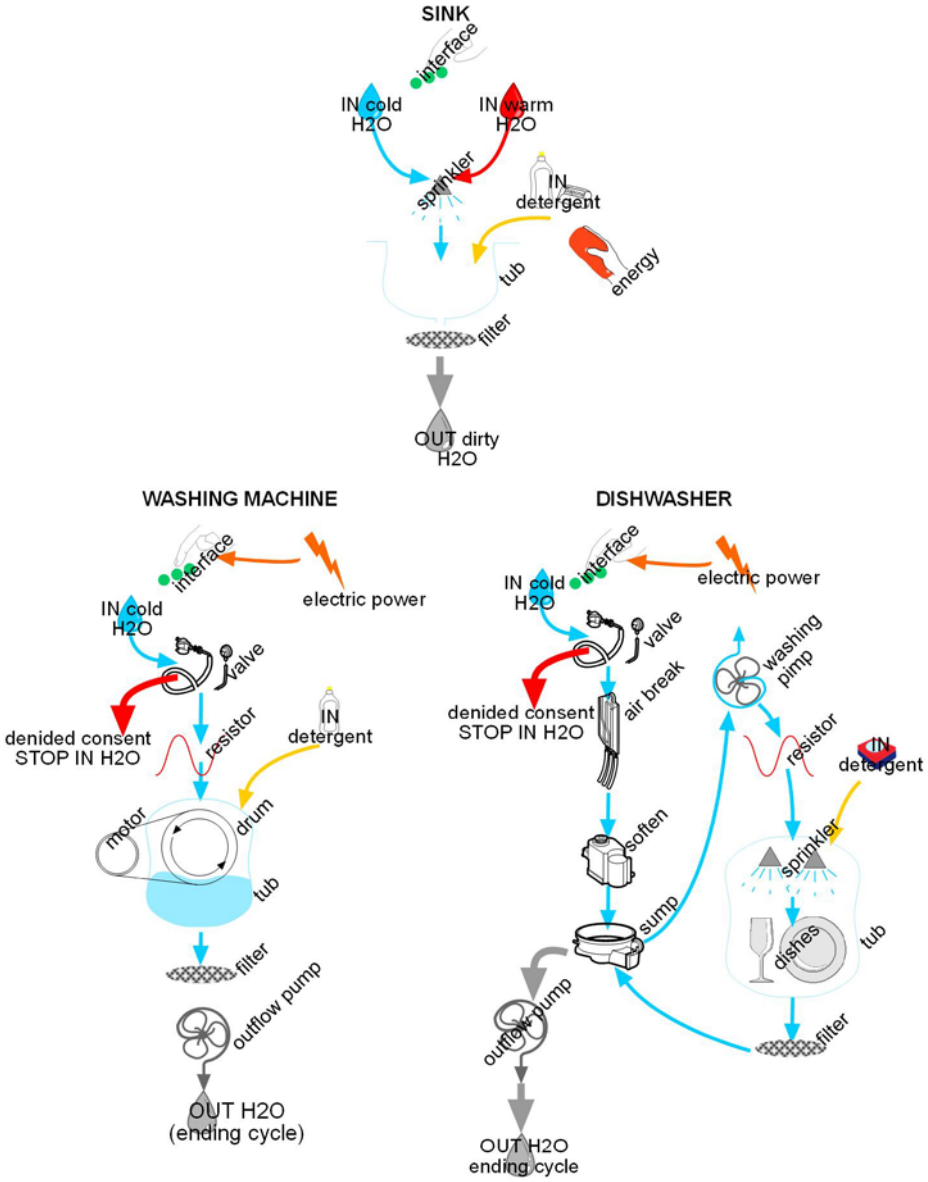

Fig. 1: General schemes underline fundamental components of the three systems, showing the relation between elements, energy and matter flows

In fact, the components do not function individually, they work together to carry out the principal action. Consequently, we can talk about groups of components carrying out the principal action.

It can therefore be deduced that the groups of key components which make washing machines and dishwashers work are as follows:

- control
- input/ adjustment
- washing/ distribution
- output

Having **defined the principal actions** carried out by a machine and the components that effect these actions both from a technical and perceptual point of view, **we have identified four groups of components**: a control group, an input group, a washing group and finally an output group.

Evidently, these actions are perceived by the user through the interface, the dispenser and the output group, whereas the discharge pump remains a secondary element from a perceptual point of view. Input and output are no longer properties of each component, but rather become those which act on the macrocomponents, where they will undergo the most important transformations.

This interpretation of machine function is what we have called *“logic of macrocomponents”*.

Furthermore, **the identification of the main functional categories makes it possible to underline the current redundancy in the production of components** capable of carrying out similar operations.

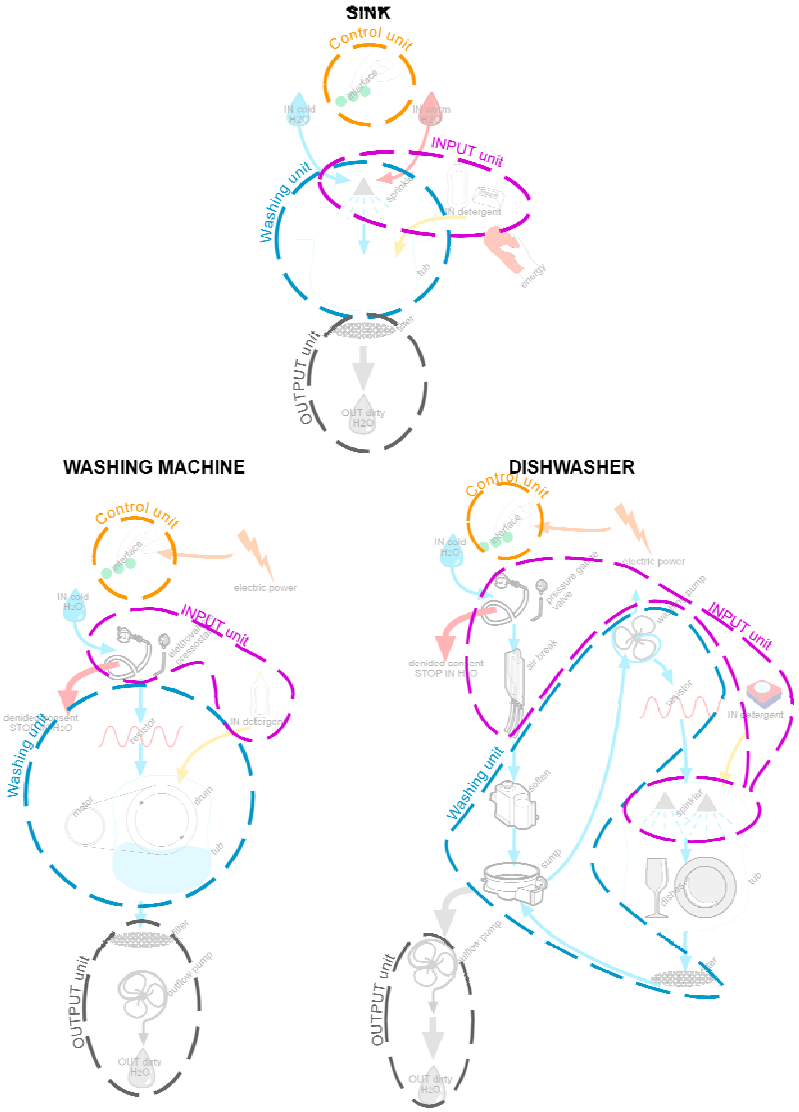

Fig. 2: Comparing the three systems can be noticed the common elements, underling the redundancy of the components of the washing system

In the specific case of white goods, it is clear that different elements are present which perform the same function. Based on the results of the analysis undertaken, it was found that it was possible to group together different elements like sprinkler, hold-up tank, filter and discharge; at the same time, the analysis also highlighted the main actions of the systems considered. The definition of the main actions carried out by the machine and the identification of the components needed in order to realize them, underlined the possibility of grouping them into families of "macrocomponents"[6], which are present both in the two home appliances and in the sink.

Reinterpreting objects according to a macrocomponent logic, it is possible to create families of products diversified on the base of the user's needs and according to household transformations in the last years. A machine designed with this vision, in fact, opens the way for a totally innovative vision of the concept of "washing machine-product". This can lead to the **creation of component families performing the same functions but with different features**, and of a machine that is designed not so much **as a unitary functional system**, **but as a product defined by individual specialized parts**. Operating in this way, home appliances won't be only simple products, standardized inside of the plant, but also objects managed during their use phase (maintenance included), in close collaboration with the buyer that will buy the necessary components in order to create its own functional system.

Taking into consideration this new logic, the research leaded to the creation of an integrable based system with some macrocomponents that can, eventually, perform the different functions of dish washing, laundry and grooming.

This kind of approach and new functional system, further than **generate operative advantages**, brings relevant environmental positive effects: **components reduction** (only the needed ones are produced, shared by different appliances), **flexibility of the structure** (by changing one of the macrocomponents you can change the general functions of the system) and **technological updating** easiness with the consequent **life extension of the product** (only one of the macrocomponents become old, not the entire product).

3. Generated advantages

This "new logic" presents some design and production advantages not only in relation to the object, but also regarding the whole production, distribution and usage plate.

The fact of designing by modules enables the production of a virtually infinite number of products of the same kind, following or creating new aesthetic expressions or offering different performance solutions with reduced costs compared with the current situation.

The transformation of the production plate could help simplify the design process, as it would not be limited to the definition of a complete individual product, but only to parts of it, and at the same time production could be outsourced to external specialist organizations, thus enabling the sharing of costs and risks.

In this case, the brand owner of the machine would benefit from the new situation, because they could share the cost of the initial investment, allowing them to focus more on marketing and service operations.

One major advantage of this kind of set-up would be the decentralisation of the manufacturing structure and the consequent possibility of exploiting the valuable know-how of

[6] Macrocomponent means a mix of relationships and components together carrying out a common function. For example, in the washing system of the dishwasher is useful to assemble resistance and washing pump in one single functional block.

local businesses such as their superior knowledge of the market and of the most suitable legislation to be applied in order to guarantee greater success of new products (flexible structure, sharing of production responsibility).

The almost global loss of the production network from the parent company and the related displacement/sharing of its “engineering/technological knowledge”, would permit the firm to focus on strengthening its brand image and brand awareness in the market. The firm would therefore gradually be transformed into a service provider in the laundry sector, in conjunction with its own products.

The **manufacturer**, lacking production lines and warehouses, could devote part of the investments, to researching, developing, innovating and running a new service which emphasizes the “macrocomponent logic”, sharing, once again, risks, liabilities and investments with the whole new system.

This “network system” operating with the local assistance centres, would provide the whole system with better efficiency.

The brand value will be enhanced and, at the same time, the macrocomponents will no longer remain anonymous but will increase in value because of having their own brand. This is perhaps the most important element of the new service, that it gives value and content to the different roles. Thus the district, the primary localization, will not be empty because the related economic value is an inseparable unit.

The maintenance staff would work in better conditions, both ergonomically and in terms of customer relationships, by being enabled to fix the machine without having to move it from its working site.

If the machine broke down it could be easily and quickly repaired by using a *courtesy module*. If there was only a minor fault the maintenance technician could carry out the repair “in situ” as is currently already the case, but the job would be much easier to carry out with the macrocomponent “in his hands”. In the case of a serious fault which necessitated a replacement part, the technician could supply the user with the substitute module and then repair or regenerate that piece back at his own shop. Finally, if there was a fault with a very expensive component it would no longer be necessary to give up the whole machine but only that macrocomponent.

Thus the macrocomponent might be dealt with all the while, in two different ways:

- either by replacing it in block,
- or by fixing it. Should the maintenance man be unable to repair the macrocomponent, the whole machine would not be dumped, only the broken part.

Technical assistance, which is nowadays demeaned because of our buy and throw away culture, assumes a renewed dimension. We can also refer to it the functional upgrading with a close relationship with the final customer.

Due to increased differentiation between product ranges, retail outlets could satisfy the requirements of a much larger group of users, managing orders more easily and generating an after-market logic, and at the same time increasing sales opportunities, thereby increasing profits. Transport from the retail outlet to the installation location would be easier and, in the case of a

fault, it would not be necessary to remove the whole machine from the premises in order to repair it.

The **end user** would profit in enjoying a great offer of products, both as far as performance and perceptive aspects. It would be easier to better fulfil and satisfy certain peculiar or particularly demanding users, than we can do at the moment.

In a sales system organized by macrocomponents, each user can go to a shop and choose the product he feels most suits his needs. This would produce a higher rate of differentiated seriality, created by the user's needs who would create his own equipment by combining different macrocomponents; but in order to make the right choice, above all he will require a greater amount of advice, for example from an energy manager[7], and assistance from the head company so as to satisfy his own customer expectations.

Crafts_Community_Design

The strategic role of design to promote local production systems

Claudia De Giorgi[1], Claudio Germak[2]

Abstract

Design can connect Crafts and Communities. Case studies from the Piedmont's region offer the opportunity to discuss roles, modalities and exportability of the model as a global/local action. Crafts, Community and Design are the three key-word to describe various design driven actions in relation to a community. Process design, in its strategic and productive forms is the medium.

Introduction

Critical are the relations between communities and actuality, with serial and standard production methods which are now breaking on through, while trying to organise their territories. We have to go beyond the aesthetics to address the current conditions of where we live and the possibilities to build, in a globalized age, a production economy that is worthy being called culture. In sum, the stakes are the possibility to get a connection between a community, its material culture and the working procedures this community makes use of, in order to make its own living.

Objectives

The Objectives are:

- definition of approach models to typical crafts that represent diverse material cultures
- definition of accepted protocols of initiatives in agreement with the community
- definition of strategies and sustainable processes to provide this sector with autonomy, far from institutions constant assistance.

Crafts

Manufatto: manually made or even manufactured? The question might seem meaningless today, given that any craftsman, whether dealing with technology or with art, makes use of advanced technologies and works on products that were created thanks to the contribution of technology and machineries, not just one but many of them, far from the factory where each worker had his/her own task and apparatus.

In his essay *Éloge de la main*,1934, Henry Focillon claims that the hand is a universal symbol of basic men's work, *"... it grabs, it can even create, we would say it is thinking"*.

It is the tenet on which the importance of modern crafts is based: adaptation and diversification, in contrast to the standardisation of serial production. Tools, later turned into machines, have always been used to ease labor. That was precisely the task of the original lathe for woodworking in Strona Valley at the beginning of 19th century.

Riccardo Dalisi writes that *"...the hand comes from the heart: each impulse of ours activates arms and hands. Our hand is between us and the sky, between the heart and the stars. With their own two hands, people have changed the world and Giordano Bruno used to say that without the hands there would have never been any civilization."*

Our contemporary society is keen on rediscovering values in manual production and in the creation of unique pieces and, as such, it cannot discard traditional objects even in a technological future.

Crafts, the "typical and artistic" objects which we are dealing with today and which are the main topic of this research, still play an essential role in society.

They are key in a process that aims at strengthening traditional and sentimental values thus fostering a sense of belonging as well. In so doing, they attest to the central role of community and material culture.

One difficulty is to define whether these processes depend on historical and/or productive contexts.

Traditional crafts typically oscillate between isolation and reaching out to communities: this is on account of the excessive power of industrial markets and leads the system to copy its models, as long as it can. It finds comfort, however, as the market proves, in that its range of quality, reliable and long-lasting products, is keyed into direct relationships, often trough a friendship relationship with the customer.

These relationships get consolidated from generation to generation; the customer expects full responsibility from the craftsman, from the design to the maintenance of the product, and, honoured by this privileged relationship, he or she will always call the craftsman "master".

Yet typical craftsmen often complain about that when the demand decreases, as it happens, this is due to the competitiveness of serial products, as the latter are supported by a distribution chain that craftsmen cannot replicate, and a level of technological updating that a crafts workshop is not fit for.

Hence we get to the ill state of crafts: the one in which craftsmen, “try to get things done” as it is commonly said, by imitating the products that apparently rule the market, thus losing their local and special production identity. This should be the starting point for policies in support of crafts, from where to propose effective strategies.

This analysis also invites to bring the figure of the craftsman into focus.

He is originally an author and an independent figure in every specific process, very susceptible, mistrustful of his own community and third parties’ advice. Yet he acts as a mediator between material culture and innovation for the whole community.

He is not ambiguous by any means, and the analysis of the crafts system proposed in the latest conference on this theme, conversely painted a portrait of craftsman with many different facets. This is obviously not unprecedented: these taxonomies date back to the early eighties, and Enzo Mari explored them amply with a book and exhibition entitled "*Dove è l'artigiano*"- Where the craftman is (1981). Andrea Branzi also followed this avenue of research, while Ugo di Pietra carried out a series of fieldwork experiments .

More in particular, some craftmen profiles can be delineated:

The artist-craftsman. More keen on hands-on experiences rather than scholarly fabrications, Ugo la Pietra, who worked as a craftsman for long, describes the *artist-craftsman* figure as a creative person with manual skills, who cannot accept any role in the indefinite crafts sector, rejected both by art and design systems. In other words: an isolated figure.

The typical craftsman. It is the central figure for this research project; work carried out locally and with elements found on the field; he/she commands techniques, processes and languages but he/she merely reproduces past objects, without a specific project and he/she sometimes re-arranges its traditional image. A figure that has been often exploited by the touristy system of folkloristic street markets, that could not make any distinction between the independency of its own work and the will to create a community, an association, a consortium.

The industrial craftsman. He/she contributes to create an industrial product with parts that make the artefact more prestigious; or, as for Twergi, a collection of crafts products from Cusio Valleys and distributed by Alessi, which is a total substitute for the industrial process, so that skilled craftsmen can work within the company itself and focus on a part of the production chain creating a serial, more than industrial, product.

The technical craftsman. At the beginning he/she is in charge of the production of special and complex parts of projects, based on someone else’s design. Then, he/she turns out to be a service provider (models and prototypes) for the industrial system, companies and designers as well. Now he/she is interested in a new dimension: the realization of highly technological products (as for lighting technology) using serial parts, sold on the market but that can be assembled according to a person’s necessities.

The luxury craftsman. He/She works in specific sectors (jewellery, fashion, old books, restoration of precious works) where the manufacturing skills must be proportioned to the value of the artefact. Considering this highly differentiated scenario, with the preservation of some interactions, the research project presents some examples of shared action which are different in their approach, for their processes, productive and economic contexts, results and time constrains.

These regional examples have one thing in common: they are the expression of an entire community and not of a single craftsman.

Community

It may seem odd to talk about community after suggesting that one of the most important characteristics of being a craftsman is being the author and maker of the whole process, from design to product. This problem is addressed differently by those, institutions and researchers for example, who do care about crafts. Actions like Piedmont's Regional Council establishment of a brand of "*Eccellenza Artigiana-that is* Best Crafts Production" has a twofold purpose:

- it is centered on craftsmen's satisfaction, by including him/her in the most popular system.
- It satisfies the public as well, as the label confirms the quality they expect to find in a product. This is not of minor importance, conversely it is a much needed desideratum.

On a different note, processes are different if they move from the quality brand outward so as to crate a community. The actions we are interested in are bottom-up movements, with the starting point in crafts, as our research proposes. Craftsmen who gather around to form associations, consortiums, communities do not so because of any pending difficulty, but, as a craftsman from Varaita Valley used to say on his first ever community meeting *"because of the need to invest for future purposes when one can do it, not just during difficult times "*. Are we to believe him? The answer is yes, and this philosophy is in harmony with the basic rule of entrepreneurial activity.

The reasons why a craftsman needs a discussion with communities remain constant.

First, in forging relationships, communities are outlets from physical and cultural isolation, something which naturally affect craftsmen. The second reason lays in the pride of belonging to a category and sharing a project. The Italian traditional tendency to form associations, "guilds" in other words, clashes with hierarchical frameworks, and too bureaucratic and structured entities, incapable to meet individual needs. Furthermore, if the local community level enables a way to check what the others are doing, we must not forget that a certain degree of competitiveness among craftsmen is one of the system's main rules, while the association offers visibility, advertisement and ultimately communal strategies. This is the spirit according to which the main Italian and Piedmontese communities were born, even if they were initially concerned with funds allocating problems.

Communities need to share their opinions about projects, which cannot be invented. This requires an initial support from public institutions, as these initiatives must receive aid. There will not be any cultural benefit if there is no social and economic progress. Is the system sharing this vision? And, if so, to what extent?

According to François Burkhardt, crafts production methods can be re-launched on the base of recovered local identities. The problem is to match universal patterns with local culture and make them attractive. A well-known datum is helpful: a centrally planned monolithic culture, based on uniformity (industrialization), is immediately followed by a culture based on differentiation and specifity (post-industrialization). By all accounts, the opportunities are at hand .

If the community is considered as a crafts team, this is a way to present possible alternatives to serial and mass production; this will however create various responses from the craftsmen, ranging from envy to admiration.

It can be suggested that the solution is mass productions.

The "typical" crafts production can count on its own clientele, one which buys expensive but high-quality and valuable artefacts. The problem is how to reach to a wider public. The team must be investing in the research on its own origins, on projects and technology. It has to develop ideas which originate from the protection of local culture and collective interests. Schools are key in this perspective.

Design

This research assess the strategic role of design to promote the local production systems.

In particular, it presents actions related to "typical" crafts in Piedmont, where some craftsmen's communities have carried over traditions, skills and material cultures from generation to generation, despite rare occasions for innovation, visibility and market.

According to this vision, the research is the first step to investigate, analyse and promote possibilities to "create a system" where crafts, community and design coalesce.

Design, that could be the new way to "bind" them together, is the fil rouge of a tale that passes through the promotion of traditions (proper languages for local material), skills (product quality) and actions regarding the production chain.

Design plays different roles time after time: the most common is the "mediator" between the request for design by the craftsmen's community and crafts itself, when products lack a sort of identity or must be recovered (this is the case of Mondovì, Varaita Valley, Lanzo Valleys).

A more unusual role, however, is that of the "promoter" of researches generating new crafts communities or strengthening them (Turin-Marrakech, Cambiano Ecomuseum of clay, Cusio Valleys with Alessi-Twergi); and finally it is also the final target, in the close future, for local crafts productions that, once joined up in a community, can advance to the creation of a more robust identity or exportable (Castellamonte, Valenza) identity.

Some of the collaborations between craftsmen's communities and designers have created exportable models for the re-organization of processes and for the re-designing of products; some other analyse the interaction between cultures and movements towards sustainability (artefacts and food, artefacts and cultural goods ...); some others introduce environmentally-friendly solutions for the working process.

Some products are interesting because they originate from open projects, considered as "guide-lines" that the communities are free to interpret in synchrony with some shared rules: sustainable working protocols and market environments where the consumer is part of the cultural action.

Therefore the home district is the first customer for the typical crafts product: bars and restaurants, the offices of the institutional communities, shops of other typical products, like food, can be equipped with new products, thus becoming a showcase.

In the following part, a selection of case-studies in Piemonte region.

Valle Varaita

Community_DesignServiceCenter_Crafts

Craftsmen, associated to form a Community, and the local Authority make a request for Design and company assistance to re-launch local craftsmanship. The action consists of the creation of a Service Center for local and regional craftsmen.

Over 60 companies are now working with wood in Varaita Valley, mainly to manufacture furniture, doors and windows but also toys, coffins and music instruments (the famous harps by Salvi company), a supply chain system of companies cutting down trees, sawing, painting, carving, lacquering, restoring operations; they even transport and assemble furniture. An exceptional case in Piedmont and nominated Wood District in 2002 by the Regional Council of Piedmont, thanks also to the presence of a paper processing company (Cartiere Burgo) in Verzuolo.

The Valley is poised to exploit its traditional manufacturing processes again, in order to get a renovated identity for traditional wood crafts, by making use of more sustainable and technologically and culturally updated working procedures. In 1999, the local *Comunità Montana* (an association of the local alpine municipalities) in collaboration with Agenform - Consortium, was entitled to participate to a European economic project the main goals of which were technological amelioration and company logistics, activities that the Agenzia del Legno-Wood Agency was in charge of. The search for new sharable guide-lines for furniture that may combine tradition and sustainable working procedures, coordinated by the *Politecnico di Torino– Dipartimento di Progettazione Architettonica e di Disegno Industriale* –- Department of Architectural Planning and Industrial Design, and the discovery of new markets, by CSIL Centro Studi Industria Leggera – Study Center for Light Industry, provided the necessary analytical framework.

The turning point was in 2005, with the realization of a *Centro Servizi di Lavorazione Leggera del Legno* – Service centre for Light Woodworking. This center, the only on of this kind in Piedmont, was financed by European Structural Funds and it is set in an abandoned plant now organized as a campus. The area is 4,500 square meters including a manufacturing shop equipped with numerical control machines, a workshop in experimental design (with the collaboration of the Politecnico di Torino), a document center for Alpine furniture, classrooms, and finally, industrial incubators. Actually, 35 enterprises received *Eccellenza Artigiana* – Best Crafts Production brand by the Regional Council of Piedmont.

With the guidance of external advisors (Politecnico di Torino – DIPRADI for the design of new products, CSIL Milan per for marketing and distribution), in 2001 the Varaita Valley's community presented a selection of prototypes representing three new collections inspired by old styles, where design was combined with traditional material culture.

Thanks to a careful philological work, the original models were re-discovered, appropriated and illustrated. They were very different from the cliché, redundant *rustic furniture* made in pine-wood that was, somehow or another, the hallmark of the local production between the 60s and the 80s.

The old furniture in the high valley houses was extremely different, as it was influenced by a wide geographical and social area that could export and pass on typologies and languages, production and decoration processes. (In fact it is called transalpine furniture).

It is no coincidence that one of the new lines under the name of *Mezzolegno* include, (like the old wood joint technique), basic and small-sized furniture, where the main characteristics are being function and light. Prominence is also accorded to expressive details (visible joints, key-shaped elements, tension members, latch closures) as for the original models in mountain-shelters.

These furnitures were manufactured for a small series production so as to comply with the capabilities of producers from Varaita Valley. No craftsmen but small sized companies, set a

system which is open to evolution and easily usable in different home contexts, not just mountain houses.

On the contrary, the other two lines interpret *engraving and clipping* decoration systems*.*

In the first one, also called *Geometrical decoration*, the old crafts traditional engraving technique consisting of geometrical images and symbols is re-interpreted in technological terms. To do so, companies that could count on technologically advanced equipment (pantographs and numeric control machines), and Service Center, were asked to produce semi-manufactured products in solid wood with mill decorations representing enlarged transalpine symbolic themes; the panels that the craftsmen from Varaita Valley carefully assemble together.

In the second, called *Scontornatura (clipping),* the innovative idea is the re-interpretation of side decorations, a constant theme in Varaita Valley's style, to be used as a handle now, for the whole furniture. The result is a real catalogue, rich in updatable and interpretable references that was created with the aim to manufacture "expressive furniture, that can be produced on a modular basis".

A further differentiation in the production is provided by the use of solid wood, an extraordinary, changeable and living material, in its indigenous species (pine, cembran, larch, oak, cherry and walnut), not painted but treated with environmentally-friendly products only (water paints, oil, wax).

Valli di Lanzo

Community_Design_Crafts

A Community of craftsmen makes a request for Design, to give the typical local craftsmanship an identity

The history of Lanzo Valleys is one of lack of means, without any high-quality production, made up of old material cultures linked to the extraction of gneiss stone, woodworking (mainly regarding chestnut and coniferous wood) and iron working.

These activities were very flourishing in the past and now a few craftsmen continue the tradition so as to produce high-quality items that, however, are extremely similar to those produced in many other alpine valleys. This is why common goals are to be re-interpreted and a cultural and commercial reconfiguration is particularly needed.

The same craftsmen started considering this in 2005, when thirteen, now eighteen, units, which are now the High-Quality Piedmont's Crafts Products brand, formed the Artimont-*Associazione Artigiani di Montagna*- Montani Craftsmen's Association. They sought design to establish strategies, guide-lines and a new identity of Lanzo Valley's crafts.

This was the occasion to take the trditional items from those Valleys into consideration, thanks to a survey and some projects designed to support the craftsmen's community and encourage communication.

Design contribution consists of an analysis of the typical Valleys' processes, identifying their peculiar elements, strong points (the "distinguishing elements" with respect to similar working procedures in other alpine valleys) and weak points. It follows that an agenda based on "showcase products" must be included, thus advocating the following strategies:

The need to promote chestnut wood, an indigenous species which is difficult to manage (this knotty wood often cracks), is now evident, but has to be reconsidered according to the incentives (coming from the Regional Council of Piedmont) for chestnut growing in the Valleys; the expressive results of which are remarkable, where the "value of defect" is accepted. Also local companies are very helpful, in fact they are employing chestnut wood in a series of very

interesting ways - fiber processing methods that would eliminate the main defects for which it was bound to be a marginal and under-classed species: the fact it usually cracks, twists and releases tannins.

This is the first response to a Community project in favour of natural processes, to reduce working procedures and promote wood as a live material.

"Naturally", this is the temporary name for the experiment, provides products which are realized with *trunk sections and boards* looking as they were simply “sketched” or used just the way they are (for bookcase supports, for instance), with knots and parts of barks, but that may adopt new technologies (working procedures and treatments that could improve the results from poor materials).

So the level of attention is constantly high, interested in all the solutions, and in a cultural heritage that is recovered and reinterpreted in a very expressive manner: the collections of *mirrors*, minimally designed, supported by big *iron nails*, an enlarged simulation of what used to be a key - product for Lanzo Valley’s economy, where large quantities of nails were produced for a range of different uses and for military boots in particular; *hat stands and domestic accessories* in wrought iron whish are designed to look unsteady; *patchwork*, a technique that wood craftsmen are free to perform, by using the waste (fragments and small axis) to be carefully assembled, in accordance with the highly complex crafts manufacture processes and fulfilling the desire not to throw or burn anything away. The small wood, stone and ceramic objects are then used on the table and in the kitchen, created to promote local gastronomic products. These objects will be exposed in fairs, gastronomic shops, bars and Valley’s restaurants, according to a program that was drawn up together with institutions.

Valli del Cusio

IndustryDesign_Community_CraftsIndustry

Two entrepreneurs understand the Design (and Re-Design) potential for products coming from the Community’s material culture, then they commission craftsmen from Cusio Valleys with the task to manufacture and distribute them through the channels of a famous Company.

Twergi is a brand involving a large community of carpenters, carvers and cabinet-makers from the Alpine Valleys in North Piedmont; Valle Strona, Cusio and Mottarone in particular. A craftsmen’s community that has always worked to produce household and work objects with two manufacturies that had the ability to disseminate their products beyond local borders.

The first firm was Piazza Battista, founded in 1865 in Loreglia. It then moved to Pettenasco in 1888, after the mill the original factory were torn down by a heavy snowfall It thus began to get a wider range of craft products, including mainly lathe products such as pepper-grinder, mortars, coffee grinder, grater, bowls, and pots. The company with the Twergi image in its catalogues (the gnome of Walser legends) kept on working untill Ubaldo Piazza’s death, in 1972, the year the company closed down. But in 1989 a second factory, Officina Alessi, leader company in the area of Cusio and a giant in Italian design by and large, rescued the firm’s fortune by restarting the activity., in agreement with the founder’s great-grand-children.

Since that year, thanks to Alberto Alessi’s passion, the small wood or wood/metal objects (another kind of material constituting sinks and household objects, the main products for the flourishing economy of Cusio-Verbano-Ossola district) have been styled by great designers according to the spirit of Twergi and produced by the turners from Strona valley, coordinated by Piazza Battista, Alessi’s supply company for Twergi products. The products were included in the Alessi catalogue and, thanks to the company’s large distribution capabilities, they reached the whole world and they smelled like different kinds of local wood as pear-tree wood, apple-tree

wood and cherry-tree wood, and were as resistant as alder-tree and walnut-tree wood and the as fresh as beechtree wood.

These are Objects which attest to an alpine material culture that has always been shared by a whole community whose special attention for high quality production has always been remarkable. These are basic objects in technological terms, but they preserve details and features that time has not changed and if anything, improved.

Alessi, a company which is strongly connected to is roots, has made a very important choice for the current economic craft landscape. It proves that craft activities may combine with industrial processes and strategies for the future, through design mediation. In this case, craft production could be a crucial element for the industrial sector, in order to set a new global position on the market, and craft activities could also find a way to abandon the culture of dependence, at last.

Turin/Marrakesh

Design_Crafts_Community

A Designer believed that his passion for Maroccan craftsmanship could be turned into an initiative for a new inter-cultural Community of Italian and Moroccan designers in conjunction with Moroccan craftsmen.

The invitation made by Milli Paglieri in 1995 to Italian and Moroccan designers to (re)interpret Arab living style (lights, textures, furniture, decorations…) was the starting point for an intercultural project on expressiveness and semantics, materiality, and the will to recover the old Moroccan working techniques to produce the items of Hafa Collection. A collection to be “Ethnical” but immediately “cross-breed”. “Double” objects – simple and complex, spontaneous and cultivated because they inform social history and material culture.

Hafa Collection was born in 1998: some Italian and Moroccan designers and artists (Manolo De Giorgi, Marco Ferreri, Lorenzo Prando e Riccardo Rosso, Italo Rota, Jeannot Cerutti, Karim El Achak, Farid Belkahaia, Elie Mouyal, Mohamed Nabili, Charles Boccara, Massimo Morozzi, Guido Drocco, Paola Navone) were asked by Milli Paglieri to re-interpret Arabic furniture and accessories with western taste.

A real and virtual artists’ community altogether, some members of which were close and others very far away, having discussions on the best products of Moroccan crafts, one of the richest and liveliest production in African and Mediterranean areas, and studying their potential over national borders.

The Marrakech’s branch office is in charge of the objects made in Morocco – Babnet Sarl, founded in 1997 with an office in the craft district of Sidi Youssef Ben Ali, a part of the city that was consistently improved thanks to traditional craft activities that, now thanks to Hafa is becoming an on-line community.

The fieldwork conducted by Babnet consists in contracting out a number of craftsmen, finding agreements on the production and organizing it in their workshops, supporting craftsmen on the different steps of their work, and finally carrying out the quality tests on their products.

Most objects are drawing-based: the result is a mix but is never the same twice, moving from the designer’s open contribution to the craftsman’s ability to interpret a project where they are free to express their skills.

The following step, granted by Babnet, is the possibility to have tailor-made productions in every sector of Moroccan crafts, to develop drawings and projects according to the customer’s request and to cope with big orders, assuring a short-term final delivery.

The goods arrive in Turin's stocks in a few days, and they are subsequently dispatched to different destinations. In Turin the Hafa Collection products are sold in the Hafa Space, adjacent to Hafa Café, a popular milieu in the Old Roman district of Turin. There one can taste both European and Maghreb food and drinks, sitting on traditional Moroccan dining chairs and reading books on Arabic literature and history; it also organizes Arabic language and cooking courses, live music evenings and meetings to promote the culture of Maghreb. In 2001 the Hafa Hammam Collection was born; in 2006 the Hafa Hammam was opened within the prestigious NH Santo Stefano hotel in Turin, in the heart of the old city.

Mondovi'

Community_Design_Crafts

The local Community, formed by craftsmen and local authority, makes a request for Design to explore new directions to re-launch typical local craftsmanship.

In the Mondovì area, the heritage left by the ceramic production is quite conspicuous. Now picked up again by locals through different types of products, it finds applications in a wide range of media such as the re-elaboration of traditional decorative patrimony of the 19th century, clay works, training centres, and finally, important public and private collections.

Collectors, decorators and heirs of the entrepreneurs of this specific field were the first who worked on the creation of a common awereness which could give more value to this ceramic heritage. Hard work paid dividends and resulted in the release of the first book entitled "The old Mondovì ceramics" by Carlo Baggioli in 1972, followed by an exhibition the following year.

In 2006, an agreement called Manufatto Monregalese between the municipalities of the former industrial district was signed, but including also also the Municipality of Mondovì, which granting the Community requests, has been strongly committed to providing value to its ceramic heritage. This commitment will result in the building of a museum dedicated to the Old Mondovì ceramics which will open its doors in 2009.

It is therefore essential to renew the role, the outlook and the identity of the typical Mondovì ceramics. Thanks to various cultural and experimental initiatives, such as the research project which is being carried out by the Politecnico di Torino – Industrial design course – this will be possible. The course is in fact oriented toward the exploration of the first possible forms, functions and expressions through which the Mondovi ceramics will challenge themselves in the world of renewal.

In 2006 the cooperation between the municipality of Mondovì and the Politecnico di Torino - Industrial design course, academic year 2005-2006, started. As many as 150 students, coordinated by the speaker and Gabriel Adriano, were involved in the project.

By combining tradition with the new functional characteristics required by home furniture, around 40 objects were created to demonstrate the potential of the Mondovì ceramics. These projects were also the starting point for further considerations, research and deeper re-designing actions. The proposals of the students are products rich in memory and meaning, that could be produced at reasonable prices using the local traditional techniques or by starting from semi-finished existing products.

The students were highly synthetic and selective. The identity features of the ceramics could be summarized in the following elements:

one colour: blue

one form: dish

one subject (if there is one): rooster

one decoration: lace

main function: eating

An expert in traditional ceramics would be quite surprised by the disappearance of the rich decorative elements made up of animals, flowers, landscapes and characters of many different bright colours. Design had to choose the best decoration in order to strengthen the shift. As a consequence only the rooster, the most distinguishing mark in the Mondovì ceramics, is able to survive, even though sometimes the rooster is nothing more than a blue imprint marking a rapid passing.

The cobalt blue laces, which according to traditions used to decorate dishes, are made with carved sponges; they become the true features of most of the products, sometimes by exaggerating their dimensions, sometimes by reducing their presence.

Through new products, Mondovì ceramics has to cooperate considerably in order to integrate the rich local food and wine sectors, and by complying with the contemporary rituals of the consumers (food and wine tasting, happy hours…). Their role must be finessed however, to contribute to the esthetics of modern domestic space (creating or evoking relaxing ambiences, enjoying moments of conviviality...) and of the outside world (feasts, fairs or relaxing surrounded by nature). The Community becomes therefore the key to promote the typical local handicrafts, thus becoming also also become the first customer: bars, restaurants, institutional bodies, shops selling other typical products such as food and wine shops, for instance which can become the starting point for promotion.

Cambiano

Design_Crafts_Community

A Designer styles and self-manufactures handicrafts in his own furnace; this experience becomes the springboard to create an Ecomuseum working to share a culture and create a new Community of Craftsmen.

The “pioneer” is Cesario Carena, architect and furnace operator who, when employed for the construction of the new furnace, started considering clay as an expressive material to design furniture in the 80s. Carena thinks of clay and of his childhood places in his own terms, fascinated by the creative possibilities that the non-working furnace provides, which is in fact an infinite supply of raw material and interesting semi-manufactured products, and by the working furnace as well.

The individual’s experience soon turns to be, in the 90s, a group’s adventure: it includes the architects/designers Guido Drocco, Luca Barello and Simone Carena and also a former employee of the brick factory, Romano Bravo, collaborating for prototype production and small productions.

The group plays with clay peculiarities (the starting size and shrinked size after baking clay, shapes, cracks, clay powder, colours, consistency, baking phase, waste) and deepens the research on the role and identity of industrial clay products (bricks, quarries, roof tiles, briquettes, etc.), and on the possibility to use them for construction sector.

Moving from a small objects to big ones, the semi-manufactured products, part of a “product-based system”, with new additional expressive and emotional values, gain new dignity and become even more valuable.

Some new series of furniture were born thanks to the work group, one of them was “Fornace&Officina” – Fornace and Shop, the main prerogative of which was to use only elements from the construction sector: industrial clay products, iron rods to reinforce concrete, shadow

gaps and metal sheets. “rude” and poetic products that led to a renovation of clay craft products and thus promotin the unexpressed potential of that material.

The group eventually founded the association La Fornace Spazio Permanente in 1993 and bean to inform the public about their work experiences through articles and publications in specialist magazines and exhibitions/events in the evocative environment of the furnace. The Hoffmann type clay burner room where the clay products were baked was turned into a show-room to display the prototype collections, which found vast consens from the public.

The following step, in 1999, was the creation of a small craft company, Clayart, to produce, special-order, and sell selected product lines, starting from prototypes.

However the goals were more and more ambitious. The association took up a project to recover the consumed part of the clay pit; anticipating the legal norms, they invested part of their revenues to transform the consumed clay pit, thanks to the advise of a group of hydraulic engineers, agronomists, landscape architects. In so doing they recreated salt marsh ecosystems, typical of the local countryside.

The real investiture of this project, however, came about in 2000 with the foundation the Munlab-Ecomuseum of the Clay, project, supported by the Provincial Council of Turin and the Regional Council of Piedmont.

A second generation of specialists and enthusiasts altogether was to be involved thus according the association new perspectives. This new combination of material and local components gave birth to a new education-based group. In the meantime, the local *Proloco* (local associations aiming at promoting their district) associations and entrepreneurs were now the essential actors to organize complex events and projects.

The Ecomuseum was created and developed to be used as an open archive, a meeting place, an experimental and collaboration workshop where one could research industrial and craft clay products production and local “know-how”, by and large.

Next case studies that we have the aim to develop:

Valenza

Crafts_Community_Design

Craftsmen get together in the new Community for Valenza’s Brand, to improve the traditional identity of jewelry making. Design could introduce this research into the process in a more analytical way, thanks to an open strategic project.

Castellamonte

Crafts_Design_Community

Where Crafts live based on a true icon, the ceramic stove, Design could give its contribution to exploit the market potential, perception and demand, through a new Community of companies interpreting different aspects of the same open project.

Design culture: from Product to Process

Building a network to develop design processes in Latin countries

Flaviano Celaschi[1], Angela De Marco[2], Elena Formia[3], Claudio Germak[4], Alessandro Deserti[5], Eduardo Staszowski[6], Ilaria Bedeschi[7], Giuseppe Lotti[8], Sebastián García Garrido[9], Nuria Rodríguez Ortega[10], Vasco Branco[11], Rui Roda[12], Diego Speroni[13], Claudio Barozzi[14], Paulo Belo Reyes,[15], Gustavo Severo de Borba[16], Roberto Galisai[17], Dijon De Moraes[18], Luis Arnal[19], Luis Rodriguez[20]

Abstract: The essay presents the results of a 2 years survey within 7 European and Latin American countries (Italy, Portugal, Spain, Argentina, Brazil, Chile, Mexico), focusing on the scientific and professional initiatives accomplished by universities and research centres in the field of design-driven innovation.

The survey shows a growing interest towards the methodological aspects of design by the observed actors and urges the formation of a "Latin network" aimed at experimenting proper design processes for Latin countries' socio-cultural and productive systems. The basic idea is that design culture, considered as a process culture, has relevant advantages in the actual relationship between production and consumption:

- Offering design a mediator's role between the crucial knowledge for sustainable development: economy, art/creativity, technology and humanities;
- Producing a "phantasmagoric" capacity (the possibility to visualize and share what is immaterial and upcoming);
- Mediating between the productive and consumption systems' interests.

1. Origins

Design culture is originating and developing in Latin countries around the problems concerning artistic design for industry, in a context featured by the relevant and systematic use by the industrial sector of practices and skills provided by the system of professional techniques and arts, commonly inclined to develop a project vision as a result of the product culture. The contribution of the academies of fine arts, as well as the schools of architecture, and the morphological, spatial and perceptive research has prevailed and conditioned great part of this culture, outlining the profile of an artist-designer oriented to a design approach traditionally linked to the productive and industrial realities that, in turn, have frustrated a progressive and continuing permeability.

Tracing the origin of design education in Latin America, Silvia Fernández establishes a strong connection between the rapid economical growth of the 1960s and the development of training experiences: “during the 1960s and 1970s, the economies of Latin American countries, whether socialist, liberal, or conservative, generally reoriented themselves towards a policy of import substitutions and industrial development. Design was placed within this overall industry policy. The creation of the first institutions for design education proliferated” (Fernández 2005, 3). According to the author, the process of institutionalization of the discipline, closely related to the influence exercised on the local culture by the Hochschule für Gestaltung (HfG) in Ulm that “offered in this context an operative, concrete answer to the challenges of industrialization” and “championed the insertion of design into the industrial process” (Fernández 2005, 4), knew a new season in the 1990s, still active nowadays. On the other hand, the origin of the first design degree courses in Latin Europe is even younger and dates back to the last decade of the XX century.

2. Breaking elements of the historical unity

Starting from those days, the development of high level training for design in the universities of these countries has been associated to the need to rearrange, adapt to the local cultural and productive system and develop a more systematic and precise knowledge about the design-driven innovation procedures. At the same time, industrial production, primarily focused on raw material extraction and commodities production, has been influenced by the risk resulting from the development of Eastern countries (above all Russia, India and China). This obliges us to reconnect design practices to industrial and economy management, starting from the development and the possibility to share innovation models that can mainly focus on cultural diversity and on the different kinds of local production procedures.

Signs of this change emerge from the analysis of the initiatives that characterised the recent activity of the universities and professional design systems in the Latin countries.
The birth of institutions that wilfully integrate research-education word with productive-experience one and the rise of scientific contributions and specialist training programs that focus on this topic are only two among other elements clearly connected with the transit of the institutional, professional and social attention from the product to the process culture. A process that takes advantage of the possibility of valorisation and comparison permitted by the growing diffusion of intellectual exchanges between training realities, all over the world.
The rise of professional associations, networks and institutions assembling subjects in charge of making quantitative/qualitative analysis and researches connected with the productive reality represents another important sign to value this evolutionary process.
At the same time, the diffusion of European programs for the international cooperation towards innovation is an important element for the examination of the process: they have recently been and are a way to legitimate an international step towards the design process culture, but also a methodological practise for the subjects involved. The nature itself of the co-financed programs as a matter of fact imposes a high concentration on the organizational, control, and coordination

process; a strong attention to the temporal and the hierarchical articulation of the output; and finally a tension towards the documentation of the process for the diffusion of best-practices.

In addition to these “breaking” topics, we can say that today there is a global awareness of the fact that design cannot be pushed by big corporations anymore (such as the historical model of Olivetti factory in Ivrea, Italy), neither by top-down politics for organically oriented economical interventions. The actors involved have to recognize themselves as a bottom-up system in which the power of design and designer has to be auto-created.

The “breaking point” of the original state emerges from the following scheme, result of the survey that has been carried out for the last 24 months of the initiatives pinpointed by many universities and research centres from several European and Latin American countries, here by us represented. The scheme summarizes the development actions and points out possible opportunities of collaboration and real instruments put to use to create a system of shared values and practises.

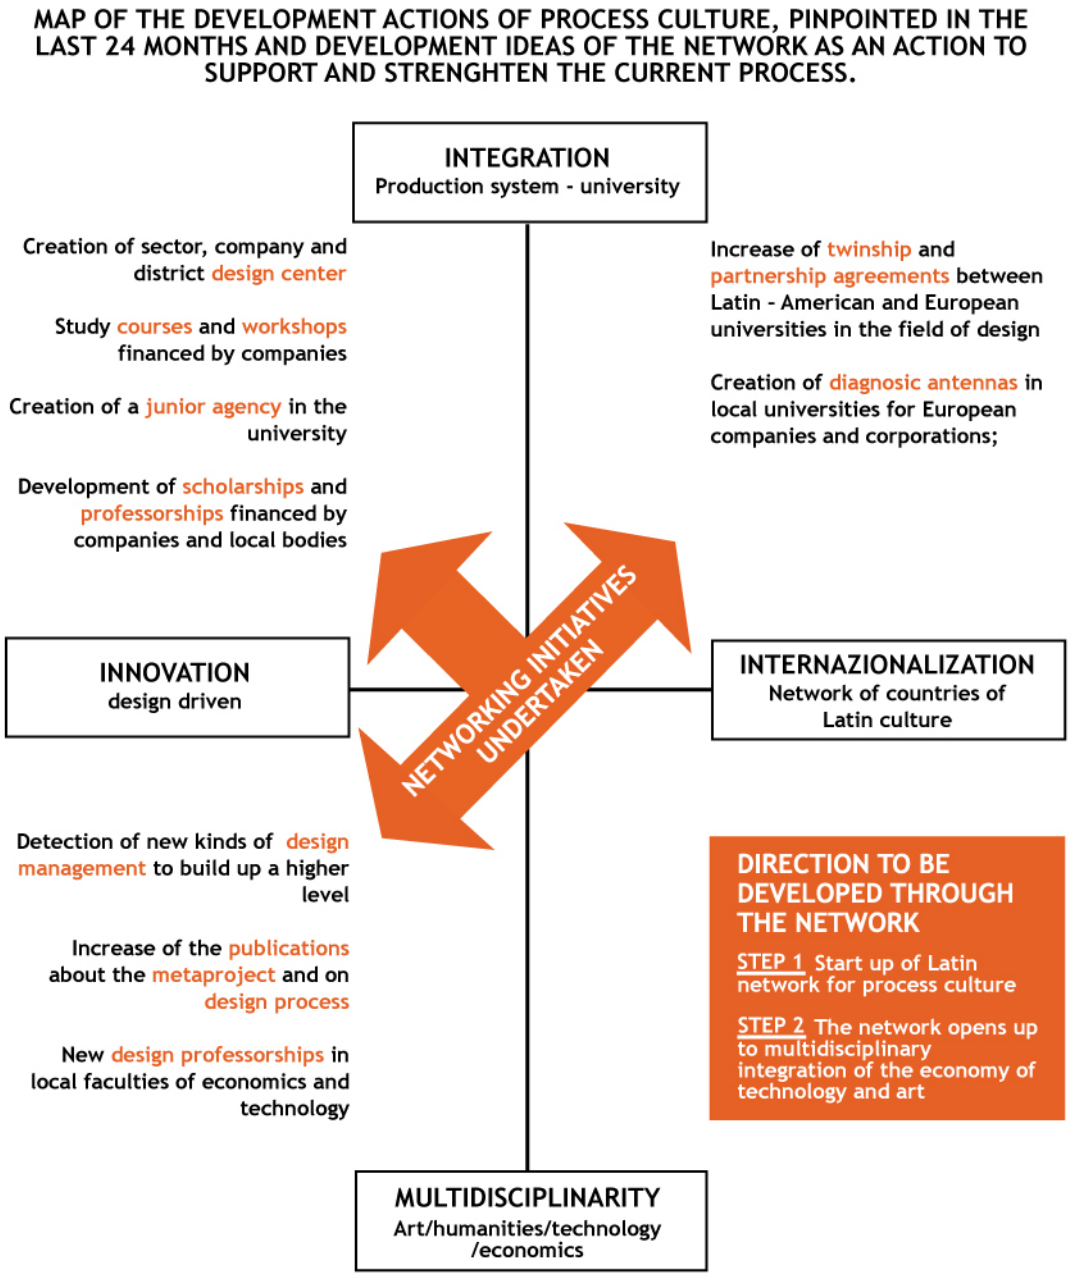

Fig. 1: Map of the development actions of process culture, pinpointed in the last 24 months and development ideas of the network as an action to support and strengthen the current process

The study implied a general overview of the main initiatives that have been divided in thematic areas based on the directions of their development. Some of the case studies have been selected as a necessary exemplification and documentation of the state-of-the-art of the research in the field of design and its future directions.

3. Integration – innovation area

Includes initiatives in which design has had a mediator role between research-university realities and the productive system. Thanks to its capabilities of transforming general knowledge into “applied research”, design has contributed to the innovation of products, services and communication instruments for businesses and agencies, helping connecting the world of research and professional consulting.

The comprehension of such ability by the productive system has favoured the birth of entities linked to universities inside businesses, production districts and associations involved in the fields of research, formation and promotion. In such environments services and laboratories are offered, in a complementary or alternative way, to implement the formation of the students, promote a design-driven process of innovation, support activities for the design-culture consolidation through exhibitions, publications, conferences and the encouraging of cultural exchanges.

Regarding Italy, we can approach the cases of POLI.design, consortium of the Politecnico di Milano that has been promoting the birth of business design centres since 1999 through the union of university and companies (Milan’s Creative Academy - Post-graduate studies school of the Swiss luxury group Richemont -, L’Oreal’s Corporate University in Rome and Gardesa research centre, a company specialized in doors and security systems), and that of the pioneer CSM (Centro Sperimentale del Mobile e dell’Arredamento), founded in Poggibonsi (Siena) in 1982 with the aim of providing the sector with a support in terms of research, innovation and professional education.
In these two cases, the design centres play a fundamental role in two directions:

- to organize activities connected with company businesses;
- to serve an homogeneous type of enterprises in terms of district capabilities.

Further exemplifications that clarify the ways of interaction between product system and university through the birth of different kinds of design centres could also be found in the Latin American context: Porto Alegre’s Escola de Design Unisinos, born from the partnership between the Universidade de Vale do Rio Sinos and POLI.design, can count upon a business consulting branch, joined with those of education and research; this academic institution, in collaboration with POLI.design, has then promoted the birth of the Cini Design Center, a research and development centre working inside the Madesa group that operates in the furniture field. Always in Brazil, the fashion and textile district in the region of Rio de Janeiro can count on the collaboration of the Cetiqt (Centro de Tecnologia da Indústria Química e Têxtil) that, in a singular structure, offers a Faculty and a Design institute, whose objectives are of satisfying the emerging needs of the textile chain production through the use of high technology.
In addition to the abilities mentioned above, design centres can also have the function of promoting design culture publicly; a model well represented by the CMD (Centro Metropolitano de Diseño, Buenos Aires). This institution assists the city’s enterprises, designers and entrepreneurs with the aim of improving their competitiveness through innovation-oriented initiatives, the application of strategic-design processes and the integration of the project in the production reality, activities well documented by publications and international conferences, among which it would be worth remembering the 2005 edition named “Diseño estratégico pyme”.
Portugal’s case study, that in 2007 saw the birth of ID+ (Instituto de Investigação em Design, Media e Cultura), represents a paradigm of the way different typologies of research and innovation centres can finally converge into a single platform of common strategic objectives.
Forces operating in the design sector in Porto’s and Aveiro’s universities have joined the CPD (Centro Português de Design) in the establishment of ID+, whose principal aim consists in the research and creation of instruments useful to the weakening of the concept of “symbolic deficit” of Portuguese artefacts (the entire range of products, systems, and services), assuming a sustainability logic as ethical reference. The structure involves actors of different nature, in the attempt of establishing a strong link between the world of experience (design practice) and that of

research (university). Appealing to the problem solving, communication and design dimension, the project tries to find the major number of alternatives for the actuation and the symbolic reinvention of Portuguese products through the creation of project groups organized on a multidisciplinary platform.

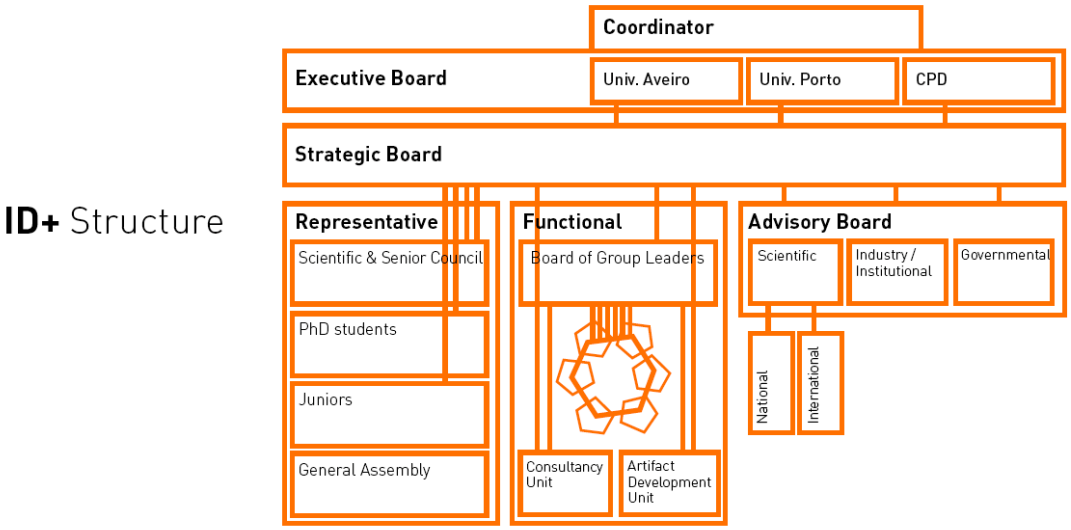

Fig. 2: ID+ Formal structure (ID+ 2007)

Along with the birth of design centres, the constructive synergy between the world of production and the academic reality has implemented projects and laboratorial activities inside the universities financed by private enterprises and public agencies. These enterprises operate in both service production and distribution sector. As examples we could mention (limiting ourselves to the co-authors of the following paper):

- Coza, home furnishing company, or Cave Gaisse, in the wine sector, which have collaborated in the 2007 and 2008 editions of the Design Atelier (second year) of the Escola de Design Unisinos, Porto Alegre;
- Cean spa, operating in the conception, project, commercialization and administration of supermarkets, has an active role in the Industrial Design Laboratory (2008) in the Eco-compatible Product Design Degree Course of the I Faculty of Architecture of the Politecnico di Torino;
- The housing chain store Emmelunga, which in 2006, also through a contest, established a synergy with the Degree Course in Industrial Design of the Faculty of Architecture of the Università degli Studi di Firenze.

In other cases, the synergy between universities and productive system has ultimately given start to the development of scholarships and professorships financed by enterprises and local agencies.

4. Innovation - multidisciplinarity area

Design, being a young and academic history-lacking discipline settles itself between four traditionally hardly-interacting knowledge systems: humanities, technology/engineering, art/creativity, economy and management.

Its attitude in catalyzing contents and synthesizing their effects in terms of form, function, value and meaning for the final user represents an essential component and constitutes the object of a growing number of studies focalizing on the so-called “metaprojectual” phase of the design process.

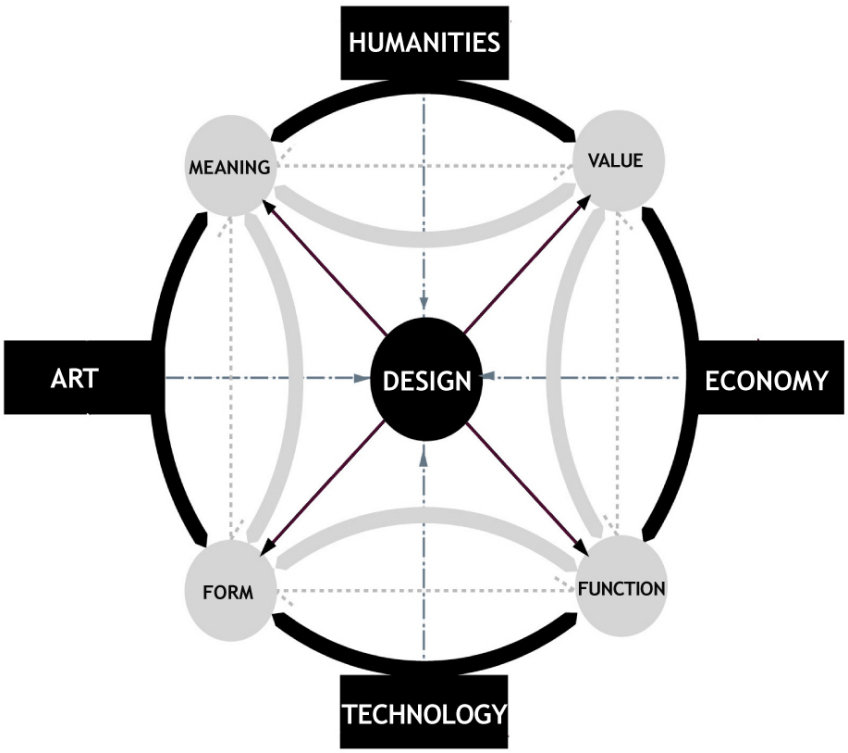

Fig. 3: Design as mediator between knowledge systems

“The metadesign is a place for reflection and elaboration of the project’s content. It originates from the necessity of multidisciplinary knowledge which will maintain and guide the activity of the project within scenery in constant mutation” writes Dijon De Moraes in his text “Limites do design” (De Moraes 1997/2008). It could be considered “the design of the design”, the phase during which we shift from a wide range observation of reality to a model of it on which it could be possible to operate projectually.
Starting its development in the 1990s, with market’s globalization and the turbulence of the context in which production and innovation processes were born and breed, the reflection on metadesign has produced a great number of publications. Other than the De Moraes’ text mentioned above (always limiting us to the co-authors of this paper and the years 2007-2008), it seems significant for us to point out the almost contemporary publication of:

- “Design e innovazione” (Celaschi, Deserti 2007), which elaborates the articulation in phases of the design project, giving particular attention to the phases of observation of the reality and the constitution of a model;
- “L’uomo al centro del progetto” (Germak in course of publication), which gathers different essays centered on the role of the designer during the process of innovation.

Metadesign is also subject of study in all of the observed countries. The survey has in fact detected the existence of courses specifically dedicated to metadesign (for example the “Metadesign Laboratory” of the Degree Course in Industrial Design of the Design Faculty of the Politecnico di Milano, the module of “Innovation, Management, Communication” of the Eco-compatible Product Design Degree Course of the I Faculty of Architecture of the Politecnico di Torino...), but also the

great emphasis given to the “design of the design”, in the field of degree courses and didactic modules in industrial design (for example the Industrial Design Course of the Universidad Empresarial Siglo 21, Cordoba, Argentina…). In some cases, the articulation of the plan of studies retraces the phases of the metadesign, progressively focusing on the methodological setting, on the “investigation” techniques, information modelling, the project and its representation, with the aim of conferring the student an “autonomía frente a un problema de diseño, siendo capaz de coordinar y tomar decisiones, un estratega que domina integralmente las variables de un proceso de diseño. Capaz de reconocer e integrar conocimientos y a otras disciplinas, aportando con desarrollo concreto a los desafíos de comunicación, gestión, forma y producción” (Pontificia Universidad Catolica de Chile. Formative objectives of the “Licenciatura del Diseno”. http://www.puc.cl/dno).

In the laboratory-oriented subjects, it is easy to find a particular and shared setting of the initial phase: the starting point of the project that is presented to the students is not a structured and circumscribed brief but rather a “problematic field” of vast entity. The initial “problematic field” is therefore broadened and enriched (a humanistic approach in opposition to the “elaboration” proper of a more rationalistic approach) to be simplified afterwards through a progressive re-modelling of knowledge: the prevision of intermediate project steps such as the “tema general”, the "concepto general” or the “scenario” is commonly used.

This attitude to the initial problematisation (which is generally dedicated the 50% of the design time) and to the self-individuation of the design theme, legacy of a historical gap in the link between design industry/world, is to be considered as a particularly significant attitude in the actual market’s context that shows a business world always more oriented into the externalization of the “research for a sense” to external consultants.

The holistic vision of the profession of the designer that derives from these reflections sets the problem of a redefinition of the denomination of some degree courses and titles of the polytechnic matrix. The “titulación” of “Ingeñero técnico en Diseno Industrial” had for example acted on the perception of the student (as detected by Malaga University’s board for Innovative Education), putting in perspective its commitment and interest towards the disciplines of aesthetical-critical, graphic and artistic-expressive matrix. The board, in observance of its denomination, has activated a series of innovative education measures with the purpose of encouraging student’s motivation through the construction of an interactive *disenoteca.*

The valorisation of design’s multidisciplinarity and capacity to aggregate and that of the designer’s strategic mission develop in a much more advanced way in the field of high education, where the promoting institutions are more autonomous and the orientation towards the market is stronger.

The very own Universidad de Málaga is taking care of the module of “Identidad, Marca e Imagen Corporativa” of the Master Internacional en Direciòn de Comunicaciòn organized by the Universidad Catolica de Murcia, which has students coming from all the principal Latin American countries.

For example the Master in Design of the Università degli Studi di Firenze, the Master in Strategic Design of the Universidade de Aveiro, the Master in Design Strategico of the Escola de Design Unisinos of Porto Alegre, the Curso de Pós-graduação em Gestão do Design nas Micro e Pequenas Empresas of the Universidade do Estado de Minas Gerais, the Maestría en Diseño Estratégico e Innovación of the Universidad Iberoamericana of Mexico City all have a management and strategical orientation.

Designers’ capacity of assuming the role of link between the business dynamics, the socio-cultural processes and the client’s desires has made possible for them to be recognized by agencies and research structures in the technological and economical fields, which have opened their very own design courses and teachings.

Representative examples of this fact are the courses instituted by the Università Bocconi of Milan (for example the masters in Fashion, Experience & Design Management, now at its eighth edition) or the program of the Gestão do Design held by the Senai (a Brazilian industrial association) in 14 states of the Federation, counting over 40 “Núcleos de Apoio ao Design” (NAD), and in 13 different industrial sectors, from the production of furniture to the industrial automation of chemical industry.

The presence of a design area in a business-oriented university such as the Universidad Empresarial Siglo 21 which general objective is “Formar líderes emprendedores, capaces de asumir posiciones de responsabilidad en la creación y distribución de la riqueza. Líderes que

contribuyan a aumentar la eficiencia y competitividad de las organizaciones, y que aporten a lograr que el país sea cada vez más desarrollado, ético, solidario y equitativo" and "Desarrollar la capacidad de resolver con investigación, los problemas que el país demande a la Universidad" (Universidad Empresarial Siglo 21. Mision de la Universidad. http://www.uesiglo21.edu.ar/Canal) is also of significative relevance.

5. Integration - internationalization area

The exchange of experiences, contents and competences between universities, professors, researchers and enterprises belonging to different national settings of the Latin area has favoured reflections on the states identities, geographical areas and actions in favour of the local development.
The increasing number of partnerships between Latin American universities and European ones can be seen as a first signal of such trend: it is significant the example of the Escola de Design Porto Alegre, born by the partnership between the Universidade da Vale do Rio Sinos and the consortium POLI.design (Politecnico di Milano) in 2005.

The progressive process of internationalization and the creation of partnerships between the Latin countries is therefore confirmed by the increasing mobility of students, researchers and professors; a process that encourages the sharing of academic models, research themes, cultural activities and professional careers. Exchange programs active at different levels of the students' career are available in all of the universities involved.

Design's role of cultural mediation in the creation of partnerships is finally evident in the constitution of associative agreements between universities, local agencies and productive systems in the pursuit of local development and valorisation of the single realities.
A shared desire to compare "las dimensiones de lo local y lo global provejéndole al diseño un espeso y fèrtil campo de validación: ser vehículo cultural en el mundo virtualmente uniformado por la tecnoclogía y compulsivamente regido por el consumo" (Cervini, Kayser 2004) is getting increasingly noticeable.
With this in mind, it seems useful to mention a few cases witnessing how integration systems at a supranational scale can contribute in providing incentives for valorisation projects at a local scale.
The first example is linked to the growing associative phenomenon that represents one of the most crucial and distinctive topics of the contemporary debate in regard to the recognition of the design's world professionalism. The ALADI (Asociación Latinoamericana de Diseno) is the only supranational design association in South America: it reunites representatives of training institutions and of professional, business, promotional and cultural associations, both of the private and public sectors. It was born in 1980 as "entidad que agrupa y representa a los diseñadores Latinoamericanos que promuoven la insitucionalización do Diseño Industrial Como disciplina tecnologica necesaria para el desarrollo social ecónomico y cultural de la región" (ALADI. Acta de Constitución. http://www.aladi-design.org/Historia) with crossing objectives developing at a political but also institutional, formative and communicational level. As years went by Uruguay, Paraguay, Dominican Republic, Porto Rico, and Bolivia (as last in 2007) joined the original group formed by delegates from Brazil, Colombia, Costa Rica, Cuba, Chile, Ecuador, Guatemala, Mexico, Nicaragua, Peru, and Venezuela in the composition of a complex map of territorial realities. Today it promotes a great number of initiatives including conferences, exhibitions, contests and even teaching programs and research projects.
To the strength which is implicit in the associative action, international research projects are joined demonstrating the extent of the synergies in design culture. We could name two examples taken from the activity of an institution that has historically developed a particular competence in the creation of communitarian and, in general, international projects. Between 2004 and 2007 the Degree Course in Industrial Design held by the Università degli Studi di Firenze, together with Florence's Isia, the II Università degli Studi di Napoli, the Ecole des Beaux Arts de Marseille and the Institute des Beaux Arts de Sousse has started the project "Abitare Maditerraneo I e II" with the

aim of contributing to the creation of an added value for the local manufactures in terms of competitiveness and starting from the definition of a specific identity. The project has counted the collaboration of institutional agencies (European Union and different Regions) and business enterprises located between Italy, Spain, France, and Tunisia, joined by didactical structures. The project has implied two kinds of relapses:

- direct (the definition of a “Manifesto dell’Abitare Mediterraneo”; the realization of about 30 prototypes developed by the joint of enterprises and designers from the two sides of the Mediterranean; the publication of a market study about the potentials of a Mediterranean trademark and products);
- indirect (the work on an alternative concept of Mediterranean based on the desire of a confrontation of people, cultures, development models; the creation of lasting relationships between the students involved; the confrontation between the project schools).

The same Graduate Course, in collaboration with San Paolo’s Universidade Presbiteriana MacKenzie and Brazilian ONGs operating in the waste recycling sector (Aldeia do Futuro, Monte Azul, Ricicla-Florescer, Arrasto), has therefore activated in 2004 the “Design Possibile” project (actually in development). The objective was reached through a complex methodological procedure that started from the creation of mixed Italian-Brazilian groups of students and made it to the realization of prototypes even contemplating the hypothesis of a distribution of these products. Finally it consisted in the helping of Brazilians ONGs operating in the sector of the recycling of production waste (jeans, tissues, wood, PVC, marketing banners) to widen their market through design.

6. Internationalization - multidisciplinarity area

Considering the documented and increasing intensity of exchanges and collaborations between the cited organizations, the formation and consolidation of a cultural bridge between the main Latin European and Latin American countries appears to be highly appropriate: a Latin net could afford in a systematic and conjoint way the topic of *design process culture*.

Despite the existence of studies and formation/conference practices promoted in the last 20 years by universities and design centres of the considered countries, these came undeniably late when compared to analogous initiatives held in the Anglo-Saxon world.

The different socio-political and economic history of the UK and of many Anglo-Saxon countries in respect to Latin countries have stimulated a much more precocious maturation of the methodological culture and a diffusion of it on a global scale, as the only available tool.
The manufacturing boom of the end of the 19th and beginning of the 20th century put into motion modern benefits and constraints for living and working. Disciplines such as architecture, town planning, engineering and product design, whose growth has always taken place alongside the industrial development, began to tackle new types of problem-solving past traditional artefact making.

The first well known public evidence of the “design methods” studies dates back over 40 years ("The Conference on Systematic and Intuitive Methods in Engineering, Industrial Design, Architecture and Communications" organized in 1962 by John Chris Jones and Peter Slain). Since then, the number of studies has increased and expanded, giving origin to a multiplicity of approaches and methodologies that share the belief in a pragmatic and rigorous method to solve problems through design, and that are commonly embodied in the generic definition *of Anglo-Saxon design process culture* (also considering the common linguistic substrate of the proposed definitions and practices).

The cited approach has generally been applied also within Latin American countries, due to the strong US influence and according to the rationalist design education of Ulmian derivation.

In the absence of autonomous and codified methodologies, the design process has absorbed, also in the European Latin countries (characterized, as Latin American countries, by a late industrial development in respect to the UK), an Anglo-Saxon setting.

The relationship strengthening between the Latin countries of the European and American area seems to be a vital opportunity for a *choral confrontation* with the “English speaking” design process culture, to understand the different theoretical and practical strands and common guidelines and characteristics and, alternatively:

- to verify the possibility of an aware adhesion of the Latin countries to the already diffuse methodologies;
- to distil, from the analysis of the studies realized up to now and of the empirical experiences accomplished by the different actors of the net in an independent or aggregated way, the characteristics of a possible common formulation of the Latin design process.

This unifying objective is extremely topical if considered as a singular case of “post-colonial study”, prospecting a progressive moving closer and “familiarisation” of countries historically playing the role of colonizers and colonized and their “coalition” in the presence of a transversal cultural *colonization* by the design process culture of Anglo-Saxon setting.

The hypothesis that supports the formation of the network (and is partially supported by the observation of the cited cases) is that it is possible to find some common elements in the design process approach shown by design professional and researchers of the Latin American and European countries. Constitutive and originative components of the mentioned approach could be inferred by some peculiar characteristics of the observed countries, such as:

- the attitude to syncretism, particularly showed by “young” multiethnic countries, such as Brazil (or Cuba and most of the Caribbean countries);
- the culture of industrial symbiosis and collective identity of the industrial clusters and local productive systems, particularly developed in Italy;
- the prevalence of a humanistic approach to the project and the emphasis on the initial stage of the design process: the "critical problematisation” (already highlighted in this paper with reference to Latin American cases) that considers the so-called “brief” as a cue for the opening of an enlarged problematic field.

The ideal scenery to which the proposed network project tends is the joint construction, in the long term, of a peculiar design process culture of Latin setting.
Possible instruments for the realization of the scenario are:

- the creation of a virtual expandable network for the exchange of information/experiences by researchers from the European and Latin American countries;
- the foundation of a magazine (printed and online) to collect the researchers’ contributions;
- the establishment of a programme of meetings/conferences to allow the frequent relationship between people and keep alive the debate on common issues through periodic deadlines for the delivery of the research advances and the celebration of the results.

First concrete result of the systemic and transnational knowledge-sharing is the birth of the Design Process Latin Network, to testimony the high relevance of the proposed issues.

DESIGN VISIONS PROPOSALS AND TOOLS

Ethics and aesthetics in industrial production:

Possible ways for the design in this new century

Dijon De Moraes[1], Clarice Figueiredo[2]

Abstract

Many researchers engaged in the issue of industrialization, the environment and consumption emphasizing the importance of consumers to the success of the environmental sustainability of the world.

This reality leads us to believe that a new aesthetics related to the social and environmental sustainability of the industrial production will occur through many ethical and behavioral changes of the current population and consumers. This collective change of behavior will turn into a new reality of an aesthetic of new “clean” products which will work as an ethical reference to a new aesthetic formal reality.

By accepting the products developed inside of this model in a pro active way, the consumers would legitimize a new possible aesthetic product in the name of a sustainable planet. Moreover, the consumers will have done their share in the trilogy of production, environment, and consumption.

Keywords

Ethics and sustainability; Ethics and consumption; Ethics, aesthetic and environment.

1. Introduction

Since the nineties, questions related to environmental sustainability have been considered as an important topic for many researches. It makes the thoughts about this subject pass through different scopes of knowledge with distinct interest and approach. The current approach concerning the triad production, consumption, and the environment intensifies significantly when the relation between the quick technological evolution, the raw material with free movement, and the globalization phenomena or the increasing of production in many countries are considered. According to Manzini, "man's capacity to manipulate materials and information never been so deep and wide as at present, but the total result is the production of an artificial environment, each time more alike with a second nature in which the laws are not clear yet, but mysterious. All of this induces a revision of this artificial world when grounds for reflection are inserted in the culture of the project and industry" (MANZINI, 1990)[3].

One attempt at rapprochement in this sense would be the insertion in a pro active way with the consumers to the debate about the socio-environmental sustainability, recognizing that they are the participants in the results that is actually known about the environmental impact. In fact, a lot has been done to actually desensitize the consumers to denied products that come from a polluting production. In the same way, a lot of effort was wasted looking for the spread of consciousness consumption. Indeed, a lot has been done looking for the control of the discardable after the use of the goods semi durable and diary household consumption.

But the actual stage that the world industry is presented as a quick productive dissemination and the significant increase of the consumers' number that requires other actions must be applied, while looking for the sustainable preservation of the environment since the increase of the consumption from the Newly Industrialized Countries population, and in particular the population from the Southern Hemisphere, has to be recognized.

In the same way, it is believed that the socio-cultural influences has an important contribution to the industrialized products conception, weather every product unconsciously or not is a product from the interaction of the actors involved in the conception of the art crafts with the socio-cultural reality. This fact is more clearly defined when we turned back to the popular art crafts production. Indeed, the art crafts have been the result of man's conviviality with their autochthonous culture, traditions, beliefs, and religiously processed into spontaneous material culture.

In the material culture that comes from the industrial culture, even though in a tacit way, it is also possible to observe the culture influences specially in the urban territory thru the huge scale of industrial products. In this way, the Design as discipline that consider the aesthetic as part of the contemporary industrial production will be able to use its attributes as a strategic discipline and a tool of projectile culture to insert to the consumers the possibility of absorption of new aesthetic that consider the ethical environment principles as aesthetic reference of the industrial production to the third millennium.

The aesthetic has been understood as a reflex of man's behavior as a social person, here understood, as a collective group about their conduct and human attitude. It means that the ethic that is able to influence the aesthetic of our material culture. So that, it is possible to be said, for example, that exist a military, native and religious attitudes and behavior of different types of social groups.

Moreover, through ethics it is possible to feel new types of aesthetic sensitivity not only as images, but also as a metaphor of a conjunct full of meanings or concepts and significance or

[3]MANZINI, EZIO. *Artefatti*: verso una ecologia dell'ambiente artificiale. Milano: Domus Academy, 1990, p.50.

values with which companies can associate. Because of that, aesthetic formal codes offer recognizable styles, as example Bauhaus, Streamline, and Ulm. They had a strong theory, culture, behavior basis concepts which are in accordance with its aesthetic, what this means is that that they used to follow behavioral esthetic and conduct that they believed and defended.

Methodology

Through the dialectic method's affinity with the complexity phenomena and its laws as "reciprocal action" where everything is related and "dialectic changes" where everything is processed are considered as references to this study. "Therefore, to the dialectic things are not analyzed as fixed objects, but in movement nothing is over, always transforming and developing. The end of a process is always the beginning of the other.

On the other hand, things do not exist isolated, unconnected with each other, and independent, but as a total, together, and very consistent. Not only the nature, but also the society is composed of objects and phenomena are organically connected to each other, interdependent one on the other at the same time, conditionally to each other. Stalin (In: Politzer et al., s.d.:37) refers to this interdependence and reciprocal action as the fact of why that the dialectic method considers that any nature phenomena can be comprehended when it is observed separately or out of the phenomenon around. Because any phenomena from any nature can be converted in and against sense when it is considered out of the conditions around. When it is out of these conditions, on the other hand, any phenomena are possible to be soluble with the phenomena around. When it's considered as it is that are conditioned thru phenomena around" (MARCONI e LAKATOS, 2003)[4].

Text
Modernity and Industrialization

It is impossible to despise the industrial production which is inside of the modernity context lived has become one of the biggest problems to the environmental sustainability of the XXI century and because of the modernization of the XX century became a synonym of industrialization, but no method was introduced in the modern projects looking to decrease the consequences that the development brought intrinsic to itself. According to Bonfantini, "our environment today is composed essentially of colonized and transformed territory due to the good and to the bad by man, their activities, goods, goods market, industries, machines, and the garbage are types of pollutants, weather desired or not. But, all this came from the human colonization and in the end, the whole world is made of arts and crafts" (BONFATINI, 2000)[5].

But if the contemporary world was also made by arts and crafts and industrialized products that for some way it completes itself, we must know that the destiny of the waste from the development of the industrial production was not considered. The result of this world's modernization processes is the good and bad things that were brought through it to the humanity of the XXI century. As the modern legacy remains through the technological evolution and through the quick productive spread around the world, however, some action is necessary to maintain in an acceptable way the world's progress through industrial development and environment.

It is interesting to observe that the modern, rational functionalist project that is in the logic of the progress established with its formulas pre dimensioned should have a better organization of the social order. As consequence, its benefits would be spread out to the humanity. This

[4]MARCONI, Marina de Andrade e LAKATOS, Eva Maria. *Fundamentos de metodologia cientifica.* 5ª ed. São Paulo: Ed Atlas, 2003, p.101.
[5]BONFANTINI, Massimo. *Breve corso di semiotica*. Napoli: Edizioni Scientifiche Italiane, 2000, p. 09.

project with its structured and consistent concepts guided the world's industrial and technology development of the strongest countries in the Occident, as well the communist countries during the XX Century.

The control under to the downfall of the humanity destiny made part of the modern project. "According to Jeremy Bentham and Michel Foucault the flow under to the downfall of the control and the fact to turn the action to supervise a professional activity of high quality were things that unified many modern inventions, such as schools, military places, hospitals, psychiatric clinics, hospices, industrial parks and jails. All these institutions were factories, and since all the factories were localities with structured activities seeking looking for to obtain pre established results" (BAUMAN, 1999)[6].

However But the modern project with predictable control about the human destiny looking forward to a better life seems to not have accomplished its whole mission. The dream of a modern world following a clear and objective logic pre established where all the people or a big part of the people would have access to a better life through industry and technology did not work. Nowadays it is clear to observe its disability to not have expected the effects and consequences of the huge industrial production the environmental problems. It is interesting to remember that presently, nowadays because of the quick spread of the world productivity, the environmental problem and the unbalanced nature has not localized interest in everywhere independent of location and geographical position in an entire context way.

Therefore, this new reality contest the objective and linear modern logical showing that the consumers were not called as participating in the world industrial destiny, even though having been the users of disposable objects and nondurable goods. It means that in the modern project with a large control and foreseeable ordination was not considered in neither an environmental education or the ecological consciousness in a systematic and collective way.

The debate about the shortage of natural resources, the estimates of the environmental impact, the control of the consumption of nondurable goods, and the conscious discard was not part of the education that constructed the modern society.

The Ethic Dimension and the Environment

The word ethic has origin in the Greek as *ethos* which means the study of the judgment assessment concerning human behavior. It a way of being is the way of been and behavior. It is the real character. [7]

Philosophically ethic is defined as means what is good for the person and to the society, and its study helps to establish the nature of duties in the relationship between the person and the society, so that its values are realized by the world. To live in society means to respect the moral and ethics to the peaceful living looking forward to obtaining overall harmony.

It is already known that moral values from a social group develop a normative mandatory character. So, the moral can be understood as a conjunct of the crystallized practices from the habits and conventions of a historical society. So, the ethic explains our moral behavior. According to Sanchez Vasquez "the ethic is the theory or science of the moral behavior of man in society; this means that the ethic is the science, in a specific way, of the humans' behavior". Continuing his explanation, just as the moral theoretical problems do not identify with the practical problems, even though they are much related. It is true that we cannot be confused between the moral and ethic. The ethic does not create the moral, at the same time all the morals suppose some principles, and behavior rules, but it is not the ethic that establishes it in any community. The ethics is faced with an experience historical social in the moral territory, it means that with

[6]BAUMAN, Zygmunt. *La società dell'incertezza.* Bologna: Ed.Il Mulino, 1999, p.102.
[7]HOLANDA FERREIRA, Aurélio Buarque de. *Novo dicionário da língua portuguesa*. Rio de Janeiro: Nova Fronteira, 1986.

many moral practices being used and from it the necessity to determine the essence of the moral, its origin, the objectives and subjective of the moral attitude, the basis of assessment, the nature and function of the moral judges, the criteria to justify this judgment, and the principle that command the changes and succession of different morals systems" (VASQUES, 1997)[8].

The ethic objective is to determine what is good for the person and the society. The ethic human being is to do something that benefits the other. It means do no harm the next. It is the cultural codes that obligate us to a certain way to behave, but at the same time it protects us. The ethic is an observer of the humans' behavior pointing out the positive and negative, the good and bad, the fair and unfair, and the mistakes. The ethic point out of the basic principles in which the human being's behavior must to be subordinated. It is considered to Marcus Acquaviva as a "dignity moral philosophy" [9].

Nowadays, the discussion about the ethic brings with it a concernes, about as quality of the life and the quality of our planet. Ethical possibilities are non existent if people do not understand their responsibilities for their actions and omissions. According to Francisco Albuquerque, "the ethic is translated on the search for the knowledge of how to construct what has to be" (ALBUQUERQUE)[10]. It means that the ethic is a vital element to the production of the social reality where is expected that man turns responsible for the evolution and development of the present and future generations.

According to Gabrielle Caccialanza, "In other directions the science is connected to ethics [...] In front of huge challenges is when the humanity of the third millennium faces the ethic anthropology disorder that goes with the modernity construction and actually progress. Think about these values that in each year is devastated a surface of forest equal to 150,000 Km or a half of a country as the size of Italy. A situation in which about 40 species disappear per day. It is obvious that science is mindful to establish a pact of collaboration with an ethic without less anthropocentrism and utilitarianism" (CACCIALANZA, 2005)[11].

So, the ethic would be the key to environmental preservation and conservation in many meanings and ways possible to the protection of the humans' dignity with their culture and values. It means a sustainable life in the Earth. The project of changing this way will be consolidated when we observe the ethics' concepts. For that, it will have to have an effective collaboration of the whole society which means a collective construction to redo the actual scenery as a new humanism planetary.

Ethic and aesthetic in the industrial production

The historical approach way of the XX Century shows that there is always a parallel between the vanguard artistic movements with the style and aesthetic of the art crafts thru the industrial products in a material culture space. It is able to point the Art Noveau as reference of the life style and habits of the European people from big cities during its expansion at the end of XIX Century and in the firsts decades of the XX Century when the productive ways, still in a consolidation process, looked for in the flower references of the Orient as its main aesthetic element. The life style "outsider", the colonies exploited with its forests and savannas, the movie, the photography, and the reproduction through Graphic Arts would spread the aesthetics of The New Style which finished with the past and started the modern era.

It is interesting to understand that the relation between ethic and aesthetic in the *Art Noveau* movement was not conceived in a consciousness and systematized way through the

[10]ALBUQUERQUE, Francisco Uchoa et al. *Introdução ao Estudo do Direito*. São Paulo: Saraiva, 1982, p.132.
[11]VALLE, Luciano (org). CACCIALANZA, Gabriele. *Ri-Abitare la Terra*: la scienza, l'etica, l'ambiente. Como/Pavia: Ibis, 2005, p. 54-55.

industrial production, but it happened through a natural and spontaneous process between the life style of the epoch and the mechanic manufacturing process in a greatly increasing phase mainly in at the European Countries that named it differently such as *Jungendstil*, *Sezession* e *Liberty*. All these are translations of this style that was the first to be applied in Arts, Interior projects and then in daily objects such as jewelry, furniture, and etc.

In a way more structured and international, it is possible to quote the Bauhaus experience as the first school to present a consistent and close relation between the shape, function, and the production of industrial goods preceded by an ethic and behavioral theory established before. According to Bürdek, "except of the writer Gerhard Marx was chosen by Gropius only abstract artists or from the Cubism painting such as Professors from Bauhaus as Wassily Kandinsky, Paul Klee, Lyonel Feininger, Oskar Schlemmer, Johannes Itten, Georg Muche, and László Moholy-Nagy. Because of the development of the industrial production in the XIX Century, the union united between project and production was separated. The fundamental idea of Gorpius was that in Bauhaus the Art and the technique should become a new and modern united unity. The technique did not need the Art, but the Art needed the technique which was the emblem phrase. If the Art and the technique would be united, the notion of social principle would have happened resulting in the consolidation of the art and the people" (BÜRDEK, 2006)[12].

The proper term "to consolidate the art in the people" show us the ethic position of the ideal professionals of Bauhaus. The project of this school (1919 to 1933) that started right after the First World War where the poor and divided Europe started its reestablishment of their process must be considered. Therefore, the style recognized as "Bauhaus" begin from a social conscience which was looking for the elimination of the superfluous decorative things that existed in the industrial products, whichever the constructive and productive manufacturing facilities. The proper Bauhaus Manifest, because of the union between artists and artisans and the common good of everybody which means Architects, Sculptors, Painters and everybody should go for the Arts and Crafts [...]. Arts and people should construct a unity. The Art can not be a pleasure for a few people, but the happiness and life of the most of the people and finally having the happy union between "Art and Technique", as the Manifest stated. It is through, that it is possible to find in the *Deutscher Werkbund* (1907) of Hermann Muthesius and in the Neo-Plasticism of Theo van Doesburg, thru the *De Stijl* (1921) movement ethics principles similar to these found in the Bauhaus school. But the Bauhaus school had the merit to better sediment and translate lessons in a didactic way the ethic concepts applied on the industrial production of the XX Century.

According to the theoretical Peter Hahn, analyzing the Bauhaus' first years (1919-1923) which were decisive years to consolidate the final model and configuration of to the school. "It is suspected that if the Bauhaus had become a world culture event, it would have happened because the school knew how to translate and really practice the ideas that already had been debated at other places in a theoretical level and even at a utopian level. In fact, during the Bauhaus' first years, many heterogeneous chains occurred happened or ideas that talked about the politics and society, the economic world, industry, Arts and Crafts, Architecture, Arts, Pedagogy, and finally Philosophy, but on the other hand going to mystic and esoteric thoughts" (HAHN, 1996)[13].

The described text above also confirms the vast big theoretical knowledge that existed as the basis to the "pure" and "sober" style of the Bauhaus school which shows its commitment to give life to an aesthetic code that goes to search for find the cause and the reasoning of the moment lived by Germany and the entire Europe. According to Hahn, "When the Bauhaus begun it meant that it was the sunrise of a lost war with politics changes or the revolution of November of 1918. Misery, hunger, disengagement, and inflation were the epoch words in which political attacks and extremism was the order of the day. At the same time, the hope of a beginning radically new increased [...]. It would be impossible to imagine that the Bauhaus' students come

[12]BÜRDEK, Bernhard. E. *Design*: Historia, Teoria e Prática do Design de Produtos. São Paulo: Blücher, 2006, p.28.
[13]HAHN, Peter in MICHELIS, Marco De; KOHLMEYER, Agnes. *Bauhaus 1919-1933*: Da Klee a Kandinsky da Gropius a Mies Van Der Rohe. Milano: Mazzotta. 1996, p.37.

from the environment of young movements of protests as the *Jugendbewegung* in which their minds would have new ideas to redo their own life such as the return of nature, the vegetarian habits, fasting, nudism, nature medicine, and the common life with *Wandervogel* [...]. Many Bauhaus' students came from the war. Because of that they were full of patriotic enthusiasm and had participated as volunteers saving lives. To ensure for the social life of the Bauhaus' students was a duty for years to the school and it was done in a way that the students used to have free food" (HAHN, 1996)[14].

So we can understand that scenery was ready to the appearance of a new aesthetic code that would go within the social and behavioral reality of a people which means that it was reciprocal to its ethics conduct and behavioral that would come. The Bauhaus' Professors and students were capable of translating the moment with perfection living through the Bauhaus' ethics principles and aesthetics a legacy to the world material culture.

On the other side of the world in the United States of America another experience deserves our attention. Differently than in the post war Europe, the U.S.A in the beginning of the XX Century had an industry in expansion and it begun its process of techno manufacturing through the world. The strong immigration which occurred for a long time made it possible for the influence of many cultures and new possibilities of styles and aesthetics from within inside that Country. The tradition of an oriented product to the market and the huge spread of the consumption made the American Design at the first decade of the XX Century to have a strong emphasis in its sales and in the obtaining of market success. In this way, the American Design used the objects' shape and style more as a sale strategy than an intrinsic content to the industrial product. In the American concepts, the Design was something that could be inserted after the production as a cosmetics final make up.

In this way, the recognized "styling" appeared in the U.S.A. which is the basis after the 20th century until the 50th of the highest glamour and recognition of the "Streamline". This movement had as basis in the aerodynamics principles that came from the efficiency of the organic shapes of fishes and birds, as well the drop of water applied to the trains, shapes, and airplanes' design which had the velocity as projectile reference. It is interesting to observe that this practice also influenced other products that were far way from the aerodynamics products such as radios, cameras, and office machines. It was a symbolism content without any functional motivation.

Therefore, the "streamline" begun as the American modern translation, as well as indicating to the world of its productive capacity through a strong line of industrial context. According to Burdek "The Designers used to see their work as a way to make the product more irresistible which means looking for interpreting the users' hidden desires and hopes and to project it on the objects in a way to stimulate the purchase. Separated from his technical solutions, the designers were employed only to solve these kinds of problems" (BÜRDEK, 2006)[15]. At this time, the designers' performance that helped to consolidate the "streamline" deserves featured who are Raymond Loewy that made the expression what is made does not sell, Henry Dreyfuss, Norman Bel Geddes, Orlo Heller, Richard Buckminster Fuller and Walter Dorwin Teague.

It is noticed that the performance of the American Designer at the beginning of the XX Century was to insert the design into the industry as a way to increase the sales and the search for the commercial success to the companies. According to Heskett, "to show the velocity and modernity as a symbol of power and did not decrease the efficacy of an object, even though did not express the function" (HESKETT, 1990)[16]. If we add the fact of the being of a huge mass of consumers that appeared through a strong medium social class we could understand that the formula was ready where the induced consumption would feed the sales and also increase the production that encouraged the consumption. The ethic behavior of the time made a "Streamline"

aesthetic to appear in a consistent way with the reality lived, which resulted in means the American industrial and economic expansion.

Returning to Europe, other experience has to be highlighted that contributed a lot to the design to consolidate in that continent mainly in the academic context which was *Hochschule Fur Gestaltung - Hfg*, The Ulm School (1946-1968). Just like what happened to Bauhaus, the pioneer's professors of the Ulm School and his firsts Rectors had its origins in the 'Concret Art Movement' who are Max Bill and Tomás Maldonado. According to Giovanni Anceschi, "Maldonado worked at Universities for more than 50 years since 1954 and made part of the Academic Professors of the Ulm School, The Hochschule Fur Gestaltung heir of the Bauhaus' dialectic. In a few years he turned to be the President of the Bauhaus School and its guide intellectual. Before it all his education of culture was developed at the humus culture, ethic and civil of his hometown which is the most European one of the South American's cities, Buenos Aires" (ANCESCHI, 2001)[17].

It is well known that the Ulm School just as what happened to the Bauhaus was established after a huge war having Europe once again as the main scene. At this time it was the Second World War. In this way, it comes to Europe's light through the Ulm School some concepts such as rationalization, functionalism, economy, normalization, and neutrality. To Andrea Branzi, "the methodology proposal by Ulm to impose at that time followed away of an objective rule indisputable, which would propose a new way to a Germany and Europe looking for certainties after a lost war and so many horrors and wrong dreams. What was the main Ulm's theorem? Which approximated strategy is the proposal to a universe of his industrial objective? In fact, the school proposed a substantial cooling of its own object, a naturalization of its expressive values and signs through formal codifiers of a big purity, in which, at the same time prevents the visual and mechanic arrogance" (BRANZI, 1988)[18].

Therefore, it is noticed that rationalism proposed by the Ulm School would meet the modernity project increasing in Occident and brought forth from it as collaboration of the scientific and methodological rigor applied to the design activity. Inside of the lived scenery Ulm brought intrinsic to its projectile model the concept of benefit dissemination of industrial production to everybody and even expanded the design performance to the medical areas, to the disabled persons, the transports, the work tools, and the communication. Ulm intensified the social function of the design and inserted its fundamentals, the debate about the peripheral and underdeveloped countries. According to Bonsiepe "the test about the relevance of the Ulm's model in the peripheral countries predicts therefore the main characteristics of this model. Certainly the international composition of the Hfg Ulm's Professor and students was not casual. In fact, the program had characteristics that expended out of the intern situation of Federal Germany. It does not mean that the Ufg Ulm wanted to have an international value. It was conceived by the industrialized countries, the center or metropolis center, but it also met the Countries which the industrialization as an instrument to reduce its own technological dependency to generate wealth and wanting a modern culture standalone […]. The rationalism was opposed to the poverty and exoticism that prevented the paternalism behavior of the simple social assistance" (BONSIEPE, 1995)[19].

In this way, we can attest that the ethic and theoretical concepts of the Ulm School agreed with the aesthetic results of its production conceived into the material modern culture. The aesthetic developed, decodified and practiced in the Ulm's model even though it had been conceived in a "Center" and its reality lived was accepted and amplified as a periphery context. Ulm put in the center of the debate of the aesthetic antithesis that extols the consumption and

refers to the superfluous, and inserted in the context of the culture a new aesthetic that came from the rationalism and the functionality. The Ulm also claims as reference to the project the productive facility, the manufacturing technological and its methodological rigors and in the theoretical way that is closer to the reasoning and positivism.

Conclusion

It was observed during the development of this article that the ethic as a model of behavior and life style, and the aesthetic as formal decode of the meaning, and the meaning of the human's social behavior always maintained a reciprocal relationship with each other. Moreover, it completes each other in a constant state of mutation. It means man as a social actor and the industry as an agent of production of goods of mass consumption that works in scenery where the ethic behavior is used as reference to the industrial production and it is based in the human necessity to the conception of new arts and crafts.

The historical way of the relationship between ethics and aesthetics shown here and presented through 2 cases such as *Art Noveau, Bauhaus, Streamiline*, School from *Ulm, and the interesting experience of the Russian* vanguard demonstrate and prove that the close interrelation exists. In the same way, the environment and the human's socio-culture in relationships through their behavior and life style that are presented as elements to be codified as aesthetic references of the industrial production.

As complementary scenery, the discovery of new materials, as well the appearance of new productive technologies also influenced the conception and the aesthetic shape of the industrial products. Nowadays, as never ever seen before the evolution of the productive technology, as well the appearance of new raw materials offer a real revolution in the use and shape of the art crafts. Plus the socio-culture influence as a determinant fact to the formal configuration and condition of the products inside of our material culture. With this sum of factors and attribute, the objects begun nowadays of being developed not only through the functional and productive aspects, but also through the aesthetic factors, which are related to sensitivity, emotion, and feeling.

It is legitimate to say that through the appearance of new polymers such as the polymers, thermo polymers, thermoplastics, composites, light alloys, synthetic fibers, and others made it possible to decrease of the easy production process' time and the number of components of the product bringing, as consequence to the consumers new ethic messages, new aesthetics references, and new consumption experiences. Due to the capacity of new materials of today, being soft, light, transparent, translucent, and others, as consequence new products have arisen, which bring the people new values very difficult to measure before, such as emotion, the value of like, and perceived quality.

But this same technological capacity that got to know how to introduce a revolution of the habits of the XX century, one another hand did know at the same way to establish new sceneries that pointed to a environmental socio cultural able to be between the ecological and environmental ethics. The application of a linear mechanics and rationalist model to the modern world project as well the distancing of the relationship between the industrial development and the environment has, as result the water, air, and earth pollution, the ozone hole, the greenhouse effect, deforestation, desertification, and the increase of the nature phenomena or catastrophes. The environmental philosopher Luciano Valle complete like that "about the relation with nature, the modern man stepped back in comparison with big religious and philosophic traditions of the past, it was not known how to maintain the environmental knowledge that can be synthesis

through the Taoism statement which says: *that the wise man lives in harmony with the earth and the sky*" (VALLE, 2005)[20].

In the limit f the XXI Century only started, it seemed appropriated to talk about others possible relation onside of ethic and aesthetic trilogy and industrial production. The aesthetic of the new Millennium in this context would be directly attached to the environmental ethic in the way of looking for to interact with the social behavior and sustainability of the planet. The thinking and debate between the ethic, aesthetic, and consumption are already mature to have its own personality or even an own epistemological way. But, about the industrialization, environment, and consumption is evident in the same way, the importance and the place of the consumer as a protagonist and main actor to the success of the environmental sustainability of the planet. Only thru the consumers the appearance of a new aesthetic consistent with the reality lived actually will be able to be legitimated. It means that the challenge that look for the environment preservation and the life quality to the future generations. This new aesthetic would have as basis different compositions of reusable plastics, the dot and line colored of the packaging papers, and recycling objects, and even the monochromatic of the products made of a unique material en renewable

In this new aesthetic model pointing as a possible way to the XXI Century which meets the environmental sustainability of the planet would have place for imperfections of products made of new and different types of raw material produced with clean technology of low environmental impact or even semi crafts. According to Manzini, "the development of clean products can come with clean technology, but it certainly requires a new projectile capacity. It is very possible to get clean products without specialized sophisticated technology. Inside of this contest, the design paper is highlighted that can be observed as an activity that unifies the possible technique with the ecological necessary promoting new social proposal culturally appreciable" (MANZINI e VEZZOLI, 2003)[21].

When the developed products were accepted in a proactive way inside of this model, the actual consumers in the name of a sustainability and clean planet would legitimize a new possible aesthetic to the design of the third millennium, and to do its part in the trilogy of the production, environment, and consumption. But these concepts are recognized and did not makeup part of the exact values and objectives of the subjects that built the modern strength of the XX Century. So, this generation must use the industrial development gathered from the modern project and insert it in this context with the production of products eco sustainability and eco efficient having as reference the environmental ethic and aesthetic to the conception of new arts and crafts of the industrial production to a second modernity to be built during the XX Century.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Supporting Communities

Design led collaborations exploring the creative and economic potential of materials made from waste.

Jakki Dehn M.Des. RCA[1]

Abstract

This paper describes findings from the research programme; 'Creative Resource' which focuses on the sustainable development of materials and the design process. The work examines the material connections between design, culture and environmental preservation.

Interviews conducted with designers, manufacturers, retail outlets, environmental managers, the waste management industry and government organisations from Europe, USA and Asia, form the basis of case studies describing design companies and manufacturers who are testing the significance of environmental concerns as a stimulus for design innovation and commercial success.

This paper considers the idea that we cannot sustain our future without industry and technological advance. For industry to survive, we need to make sure that appropriate innovation is recognised and that the supporting communities are nurtured.

[1] Reader (Product and Furniture Design) and Director of the Creative Resource, Research, Kingston University, Faculty of Art, Design and Architecture, j.dehn@kingston.ac.uk, Tel: +44 (0)20 8547 8374

• Introduction

I am a reader in Product and Furniture Design at Kingston University in the UK and I have a background in the design industry and education. I currently direct a research programme called 'Creative Resource', which focusses on the sustainable development of materials and the design process. It is work that I have been involved with for over 10 years, the two main outcomes currently are an international travelling exhibition and a virtual and physical sustainable materials library housing over 1,200 samples from 14 countries, many of which are made from 100% recycled waste.

This paper considers the idea that we cannot sustain our future without industry and technological advance. For industry to survive, we need to make sure that appropriate innovation is recognised and that the supporting communities are nurtured.

I would like to talk today about:

- The importance of designers' involvement with the development of materials and products made from recycled waste.

- How the design process is evolving in order to maintain markets, whilst sustaining well being and using less primary resources.

- The impact of this work upon local communities.

- The importance of education in understanding the value of materials.

Almost everything we do creates something that we throw away. The result is bulging landfill, fewer natural resources and catastrophic environmental strain that compels us to take stock of what we care about, what we value and what we discard. Up to 90% of the material that we throw away is recoverable. Someone somewhere has the imagination and the ingenuity to transform this rubbish into a resource.

"Across the board, most studies show that recycling offers more environmental benefits and lower environmental impacts than other waste management options". (Georgsen. 2005)

Since 2000 there has been support from the UK government who have invested hundreds of millions of pounds into the Waste and Resources Action Programme (WRAP), not only to reduce waste but to turn it into a valuable resource. Contrary to public perception their research now shows that recycling is environmentally and economically viable.

There has to be no greater concern for designers and producers today than the environment. But even though the implications are so far-reaching. the concept of sustainability is not well understood. Legislation about the use of materials and hazardous substances means that unless designers develop sustainable design and construction processes, the manufacturing industry will not be economically effective.

"Historically people have been wary of recycled products in that they feel that they're not as good quality". (Cooper. 2005)

The public's perception of recycled materials seems to still be more negative than positive. Some industries do not bring recycled content to the consumers' attention; others endeavour to use it as a marketing ploy.

As part of the Creative Resource research, funded by the Arts and Humanities Research Council; over the last four years, 40 interviews have been conducted with designers, manufacturers, retail outlets, environmental managers, the waste management industry and government organisations from Europe, USA and Asia. These form the basis of case studies describing design companies and manufacturers who are testing the significance of environmental concerns as a stimulus for design innovation and commercial success.

The purpose of the travelling exhibition, Creative Resource, was to highlight these case studies and to give the wider public an understanding of the potential economic and creative value of the materials that are often thrown away. The hope was to change the public perception that recycled is lesser value by showing a sophisticated range of materials and products containing recycled content, which do not necessarily make you visually aware of it. To date the exhibition has been visited by several thousand people aged 5 – 80 years old and it has also been used as a backdrop to seminars and debate with local councils and the recycling industry.

- ## Creative Resource Exhibition

This exhibition is about the value we place on materials and the design innovation that can transform our perception of waste.

It comprises of five free standing material sectors. The products on display here show that using recycled materials makes business sense. The benefits are not always immediately apparent but, for many designers and manufactures, that's the point. Their products have a direct impact on quality and consequently on waste reduction. There are about 230 material samples on display which can be touched and 110 products containing recycled content.

From looking at this chair designed by Phillipe Starck, you would not know that it is made from recycled aluminium, the material looks no different to the original. Phillipe Starck's involvement means that the form has changed significantly from the original cans, which has added substantial value to the product.

- # Importance of designers' involvement

Designers understand the importance of taking a risk and exploring both the use and content of materials and they realise the benefits of collaboration. I would like to talk about some of these case studies and describe how work with materials that would normally be thrown away has supported economic regeneration in areas depressed by the decline of traditional industries.

- ## Plastic case study: John Elson, JEDCo, UK

Fig. 1: Scaffold Plank. Recycled Polyethylene and waste fibreglass. Developed by Jedco, manufactured by Uniq Extrusions, UK The economic, environmental and practical benefits of this product over the traditional wooden plank have created new markets including the off shore oil industry.

“I think that it was probably our enthusiasm that carried it through to the latter stages, it became apparent that we could economically use recycled materials……the costings were always slightly better than using virgin plastic.” (Elson. 2004)

John Elson of Jedco, a small product design consultancy, was approached in 1997 by a group of entrepreneurs to develop a plastic scaffolding board. During close collaboration with the plastics industry to develop the right material in the right way, it became clear that the majority of the board could be produced from a mixture of recycled polyethylene reinforced with waste glass fibre. The main impetus was not environmental but economic. It would cost less to manufacture in recycled materials and could address the needs of a wider market. It can be used in sensitive interiors where the dust and debris of the traditional scaffold board are not allowed.

The resulting board introduced in 2004, has many advantages over the traditional wooden board: -

- It is 20% lighter and unaffected by wet conditions enabling more efficient transportation, faster erection and dismantling.
- No splinters, sharp edges, warping, knots or rust.
- Dust free for use in sensitive interior environments.
- A safer, non slip surface.
- Greater resistance to salt water, oil, solvents, and acids.
- Lasts three times as long.
- Lower maintenance.
- Can be colour coded and have company names for added security.
- Conforms to all European platform loading standards.
- It is 100% recyclable at the end of its life.

The manufacturing plant in Wales has reached its capacity of 240,000 boards per year. They will purchase new equipment to increase capability for a growing market, the off-shore petroleum industry. The fire retardant used in timber on oil rigs reacts with the salinity of the sea water causing rapid deterioration, requiring it to be replaced every few months. This plastic plank, totally fire retardant and unaffected by the sea, makes it a safer and longer lasting alternative.

They are considering building a new plant in Dubai as Saudi Arabia exports very little and container ships leave empty all the time. They could use this capacity to sell scaffold planks into the southern hemisphere.

Jedco employ about five people, through their innovative work (the environmental implications of this project enabled finance from the Welsh Development Agency, for a specific factory to be built in South Wales,) they have enabled susbstantial economic regeneration in an area depressed by the decline of the coal and steel industry. Having taken the risk, the product has been extremely successful and major new markets have been found.

- **Glass case study: Jim Roddis, Paul Chamberlain and Gary Nicolson + Sheffield Hallam University.**

"If I was outside academia, unless I was in a cash rich company that dealt with waste glass, I would never have been able to address this problem. The thing about academia is that used in the right way it can be a positive boost for commercial industries." (Roddis. 2004)

In 1994 Professor Jim Roddis of Sheffield Hallam University collaborated with product designers and fine artists; in answer to a call by the Department of Trade and Industry to develop commercial markets for the growing quantities of green glass collected in this country.

"When you look back on the development; the idea and potential application came in those first 2 or 3 years but it's taken the last 6,7,8 years to make it a real product. It's been a hard slog… seeing it through to reality. Getting patents, sorting out the production and that's where I think that a lot of other materials probably fail." (Chamberlain 2004)

They developed TTURA; a cast composite which is 85% recycled container and automotive glass cullet mixed with a water based resin. The material was developed with local manufacturers, Resin Build, so that the commercial benefits would have a direct impact on the economy of the region.

After years of collaboration and testing TTURA is now a commercial success and is licensed to manufacture by four companies. It is used both externally and internally for cladding, paving, flooring and corporate and domestic furniture.

This material is the result of a successful collaboration between designers working in education and local industry which has made a substantial contribution to the regeneration of in an area suffering badly from unemployment.

Professor Roddis is now developing a translucent, recycled glass brick which will hold light for a time after a power failure to guide people out of a building.

- **Textile case study: Siem Haffmans; The Netherlands.**

"It's a second hand material and here we tried to upgrade it to a fashionable top market product." (Haffmans. 2005)

Siem Haffmans is an industrial designer based in Amsterdam. After meeting people working with plastic recycling within the poor neighbourhoods of New Dehli in India, he began collaborating with Ellen Sillekaens, a design graduate, to design a bag for the European market made from recycled plastic bags.

"We made the brand Rag Bag to make it recognisable…. through this brand we also try to communicate the story behind it" (Haffmans. 2005)

Ragbags are fashionable products made from recycled plastic bags and sold in Europe. The production is handled by a women's cooperative in India who wash and clean the collected plastic bags, then press and make them into new products.

Thanks to the designers' involvement, the Rag Bag project has a direct social and economic impact on the local community creating jobs for about 50 people and giving rag pickers higher rates of pay for better quality plastic bags. This product highlights the global impact design can have on employment opportunities as well as helping to change the perception that recycled is lesser quality.

- # How the design process is evolving

  - ## Textiles case study: DesignTex + Steelcase, USA.

"We were trying not to have any compromises aesthetically in the product, we knew that there had been textiles like hemp or organic cotton… we wanted something that was sophisticated and was going to appeal across the board to all of our customers, not just the customers who were keyed into sustainability." (Derby 2006)

Larger businesses such as DesignTex, a subsidiary of Steelcase understand the importance of sustaining markets by working with the needs of their customers. Their size gives them the potential to collaborate with international experts, to become leaders in developing sustainable materials and ways to conserve virgin resources.
Their core business is supplying surface materials to commercial interiors.

They collaborated with Rohner Textil, a mill in Switzerland, looking for a way to dispose of their wool and ramie waste and Ciba Geigy, to develop non toxic dyes. McDonough Braungart Design Chemistry gave them the overview, checking material sourcing and production and developing ways to conserve petroleum, energy and water. The outcome of this early work was Climatex™ a mixture of wool and ramie whose manufacturing process reportedly leaves water cleaner after the process than before. By going on to mix wool with lenzing a type of viscose with an inherent flame retardant; they were able to produce Climatex lifeguard, a sustainable, biodegradable flame retardant fabric.

"Almost all of the panel fabrics that we create these days have recycled content". (Derby 2006)

DesignTex are now working to produce a Sustainable Textiles Standard to help the industry and the consumer evaluate and compare textiles. They understand that recycling is part of a wider view and are hoping to develop a material from the post-industrial waste plywood from Steelcase.

The Think Chair with 47% recycled content is a sophisticated mass produced product and a good example of the benefits of international collaboration.

3.2 Ceramic Case Study Gifu Prefecture, Japan

Fig. 2: Olivia Tableware 20-50% recycled ceramic clay. Manufactured by Gifu Prefectural Ceramics Research Institute, Japan By increasing the recycled content of the clay, the firing temperature could be reduced, which in turn reduces CO_2 emissions, saves energy and fuel costs.

"So everyday there are people from the northern to the southern end of Japan sending broken ceramics to our press. If it was aluminium cans or newspaper they would not send it this far. But ceramics is something people have a big attachment to; so they don't want to throw it away". (Hasegawa 2005)

In the late 16th century in Japan, unique techniques such as Shino Ware, Oribe and Kizeto were developed. This meant that ceramic pieces were fired at a high temperature and would not decompose in landfill. Today the ceramics industry is an important part of Japan's gross national product. They mass produce ceramics and have repeatedly dug, fired and disposed of the local ceramic clay.

The technology required to recycle ceramics has not been given much consideration in the UK. The Waste Resources Action Programme has viewed the market as minimal and left it alone. In Japan the view is different. The history of ceramics is built into their culture, something that they have a big attachment to. In order to sustain the industry; they have felt that it was important to introduce recycling technology.

"95% of people said that they would not mind buying recycled ceramics, as long as it was well designed and functioned well." (Hasegawa 2005)

To investigate the possibilities of reducing their environmental impact several manufacturing companies linked with a logistics company who began by talking to the end user. They discovered that people had no problem with using recycled ceramics as long as it was not from sanitary ware and was well designed.

Local industries collaborated with research institutes and scholars; working for the reduction of the environmental burden at all stages of a products lifecycle, not just the manufacturing and recycling. They wanted to shift peoples' values from material concerns to the human heart and hoped that the warm feeling of clay would help this to happen. They organised workshops where consumers could experience recycled clay at first hand, either by making musical instruments or through tea ceremonies where participants could make their own tea bowls. The project was so successful that in 1999 they started collecting waste and selling recycled ceramics.

As a result of their environmental concerns the industry discovered the following unexpected benefits of working both with designers and recycled clay:

- Ceramic products are only made from one material which makes them easier to recycle.
- Recycled tableware is as durable and heat resistant as newly produced ceramics.
- By increasing the recycled content of the clay, the firing temperature can be reduced, which in turn reduces CO_2 emissions, saves energy and fuel costs.
- The main CO_2 problem is caused by washing the dishes which the manufacturers cannot

control, but the designers have tried to make the texture of the ceramics such that it does not retain so much dirt and so uses less water to clean it.

They have now linked with an organic food producer, 'Radish Boy' who will collect ceramics for recycling when they deliver their food.It is interesting that this material driven, local and interdisciplinery collaboration has given an indication of future sustainable working methods.

- **The importance of education in understanding the value of materials**

Many of the interviewees participating in this research had links with education and felt that this was a vital part of their work. Using case studies to continue to look at different working practices, I would like to describe how designers have found ways to integrate their environmental concerns about material value within the educational process.

4.1 Glass case study: Maria Ruano, Bedrock Industries USA.

"We wanted a beautiful product that would appeal to people whether or not they cared if it was recycled". (Ruano. 2005)

I first met Maria in 1994 when she was just starting out, it was good to meet 10 years later and find out how she had developed such a successful business. She said that it took about three years, getting glass, getting it crushed, getting kilns made and then finally realising that it was going to work.

She describes herself as an activist, she was keen to produce tiles, but wanted the work to have more of a purpose; she wanted to use a waste product. In 1993 she started manufacturing 100% recycled glass tiles with a facility producing 35 / 40 tiles a day. The early business was sustained by diversifying into the gift market. For maximum efficiency the staff are all trained to do each other's jobs when necessary. Now they have the capacity to produce over 500 tiles a day.

Maria gives school children tours of her manufacturing facility and runs a 'Bottle Drive' to generate material. Bedrock pays 20 cents a pound for cleaned, label free bottles. Children have funded school trips by collecting bottles, which gives them a clear understanding of the potential value of these products that would previously have been thrown away. People on welfare can engage with this activity and make money without having to claim it. The working practices of this small company has a positive impact on the local community.

St. Christopher School, UK.

At St. Christopher School in Letchworth in the UK, each year the children are invited to design and produce garments around a particular theme entirely made from waste products. The resulting fashion show highlights innovation, making rubbish look stylish

and raises funds for charities of the childrens choice. Here the children gain direct experience of turning rubbish into an economic resource that can have a positive impact on other communities.

4.2 Plastic Case study: Richard Liddle, Cohda Design, UK.

Richard Liddle's research grew out of a concern for the amount of waste plastic packaging that he saw being thrown away and a frustration with working with conventional recycled plastic material, which was only available as flat board, when plastic can be moulded so easily into three dimensions.

In collaboration with Colin Williamson from Smile plastics, the Welding Institute in Cambridge and the Royal College of Art in London, Richard has developed a process to extrude recycled high density polyethylene (HDPE) at the point of waste collection, such as a supermarket car park. By recycling waste instantly, he hopes the process will raise awareness about the value of the material. His extrusions have the potential to take endless forms and will create a different aesthetic in furniture using recycled plastic.

His idea is that at the same time as shopping in a supermarket you can make yourself a chair from your waste. He also hopes to demonstrate the potential of this process in schools.

Fig. 3: RD4 Chair Recycled High Density Polyethylene Design by Richard Liddle of Cohda Design, UK. His Extrusions have the potential to take endless forms and create a very different aesthetic in furniture using recycled plastic.

4.3 Environmental Design, Case study: Professor Fumikazu Masuda, Open House, Japan.

"One day I was walking beside a beautiful river in Kyoto and found something just thrown away, just dumped by the river, this beautiful environment, I was upset and soon after I noticed that it was a washing machine I had designed a couple of years ago." (Masuda. 2005)

Professor Masuda says that he was so shocked by this experience that it compelled him to think more about the consequences of design. In the past traditional Japanese craftsmen knew everything about materials and he felt that it was essential for designers to go back to their understanding of materials. He spent three years developing this range of 'Sustain' stainless steel. A material which already has some recycled content, is long lasting and has a coloured surface which requires no additional application. When the steel is melted down again, the colour which is produced by an oxidised layer disappears.

A few years ago his company bought a rice field and twice a year he goes with his work force and students from Tokyo Zokei University to plant and harvest the rice which is then shared amongst them. This experience gives them an understanding of materials and the environment and how the land works so hard to sustain us.

4.4 The Banana Textiles Project, Tama Art University, Tokyo, Japan.

“Ecological design’ refers to a type of design that is developed based on traditional values and by learning from the lifestyle nurtured by our ancestors who lived in harmony with nature”. (Tama Art University. 2008. p18)

Finally I would like to describe a project at Tama Art University in Japan, that I saw earlier in the year when I was asked to participate in a public critique and seminar about the textile students work, developing product from waste banana fibre. This project describes a future way of working with waste in order to develop material and product that will in turn support communities.

Tama Art University believe that it is vital in the field of Art and Design to re-examine the relationship between people and nature, they understand that studying environmental issues must be part of the regular curriculum. Supported by the Ministry of Culture, Education, Sports, Science and Technology and the government of Haiti, the project was to consider the use of fibre from banana tree branches to design environmentally friendly products. The goal was to produce commercial products that would contribute to a more sustainable world as well as cross cultural communication through the introduction of specific design and technological information that could be used in developing countries.

The students learned at first hand from one of Japan’s living national treasures about the tradition of producing basho cloth (woven cloth made from banana branch fibre used for kimonos). This craft takes years to learn and starts with growing the actual banana tree. They also had specialist instruction on the extraction of the fibres and making paper. Their final designs exhibited earlier this year, included fabric, clothing and products which were beautiful, desirable, innovative and useful. The traditions of textile manufacturing techniques were evident but the concepts were based firmly in the 21st century.

“I feel that the number of people who really care about the environment is still very small. I was among those who didn’t care. However, I realise that one’s mind can be changed by learning and experiencing. To promote genuine environmental consciousness, we should provide people with opportunities for touching and feeling”. (Yoshimu Ohtsu. 2007. P18)

The educational environment is a good place to experiment with these ideas. Students can work with industry to test the significance of their design concepts, whilst educators can talk about cultural and material values. If designers understand their traditions and the value of craftsmanship, if they are open to interdisciplinery collaboration, innovative business can be developed from locally sourced materials that will continue to support communities.

5. Future directions for Creative Resource.

I am now updating the research project web site www.rematerialise.org This database was produced in 2001 giving free access to about 80 less resource hungry materials. We are now adding the new materials so that the architects and contractors involved in producing the temporary structures for the 2012 Olympics in London can access and use the information. I am hoping that the updated website will be live by the end of the

year.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design, local development and fair tourism

The EKIT project

François Dupont [1]

Abstract

Already quite widespread, tourism has entered an unprecedented phase of growth. Along with the intensification of tourist flows predicted by forecasts arises the issue of tourism's harmful effects upon indigenous populations. Hence the birth of "fair tourism," a practice enabling rural communities to accommodate foreigners and thus benefit from a complementary source of income. However, difficulties to adjust - affecting both the travellers and the local populations - hinder the progression of this new trend and prevent it from spreading out.

My project addresses health and intimacy issues that hamper the well-being of travellers, without shaking village habits too brutally nor imposing heavy infrastructures. It opens paves a way towards a progressive improvement of these conditions while being based on local resources and uses that each one can accept.[2]

[1] François Dupont, Student, l'Ecole de Design Nantes Atlantique (Nantes Atlantic School of Design), f.dupont@lecolededesign.com

1. Introduction

To complete my five-year course in product design, I decided to work on a final project related to fair tourism. I thought it up as a means to contribute to a more fair and sustainable development in developing countries. This personal will stems from a reflection I have been leading since my previous project which brought me to the Andes where I worked in collaboration with an anthropology foundation, and during which I had the opportunity to discover isolated communities some of whom are turning to specialized tourism.

Following a six-month stay in South America - in Bolivia - I indeed engaged in a deep thought process which led me to question the very bases and values of the massive consumption-grounded society we live in and to question my future job as a designer. I decided to choose a project theme that would allow me to keep on taking stock of this outstanding experience. A trip during which I found the key to priceless treasures in the economically poorest country of the South-American sub-continent planted the seed that would later grow into my new project. Thus the different topics derived from my main theme and the decision to study responsible travelling i.e. fair tourism - a notion based on an economic logic fostering support to economically challenged populations - came to me almost naturally.

2. Tourism : weight and stakes

Opening up to tourism by coming up to travellers' new expectations is a way for developing countries to become integrated into the world and to find their own voice. Attracting foreigners can also be a development factor in that it promotes the assets of the territory and the good qualities of its inhabitants. However, the increasing importance of this activity is but little known and its consequences remain largely unsuspected. To engage in a project related to tourism is thus a way of contributing indirectly to these improvements, taking both its positive and negative impacts into consideration.

The tourism-related tidal wave

Tourism has obtained impressive results bearing witness to its broad scope. After an outstanding boom that lasted all throughout the second half of the 20th century, it recently entered a new phase: far from slowing down, the growth of tourism is about to make an exceptional leap. Social crises, political conflicts, economic issues, nothing seems to be able to hinder the development of this already overwhelming sector that keeps increasing year after year, sometimes even exceeding the estimated results announced by world institutions.

Some indicators enable us to better evaluate the ignored but nevertheless spectacular situation of tourism. First of all, the benefits generated by tourism exceed (or equal) those generated by oil exports, foodstuff exports or by the car industry. Moreover the rise in tourism-induced benefits is higher than the growth of world economy. Finally the number of international arrivals (i.e. the number of travellers in a foreign country) is constantly increasing. From 25 million in 1950, they upped to 800 million in 2005[1]. Over the past three years, they increased by more than 20%. But the most significant example of the incredibly dynamic progression of the tourism industry lies in the forecast for 2020. Indeed, the World Tourism Organization predicts 1,6 billion international tourists per year by 2020.

Thus, tourism will double and soar up to the rank of most important industrial branch. This news, which paves the way to many development prospects while foreshadowing worrying consequences, lets us guess that we are about to witness a true tourism-related tidal wave !

A weapon against poverty

The dynamic nature of tourism represents a new economic opportunity for developing countries who invest more and more in this sector. Travel agencies keep proposing more and more trips to such destinations in order to meet the requirements of customers more and more eager to travel to developing countries. Today, some of the weakest economies are largely dependent on tourism-induced incomes, which bear witness to a real interest in this sector. Indeed, world organizations and local players are currently going on a crusade against poverty by waving the weapon of tourism. The priorities of the UNWTO are consistent with the United Nations' Millennium Development Goals defined for 2015[2], three of which undoubtedly involve tourism :

- objective 1 : "Eradicate extreme poverty and hunger"
- objective 7 : "Ensure environmental sustainability"
- objective 8 : "Develop a global partnership for development."

The fact that tourism requires a wide array of skills directly and indirectly entails the creation of many jobs, for example in the fields of hotel trade, construction or local arts and crafts. In rural zones plagued by the exodus of the young towards urban centres, tourism can be one of the main ways to cope with the disappearance of traditional economies. Thus it is an important factor of economic and sometimes human development, that many developing countries are determined to make use of.

Harmful effects

But tourism is a two-edged weapon. Indeed, worrying drawbacks give rise to particularly harmful sociological and environmental consequences.

First, despite the fact that developing countries receive more and more visitors, developed countries still benefit more from tourism-induced profits than developed countries do. Indeed, according to the UNWTO, between 1990 and 2005 there was a close to 12 % increase in market shares for international arrivals in developing countries. Tourism incomes increased by 76% in the Last Developed Countries while other countries record a 41% average growth in tourism-induced profits. However, Francoise El Alaoui, a French expert in tourism management, stated that at least 60% of this money returned to developed countries who now have total control over this sector[3]. Western agencies impose prices on players of the host regions. Between underpaid workers of the South who work in conditions sometimes very close to notorious exploitation and operators of the North who enjoy with impunity much more than them by benefiting from the resources of the developing countries, the gap is little by little widening. Thus the first report is a very strong inequality.

On the other hand, tourism generates serious instability issues. The arrival of foreigners in the most traditional environments tends to erase essential cultural features. This is one of the

instability factors addressed in our project. Considering foreigners' growing wish to visit rural areas, native populations propose excursions which still are often unsuited or stays which have an only partially controlled impact. Beyond material difficulties, the presence of accompanied tourists and independent travellers sometimes disrupts community harmony: though Western tourists do not harbour any evil intentions, native populations can sometimes be disturbed by inappropriate behaviours they are not familiar with. When completely different (or even antagonistic) cultures meet under such conditions, the damage done to the cultural heritage and the identities - undoubtedly the greatest richness of these people - lead local populations to a critical situation. But this loss can also be brought about in many other ways : More generally speaking, both folklorisation and deeply ingrained stereotypes reinforcing prejudices and letting wrong ideas seep into the tourists' fantasized vision of faraway cultures are other common factors in which this problem is rooted. Caricatured standards are then sold throughout the world as the setting of a play in which one can see predictable and predicted scenes enthralling clueless foreigners.

Moreover, the ever-growing number of environmental disasters such as the disappearance of animal and vegetal species, the disruption of ecosystems or the increase of natural resource consumption due to the flow of tourists is also an issue. This project also takes this point into consideration.

Finally, a great paradox could be observed: the expectations of both tourists and local populations become contradictory. The former, though eager to enjoy the most authentic (preserved) aspects of their host countries, have a hard time renouncing the material comfort typical of their own smooth way of life. Trips are thus often adapted to their Westerners' needs. Under the weight of their increasing number, they thus involve the destruction of the cultural shift they were looking for. As for the latter, they try to attract tourists in order to have a new means of subsistence but they mistrust these foreigners, whom they see as a real threat invading the lanes of their villages with their alien practices that natives generally don't anticipate and can't legitimately accept.

Thus, tourism paves the way to an inequality and an instability made obvious through economic and social consequences. Far from fighting against poverty, it contribute to its increase !

An ethical concern

For a few years now, all the players of the tourism industry have started to realize that only with a preliminary questioning of its traditional operation and its organization could tourism lead to a fruitful development through poverty reduction. Thus, following the example of fair trade, the sector tries to evolve towards more balanced and fair practices. Indeed, some speeches now integrate an ethical dimension and the actual shaping of tourist activities is seen in a more respectful light. On October 1st, 1999 the General Assembly of the World Tourism Organization held in Santiago, Chile, approved the Global Code of Ethics for Tourism[4], which defines guidelines to contribute as early as today to Millennium Development Goals. Many associations also follow this trend. In France, it is the case of UNAT (National Union of Tourism Associations[5]) which created the ATES : Association for a Fair and Responsible Tourism[6].

Vis-a-vis with the crushing weight of tourism, with a new phase of growth stronger and more durable of this sector, with the expressed objective to reduce poverty thanks to its development, with the threat of a critical increase in inequality and instability which clearly limit its effectiveness

by involving already for a long time contrary effects to those required, this new orientation based on ethical concerns is the first sign of some efforts aiming at establishing a fair and more sustainable tourism activity rooted in local development specific to regional territories.

3. Fair tourism

Under the impulse of some players, tourism has changed. Efforts to reduce negative consequences and to stimulate the positive effects of this sector have led to the development of a new economic strategy based on local development. Moreover, tourism is organized to respect an accurate value system and to meet the expectations of a new category of travellers, thus contributing to a fair and more sustainable internationalization.

Local development

Local development is also based on of sustainable development[7] principles and is focused on involvement by local players. It requires a collaboration process and the pooling of various competences and means. It makes use of specific and localised territorial resources, but regional populations use their own heritage often exploited by external powers which have more material, financial and political resources. In developing countries, local development thus restores the balance and reduces the colonial-like effect of a highly hierarchized development controlled by foreign players, that is the case of tourism such as it is currently organized.

Local development is an alternative trend against some capitalistic policies allowing only a happy few, to benefit from a country's riches. Thus, it offers lower class populations in developing countries a new source of income and also new possibilities of valorisation.

A value system

Fair tourism is driven by people gathering together to share and defend values such as exchange (between people), respect (of cultures and populations), responsibility (of travellers),

solidarity and equity. According to UNAT, fair tourism "centers travel upon human beings and encounters while taking part in a territorial development effort. The involvement of local populations in various phases of tourism-related projects, the respect of each individual, of cultures and of nature and a more equitable distribution of the resources produced are the foundations this kind of tourism is based on."

A different type of globalization

Fair tourism defenders are striving to give a real voice to economically challenged ethnic groups, excluded and left aside in the world of today, by refusing to be a part of their gradual disappearance in a society that brings down boundaries between peoples but unfortunately also harms them by disaggregating traditional native identities. Fair tourism tries to help local traditional cultural identities find their own voice on a worldwide scale. The aim of fair tourism is to avoid erasing and freezing endangered cultures so as to let them evolve. We must avoid both getting lost in the propaganda of a futurism ruling out "ancestrality" and taking refuge in a prostration for a past fixed for ever and ever.

This fair alternative tourism thus refutes as much single-cultural impoverishment as cultural inertia, and refuses both "ultra-internationalist" speeches and "anti-internationalist" ravings and rantings. It stands up for a real "alter-globalization" (an alternative for a different kind of globalization).

Fair travellers

In spite of information and accessibility issues, a new category of tourists was born and has already shown a real interest in recent proposals. Travellers who are aware of stakes or of some stakes hidden behind tourism exist, although they still represent a minority. Their interest is still quite significant: according to a survey conducted by French institute TNS-Sofrès[8], 72% of French travellers are interested in this new type of tourism. These new tourists rather define themselves as travellers[9]. That shows a desire to travel respecting a harmony they don't want to disturb (49% say that they want to travel in another way[10]). Experience is one of their most important expectations. The desire to travel differently is today expressed in a very straightforward manner. For a fair traveller, meeting traditional people and coming into direct contact with resourceless populations in developing countries is a way to fulfill their search for authenticity, that is to say for a preserved traditional way of life. A vast majority of associations familiar with the issue say they are interested in fair tourism, especially people already participating in human and social actions.

As an unprecedented boom in tourism is under way and as ethical awareness is rising in this field, travellers are growing more and more interested in the idea of an alternative to mass tourism. 93% of them declare they are ready to meet local populations so as to reach a better understanding of their culture and environment, to pay more for their trips with a view to contributing to local project funding, or to taking part in social action[11].

Some specialized agencies came to life and now propose specific offers. Tamadi[12], a Franco-Belgian association, organizes stays in rural zones in Mali and Madagascar. Their support was of great help in defining the EKIT concept.

The limits of fair tourism

Fair tourism is still limited due to the fact that numerous conditions are necessary to set up projects related to this concept. It is also strongly limited because there is no response to certain real persistent problems. The tremendous cultural gap between natives of isolated traditional communities and travellers remains one of the most significant issues. Lack of information hinders the prevention of involuntary behaviours which could confuse indigenous people and could be considered as unrespectful or even insulting. Moreover, fair tourists are sometimes confronted with the difficulty of adjusting to daily gestures and lifestyles sometimes too remote from ours, as in the case of stays organized in rural villages where health and intimacy issues have not been solved yet. Lack of compromise in certain daily uses which can neither be fully experienced by travellers nor be completely rejected, are a threat to the viability of fair tourism.

Notes :

7 : For more information about sustainable development, see Brundtland Report « Our Common Future », established in 1987 by the « World Commission on Environment and Development » and chaired by Gro Harlem Bruntland. The sustainable development definition is given at the beginning of the second chapter « Towards a sustainable development ».

4. The EKIT concept

Though it does not claim to solve all fair tourism-related problems, the EKIT project provides an answer to certain frequently encountered difficulties. EKIT stems from a design approach adapted to the particular context of developing countries and contributes to a more sustainable development for traditional rural communities willing to engage in harmless and beneficial tourism-oriented activities.

Currently, organizing fair stays in rural villages comes up against basic health and intimacy issues. Very often, solutions unfortunately in contradiction with fair tourism principles impose themselves, like architectures with heavy facilities in very traditional and isolated regions. We can notably consider the example of tourists who have rooms with showers with running and heated water. That represents a great contradiction regarding traditional native ways of life who wash in the river or with much more simple means. Moreover, for travellers, living here according to their western habits strongly limits the traditional life experience they were looking for. On the other hand, tour organizers such as Tamadi try to improve health conditions in residences so that villagers can host travellers in their homes ; a practice beneficial to both families and tourists. However, solving these issues is a gradual and lengthy process far from being completed yet.

Bought (or possibly manufactured) by local village associations, EKIT is a personal hygiene kit for travellers. This solution can be used anywhere in any type of environment because it doesn't have any architectural impact and because it is composed of common objects. EKIT is a compromise between two different cultures (that of the foreign tourists and that of local populations) and between limited means (as well material as financial) and minimum health and hygiene needs. Each family can borrow and use this kit when welcoming foreign travellers in their

house. Usually, only those whose dwellings have been transformed can host tourists. However, modifications are always reduced to a sum of small installations, like for example cemented grounds in spaces used to wash oneself, and are too expensive to be made in all houses. Moreover, generally, modifications are accepted only if they are minimal, that strongly limits these architectural solutions. With EKIT, host families can change according to periods, by taking turns in borrowing the kit and all villagers can thus benefit from the repercussions of the fair tourism organized in their community. Finally, avoiding creating too brutal a rupture with their customs, these objects can also be used by villagers : when the kit is well accepted, they can indeed adapt themselves. Each tool is also conceived in agreement with local cultures.

EKIT is thus presented as a pragmatic solution, which enables tourists to test conditions close to the native daily life. Each tool induces essential gestures and is easy to use. Moreover, EKIT fosters awareness and respect of the constraints related to water consumption. In areas where water is sometimes a rare and very precious resource, no waste can be tolerated. It thus enables us to keep track of the volumes consumed and spurs us to throw used water (which often stagnates in house yards or on the streets) far off residential areas. It is then used to water plants which produce an entirely natural soap, which then replaces that imported from the cities, coming in bottles the accumulation of which represents a serious ecological threat in isolated regions. Using natural soap enables one to re-use water to also cultivate vegetable species employed in a traditional way or by the pharmaceutical industry to produce specialized remedies and medicines. EKIT offers at the same time equity of a respect of host communities, better health conditions, a reduction of certain environmental issues and the stability of customs in harmony with a natural and culturally traditional environment.

The kit is composed of a small vat to wash oneself, of a graduated bucket to draw clean water, of a container to collect used water so as to throw it elsewhere or to re-use it, of two minimum water consumption sprinklers to wet and rinse oneself and feet between which a wire can be hanged to protect oneself from glances like behind a folding screen.

All the items of the EKIT solution are manufactured with local resources and techniques and made of a natural material : wood. So, this kit is affordable for rural communities who can gradually use more and more of these small personal hygiene devices so that in the end each family can benefit from this solution.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Sybaris

Fast good food

Fabien Vesseron[1]

Abstract

Sybaris is new kind of fastfood whose purpose is to help people to develop a sustainable behaviour toward food.

Inspired by modern habits about the way we eat and various regional events concerning traditional food. Sybaris is the result of a design approach which combine sociologic facts, a true development's will, uttered needs and existing technical solutions.

So as to build in everyone's daily routine with as few matters as possible, design has to step in and formulate a solution by cristallising through materials, links between people and mores to set a brand new conduct.

[1] Ecole de Design de Nantes Atlantique (FRANCE) – industrial design student, fab.ves@gmail.com

Introduction

Food issues take an important place in our contemporary World. They are related to all of the four components of Sustainable Development: economy (food markets, purchasing power), society (health, life style), environment (agricultural issues, wastefulness) and culture (traditions, rhythms). Regarding to food issues, the world is going wrong and this is true as well in the poorest as in the richest of the countries.
In Europe, we now know that the ongoing change in food practices is leading to problems: environmental problems, health problems, cultural and social negative changes. Design has taken part in this negative change by proposing attractive products whose effects are harmful. A special role in that matter is played by the fast foods. How can Design, who took part in creating this infatuation, reverse it now?
A solution could be in creating highly attractive places, proposing attractive services but avoiding every negative effect that exists currently in “traditional” fast food. Those places would highlight local and seasonal products through quality and pleasure among life's rituals.

Aims

Starting from this point came up the project named *Sybaris*. The name is from the world sybarite who defines someone who likes sophisticated and sensual pleasures, particularly about food.

The project *Sybaris* takes the shape of a space located in town centre, committed to tasting local recipes and/or buying natural local products in order to cook at home. Its specific designing proposes answers to five main issues of development:

Sustainable supply chains

Nowadays, we are used to eat products from all over the world and anytime of the year. We forgot seasons and don’t care about the distance the products crosses to reach the ladder. The effects of this behavior are disastrous for the environment and detrimental for the local economies. Most of the supermarkets and fast-food restaurants follow the trend by proposing the same products all over the year without regard to the environmental cost (Patrick MIGNARD, 2001[2]). While the customers seem ready to break their habits, hypermarkets and popular fast foods seems to ignore it.

How can design serve the new trend? *Sybaris* proposes to highlight a sustainable approach to supply.

Inspired from the french AMAP (a consumer order in advance a basket of chosen seasonal vegetables to the producer and take advantage of it whatever the picking is), the aim is to involve local producers in the project by signing in a charter who certifies responsible farming and sustainable supply. This way *Sybaris* ensures the consumer that the products are coming from the region, are cultivated in a responsible manner and also that the producer was properly compensated. All the specific needs of a restaurant will be provided by this actors, for the basic ones, *Sybaris* will work with suppliers like Metro cash and carry or Pomona for the grocery.

[2] Patrick MIGNARD, march 2001, in http://www.alter-france.net/article.php3?id_article=903

More than enjoying a famous regional meal made from fresh local products, the consumer will also have the possibility to buy fresh products from the first to the fifth range (natural state, ready to cook, etc.). Mostly the same products that will be used in the recipes proposed to the customers. So as the Slowfood movement promotes it.

Health considerations

People, especially 30 to 50 years old, now tend to realize how important is the relation between food and health (Credoc, 2005[3]). They ask for more transparency on what they buy (LSA n°1996, 2007, page 78[4]). In times of doubtful climate, food safety tends to be a primary consideration. The attention is special while considering children when consumer enquiry shows that it's hard for young generations to reckon fruits and vegetable as a pleasure. Last but not least, the weight problem tends to be worrying. The average percentage of obese reach about 14% of the adult population. Moreover, a report from the IOTF (International Obesity Task Force) in 2005 announced that obesity concerning children has increased from 5% to 18% in 25 years. It is mainly due to unstructured alimentary behaviors toward an overmuch offer. Inadequate food in inadequate quantity without enough sport, and with the modern plague named stress. *Sybaris* proposes to its guests, during the midday service, three different sizes of plates. By the way, he has to choose between a large plate, a medium and a small or three smalls. He may privilege the quantity or the diversity. Of course the size of the starters and dessert is related to the main course. Plate's size is calculate contingent to a certain glucidic portion that is required for an adult. The dinner service is no exception to the rule, but the difference is in the meals served. A lighter menu than in midday is put forward, as it is recommended by healthy measures.

Legacy's revival

cooking traditions are part of local identity… and one of globalization's first victims. For instance fast food is a global trend that ignores local recipes and products. Especially city dwellers are aware they're losing a part of identity by living far from the countryside which is closer to traditions (IPSOS insight, 2000[5]). Many dishes, vegetables and the way to cook them are forgotten and one of the consumer's wishes toward supermarkets is the ability to buy products of local producers (TNS-Sofres, 2007[6]). Furthermore, cooking as a "do it yourself" activity is more appreciated, various emergent television programs and their success witness it a lot. Sybaris offers two possibilities: the same menu composed by traditional recipes of a large selection of regions in every place or to focus on the very region specialties by proposing a deep immersion with very specific recipes.

The project involves the intervention of food designers and regional cooks in order to give a new aspect to traditional and local recipes using design approach on strategy. People such as Ferràn Adrià, the chemist Hervé This or the French chef Pierre Gagnaire are actually doing a whole

Opinion poll: Amongst you can find in it, what would make you come again in supermarkets?

questioning of traditional cooking by adding new techniques in their meal composition. The aim is not to copy such a work, but renew the old grandmother recipes in order to make it lighter, more contemporary.

Sustainable materials

The design's role is also to combine both modernity and tradition in a real furniture design knot. By the way the graphics of the restaurant is inspired from the old massive wooden table and bench, all-sharpened, with stone-appearing cliché of the old farms. The result is a soft, rounded furniture in MDF in order to decrease the environmental cost that a noble essence would have brought on. A Zebrano veneering covers this material in order to follow esthetics of wooden veines and give a natural aspect to the pieces. Instead of stone, Corian is used for every plane work surface due to its durability and efficient molding properties. The main graphic charter is inspired from wood, with dark and light browns, a butter cream yellow and a deep blue used to replace the traditional biological green. The utensils are designed in two different kinds, the first one is permanent, and sees glasses in true glass, stacking plates for each portion, and inox cutlery covered with a poplar essence grip. The throwable one is used for the takeaway and enjoys a glass in polylactic acid, which recycle better than a classic polyethylene, plates in sugar cane and cutlery in compressed corn, all new sustainable materials which satisfies to environmental norms DINCERT-CO and EN-13432 about biodegradable tableware.

Social changes

Our ways of life are deeply changing, especially eating habits. Today we spend from fifteen minutes eating to hours, depending on the time we have and the people we are eating with. Moreover we tend to be less regular in our meals (Credoc, 2006[7]). Based in this observation *Sybaris* is adapted to our new habits, combining two atmospheres: a first one close to the very principle of fast food. Somewhere you can eat quickly, depending on your hunger and the time allowed to your lunch, something good which will keep you full of energy until the end of day, and a second one unfolding in the evening and revealing a restaurant-like place, both proposing the same products. The designing of the space has to take into consideration those actual behaviors by adapting the furniture and the space. As it is said on the very beginning, *Sybaris* will take place in the heart of every region's main cities. It is dedicated to an active and quite young part of workers in search of an healthy place to eat quickly, and to have fun in the evening. But it is easy to extend the kind of customers to seniors and families.

By combining these themes, Sybaris wants to be the first national movement encouraging a healthy regional identity devoted to a global and responsible development through a fast-food chain competing with "traditional" fast foods.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Is design the answer to cultural acceptability of waterless toilets?

A collaborative approach to design research

Dena Fam [1]

Abstract

The adoption of waterless toilets could potentially reduce domestic water consumption in many western countries by approximately 20% (ABS, 2001) but this reduction, and the environmental gain it represents, is strongly dependant on the cultural acceptance of this technology by the end-user (and openness to the behavioural changes its operation would require). As Verbeek et al have noted, *"The environmental crisis is not only a technological problem, but a cultural problem as well" (Verbeek & Kockelkoren 1998)*, which suggests the need to redefine the role of the designer beyond the development of technical considerations and finite solutions to the facilitation of more systemic social change (Morelli 2007) where users and stakeholders are considered important collaborators in the design research and development process.

[1] Supervisors - Dr. Cynthia Mitchell, Dr. Juliet Willetts & Dr. Abby Lopes

Introduction

The traditional focus of design research has been product oriented, market driven and focused on finite technical solutions to problems. As Papanek has noted, design emerged as a profession in the early 20th century with the primary purpose of analysing, creating and developing products for mass production (Papanek 1984). So it is no surprise that one way design has responded to sustainability has been to 'commodify the environment' as seen by the proliferation of 'green products and technical solutions' on the market (Shove 2003). Consumer-oriented product design is centred around a narrow set of economic concerns and although it may be politically sensible to promote green consumption of products and services and 'green' ways of living, the question is whether consumer choice is the best way of encouraging behavioural change (Shove 2003).[2]

Behavioural change strategies are increasingly being linked to product marketing campaigns that do not require engagement which directly challenge a consumer's values about consumption. Rather 'green' behaviour is built into technology or products such as water efficient toilet cisterns, low flow shower heads and energy efficient light bulbs (Crompton 2008). The benefits of 'behaviour steering technology' is not being discounted here as a means of reducing resource consumption. As Jelsma has noted, technical devices have the potential to script and enforce the user in environmentally positive ways (Shove 2003). But the benefit of scripting behaviour through technology fails to engage users in the need for significantly reducing consumption[3] and the broader issues of sustainability required to cope with the emerging environmental crisis. Christensen has noted:

> *"…designs at the level of individual items or systems, however efficient they may be in various respects, do not add up to a sustainable whole." (Christensen 2005)*

There is evidence to suggest that any adequate approach for tackling environmental challenges, will require "engagement with the *values* that underlie the decisions we make and a sense of who we are" (Crompton 2008, p. 5), not just a reliance on technical efficiencies and green marketing strategies that bypass the need for significant behavioural change.

For significant behavioural change to occur there needs to be an alignment between *practices* of everyday living and the *values* that drive those practices[4]. Research into Self Determination Theory (SDT) conducted by Brown et al suggests the reasons why ecologically responsible behaviour is adopted is important for the behaviour to be maintained and pursued (Brown & Kasser 2005). For example, if an activity is adopted to uphold a set of *intrinsic* values, such as,

---

[2] This is not to suggest that 'green consumerism' should be discounted as a way of influencing front-end purchasing decisions but rather to suggest that perhaps it is the role of the designer to look at the broader system within which these purchasing decisions are made and the net effects they may have.

[3] Ecological footprint studies show that we need a significant improvement in how we utilise resources (as much as 90% less energy and materials - a Factor of Ten) to meet human needs equitably within our planet's carrying capacity. (Schmidt-Bleek 2008)

[4] It is important to note that there may be a combination of values or contradictory values occurring at the same time, for example the desire to save water but the enjoyment of having hot showers, therefore the user may buy AAA shower heads to save water but feel less conscious about having long showers – creating a rebound effect of overall increased consumption. The rebound effect in relation to technically efficient systems has been noted by Schmidt-Bleek (Schmidt-Bleek 2008)

University of Technology Sydney (Australia), Institute of Sustainable Futures, PhD candidate, Dena.M.Fam@student.uts.edu.au

personal growth, emotional intimacy or community involvement, the behaviour is more likely to be steadily adopted, as opposed to an activity pursued to uphold a set of *extrinsic* values, such as social recognition, financial success or material attainment (Brown & Kasser 2005, p. 351) This implies that introducing new technologies that require significant behaviour change, such as composting toilets, will be more readily adopted within specific social contexts where users' values dispose them to change everyday practices in the use of the technology. It is not the technology or cultural values alone which will influence behavioral change but rather a combination of the available technologies, values, existing habits as well as infrastructures that support the acceptance of a new technology (Knot & Luiten 2006).

Transitions in practice – A case study of composting toilets

The embedded habits of use associated with the water flushing toilet have been the generally accepted norm in many parts of the industrialised world for the last 100 years. This method of disposing of human waste raises serious environmental concerns not only of the amount of water used to flush and treat waste but also the amount of faecal sludge that is discharged without treatment into waterways.[5] Therefore the problems associated with water borne sanitation does not only relate to the amount of water used but also the amount of grey water contaminated by black water from the toilet. It is estimated that a person produces approximately 400-500L of urine and 50Kg of faeces per year and is flushed away with an estimated 15,000L (approx. 20% of domestic water consumption) of potable water before being combined with an additional 60,000L of grey water from the household. Therefore the relatively small amount of faeces and urine (550L/person/yr) is allowed to contaminate more than 75,000L of water per person per year (ABS 2001).

A critical factor to consider beyond the amount of water used is that considerable energy is required to remove faeces and urine from the water stream prior to disposal or reuse. Carbon and nutrients in faecel sludge are viewed by the existing paradigm as wastes and pollutants but are in fact resources that could be recovered and reused in agriculture.

Considering the expected rise in the global population[6] paired with the prediction that nearly half will face water shortages by mid century (UN-Habitat 2003) this resource intensive sanitation system seems an unsustainable option not only for industrialised nations but importantly also for developing countries where it is not affordable for the vast majority of people and does not offer an approach ensuring sustainable societal growth (Winbad & Simpson-Herbert 2004). Urban sanitary practices of industrialized countries have greatly influenced the aspirations of developing nations where the flush toilet is generally perceived as the most desirable form of sanitation. Therefore the demonstration and use of ecological sanitation in industrialized countries has the added benefit of raising the status of the technology in both contexts.

Ecological sanitation options such as 'composting toilets'[7] which function without water offers a way of potentially reusing the nutrients of human waste and are possible alternatives to the flush

[5] "In Europe, 79 major cities out of 542 are estimated to have full treatment of their sewage. For example, as late as 1998, Brussels—the political capital of the European Union—had no treatment whatsoever on 70% of its sewage prior to directing it into the waterways" (Rosenquist 2005, p. 335)

[6] There is an projected rise in the global population from 6.7billion to 9.2billion by mid century (UN-Habitat 2003)

[7] A composting toilet is a dry toilet that does not use water but rather composts the waste aerobically for up to 12 months before being sanitized, free of pathogens and safe enough to potentially be reused to fertilise soil.

University of Technology Sydney (Australia), Institute of Sustainable Futures, PhD candidate, Dena.M.Fam@student.uts.edu.au

toilet. But no matter how technically sustainable these systems may be, uptake depends on the acceptance by the intended user. Although waterless solutions are technically functional there is a gap between the current availability and the cultural acceptance of the technology in many western countries[8].

The general lack of acceptance and limited diffusion of the technology can be attributed to certain technical and institutional factors which has led to the path dependency of the existing system and the technology of the 'flush toilet' (Quitzau 2007). As defined by Rip and Kemp 'path dependencies refer to the interrelatedness of artifacts with other artifacts, infrastructure and routine' (Rip & Kemp 1998, p. 354), configurations of which make extreme changes in the direction of the technology complicated, thereby limiting alternative socio-technical developments (Rip & Kemp 1998; Shove 2003).

The historical development of waste water treatment in many industrialized countries has been a result of the co-evolution of infrastructure, technology and practices over the last century (Panebianco & Pahl-Wostl 2006). Technological development evolved as a way to deal with water pollution and subsequent outbreaks of diseases such as Cholera and Typhoid. The engineering solution to the problem originally perceived the social dimension as an external factor, however the technology is only the hardware and it is becoming increasingly obvious that the human element must be an integral part of any socio-technical transition (Panebianco & Pahl-Wostl 2006). As Shove has critically noted, the social dimension is neglected in transition literature which focuses rather on the technical system and infrastructures and as a result "sustainability is tacitly defined as a matter of resource management, efficiency and ecological modernization" (Shove 2007, p. 768). This focus neglects habits and practices of everyday living which involve consumer-citizens and transitions not only in technology but importantly also in practice (Shove 2007).

Emphasising a technological transition, underestimates the social environment in which the technology is used. For example, the 'flush toilet' is not an isolated artifact but part of a socio-technical landscape. It is made up of sewerage pipes, waste water treatment plants, water supply, extensive capital infrastructure investment, rules and regulations dictating health standards on treatment and cultural habits of use which have become embedded in western society over the last century. The combination of the artifact and the socio-technical landscape has been termed by Mumford as the 'megamachine' (Mumford 1961) which in the case of water borne sanitation has created an enormous physical barrier to change. In spite of this, the design of the flush toilet disposes it to be treated as an isolated artifact, supporting the cultural disconnection in relation to water use and waste production.

Therefore if design is to influence shifts in the socio-technical landscape towards more sustainable outcomes then considering how alternative technologies such as waterless toilets are *adopted and supported* is important for the transition to occur in practice. It is interesting to note that much of the research has been focused on how novel technologies are *introduced* rather than how they have been adopted (Rip & Kemp 1998). And importantly for the diffusion of alternative technologies, there is limited understanding about strategies for supporting and harnessing innovative niches that diverge from mainstream regimes and meet human needs in environmentally sustainable ways (Smith 2003). What is known about technological development is that technological change is inherently social (Rohracher 2006) so it would be logical for designers to consider how composting toilets are culturally accepted within a specific social context.

[8] This is not to suggest that acceptance of waterless toilets is purely a cultural phenomena, there are also technical issues and building constraints that may limit the feasibility of adoption in many areas. Eg. lack of space below the bathroom floor to install the composting chamber

University of Technology Sydney (Australia), Institute of Sustainable Futures, PhD candidate, Dena.M.Fam@student.uts.edu.au

The ‘Dry Flush’ project

Responding to the problem by designing the artifact alone disregards the well established practices associated with the ‘flush toilet’ and the configuration of artifacts, infrastructures and routines which have co-evolved over time to establish the existing paradigm of water borne sanitation. The adoption of alternative technologies that require a divergence from conventional practices is not just about *buying and installing* them but also about integrating them in *practice,* described by Lie and Sorenson as the *domestication process* (Lie & Sorenson 1996).

The ‘Dry Flush’ project, undergraduate research conducted by the author, was originally aimed at developing a design solution to issues of cultural acceptability of composting toilets within an urban Australian context. Rotaloo Australia,[9] a local manufacturer of composting toilet systems, was initially involved as an industry partner in the project where the aim was to redesign the hardware as a way of increasing cultural acceptability. The design of the toilet pedestal was user-centered and took into consideration the embedded habit of ‘flushing’ as a way of maintaining a sense of normality in use. A flushing mechanism was designed to flush ‘fine grade pine bark’ into the composting chamber as a way of adapting to the existing habits and contributing to dehydration of the collected waste[10].

The ‘Dry Flush’ project emphasised the importance of the *domestication process* which required a change from passive to active involvement in use and maintenance. Therefore the research project shifted from designing the finite solution of the artifact to the systemic solution of integrating the artifact into daily practice. This required a number of stakeholders being considered in the design research process. End-users, cleaners, maintenance staff, installers and the important part each of these stakeholders would play in the enduring effectivity of the design were considered.

With the understanding that technological change occurs in social contexts, there was a perceived need to locate a test-site for the technology. Therefore the Hazelbrook Steiner School was considered as a potential collaborator in the project. The Steiner School curriculum has an established philosophy of combining education and operational practices and has a strong commitment to environmental sustainability within the school community. They were open to the possibility of demonstrating the technology within the school and potentially offered a means by which the ‘social learning’ could occur in practice[11]. The aim was not only to design the artifact but to design the artifact’s entrance into everyday use. This was achieved by designing a template for a website which included information on how the toilet could be incorporated into everyday practice (See figure 1.)

[9] Environmental Equipment Australia is the manufacturer of Rotaloo composting toilets who became an industry partner of the author in developing the ‘Dry Flush’ toilet pedestal. www.rotaloo.com

[10] The addition of a certain amount of carbon based material such as woodchips is suggested to be added to the composting chamber and is commonly used as a way of balancing the carbon-nitrogen ratio and contributing to the dehydration of the pile.

[11] The author contacted the Hazelbrook Steiner school and the educational facilitator, Amanda Bonnie and discussed the dry flush toilet project and the school’s willingness to adopt composting toilets.

University of Technology Sydney (Australia), Institute of Sustainable Futures, PhD candidate, Dena.M.Fam@student.uts.edu.au

Figure 1. Template for potential children's website

The potential website was designed specifically for the context of the Steiner School in a form that would engage school children in learning about:

- how the toilet worked
- what happened to the waste
- where the waste can be used
- how the toilet should be cleaned and why
- what maintenance issues are involved

Importantly the website aimed to present global test sites of ecological sanitation where users had the opportunity to learn about current projects being installed and implemented in various parts of the world, encouraging the normalisation of alternative sanitary practices.

But the domestication process is not only about the practical work through which the artifact is integrated into practice. From a socio-cultural perspective there is also a need to transform the cultural categories that give meaning to the technology – this could be viewed as the *symbolic work* required in the transition. As Horan has noted through her documentation in the social history of the 'toilet', comfort has replaced utility and expanse has replaced brevity. Over time the toilet has transformed from a chamber pot under the bed to a closet behind closed doors to the current transformation in the 21st century where the toilet is now situated in a bathroom which

University of Technology Sydney (Australia), Institute of Sustainable Futures, PhD candidate, Dena.M.Fam@student.uts.edu.au

has become a site for spacious relaxation (Horan 1996). In less than two generations, many industrialized countries have come to take the convenience and comfort of the modern bathroom for granted, unaware of the inconspicuous use of water and the inconspicuous production of waste (Shove 2003). Therefore the design of the website not only served the purpose of social learning but also contributed to transforming the cultural understanding of sanitation from the conventional view as a means to dispose of waste to a means of 'closing the loop' and recycling nutrients.

Reflections

Although the importance of sustainability is becoming a commonly accepted view within our culture, what are lacking are the practices to make sustainability a reality. Design's historical tendency has been to focus on developing technical efficiencies in line with existing conventions but there is also the potential for design to facilitate new practices and routines of everyday living in line with environmental sustainability. This suggests a shift from design's finite approach of a product/system solution to sustainability to considering how the introduction of alternative technologies interacts with conventions and everyday practice.

The diffusion of the 'flush toilet' has brought with it standardized routines and practices. This has created a situation where the adoption of waterless toilets will require significant behavioural change, from passive to active involvement in use and management. The diffusion of waterless toilets must overcome many obstacles related to path dependency, which are characterized both at the systemic level and the level of daily practice. Users and stakeholders need to be included in the collaborative design process not only in relation to the development of the technology but also in developing operative strategies for adopting the technology.

This socio-technical transition requires a certain amount of 'social learning' in adoption of alternative sanitation. Therefore the potential for enabling social responsibility for managing human waste is far greater within the environment of a community with intrinsic values about the technology, such as an educational institution like the Steiner School, than being imposed on communities that do not value the technology or see the need for a change in sanitary practices.

Diffusion of Innovation theory would define the Steiner School as 'early adopters' as they are clearly a minority of the population potentially willing to adopt the technology (Rodgers 2003). The social system of the Steiner school is where the process of diffusion takes place by which the innovation is communicated among its members. The school community has common values about environmental sustainability. They have vegetable gardens educating students on principles of permaculture and recycle all their organic waste on site. The potential adoption of waterless toilets is compatible with their commonly held beliefs about sustainability; therefore there is a greater potential for an alignment of *values* and *practices*. Rogers defines compatibility as one of the four factors that effect the rate of adoption of innovation within society, (compatibility complexity, trialability and observability) (Rodgers 2003).

For much of the wider community the relative advantage of waterless toilets is difficult to perceive especially in many western countries such as Australia, where the environmental impact is inconspicuous and the convenience of the 'flush toilet' is deeply embedded in habits of use. The slow rate of adoption of technologies would categorise waterless toilets as a *preventative innovation* (Rodgers 2003) as the comparative advantage is difficult to appreciate for users. For example, the benefits of water savings and waste reduction of a waterless toilet are not obviously

University of Technology Sydney (Australia), Institute of Sustainable Futures, PhD candidate, Dena.M.Fam@student.uts.edu.au

apparent as the user is disconnected from the environmental impacts of the conventional system.

The adoption of new technologies and development of practices is a social process and as Rip and Kemp noted:

> *"Individual behaviour, organizations and society have to rearrange themselves to adopt and adapt to innovation. In this sense the introduction of a new technology is an unstructured social experiment"* (Rip & Kemp 1998, p. 346).

Design's potential in creating systemic change lies in its ability to enable the *social experiment* and encourage behavioural change beyond the limitations of a market driven technical product. In the case of the 'Dry Flush' project this meant considering the specific context for the introduction and demonstration of the technology as well as how design could contribute to the social learning process.

Conclusion

> *"Technology is not an external driver of societal change"(Rip & Kemp 1998, p. 335).*

This paper has aimed to highlight that technological change occurs within specific social contexts, where technology, society and everyday practices have co-evolved to shape conventional use of a technology. Therefore if design is to contribute to sustainability beyond the realm of technical efficiency, it must take into consideration how alternative technologies are adopted and supported and this requires an understanding of the socio-technical landscape in which the artifact is being introduced. In the case of the introduction of technologies such as waterless toilets which require significant behavioural change, this will no doubt require close engagement with not only the end-user but a broad range of stakeholders in the design research process.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Design tools for sustainable lifestyle:

the Italian co-housing experience

Roberta Conditi[1] Giordana Ferri[2]

Abstract

This paper presents a specific approach to service design based on social innovations in urban contexts. Within these social innovations the focus is on creative communities, which are "groups of innovative citizens organising themselves to solve a problem or to open new possibilities, and doing so as a positive step in the social learning process towards social and environmental sustainability"3. From the signals emitted by social innovations and from the analysis of creative communities, it is possible to reinforce these new lifestyles through service design.

Our research focused on one such creative community: Co-housing. Analysing this phenomenon raised the question of how design could help the development and organisation of these communities. The aim of this paper is to present some designing solutions to facilitate and replicate the creation of these co-housing communities whilst maintaining the quality inherent to the original innovations.

1.Co-housing - A working definition

Co-housing, a residential community with shared services and facilities, first appeared in Denmark during the sixties and is widely found today especially in Sweden, Holland, England, the United States, Canada and Japan. It is essentially a combination of private dwellings, each with its own intimacy and autonomy, with the advantage of shared facilities such as micro-nurseries, DIY workshops, laundries, guest accommodation, vegetable gardens, gardens and so on, which offer social, environmental and economic benefits to the community.

Each settlement typically consists of 25 to 40 dwellings where families and single people decide to live together, after a long process of participatory planning. In addition to being part of the building process, the shared planning stage is necessary in designing a “neighbourhood community”: before individual physical space is planned, the communal space must be designed and “filled” with the shared facilities chosen by the community itself.

There are essentially two motivations that steer people towards this new form of neighbourhood: the desire to socialise in neighbourly relationships, while at the same time reducing the complexity, and consequently stress and fatigue, of managing everyday activities.

2.General characteristics

The architectural structure of existing residential buildings, organised into day space: kitchen-dining-living room and night space: bedrooms and bathrooms, is geared to the old family model (father and mother with two children) and is no longer able to satisfy a series of needs/requirements that have changed because families have changed. The basic structure of the nuclear family has altered over the years: the number of single people is growing, couples with children are on the decrease, children stay inside the nuclear family longer and the number of multi-nuclear families (i.e. families formed after the break-up a previous marriage) is increasing. Along with this change in family structure, there have also been changes in the activities of individuals and the way residential buildings are used and, consequently, what people require of the place where they live.

Physical space undeniably influences people’s relationships, so these will differ in a tower building from those in a linear structure, in a terrace and so on. We have seen that Co-housing projects prefer low rise units facing onto an internal driveway, to facilitate relationships between neighbours. A typical Co-housing community has an external parking area, enabling inhabitants to meet their neighbours on their way home. Space is planned so as to multiply opportunities for meeting and developing neighbourly relationships.

Activities

Activities that can take place in a Co-housing community are essentially linked to the shared spaces, or are not carried out in any particular space, but always imply a more or less close relationship between people. They are therefore convivial activities (eating, having fun, opening the Co-housing community to the wider neighbourhood) or organisational activities (useful or necessary activities, general management, working, transport) caring activities (looking after children, animals and other people through little everyday jobs and errands) and leisure activities (hobbies, sports, physical and mental well-being and looking after green areas).

The Spaces

In Co-housing there is, at an architectural level a good balance between private spaces and shared spaces. There is no predefined architectural typology, even if there is a prevalence of settlements made up of private houses, which face onto little internal pathways that give easy access to a communal building which houses all shared services.

This typology however is not always possible because it is not easy to find the land in urban contexts or near the city. This is particularly true if one takes into consideration the reality of a metropolis like Milan, where it is more common to find ex-industrial buildings and areas to reconvert into private housing. In such cases it is of fundamental importance that the professionals and the future inhabitants work together to design spaces that promote and facilitate neighbourly interaction.

Shared spaces not only favour a division of space that fosters social interaction, therefore allowing and encouraging people to carry out activities they could not normally do at home, but make it possible to put the spaces themselves to greater use so as to assign other uses to individual spaces or, even better, to reduce them in size.

In general shared spaces take up 15-20% of the total area. Studies carried out on European and American *Co-housing* relieved that shared spaces have different priorities depending on the use that will be made of them, for example a multifunctional room where the whole community can meet has greater priority than a music room, where lovers of music can meet.

In a typical Co-housing project shared spaces are a communal kitchen, a multifunctional room, a living room, a children's room, a pantry, a guest room, a laundry room, a DIY workshop, an office area, a music room, a storeroom, a shopping area, a garden and vegetable patch, a gym and a room for relaxing.

3.Co-housing.it

In its research activity on innovation in housing, the DIS (Design for Sustainability) research group of the Politecnico di Milano decided to go on an informative exploration of co-housing in the area where it has experienced the greatest growth and development, the West Coast of the United States.

The most important aspects that emerged from this reconnaissance visit are listed below:

- Co-housing is growing rapidly as a new housing requirement particularly in the greater urban and suburban areas.
- Co-housing settlements are stable and generally well managed; the participants are satisfied on a relational level as well as on an economic level thanks to the economic advantages of sharing spaces and services.
- The process that leads to the birth of co-housing settlements is voluntary (group lead), uncertain (many initiatives are started but are not concluded due to a lack of the necessary competence to manage a real estate project) and very long (6/8 years are needed to move in).

These considerations lead the Politecnico di Milano together with Innosense (an angencey for social innovation) to the decision to start research into the predisposition towards co-housing in Milan and Italy.

On November 14, 2005 a opinon poll was launched to explore two relatively unknown dimensions of our daily life and our fancy: living in the city of Milan and the predisposition to

adopting a lifestyle more focussed on sharing. The initiative was sustained by Confcooperative - Federabitazione, ANCE and IKEA and over 20 associations (cultural, professional and of interest).

From the 16th November to 8th December more than 3,600 Milanese replied to a series of questions on feelings, experiences and proposal of those who live in Milan. The wide scale research (30,000 email addresses from over 20 partner associations) produced 2,800 displays of interest in co-housing from the 3,600 questionnaires completed and returned in 15 days. The socio-cultural profiling questions, created by GPF associates, allowed us to position the co-housing market in the “modernita sociale” quadrant and to size it, through successive extrapolation, to at least 20,000 families in Milan and 250,000 in Italy. The demand for co-housing mostly came from the metropolitan and urban environment (where the concept of neighbourhood has been lost), from young, double-income couples with a high level of education and from younger strata of the aging population (willing to completely rethink their life in far away places but of high environmental quality).

The profile of the interviewees was crucial to understanding how living in a city like Milan has come to be seen less as an opportunity and more as a synonym of isolation and organizational difficulty for families. 19.2% of the interviewees were between the ages of 25 and 29, 20% between 30 and 34, 15.5% between 35 and 39 and 11.9% between 40 and 44. In this age range more that 70% live in rented housing, for many not out of choice but because of the increasing costs of the housing market. The results of the study (elaborated by GPF associates) have demonstrated that:

- A quarter of Milanese suffer from social solitude and at least 20,000 families are willing to consider co-residence (Co-housing)

- Milan is a city of opportunity, it is much loved and its citizens do not wish to leave it: 43% of the sample is happy to live in this city and 80% is substantially satisfied with their home (even of it’s rented). They identify strongly with their homes, but for 60% of the sample home is an open place not a shelter.

- Of the 3,600 Milanese that replied to the questionnaire 90% denounced the loss of the community and of neighbourly relationships and therefore aspire to a life where strong social values (friendship, reciprocity, sharing…) permeate.

- 40% of the sample has never met their next-door neighbours, but 75% would like to offer help and receive help from their neighbourhood. Almost 50% of respondents would like to live in a real neighbourhood, with a baker, a butcher, a main square and history or at least in an area full of people and events.

- 2,800 families and people declared that they where interested in co-housing. At the top of their co-residence “wish list” were all those services that help one feel better and that help to guarantee a balanced life: a swimming pool, a greenhouse\ vegetable garden, a communal library and a micro nursery school.

In January 2006 two meetings were organised to present the results of this opinion poll on the topic of shared housing to the citizens of Milan and to celebrate the birth of this project with the first “co-housing party”, a shared and participated way to celebrate that was in line with the values that form the basis of the project.

The considerable and reassuring results of this motivational and market study lead to the development of the idea that gave birth to Co-housing Ventures and Co-housing.it. With the creation of a specialized division (Co-housing Ventures), Innosense decided –in the first quarter of 2006- to promote co-housing in Italy by experimenting a unique business model based on the offer of highly specialized professional services and value added that would favour a meeting between a well organized demand (in a national community) and an offer focussed on developing and designing a co-housing project.

The collaboration between the Politecnico di Milano and Co-housing Ventures managed to find a solution to the three great problems inherent in this type of project.

The first, concerning the formation of interest groups around a Co-housing project, was solved thanks to the creation of the community co-housing.it. The idea behind the project is that the internet will be the best tool for finding the critical mass of people interested in each project.

Co-housing.it aims to be:

- a centre for collecting co-housing related information and experience through its website, newsletter and study journeys throughout the world;
- an aggregation tool that facilitates the creation of groups of people interested in co-residence and their meeting with the estate developers able to build such villages;
- a display window for the various proposals and opportunities for creating co-residential villages;
- a point of reference for the creation of professional networks (architects, urban planners, social facilitators…) able to contribute to the creation of new communities.

The second issue concerns the identification of suitable areas for creating co-housing communities in areas that are promising from a city planning angle, undergoing significant transformation and regeneration, well-served and linked to the main city.

Co-housing Ventures, part of Innosense Partnership, offers professional assistance to members of co-housing.it who have already formed a co-residence group of at least 10 families living or wishing to live in the same area. Services offered (at the best market conditions) include:

- finding a suitable area,
- compatibility checks on an area or building for restoration,
- looking for other project participants,
- community development support,
- preliminary and executive participatory planning,
- legal assistance in setting up the co-operative venture,
- fixing terms with builders,
- presenting plans to Local Councils.

The third and final problem area concerns the process of residential community development, i.e. organising demand. This is the most important task of the Foundation and in practice a question of managing an assisted, facilitated process lasting 6-9 months, by which a group of people and families builds up their own co-housing vision and project (how to live in co-housing, what to share, how to manage shared services and so on).

4. How does design relate to this?

Let’s stop for a moment and reflect on a classic definition of design: Peter Behrens for example defines design as a discipline that puts in place a “rearranging of the visible” and controls a process which takes into consideration aesthetic, usage and functional values to favour a wider exploitation of the product. Although this definition may be bound to a specific historical

period it contains the fundamental concept of design - **reproducibility**, **shape**, **performance** and **diffusion** - which are still valid today.

There is another aspect that accompanies the design project that is included in this definition: when the designer thinks of a new object he thinks about a family of objects and these represent a set of actions which outline a concept of day-to-day life, this concept then suggests a lifestyle.

And this is the point; the designer's horizon is not only the object itself but the lifestyle project that it represents.

Let's now turn to the aim of our research; the designing of services for a co-housing community and relate what we do to the definition set out above.

Surely, our object is to make it possible to **reproduce** an experience (co-housing), which currently happens spontaneously and occasionally. To try to put together the instruments which will allow us to spread and reinterpret the models that emerge, and the consequent living concept. Our work aims to design new services or reinterpret existing ones, in other words **to shape** that which initially was only an intuition. Our activity tries to capture innovation and the possibilities inherent in reality, to develop and optimise their **performance** in their sphere of usage. It is nothing more than what was traditionally done by a designer: performance and shape. Finally it can be said that the social development at the base of the project, which leads to a collective sharing of the results, contributes to the **diffusion** of a lifestyle.

Design has always worked on lifestyles, on anticipating and picturing new lifestyle and it still does this today but the horizons within which it moves have become wider and also embrace the design of relational systems.

This does not mean that there is no novelty; on the contrary, this correspondence shows us that one fundamental thing has changed: the reality that surrounds us. The design of systems finds its reason for being in the shift of society from products to services.

5. Designing co-housing: the group

The shared plan, outcome of twenty or so meetings, on-site inspections and actual co-designing workshops, covers all the characteristics and requirements of a residential co-housing village:

- the layout of dwellings and spaces (with a special eye to green areas and shared facilities),
- service and property management modes,
- the standard of building and quality of materials,
- ecological building and sustainability aspects,
- overall set up and management costs.

Only on completion of the preliminary shared plans do the families and individuals sharing the project jointly commit themselves financially to realising the building project. This will be completed over the following couple of years, either directly or in partnership with the property developer who offered the area and will oversee the building work.

To undertake this task the Fondazione Co-housing Italia (Italian co-housing foundation) uses specialised social facilitators, service designers, and specialist consultants in engineering management, finance and property rights. The Foundation calls on professional collaboration

from Co-housing Ventures for the initial architectural planning of shared spaces and for project management.

The first all-Italian adventure in Co-housing is called “Urban Village Bovisa 01”: just a few steps from the Politecnico di Milano, in an ex factory, a community of around 30 dwellings is being developed with 700 sm. of shared space to plan.

The residential community building process started on 17th June 2006, bringing together all the families and people interested in the project. A large space in the heart of the Bovisa neighbourhood, the Scighera, was chosen as the meeting place for participatory planning: a place for socialising, relationship building and cultural production. Here, the would be co-housers initially got together and began reflecting on the cultural aspects of living together.

The participatory process is co-ordinated by a project manager and run by social facilitators who show participants how to reach a consensus in decision making. Its main purpose is to involve those interested in building a shared vision of the community, and help create a group identity based on shared values. Process participants initially came together around a discussion table, using interaction techniques such as brainstorming and workshop sessions.

At the warm-up stage a representative group method was used as it is useful in building shared community values.

A two day workshop was planned for the following meeting, with the aim of reaching a shared idea of the future living scenario. During the workshop the co-housers identified the activities they wish to share and how these could be located in the communal spaces in Bovisa, giving some idea of how the community wants to use this space. During this phase, participants used one of the tools created by the group of service designers to facilitate the users’ choice of activities: activity cards. These consist of a pack of 65 cards, divided into 4 macro areas (conviviality, take care, organisation, time for…) and 15 categories (let’s eat, leisure, open the co-housing to the external, courses and culture, children, animals, building neighbourliness, useful and necessary, management, work, mobility, hobbies, sport, well-being, green space), where the poetic nature of the communication appears. The graphics of these “playing cards” were thought up to highlight people’s actions and gestures: by only lightly sketching places we wanted to take actions out of their physical context, giving them greater importance and enabling people to sketch the physical location in their own minds. It was interesting to observe how the “activity cards” spurred all the community members to discuss and express concrete preferences.

Fig. 1: the use of the activity cards

The final meeting of the first stage was a technical meeting where the architectural planners were invited to answer queries.

The group building process is basically divided into two stages: the “visioning” stage that we have just been talking about, and the planning stage, which is yet to come. The first part of the facilitation project has in fact just finished: families have financially committed themselves and have enrolled in the co-designing stage. This includes site planning, shared service and facility design and the planning of private spaces, and consequently the definitive building offer and the contract of co-operative association.

Teamwork was fundamental for a good start to “Urban Village Bovisa 01”. The role of the designer was also fundamental in the approach to this new project, not only for the design of some instruments or tools but also in setting out the guidelines and overseeing the whole process. Both the process and the instruments were tested out by the designers within working groups during a series of preliminary meeting held at the Politecnico di Milano. In these meetings the effectiveness of all the tools (from the classic “post its” to the more original “activit cards”) that would be used as well as the linearity of the process were assessed so as to decide on the methodology to administer them with the end-users.

For example, we initially intended to leave a pack of “activity cards” with each nuclear family so that the co-housers would have time to weigh up all 65 possible activities. This possibility was then discarded because we realised it was important to get people talking about the idea of sharing, to express concrete preferences and discuss them together in order to reach a shared decision.

The “activity cards”, like the other working and visualisation tools, are part of a “toolkit” created by designers to facilitate dialogue between users, and between users and professional planners. It is a set of organisational support tools that leave people free to express themselves, along with the task of planning part of project together.

Since we do not study subjects/ materials but problems and problems can range through the confines of any subject\subject or discipline, to design a “toolkit” for co-housing we looked into the techniques and tools, which are normally used in shared planning processes, with the intuition that a kit could help to make the first Co-housing training experience easier.

The activity cards help the group to focus on the common objectives but are above all tools that will help us during the planning stage to visualise the first shared scenarios.

6. The design of co-housing: designing services

Our experience in the design of services for co-housing communities was based on a simple and straightforward methodology, which basically aimed at bringing out experimental ideas from either the explicit requirements or the unexpressed needs of the cohousers.

Which requirements were brought to our attention? Here are some examples from the Bovina experience:

- We would like to save some money by setting up a system of shared shopping of goods and tools for the maintenance of our houses, bikes and scooters.
- We don’t want to hire a porter; instead we would like to put in place a virtual “smart porter” as a reference point to communicate and exchange information amongst us. We would also like to organize common dinners.
- We’d like it to be a place where we can meet to celebrate birthdays, to spend an evening together, to watch films; we’d like it to be a place to invite and meet friends and relatives, where children can play; where we can share our skills and knowledge, exchange readings and musical tastes. We want our living room to be multifunctional and large enough to cook, have meals together, celebrate, meet up, watch films and have a chat in freedom.

Taking this as a staring point we now “read” the requirements that came out - some evident and many others less so or even hidden. We especially focus on the actions which are implicit in the needs (e.g. eating, caring): we look into their complexity to outline possible solutions to the problems which could arise.

We divided the co-housing services into three distinct types, each corresponding to a different design level, and we used them as our main investigation tool. The three types are:

Community services: these are services, which come about in a communal space in which they find their main reason of being. They primarily satisfy the need to be together and on a secondary level the need to make daily actions efficient.

System services: these are all the services that organise resources, human and material, according to a specific objective. They presuppose a shared desire to optimize time and running costs. Unlike what happens with the community services, the management aspect is contemplated in the design stage. Some examples would be a doorman and shared babysitting.

Instrumental services: these contemplate shared choices and duties but do not require any specific rational involvement (laundry room, tools, car sharing).

In general, the two plans that emerge are: the putting in act of the service idea within a space (architectural design) and the formalisation of a service within a process (organisation and management).

This division is used to cross at different levels (the typologies of service) various problematic areas (in other words, the design questions) picturing the scenarios in which the final choices will operate. Lets look at this in more detail with an example:

EATING (I do not have time to do the shopping, I eat badly because I rush my cooking, I eat alone, I'd like to have a vegetable garden but I can't afford it)	Community Services (space and management)	System Services (managment)	Instrumental Services (maintanence and control)
BUYING FOOD 	☐ Communal pantry, in other words there will be a supply of basic products to be shared	☐ Group buying or local exchange community	☐ Electrical appliances such a freezers, cellar for wine and cold cuts, storerooms etc.
PREPARING FOOD 	☐ Communal kitchen	☐ Having a shared cook, taking turns cooking, cooking lessons	☐ A brick oven, a slicer, a grill, a big oven, a kitchen robot, domestic mills etc.
EATING FOOD 	☐ Communal dinning room		
PRODUCING FOOD 	☐ Vegetable garden	☐ Buying directly from the producer with involvement in the cultivation	

As can be seen from the table, a primary action (eating) can be divided into different activities, which, once crossed with the typologies of services that we have identified, produce different scenarios.

Lets consider a request made by the co-housers: “We would like to save some money by setting up a system of shared shopping of goods”. This could mean getting organized communally to buy food (thus saving time and money) but it could also mean having a communal pantry from which to draw on daily (thus reducing waste and time spent on buying supplies). To these two different actions correspond two different solutions: in the first case it is necessary to provide a common space for the conservation of food; in the second case this is not necessary; in both cases it is necessary to plan the management of the process.

Another request: “We want our living room to be multifunctional and large enough to cook, have meals together, celebrate, meet up, watch films and have a chat”. This request opens up several scenarios, quite different one from the other: from the idea to have a common kitchen to use periodically and where turns are taken in cooking for everyone to having common dinning room where everyone can eat together what they have prepared individually, to having a cook at the communities disposal who could also be a member of the community.

These possibilities of sharing open up to different design solutions depending on the degree and frequency of the sharing: for example it might be decided that there will be very minimal individual kitchens and aim at making the common kitchen a place where it is possible to prepare more complex meals thus keeping in line with the co-housing ideal which is that of optimizing resources both human and material. The role of the designer is crucial here because he is able to interpret the requests experimenting unique solutions to the use of daily space.

Once identified and chosen the principal scenarios are **simulated** mostly to bring out any differing views among the co-housers and to anticipate possible problems or changes of opinions in the light of experience.

In Bovisa the simulation was a fun and important moment where participants “enacted” the daily actions imagining they where in the spaces set out for them. The co-housers divided into four groups and simulated the use of the laundry room, kitchen, garden and living room. In 20 minutes each group wrote a script and acted it out. The representation brought out many themes connected to the specific space and to the desires of each member, from these discussions it was possible to obtain design indications and points of view that had never come up before.

This experiment lead to considerable in-depth examination of the scenarios and their complexity; from this a detailed design began to take shape.

The simulation, carried out as an experiment for the moment, represents for us an interesting perspective to elaborate on for the design of services that involve a community.

Fig. 2: the simulation - project “Urban Village Bovisa 01”

7. Conclusions

If the transformation of the prevailing living model, which took place at the beginning of the century, was the result of technical-scientific research which then became common heritage, here on the contrary it is social innovation that poses challenges that must still be met.

The contents of co-housing still do not have a corresponding form, which is equally innovative and capable of receiving it: social innovation has not been taken into technical and scientific thought, which is only now beginning to question the problem.

The co-housing experimented until now do not have their own formal nature but are a more ore less creative collage of housing types already experimented and of tools thought for traditional living. This could be a fertile ground for experimenting aimed at developing new housing models

What would be interesting would be to manage to pick up all the suggestions from co-housing and ideas for a general transformation of housing, in other words interpreting co-housing, notwithstanding the specific choice of living together, as a “symptom” of a common feeling in formation, like the nucleus of a significant change in the way we live and consume. Who wouldn’t want, for example in their own building, a common tool shed or a virtual “smart porter” capable of using the information and skills of all the tenants, and maybe even managed online?

For these reasons co-housing represents for us a laboratory to fine-tune shapes and processes, which to different extents may matter in our everyday to come.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Creative Places for Collaborative Cities

Proposal for the "Progetto Habitat e Cultura" in Milan

Teresa Franqueira[1]

Abstract

This paper presents a proposal for a pilot project in an old milk factory in Milan, which is part of an ongoing PhD research that aims to develop a solution to enhance the growth and development of creative places for a new urban everyday life. Places where groups of people collaboratively promote and manage a mix of creative initiatives in the fields of art and culture, economy and production, social services and urban regeneration.

This places help to shape a different city. A Collaborative City, that is, a city with kernels of creativity, where people interact and enact creating a symbiosis of activities that promote sustainable lifestyles, an active citizenship, social inclusion, cultural diversity and new economic models.

It is a city where hierarchies are transversal instead of vertical, i.e, where local authorities (urban leaders) create opportunities for mass participation, bottom-up creativity and collaborative services.

1. Introduction

The great demographic concentration in cities and the fast paced rythmn of technological change, together with the phenomenon of globalisation, have converted the city into a big crossroad of cultures, but where ever-increasing individualism is dominant. Interestingly, in the same way globalisation has prompted the rebirth of the “local”, rugged individualism has revitalized the idea of (or the need for) community.

From previous European researches (EMUDE, in particular) surfaced that a dynamic new form of community emerging is emerging, which is based on a diffused creativity put co-operatively into action by “non-specialised” people, representing a significant expression of contemporary society. The EMUDE research has defined these enterprising people as creative communities. That is: groups of innovative citizens organising themselves to solve a problem or to open new possibilities, and doing so as a positive step in the social learning process towards social and environmental sustainability (EMUDE, 2006; Meroni, 2007).

These communities are an alternative to the system, generating outputs alternative to it. They are born from the inertia and lack of flexibility of governmental bodies and the failure of nation states and their welfare systems to address the very complex problems modern society is faced with. They are groups of people who create places where they can, in groups and colaboratively, develop various activities. They produce culture, alternative economies, environmental and social sustainability, socialisation and collaborative services.

What social entrepreneurs and creative communities have in common is that they are ordinary people that invent new ways of overcoming everyday problems and of participating in public and social life in an active way.

This activity, not so common in a society mostly characterized by passivity, derives from the will to promote change and not to sit back and wait for the traditional institutions to solve all everyday problems. And they are put in practice by creative people that persist and invest in their own ideas and are able to convert them into innovative services, responding to everyday needs. These ideas are social innovations, that is, new ideas that work to meet pressing unmet needs and improve peoples’ lives (Young Foundation, 2007).

These places and these groups of people can be found worldwide, and even though they are not mainstream they can operate major shifts and changes to society. As Mark Penn refers, it takes only 1 percent of people making a dedicated choice – contrary to the mainstream’s choice – to create a movement that can change the world (Penn, 2007).

2. Collaborative City

Between 2007 and 2008, for the first time in history, more than half of human population, 3.3 billion people, will be living in urban areas. By 2030, this is expected to swell to almost 5 billion. The future of cities in developing countries all depend very much on decisions made now in preparation for this growth (Martine, 2007).The impact of globalization on city growth patterns marks a critical difference between past and present transitions (Cohen, 2006).

CEOs for Cities[2] has defined the areas in most urgent need of fresh thinking in cities as: 1. The Talented City (Developing, maximizing, attracting and retaining talent); 2. The Innovative City (Fostering innovation and entrepreneurship); 3. The Connected City (Fostering connections that link people with ideas to talent, capital and markets; cities to regions; and regions to the global economy); and 4. The Distinctive City (Capitalizing on local differences to build local economic opportunity). According to CEO, cities performing well on these dimensions are destined for success. These dimensions make cities more competitives, but these strategies have a strong economical dimension.

What in the past was a competition between countries nowadays is a competition between cities. As countries before them have battled for technological supremacy, cities now strive to implement strategic plans that will grant them a place as financial and cultural powerhouses in the globalised world.

Cities are the main beneficiaries of globalization and the progressive integration of the world's economies.They incubate new businesses, connect people, ideas, money and markets and house most universities. In our increasingly diverse society they are the crucibles for connecting cultures and generating opportunity. People follow jobs, which follow investment and economic activities.

Today's cities must speak to a world well beyond national government. They have been benchmarked against each other in terms of liveability and wellbeing, economic and cultural offer and according to the functional importance they have in various global networks (Young Foundation, 2008). They need to attract investment, inward-investing companies, property developers, the talented the world over. To survive well, cities must play on various stages – from the immediately local, through the regional and national, to the widest global platform. (Landry 2006)

And this competition is continously reinventing the way cities position and envision themselves. London had a plan to become a creative city, now it has commissioned a study on how to become a collaborative city. Toronto and Brisbane, amongst others, also follow in the creative trail, whilst Berlin has in its local agenda 21 strategies to foster not only creativity, but to become a sustainable, social and participatory city.

There are many self-nominated "Creative cities" (Landry, 2000 and 2008) either because they have a huge concentration of creative professionals (Florida, 2004), or because they have a strong role as "art cities". In recent years creativity has been introduced in economic and urban policies as a key resource to compete in the global knowledge economy. Many creative city strategies have focused on providing the spaces - physical and social environments – to stimulate the production of creative contents and communities, the start up of value added economic activities and the regeneration of degraded urban areas [Creative London, 2005]. On closer examination most of these city strategies have been actually concerned with strengthening the arts and cultural fabric and/or fostering the creative industries (Landry, 2005) which have the

[2] CEOs for Cities is a bipartisan, nonprofit alliance of US mayors, corporate executives, university presidents and nonprofit leaders, that works with local and national policy-makers to advance the economic competitiveness of cities.

potential for wealth and job creation through the generation and exploitation of intellectual property (advertising, architecture, art, crafts, design, designer fashion, television, radio, film and video, interactive leisure software, music, the performing arts, publishing and software creation).

But, a creative city, regarding its social and sustainable dimension is, in our working assumption, more of a Collaborative City, that is, a city with kernels of creativity, which are constituted by: social services, artistic and economic activities. This collaborative city is a place where people interact and enact creating a symbiosis of activities that promote sustainable lifestyles, an active citizenship, social inclusion, cultural diversity and new economic models. It is a city where hierarchies are transversal instead of vertical, i.e, where local authorities (urban leaders) create opportunities for mass participation, bottom-up creativity and collaborative services. It is a creative, connected and collaborative city.

A collaborative city is open, as opposed to the structure of other urban government tipologies, usually closed. What we can observe in very many urban strategies is this shift from systems enclosed in themselves to open systems and a growing political will to envolve citizens in the decision making process, to invest more in culture and intelecual capital.

For traditional institutions and organisations this means working differently, in collaboration with people who are not usual partners. It also means that informal networks between organisations, based on personal peer- to- peer contacts rather than formal arrangements, will become increasingly important (Young Foundation, 2008). To do this they need to develop an adaptive capacity that enables them to change the way they do things.

3. Creative Places

In tandem with the creative city's debate, there is a discussion about old ex-industrial areas and their potential for sustainable urban development. Europe has a rich legacy of industrial archeology, due to its heavily industrialised past followed by the relocation of heavy industries to other parts of the world. It now has to find new uses and solutions to these empty and abandoned places.

The passage from a period of industrial prosperity to a post-industrial one disfigured entire urban areas. It left behind not only abandoned industrial sites, but made many of the inhabitants jobless and transformed previously booming neighbourhoods in rundown ones. But this reality also opened unforeseen perspectives, as some of these abandoned places were re-occupied, converted to new uses and gradually began a new life.

The "available" architectures of these buildings were able to adapt to the most unlikely projects, and welcomed change. Open-ended in their essence and with no predetermined role they welcomed new experiences and were open to various re-interpretations. Together, the mindsets, skills and values embodied in these re-interpretations help make places out of simple spaces.

These renewed and converted places upgrade the urban environment of entire neighbourhoods. They encourage people to get involved in civic initiatives and to get together to back common causes, they provide emotional and intellectual outlets in creation, and in doing so they help people to form a better relationship with their environment and their lives. They promote social cohesion and inclusion and become active agents of a participatory democracy.

They form the backbone of what we consider, for the purposes of this research, creative places. Creative places are a new type of urban spaces where groups of people collaboratively promote and manage a mix of creative initiatives in the fields of art and culture, economy and production, social services and urban regeneration.

Creative places are the hotbed of innovative societies, in the sense they promote the exchange of existing ideas and visions and their recombination in innovative mixes (Leadbeater, 2006).

In the framework of this debate, the ongoing research intends to explore Creative Places' economic, cultural and social role within contemporary cities, investigating how they actually manage to reconcile economic and cultural development with the regeneration of citizenship and identity. More particularly, to explore the potential of Creative Places in order to propose a strategic plan and design tools that support urban regeneration processes and allow Creative Places to integrate their physical, social, cultural and environmental dimensions.

In this respect, our hypothesis of work are the following:

- Creative Places are expressions of emerging urban culture, identity and citizenship and, at the same time, they are social laboratories where these urban culture, identity and citizenship are actively and continuously produced and reproduced.
- Creative places enrich city life, promote an active citizenship, improve cultural diversity, and generate a system of relationships with the neighbourhood and the city.
- Creative Places are experiments for a sustainable city: places where creative communities can conceive and develop sustainable ways of living and producing, re-assigning new meanings to physical spaces anticipating some aspects of what could be a sustainable society.
- The re-use of abandoned spaces helps in sustainable urban regeneration and reinforces the sense of identity and belonging.
- One of the strategies for sustainable urban regeneration may be based on a facilitation process that transforms abandoned spaces in creative places.

To clarify what these places are, how they work, and what they produce, two case studies are presented, UfaFabrik in Berlin and Grote Pyr in The Hague. The data and its interpretation are the result of extensive desk and field research.

4. Case Studies

UfaFabrik. The UfaFabrik is a one-of-a-kind European experiment in community. What began in the 70's as a "squat" of the old Berlin Universal Studios led to the transformation of the buildings and extensive grounds into a local artistic, social service and ecological centre. Many lower income families living nearby were initially skeptical of the artists' intentions. But over time, this redevelopment process used the arts to engage, include and ultimately revitalise the entire community.

In 1979, West Berlin was one of the priciest cities in Europe and affordable housing was not readly available. Consequently, some individuals, resorted to squatting – the practice of occupying and living in abandoned buildings. One building taken over in this way was the former Universal Studios film studio in Berlin. The studio, famous for many productions throughout the 30's and 40's, was abandoned after the Second World War. In 1979 a group of young artists moved into the dilapidated facility, shortly before the planned demolition of the buildings. This action was referred to as the "Big Post Robbery" as Universal Studios had sold the buildings to the local post office.

The grounds of the former UFA Film studios in Tempelhof are „peacefully re-activated" on the 9th of June. A large banner was placed at the entrance reading "Welcome" to invite all of those interested to take part and to interpret the plans of the activists for themselves: a place, where the wide range of social spheres can be brought together in a co-operative project.

45 people decided to live together in a residential community, shared their income and took the chance to build their own sustainable village in the metropolis Berlin. New ideas have been implemented at the ufaFabrik over the past 25 years, involving ecology and sustainable development, the testing of concepts for producing culture and approaches to social development and neighbourhood work.

Today the activities of the 30 residents and over 200 co-workers continues to be informed by the vision of shaping a meaningful integration of living and working with culture, creativity and community. Each of the residents is in charge of a sector of activity. Some of these activities at UfaFabrik include: An International Culture Centre that offers free space for performances; the Neighbourhood and Self-Help Centre, providing assistance with social, health and family matters (services include family care services, a day-care centre, ecology programmes for local school groups and a Medical Centre); The Children's Circus School committed to the development of talented young performers; A Children's Farm (open door for children, keeps animals seldom seen in the city: pigs, chicken, geese, ferret and ponies); A private school; In-house Organic Bakery , Natural Foods Store and Confectionery; a variety of Ecology Projects combining food production and alternative energy systems; The Café Olé. They also organize workshops ranging from parents dancing with their 2-year-old kids to senior citizens practising chinese qi-gong meditation, Aikido and Tai chi skills as well as classes for dance, afro-drumming and brazilian percussion, among others. (Figure 1 - UfaFabrik)

Grote Pyr. The Grote Pyr is the "offspring" of the Blauwe Aanslag, a former tax office squatted in 1980, which was (forcefully) evicted in October 2003. The City of Den Haag offered what is now the Grote Pyr for sale to the former inhabitants of the Blauwe. Since 2002, the inhabitants (20 adults plus 20 children) and user-groups have been busy with the renovation of this monumental school building from 1907 into an ecological freespace. As this building is a national monument, the residents have the legal obligation to maintain the façade and its original characteristics, whereas the majority of the classrooms and the enormous attic are being modified into living and working spaces.

Common spaces are managed and cared by everyone, but this is more than a courtesy amongst residents; according to the set of rules governing the Pyr, each of the residents and companies present has to work 8 hours/month towards the management, maintenance, renewal and cleaning of common living spaces – or pay 80€, in case of unavailability to meet this obligation.

In this place people cook and eat together, share utilities and bits of their lives with each other. They meet together once a month to discuss practical problems, to divide tasks and to monitor the works in the school and the management of the common spaces – as the garden, amongst others.

There are different activities in Grote Pyr, from cultural ones to economic ones, like a blacksmith's shop; a bicycles repair and conversion shop; a biologic catering company; a theatre group; a photography studio; a ballet studio; an interactive museum where children can play with materials and make their own scientific experiments, exhibitions, events and lessons; and a restaurant open to the public.

Grote Pyr represents, for the city, a place of social sustainability and a link between the centre and other zones. (Figure 1- Grote Pyr)

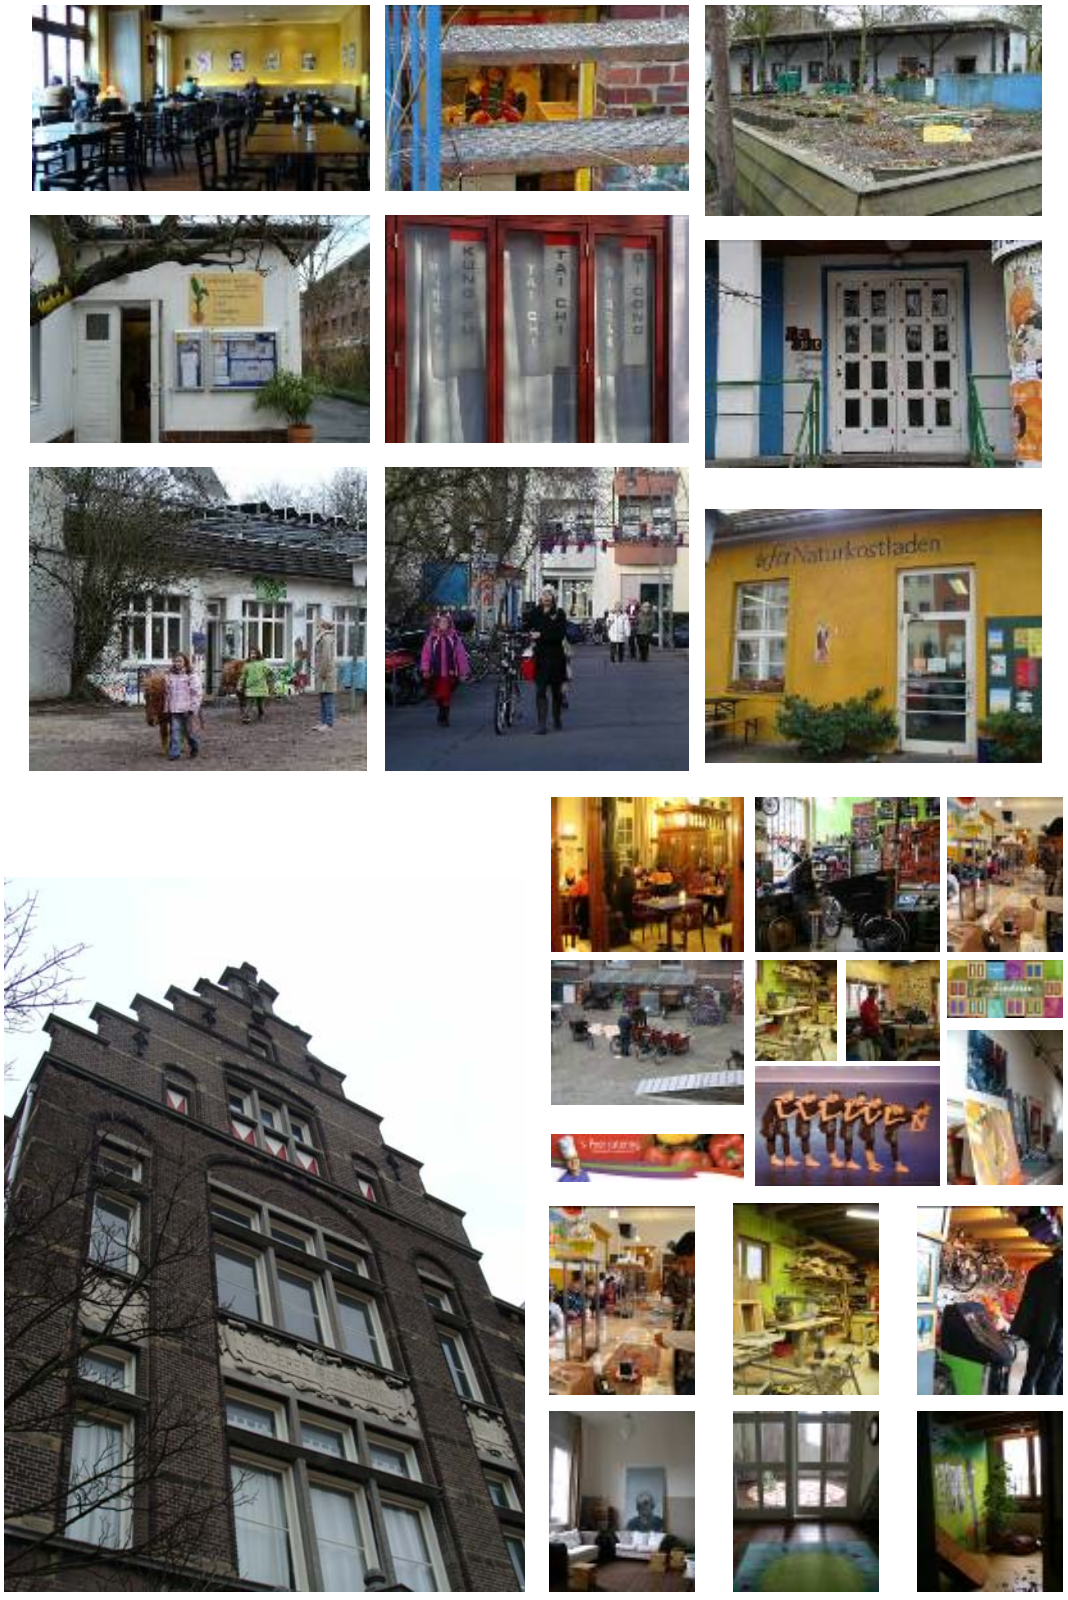

Fig. 1: UfaFabrik (above) and Grote Pyr (bellow)

5. Project *Habitat e Cultura* for Locate di Triulzi

Project's Background. The Province of Milan is proposing a pilot project "Habitat e Cultura" for the creation of a multifunctional centre in the old milk factory of Locate. This centre will host a library, a cultural hall and, at the same time, the headquarters of 20 associations from Locate di Triulzi. Departing from this specific project "Habitat e Cultura", and drawing on international best practices identified through a combination of desk and field research, this investigation will identify and develop optimal strategies for building the necessary infrastructure in which sustainable collaborative services can flourish.

The Habitat e Cultura project is part of a larger programme put in place by the Milan's provincial Directorate of Culture and Integration, constituted of three projects concentrating in the experimentation of integrated cultural systems in the region. It is aimed at creating and activating new cultural instruments for community development, social cohesion and integration.

Context. Locate di Triulzi is a municipality with 9.000 inhabitants in Milan's province, with an area of 12 km2 and just 10 km away from the city centre.

The old milk factory is situated in a strategic location: close to the overground station, accessible through the main pedestrian circuits of the municipality and close the centre but in an area undergoing major residential renewal works.

These characteristics make the Multifunctional Centre a service with obvious supra-municipal potential.

Project's Object and Objectives:

- To build the identity of the Multifunctional Centre, differentiated from the individual identity of its multiple component parts.
- To design the interactions between all the different parties and the management of some internal and shared services
- To access the skills and competences present in the centre and propose collaborative services (developed jointly), maximising the potential of existing resources.

In the first phase of the project's development, a workshop with the associations was organized.

Summary of the Meeting with the associations involved in the Locate di Triulzi's project. The first part of the meeting (introduction) was dedicated at introducing the objectives of the project and showing some case studies able to inspire and stimulate the ideation phase (suggestions). In the second part the association's representatives were asked to share their ideas (team building) and to discuss possible ways in which the project could be developed (brainstorming). The third phase was dedicated at compiling and comparing the participants' ideas in order to promote the dialogue and establish some common grounds (Data organisation). Finally, the importance of creating a differentiated identity for the Centre was discussed (conclusions). To structure the discussion and help in the brainstorming session, the participants were given cards in which they were requested to state their opinions on some specific issues.

Workshop proceedings and results

Atendees. 14 associations:

1. *Associazione Culturale Namastè.* Promotion and comercialisation of fairtrade products and intercultural activities;
2. *Associazione Genitori Insieme.* Training, inetgration, and promotion of the role of the family
3. *Associazione Puer.* Childhood
4. *Comitato Bambini Bielorussi.* Commited to promote the well being of native Bielorussian children
5. *A.N.P.I.*. Anti-fascist movement during World War II
6. *Laboratorio Musicale.* Classical and contemporary musical training
7. *Ass. Artisti Locate*. Arts
8. *Centro Aggregazione Giovanile.* Pedagogical and educational activities for pré-teenagers, teenagers and youth
9. *Ass. Il Centro Culturale Sport &T.L..* Sport
10. *Ass. Teatro Laboratorio La tela del ragno.* Theatre
11. *Gruppo Hobbisti Locatesi.* Hobbies and free time
12. *Motoclub Locate di Triulzi.* Motorcycle enthusiastics
13. *Auser Locate*. Promotion of the active and social role of senior citizens and people with difficulties
14. *Ass. Teatrale Ciclotimici.* Youth Centre's Theatre group

Discussion. From the discussion of the project's objectives and the possible scenarios presented to the participants, it emerged the need to coordinate the existing resources of each association with the new resource materialised in the Multifunctional Centre site, in order to tackle the problems the associations already face and the ones that might arise from the new structure.

The issues that have concentrated most attention were: *accumulated experience*, *space and identity*, *material resources*.

- *accumulated experience.* common activities; more visibility and the creation of a network between the associations.
- *space and identity*. sharing spaces; creation of a new identity for the Centre that is more than the sum of the individual identities of the associations involved; ability to maintain their individual identities, not being dissolved in the Centre's new identity.
- *material resources*. the associations' activities are very different; preference for maintaining their own spaces and instruments; the new reality gives the opportunity to share resources and maximise them, by doing things together; management of common/shared resources; running of common spaces; schedule of each individual association's activities; creation of a structure to ensure the management of the organisational aspects and to distribute responsibilities; create an effective self-management system.

Brainstorming cards. Participants were given cards, which they had to fill in individually, to access their opinions on the following points:

Card nº 1

- What can the Multifunctional Centre mean for Locate di Triulzi? (3 adjectives)
- Propose a name for the Centre
- What can each of the associations do for the Centre?

Card n° 2

Participants organised themselves in groups, with a representative of each association, to discuss the individual results of card n.1, and achieve a consensual group card on the following points:

- What can the Multifunctional Centre mean for Locate di Triulzi? (3 adjectives)
- Propose a name for the Centre
- What are you willing to share (material resources and competences, 5 proposals)

Answers to card nº 2

To Question 1: What can the Multifunctional Centre mean for Locate di Triulzi? (3 adjectives)

The answers to this question are summarised below:

Entertaining

Attractive/ Pleasurable

Culture/new creations

Meeting/gathering/sharing

Diversity/ openness

Driving force/catalyst

To Question 2: Propose a name for the Centre

Some of the names proposed are linked to a specific cultural and territorial context, others highlight a vision of the Centre as a place to create and promote a new community dimension for Locate.

Princess Cristina Di Belgioioso (local history)

Agora (place for public meeting)

The ideas' central (place of doing)

Ideas Factory

The milk factory of ideas

Active level (place "alive" with creation)

To Question 3: What are you willing to share (material resources and competences, 5 proposals)

The participants have shown interest in exploring ways of sharing know-how and resources, and willingness to rethink their own contributes. Points emerged:

Motivation /Responsibility

Efficiency/ Availability

Association's Visibility / Communication

Volunteers

Contacts/Collaboration

6. Proposal for Locate' Milk Factory Multifunctional Centre

Starting with these preliminary results, some proposals have been developed. As this is a participatory project, there will be more meetings with the associations to answer to their needs and to limitations in the project.

Since some of the association's representatives have demonstrated difficulties in imagining some of the possible concepts (like the organizational model and self-management, the sharing of responsibilities and material and imaterial resources, and the offer of joint activities), possible scenarios to materialise those concepts have been developed, ir order to stimulate and feed discussions in the next meetings.

Some of the premisses for the concept and project development derive from a particular historical heritage in Locate.

Premises for concept's development. In the late XIX century Locate di Triulzi was considered a progressive municipality thanks to the social and educational initiatives promoted by Cristina Belgioiso, and it can reclaim this progressive status through the successfull implementation of the Multifunctional Centre and the activities to be developed there.

The pilot project, proposed in the framework of the Habitat e Cultura initiative, can place the Province of Milan, in particular the municipality of Locate, in the vanguard of a worldwide phenomenon as referred in this paper. A phenomenon based in cultural innovative actions that promote social cohesion and integration, community's development, a sense of belonging and collective identity, sustainable behaviours and active citizenship.

The functioning strategy proposed for the Centre is based in the study of strategies adopted in similar cases and in the know-how accumulated by DIS in similar past interventions.

Three functions were identified as a conceptual framework:

- **Cultural** function - the centre as a reference point for cultural activities.
- **Social** function - the centre as a hub for activities with strong social carachteristics.
- **Urban regeneration** function - the centre as a hub for the creation of positive relations between the diffent actors, the citizens and the urban territory in which it is located.

Also, three dimensions were identified regarding the design framework for services & activities:

- **Quality of the human resources** available in each of the associations and their competences
- **Openeness** to the city and its citizens
- **Introduction of the best practices** identified at international level

Proposal. From the cases studied it is possible to extract some models, or a mix of models and the project can be develped at two levels:

1. Management (organisational system & infrastructures' sharing system)

2. Services & Activities (for the local community - offered by single associations and in cooperation with others & monthly activities, workshops, courses, events)

A draft of a system map was developed, detailing what spaces and resources could be shared. In the same way, a draft of a system map was developed regarding possible common activities.

1. Management

Regarding the Organisational system. After the workshop with the associations, the available elements are the number of participants (14), and their area of intervention.

The system of management and organisation should be structured to enable responsibility sharing . A speaker should be elected, in representation of all the associations. This figure is to be responsible for organising a monthly meeting between all the representatives of associations, and representatives of other sectors involved in the Centre's smooth running.

Also to be elected:

Responsible for the management of material resources

Responsible for the spaces' management

Responsible for coordinating and managing the activities on offer

Responsible for the digital platform (both intra and inter net)

Responsible for communications on behalf of the Centre

Positions should be rotated every 6 months, allowing for the participation of all associations.

Infrastructures' sharing system. Besides the Library and the entertainment venue, there are some spaces that can be shared and used by every member of the Centre. A conference room, a meeting room, a storage room and also a kitchen.

A restaurant/café could further open the centre to the local community and forge stronger ties between the centre and the general public, since it is a socialisation place by nature. It can also play an important role in the dissemination of good eating habits and practices.

Regarding the material resources, it is also possible to share the Fax machine, a Copy machine, a DataShow and some Consumables. (Figure 2 – Shared resources)

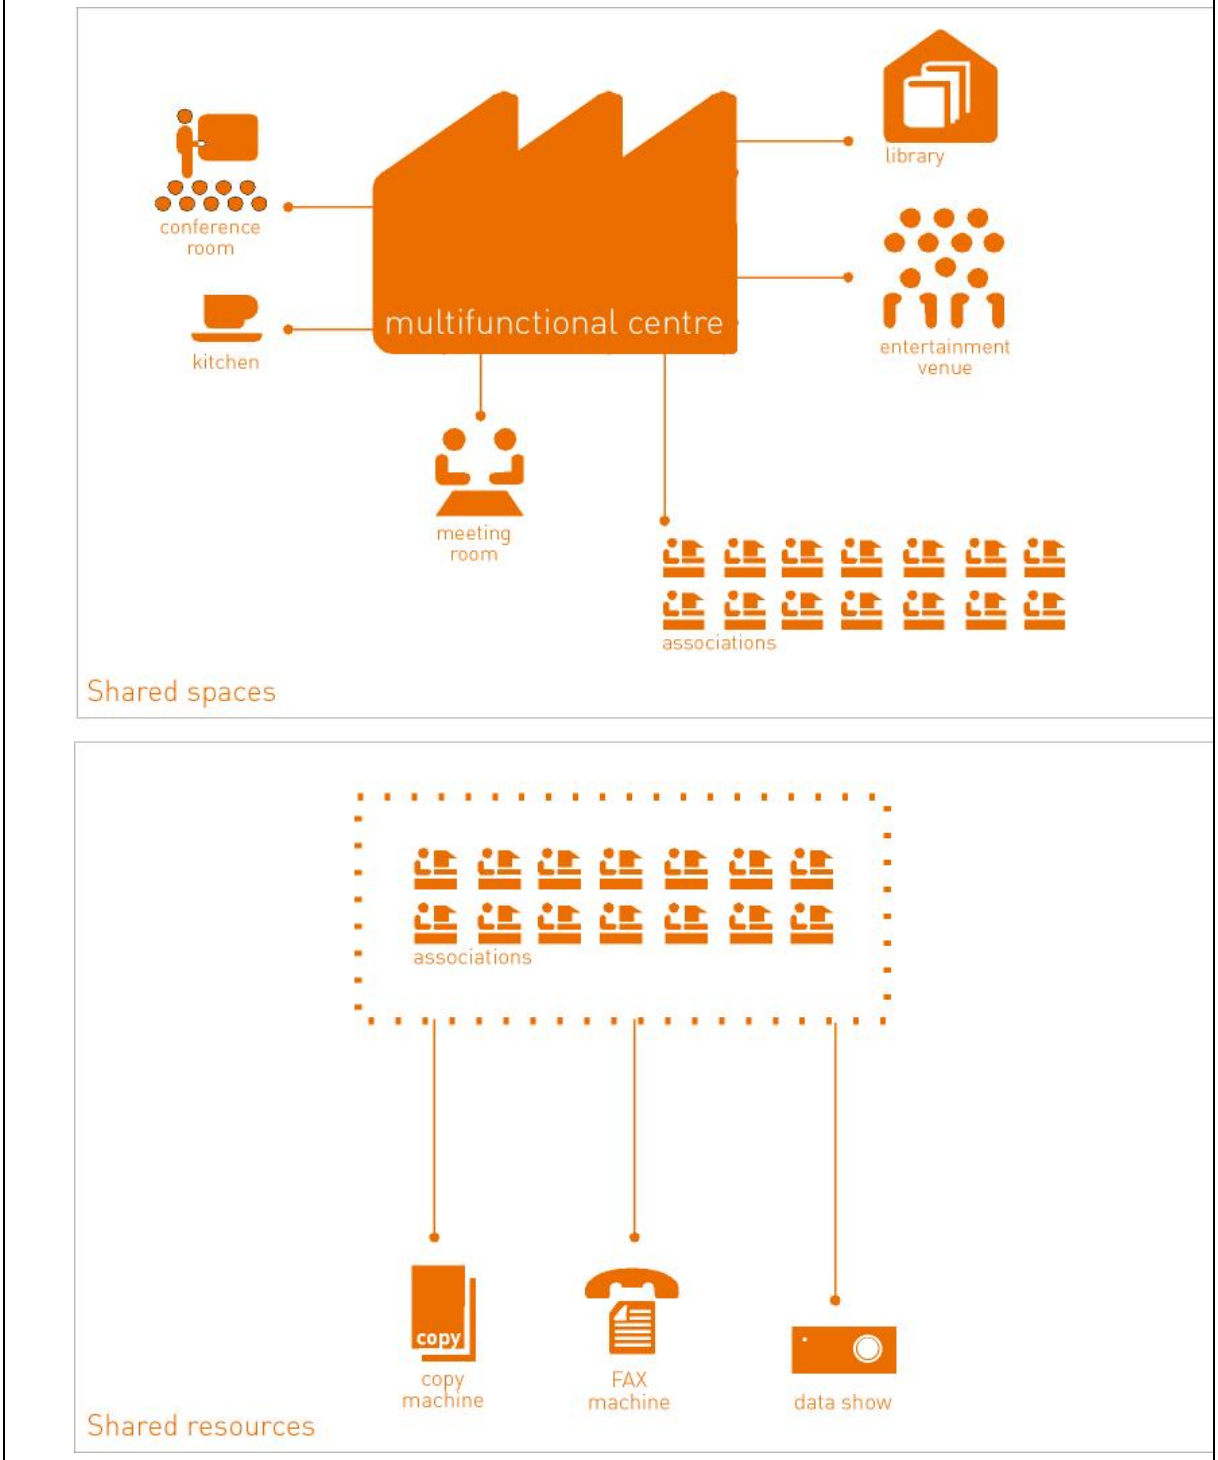

Fig. 2: Shared spaces (above) and Shared resources (bellow)

2. Services & Activities offered by single associations and in cooperation with others & monthly activities, workshops, courses, events

Each association must carry on with their own set of activities, independently of the others, but on a monthly basis they should get together (in groups of 3 or 4) to offer a common activity/project, taking advantage of the existing synergies and competences.

They should organise workshops for a wide public, inviting experts when possible. Participation in those workshops chould be paid, and money should be distributed between participating associations and used to finance the costs of organising them and pay possible guest speakers.

There are some possible activities to be organised in cooperation:

Cultivating a **vegetables garden** – [AUSER + PUER] (Figure 3 – Activity 1)

With this resource, some workshops and eventscan also be proposed by some associations:

Organise lectures/workshops with or for schools about farming, horticulture, etc. [Genitori Insiemi] (Figure 3 – Event 1)

Organization of open days dedicated to gardening [Gruppo Hobbisti Locatesi] (Figure 3 – Event 2)

Prevention & Safety on the roads targeting children and teenagers [Motoclub + Genitori insiemi + Teatro Laboratorio La tela del ragno] (Figure 3 – Activity 2)

Creation of an **intercultural centre**, with multiple activities directed at children. Complementarily, a museum could be created where to exhibit the different national traditions, behaviours and heritage [Namastè + Pro Bambini Bielorussi + Laboratorio Musical + Artisti di Locate]

. Creation of a lab for the development of creative skills [Musical Lab+ Gruppo Hobbisti Locatesi + Teatrale Ciclotimici]

Monthly they could offer workshops teaching how to play musical instruments and acting. These could be on offer for scheduled school visits, or could be held on a regular basis, to a wider public.

In the **Library** it can be created by all associations a Reading club and Ludic centre, and a shop of second hand books offered by the local community.

Reading and acting of children's plays [Teatrale Ciclotimici + Teatro Laboratorio La tela del ragno]

In the common **Kitchen** there could be also some culinary workshops, with the participation of other associations and the wider public – like ethnic cuisine workshops to foster integration and awareness of the other.

For instance, the NAMASTE association could sell their products to the restaurant, and could even, depending on the garden's size and production, organise an organic garden to supply the restaurant – or at least some specialities.

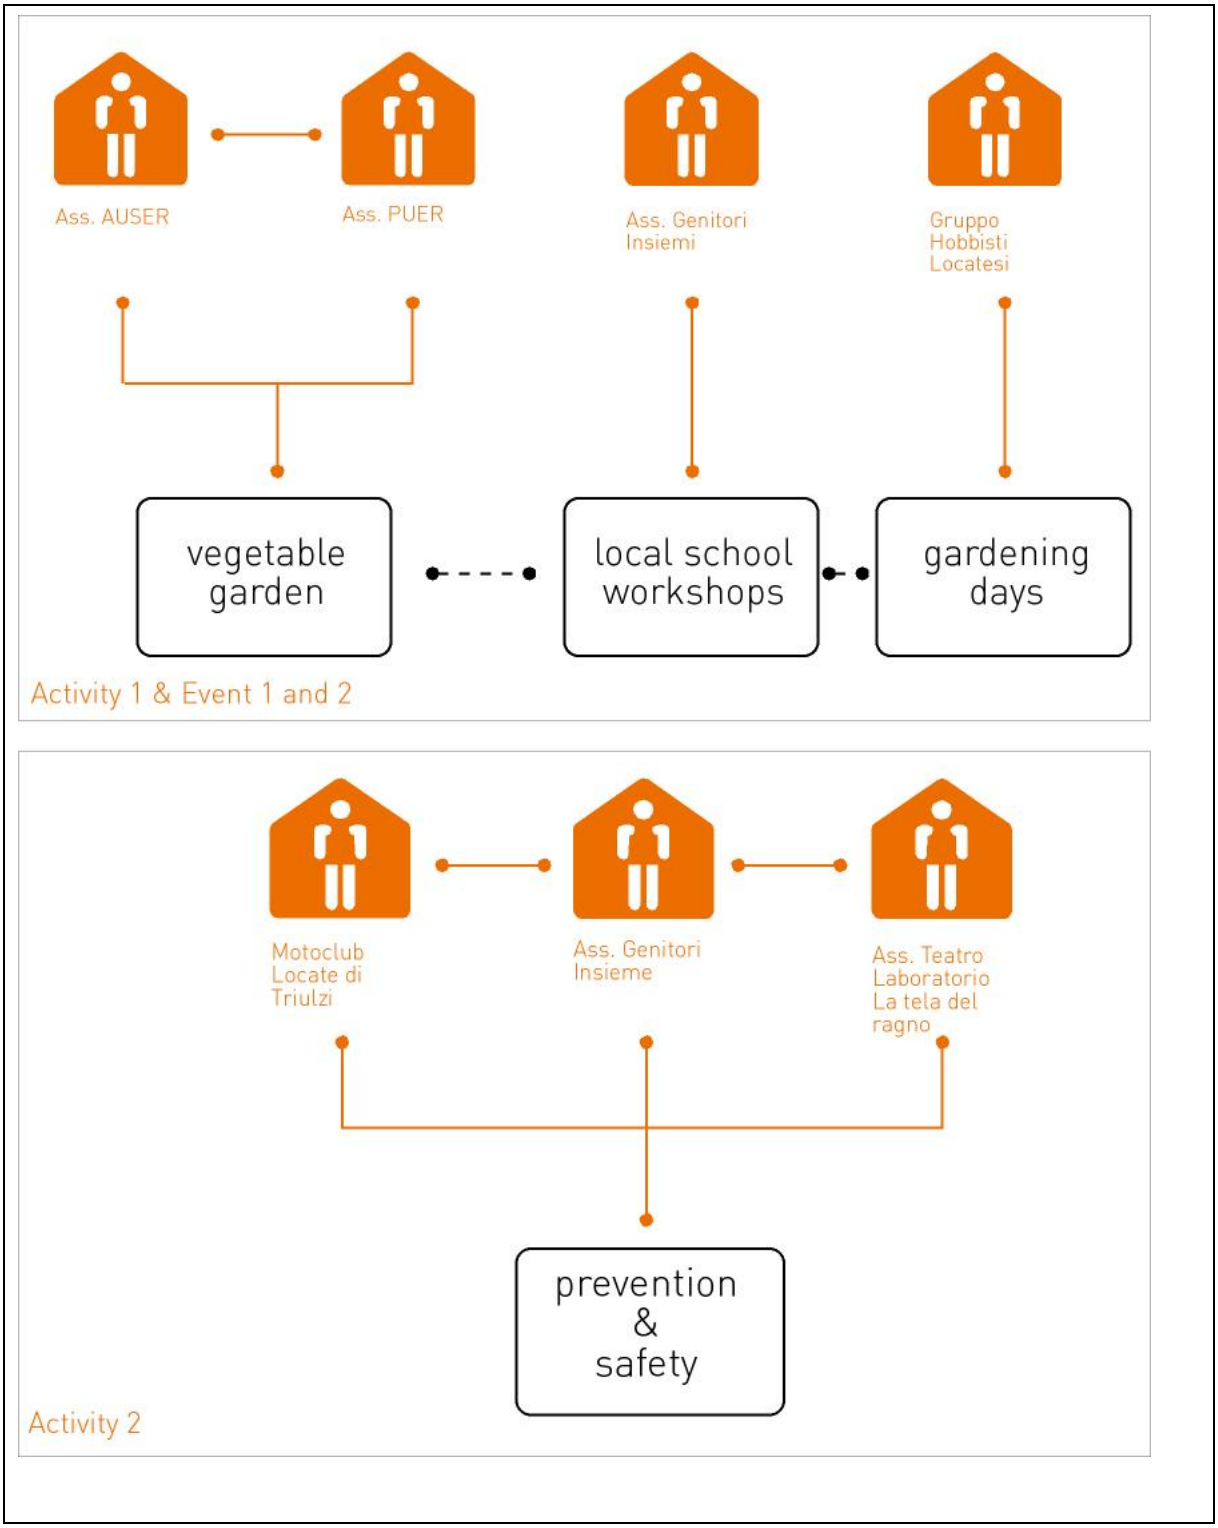

Fig. 3: Vegetables Graden & Events (above) and Prevention & Safety Day (bellow)

These are some of the possible scenarios that can be developed in the Centre. Nevertheless, all proposals will be developed on a participatory basis,i.e, with the inclusion, participation and feedback from all associations involved.

Preliminary conclusions. This is an early stage of an on-going project and only after the meetings with the participating associations we will be able to define a more detailed brief.

As a first observation we highlight the resistance on the part of some of the participants to the idea of sharing spaces and resourses, due to the fear of loosing identity and independence. The difference from the case studies analysed is evidently the existence of a physical space being offered by local authorities. In the cases of Ufa Fabric and Grote Pyr, the participants had common goals, but lacked a place where to develop them. In Locate the opposite occurs - the associations have their own individual headquarters spread in the territory, and pursue their own specific goals. The idea is to enhance their output by allowing them to benefit from each other's skills and competences, creating synergies that impact positively in their common goal of providing a service to civil society.

On a more positive and inspiring note, other associations, more open to the idea, regard this option as an opportunity to introduce innovation in their activities.

"…creativity is often highly conversational and so innovative societies need to be populated with spaces, real and virtual, where people mix, publish, talk and debate. (…) Without such public platforms society becomes balkanised, sectarian, and divided" (Leadbeater, 2006:9)

7. Conclusions

For too long urban design involved only architecture and land-use planning. Now other professions began to form an essencial part of the city-making. We have learned that the physical alone does not make a city or a place (Landry, 2006). So our vision of a possible city is based in the idea of a Collaborative City.

In a closer look to this city, we discover its severals hubs, in particular places made of and by people, which work as creativity incubators, laboratories of new cultural experiences, centres of social and solidary dynamism where new economic models are being forged.

Places where people lead sustainable lifestyles, and from where they are able to show to the remainder of society how traditional ways of life can be changed.

Amongst the possible approaches to sustainable development, we give a special focus to the design of services oriented towards new social models, in order to develop and strengthen cultural identities and sustainable lifestyles. In this sense, the innovation driven by design operates within an integrated system, with multidisciplinary teams that can help to build new social scenarios. These scenarios presuppose new attitudes towards the unsustainable patterns we adopted, implying new business strategies and new ways of promoting quality of life and well being. This scenario offers design a different approach and a new opportunity to develop and enhance a sustainable future.

Design is about culture and creativity, is about problem solving, and these "projects" are solving problems arisen from everyday activities that people have to carry out in this complex society.

In these framework design should act as an interface between two levels (top-down and bottom-up initiatives), for top-down initiatives are strategic whilst bottom-up ones are more tactical or operative. Design has the capacity of being both strategic and tactical, this means that design can potentiate people's and government's visions, creating scenarios according to those same visions, benefiting city life in meaningful ways.

Abstract

The DEEDS (DEsign EDucation & Sustainability) project, funded by the European Union Leonardo da Vinci Programme, comprises a partnership of five institutions from the European design and sustainable development communities, embracing Higher Education, research and practice. This paper outlines the background, evolution and outcomes from the project which currently include a set of core principles, SCALES, diverse resources available via a web site, an evolving Teaching & Learning landscape of 'pods' (the Pod-scape), new student projects, and more. DEEDS has embraced a platform of mutual learning by engaging diverse members of the design communities, with various actors and stakeholders to create a participatory platform for embeddiing 'sustainability into design and design into sustainability'.

1. Introduction & background

The first post-modern design manifestoes referencing ecological imperatives emerged in the 1960s (Jencks and Kropf, 1997). Green and ecological design in the late 1980s evolved into eco-design and Design for the Environment (DfE), with an emphasis on eco-efficient ways of designing. By the late 1990s, the canon moved on as Design for Sustainability (DfS) gained credence. DfS in this context is understood as comprising a wider spectrum of objectives, adding a social, institutional and ethical dimension to eco-design. Sustainability in this view is a complex concept involving four axes or dimensions: environmental, economic, human/social and societal/institutional [Fig. 1], making it probably the most difficult governance orientation ever suggested (Spangenberg et al., 2002). Little wonder then, that DfS, 'sustainable design', or 'sustainability design', still lingers on the outer boundaries of design education and practice (see for example in the UK, Otto 2003, Richardson et al 2005; in Denmark, ICIS/University of Lund survey 2005). Observing this lack of progress led the International Centre for Innovation and Sustainability (ICIS) in Denmark, to see the need for a transition solution and apply to and receive funding from the European Commission Leonardo da Vinci community Vocational Training Programme to set up the DEEDS (DEsign, EDucation & Sustainability) project. DEEDS comprises five partners: ICIS, SERI (Sustainable Europe Research Institute Germany e.V.), BEDA, (Bureau of European Design Associations), University of Brighton and the Academy of Fine Arts, Poznan from five EU countries, Denmark, UK, Germany, Poland and Belgium. DEEDS primary aim is to 'Integrate Sustainability into Mainstream Design Education and Design Practice in the EU Countries' by improving the skills and competences of design educators and practising designers, and the quality of, and access to, continuing vocational training for the target groups. The aspiration is that DfS can be inspired, inspiring and innovative in helping, through and with design, to deal with sustainability issues that figure prominently in the public and political domains, and help the EU meet its strategic sustainability objectives expressed in the EU Treaties.

Indeed, DEEDs activities are already influencing the EU policy agenda with the better integration of sustainability into BEDA's lobbying role and its potential inclusion as a fundamental component of the design policy for Europe which BEDA is currently working towards with the European Commission.[6]

The final outcomes of the DEEDS project will encompass an open source website and a manual including case studies, educational models and methods, tools and skills which will demonstrate and teach DfS to the target groups.

2. Early phases of the project

Early research sought to understand (by literature survey, questionnaires and workshops) the barriers and needs to implementing sustainability beyond rhetoric for the two key audiences, design teachers in Higher Education and designers in professional practice. This process guided the early development of the web site, (DEEDS, 2007-

[6] Following BEDA's meeting with EU Commission President Barroso and Commission Vice President Verheugen in October 2007 and January 2008 respectively, the Commission has indicated that it will produce a 'Communication on Design' in 2009.

2008) generating a platform for presenting theory and T&L models. Concurrently, DEEDS set about determining the underlying principles that might guide the creation of a Teaching and Learning resource for these audiences. DEEDS believes that sustainability is complex and holistic requiring people to understand, imagine, design and solve problems together or in synergy, addressing the different aspects and interrelated levels of the contexts involved (see for example Fuad-Luke; Manzini; Walker; Wood in Chapman & Gant, 2007; Wood, 2006; Manzini and Jégou, 2003).

3. Needs & barriers of key target audiences

The UK Design Council's report (Richardson et al., 2005) highlights the typical barriers, real and perceived, cited by design practicioners and educationalists [Table 1]. Their findings for educationalists are supported by Dawe et al (2005) who identified four major barriers to the successful embedding of Education for Sustainable Development, ESD: overcrowded curriculum; perceived irrelevance by academic staff; limited staff awareness and expertise; and limited institutional drive and commitment. Evidence from architectural design, for instance, noted various barriers & obstacles (Fowles et al., 2003):

- The professional bodies, ARB/RIBA, acknowledge sustainability in their validation criteria but it is compartmentalized and relegated to technology subjects rather than integrated into professional practice and/or a cultural context.
- Design tutors tend to have a defensive attitude towards sustainability, especially in areas where they don't have the expertise.
- Architectural design educational culture tends to encourage the expression of the ego through formal design, whereas more emphasis needs to be placed on societal and global needs.
- Sustainable design is tangential to rather than embedded in mainstream architecture.

Iball (2003) found that many post-graduate courses in architecture emphasized technical and quantifiable environmental issues, but neglected a wider, more holistic, educational response in environmental, social, economic and cultural terms as needed for substantial sustainability. The same general observation was made during worldwide (English speaking) survey of post-graduate courses in eco-design/sustainable design with a product orientated focus (ICIS/University of Lund, 2005).

The authors of this paper have experienced a variety of responses when giving lectures about DfS from well-renowned design colleagues, i.e. comments like 'teaching DfS is a dogma which does not further creativity'.

There seems to be a myth attached to 'sustainability issues in a design context' among many design students, teachers as well as professional designers, which places sustainability in a box of non-creativity, restrictiveness, 'old hat' and other metaphors from previous decades.

An invited panel of external critics, comprising design practitioners and educationalists attended a workshop in Brighton, UK in May 2007 (DEEDS, 2007) and

with the Partner team, together defined the barriers [Table 2] under the socio-cultural, political and economic categories of money, structural/institutional, education, consumers and cultural temperature/human values. They also invoked the 'silent witness' of the neglected environment, aka nature. This collective perception of the barriers clearly demonstrates that the task of mainstreaming sustainability into design will inevitably require professional *and* personal transformations in thinking and behaviour.

This idea was further supported by the findings of the survey conducted by the Bureau of European Design Associations (BEDA) which was targeted at practicing professional designers. To reach this audience, (no survey was conducted of either design schools or client companies), BEDA surveyed its professional design association members across Europe (20 members of a total of 39). The questionnaire comprised only 4 key questions (being mindful of how difficult it is for practising designers to find time to complete a questionnaire) and it was issued in Danish, Dutch, English, French, German, Italian, Spanish and Slovenian to increase the response rate. The questionnaire is set out in full at Appendix 1. 283 individual responses were received from 14 European countries (listed at Appendix 2). The breakdown by design discipline is at Appendix 3 and some analyses of the questionnaire are given in Table 3.

From the responses received to the Question 3, "As a professional designer, what do you believe are the greatest barriers to practicing sustainable design?", (where a score of 1 indicates no barrier and a score of 10 indicates a significant barrier), it could be inferred that the three key barriers to the application of DfS/Sustainable design set out in the question did indeed resonate with respondents.

Just under 50% of all respondents scored 6 and higher for the barrier, *'lack of knowledge of designers'* with the largest number scoring on 5 (22.3%), perhaps indicating that whilst designers feel their own knowledge to be insufficient, they are hesitant to be too critical of their own practice [Table 3a],. Only 28% suggested that designers have adequate or sufficient knowledge, (scoring between 1 and 4).

On the other hand, for the barrier, *'lack of knowledge of clients'*, [Table 3b], 75% of respondents scored 6 and higher with just over 24% scoring 8 and 21% scoring 10, perhaps indicating that the profession as a whole perceives the client's knowledge of sustainability issues to be inferior to its own and the clients' lack of knowledge to be a greater barrier to sustainable design practice than their own lack of knowledge.

Regarding the barrier, *'lack of training at design school'* [Table 3c], just under 63% scored 6 and above with the largest percentage (nearly 19%) again sitting on the fence and scoring 5. These two scores combined total 81.5% of the respondents scoring 5 and above – thus expressing their perception of the need for better training of sustainability issues at design school, (indeed just over 16.5% scored 10 – quite a large percentage thus perceiving design school training to be inadequate).

The questionnaire (Question 2) also provided some insight on the profession's view of its own access to tools and process to support the implementation of sustainable design practice [Table 3d], where a score of 1 represents, 'we have no tools and processes', and a score of 10, 'we already have sophisticated and proven tools and processes', only 3.83% scored 10. Indeed, only 36% of the respondents scored 6 and higher with the largest group (24.4%) scoring 5. Nearly 28% scored between 1 and 3

with a total of just over 64% scoring between 1 and 5. This infers that whilst designers believe they have some knowledge of design for sustainability, they are both less confident about developing tools and processes to facilitate the implementation of that knowledge, or do not know where to find them, (or that their perception is that the tools are few and/or simply do not exist).

A picture was gradually emerging concerning the needs of the DEEDS target audiences. The importance of understanding the motivation and incentives was paramount [Table 4], as was the importance of 'value addedness' of sustainability in the design context. While there were varying lexicons to describe the different target audiences, the promise of something new, inspiring and innovative that improved future job prospects seemed common benchmark incentives.

Most users of the DEEDS web site and resources want something they can immediately use to create 'positive impact' (answers; tools; solutions; examples). They also want to be empowered with new competences – a serious challenge, as this often neglects the learning need associated with developing a broader, sustainability-based approach.

Design educationalists/teachers can be motivated and attracted to sustainable design by helping them to reduce their workload, giving them new methods and T&L learning models while enhancing their status and job satisfaction by adding new dimensions and challenges to their intrinsic assessment and evaluation criteria.

For design practitioners to be motivated to learn about and implement sustainable design practices they need to see a clear connection to an increased potential for business growth. Design companies need to be able to demonstrate greater added-value for their clients, as well as gaining benefits for their own companies in terms of better-quality projects and outcomes. They need to see the link to the increased turnover (preferably with improved profit margins). Where they see a powerful additional; ingredient to their offer, (supporting distinctiveness in a very competitive marketplace and /or aligning with the procurement policy requirements of sustainability aware clients), designers will be more easily attracted to integrating sustainable design into their every-day practice.

Design students can be motivated and attracted to sustainable design by showing them how it improves their employability and challenges their creativity by widening their horizons.

Two hypothetical examples demonstrate how needs can be met by understanding the barriers and motivation:

Teachers & students

Motivation: HEIs (Higher Educational Institutions) are often cash poor. Teachers need to look for external funding and yet are also trying to get work experience/placements for their students.

Means to overcome barrier: By finding an external client that would partner in setting a competition for the students, generating positive outcomes for the teacher and the client.

Designers

Motivation: Materials, choice of materials are central to how a designer operates.
Means to overcome barrier: By re-positioning and re-educating about 'sustainable materials' – where aesthetic, form, properties, and cost can be set against environmental & social costs; where it can be demonstrated that choice of a 'sustainable material' saves their clients money and is an important task demanding awareness of a wider context.

4. SCALES, the core principles for the DEEDS T&L approach

DEEDS derived a generic systematique of themes reflecting the complexity and multi-dimensionality of the sustainable development concept, 'SCALES', that need to be addressed when considering how design can positively impact on sustainability (DEEDS, 2007; Spangenberg et al., 2007).

SCALES is a complementary set of 24 principles based on:

- **S**kills (S – nine principles = 3 x 3 principles)
- **C**reating change agents (C - 3 principles)
- **A**wareness – systemic and context (A – 3 principles)
- **L**earning together (L – 3 principles)
- **E**thical responsibilities (E – 3 principles)
- **S**ynergy & co-creating (S – 3 principles)

SCALES was compared with other systematiques for ecological and sustainable design published since 1968 [Table 5]. The foci for manifestoes up to 1992 was largely around a holistic approach, awareness of system and context, and eco-efficient production and resource use. Post 1992 more emphasis was given to ethical responsibilities, ideas of learning together, and synergy and co-creation. The DEEDS principles embraced additional focal areas – the importance of communication and leadership, user empowerment, social aspects and the creation of change agents – and appear to be the most comprehensive set of guiding principles addressing the challenge of designing for a sustainable future(s). Later SCALES was exposed to critique in workshops by design teachers, and their students, and design professionals leading to their current iteration on the DEEDS web site. (DEEDS, 2007-2008):

Skills

DEEDS points to different skill sets:

Special skills- the holistic approach: Vital for the DfS process is the context, the interrelatedness of the different levels and aspects of the design problem and processes. It is important therefore to define and analyse problems from multiple perspectives including the four dimensions: economic, social, institutional and environmental.

Special skills related to eco-efficient and eco-effective production and resource use by developing LCT, LCA and cradle-to-cradle skills, become familiar with technological advancement, dematerialisation, zero carbon considerations, new and sustainable materials, and, waste considerations. Of equal importance is the integration of efficient service provision by designing Product-Service-Systems (PSS) and maximising consumer satisfaction by appropriate material/dematerialised option that expands user experience, emotion, relation, pride, self-esteem and awareness.

Finally special skills related to communication issues as well as leadership, are vital for the advancement and integration of sustainability practices in societies. Designers to become leaders, capable of communicating and presenting the contexts, the considerations, the pros and cons, working with clients, customers and other relevant disciplines such as engineers or economists. Making a real impact by understanding the context and culture of the stakeholders, and be able to demonstrate and communicate the importance and advantages of sustainability.

Creating change agents

This principle encompasses the understanding of the expanded field of design and its processes when implementing sustainability. The designer, in particular by using the networks (s)he commands and by fully understanding and communicating the value-added outcomes of DfS, becomes the change agent and also equips the client to become a change agent, yielding first-mover benefits. This can be achieved by using approaches which provide significant, immediate and visible benefits for the client and consumers/society through CSR, ethical consumer behaviour, cost cutting, competitive edge, waste and energy reduction.

Awareness – systemic and context

Awareness is step one in DfS. Conscious choices re design concepts, production processes, materials, energy usage, generation of waste and end-of-life scenarios are the first real steps a designer can take. To design in context, be aware of connections and consequences is a precondition for providing maximum consumer satisfaction with a minimum of negative environmental impacts (even in mass production) and a positive balance of social effects. For this behalf, positive and negative impacts, feedback loops and side effects must be taken into account.

Learning together

Sustainable design is based on co-creation, co-design, synergistic learning. Social innovation practiced and promoted more and more by designers is only possible through mutual learning, team working, inter-and trans-disciplinary thinking and practice. Reciprocity, T&L through participation involving stakeholders, form the foundation of sustainable solutions. More and more design companies engage in this way of designing, where the designer becomes the facilitator rather than the creator of design solutions – a challenge to design's collaboration and communication capabilities.

Ethical responsibilities

An ethical design company creates design solutions that do no harm (responsible design, with integrity), but contribute to a sustainable way of a “good life”.
An ethical design company offers design that enhances personal standing and acceptance, and thus social sustainability and encourages user involvement (consumer empowerment. It develops practical, functional and fun design (experiences not objects)

The ethically responsible design company is no longer a figment of the imagination of design visionaries, but a concept which design companies will have to decide to embark on sooner rather than later. As CSR (Corporate Social Responsibility) is becoming an integral part of company’s culture and business in general, the design company will have to follow suit in more than wording or could loose potential clients/market.

The professional design associations have the opportunity to promote sustainable design practice through their individual members across Europe. Indeed there is evidence that some are already incorporating sustainability criteria as a requirement of membership and it is hoped that this trend will continue to grow.

Synergy & co-creating

The imperative is to engage in synergistic collaboration. Competence clusters are practiced with great success by a number of companies in the EU. Partnerships, collaboration, sharing and including stakeholders in development of design solutions are essential elements in the implementation of sustainability and DfS. Therefore, it is necessary to engage the client, the suppliers, the consumers and the community.

SCALES offers a most comprehensive set of criteria that:

- embraces the scope of previous criteria yet adds new ones found to be essential when understanding DfS as a broader challenge than DfE**;**
- can be easily adapted and 'owned' by an individual or a group, initiating a process of learning by doing;
- can form a reference point to demonstrate how case studies embed the principles;
- allows for each principle to become the basis of a teaching module and/or an example case study;
- provide a philosophical and practical foundation for a pluralistic approach to developing DfS T&L pedagogy and practical tools serving as a benchmark.

;

5. The Pod-scape

Within the guiding ethos of SCALES and its inherent complexity, using the knowledge the project partners have collected about their target audiences, the DEEDS partners are developing a concept for a web-based Teaching and Learning (T&L) resource involving 'pods' that are located within a 'pod landscape' or PodScape.

We envisage that the PodScape will comprise the widest possible range of contributions, including resources relating to:

- pedagogic research, theories, approaches, and experiments in sustainable design education
- the practical implementation of sustainability in design education (e.g. project work, case-studies, best practice, partnership with industry);
- political, institutional, and philosophical aspects of sustainable design education.:

Pods can be created by DEEDS or by web visitors using a guide that encourages the creators to consider the new thinking, behaviour, practical outputs and experimental forms including concepts, prototypes and one-offs. Each pod is 'tagged' with information that enables other pods and other parts of the landscape to be connected, revealed and/or explored at a macro or micro scale and users will be able to navigate the PodScape according to their specific needs, either slowly, quickly, randomly or co-operatively, enabling learning by doing, by experiencing and/or by participating.

6. A new Unit of Study at the University of Brighton

As an outcome of involving various design disciplines in the on-going dialogue within the DEEDS project, a new Unit of Study (UoS) is being created in the architecture programme of the School of Architecture and Design at the University of Brighton. The envisaged 'Sustainable Practices' unit will be an integral part of the undergraduate curriculum in architecture. The motivation for introducing this new unit comes not only from the increasing awareness of the importance and potential benefits of DfS education amongst lecturers, but the growing demand by students to bring sustainability thinking into design education in a holistic fashion – as a positive, generative principle rather than an afterthought. Consequentially a group of lecturers has begun to think about ways in which existing, but isolated DfS teaching elements and expertise in various subject areas (studio-design, technology, history and theory) could be inter-linked, expanded, and turned into a common ground for future DfS teaching. The new Sustainable Practices unit is a first step in this direction: it will be staffed by tutors from the different areas, with additional input from programme-external lecturers; it will enable students to develop a holistic and creative understanding of sustainability in design; and it will act as a catalyst for the development of new, sustainable forms of design teaching across the programme. The unit will also work with, and contribute to, the PodScape. Importantly, these efforts are part of a fast growing movement across the University that promotes sustainability thinking in general and the integration of ESD into the curriculum in particular, and has lead to the recent establishment of a University-wide Sustainable Development network.

7. Co-design at the Academy of Fine Arts, Poznan

Students have been engaged in several projects to test T&L approaches within the DEEDS project, in particular the co-design approach, and tools, such as the LiDs or eco-strategy wheel (van Hemel 1994). Co-design is seen as a design approach involving participation of various actors and multi-stakeholders in the design process that is starting to be applied to commercial and social projects (Fuad-Luke 2007, pp38-43; Thackara 2007, pp70-73) Co-design is *'predicated on the concept that people who ultimately use a designed artifact are entitled to have a voice in determining how the artifact is designed',* (Carroll 2006).

Second, third and fourth year students commenced a project entitled 'Humanizing Space',in cooperation with the Poznan International Fair, in which they applied sustainability techniques to the design thinking. The project site concerns a new public space linking the four halls at the Poznan International Fair exhibition centre. Recent revitalization has made it possible to achieve a roofed space, where an existing avenue of linden trees was retained untouched. Architectural design concerned spatial arrangement and merging the elevations of existing, recently rebuilt halls, which have different dimensions and which were built in different periods. The whole area has been covered with a glass ceiling of an interesting construction.

However, the area achieved does not fully measure up to the expectations, and the objectives, and the functional arangements are unclear and complicated. The whole project requires a clear, holistic design conception of the interior, which would allow effective use of the new conditions to improve the comfort of the users. To this end the students undertook a survey of the site and interviewed many of the stakeholders involved in order to obtain their input into generating appropriate design briefs for interventions in the space that would help humanise it. Detailed designs were generated by the students who later applied a modified LiDs wheel to improve the eco-efficiency considerations of their concept designs. Student outcomes [Figs. 2a, 2b] demonstrate that 'the sustainability context expands the boundary of what design is, what it does and also who is involved….' (Fletcher & Dewberry 2002).

The project is one of three parallel eco projects at the Academy of Fine Arts in Poznan, It helps to change the awareness and sensibility for the sustainability thinking among students, young professionals and the teaching staff.

8. Concluding observations and remarks

This paper provides an interim snapshot of the basic approach and some of the achievements to date in the DEEDS project. It is expected that more substantial content will be uploaded to the web site by the time this paper is delivered. The observations and remarks to date should be seen as a work-in-progress. However, the DEEDS project is a significant positive development in the evolving story of Design for Sustainability (DfS) teaching and practice. It embeds an approach predicated on the idea that participation by designers with each other and with a variety of actors and stakeholders, is key to maximizing the value-added that design can offer to the socio-economic and political journey towards more sustainable ways of living and working, while helping to regenerate the environment, strengthen social cohesion and fostering international justice (the latter being the economic/institutional dimension of sustainability). The power of the DEEDS project is that it has evolved through a process

of *mutual learning*, between the partners themselves, and between the partners, target audiences and other stakeholders. This has generated some positive complementary outcomes - an extensive set of principles (SCALES); a diverse and growing set of resources on the DEEDS web site (DEEDS, 2007-2008); changes in T&L practice at the two Higher Education partners in the DEEDS project; and a participatory T&L landscape, the Pod-scape. At the root of this on-going process is the belief that the diverse design communities of Europe all have something to contribute to the understanding of the potentiality of *'embedding design into sustainability and sustainability into design'*.

In order to encourage dissemination of the results of the DEEDS project, and to encourage wide use of the resources generated, there are a number of key conferences and events in Copenhagen, Denmark (October 2008) London, UK (Sept 2008), Brighton, UK (Sept 2008), Poznan, Poland (October 2008), and Brussels, Belgium (November 2008). The challenge is to get the designers of Europe involved through these events or by accessing and contributing via the web site. While the European Union's Leonardo da Vinci funding for the project finishes in October 2008, the partners' intention is for the DEEDS project to continue to grow beyond the life of the project itself through increased participation. It is their hope that, in the near future, DEEDS can become a home for a better-informed, Europe-wide understanding of the significant opportunities for design that exist through embracing and integrating sustainability behaviours and know-how, which in turn, will help to future-proof those who contribute to the design industries and design communities both in Europe and beyond.

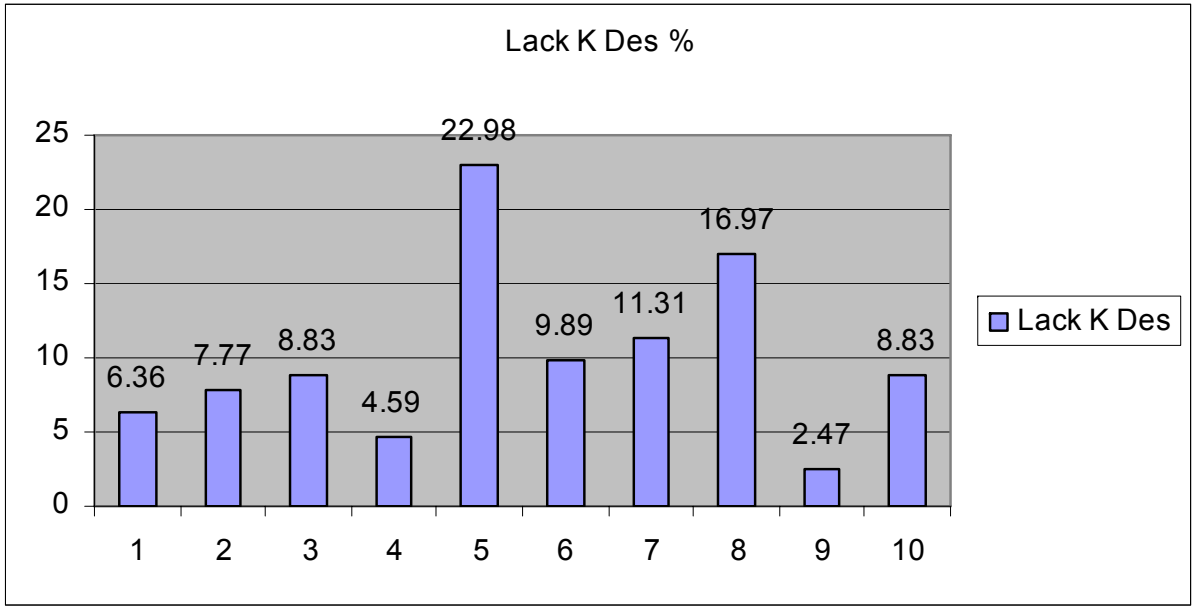
Table 1. Perceived and real barriers to designers and design educationalists applying sustainable design, after Richardson et al (2005).

Barriers for designers • Requires larger skill set • Designers not in influential positions • Unpopular/misunderstood • 'Tough sell' to consumers/clients • Perception of higher cost of Sustainable Product Design (SPD) • Lack of appropriate tools/methods • Lack of government support • Lack of consumer demand •
Barriers for design educationalists • Low level of student demand • Low level of HE institution interest, understanding &/or perceived importance, therefore little support • Low level of business demand • Low level of government support to encourage demand/curriculum change • Broad and specialist skill set (30 listed skills) • No or poor track record of graduate employment as sustainable designers • Lack of stature for design in the marketplace • Sustainability currently not seen as part of mainstream design education • Lack of appropriate tools/models and/or formal knowledge sharing network to aid students/practicioners • Lack of skilled lecturers/tutors • Lack of entrepreneurial know-how • SPD requires lifelong learning • Knowledge exchange network poor beyond specialist individuals and centres • Poor eco-literacy in school students

Table 2 - Barriers/obstacles perceived by DEEDS and external critics

Money • Ambition… • Vision… • Growth (economic) • Economic focus on mainstream/ideological ignorance • Lack of resource, time/money • That it costs more • Lack of critical mechanism to identify SD priorities • IP data methods, adendas, funding • Economic-political system/structures/values • Perceived risk by business and self-regulation that pre-empts legislation • Producers and manufacturers have to invest • Risk for the companies to invest and re-think
Structural/institutional • Synergy… • Process… • Limited capacity to risk 'out of the box (Designers) • Lack of institutional support • Lack of (democratic) participation • Vested interests, 'silos' wih power • Glass boxes • No time (ICT overload?) • Perception is fear/frustration not fun/fulfilment • Too many fragmented initiatives
Education • Lack of knowledge • Quality and dissemination of information regarding resources & impacts • Schooling vs education • No knowledge about sustainable thinking/living • Lack of 'confrontation'/'visceral awareness' • Lack of feedback at the point of consumption and hard to analyse remote impacts

Table 3a - BEDA survey of design associations' members – Scores against, ‘Lack of knowledge of designers’



Score 1 = no barrier; Score 10 = considerable barrier

Response Expressed as percentage

APPENDIX 1 BEDA questionnaire on behalf of DEEDS. – May 2007

DEEDS – A European project to create tools and processes for the development of more sustainable design practice across Europe. Embedding sustainability in design and design in sustainability.

We would be grateful if you could please respond to these three questions and return by Friday 18th May 2007 to: deeds@beda.org . Thank you.

Please tell us what type of designer/s you are. (graphic, product, interiors, new media, etc): _____

1/ Do what extent do you think design can have an impact on climate change issues?
Please circle the number you wish to choose

1= not at all 10 = a considerable and direct effect

1 2 3 4 5 6 7 8 9 10

Additional comment: _____

2/ To what extent, as a practising designer, do you feel you have the necessary tools and processes to support the implementation of sustainable design practices?
Please circle the number you wish to choose

1= I/we have no tools and processes 10 = I/we have tried and tested tools and processes

1 2 3 4 5 6 7 8 9 10

Additional comment: _____

3/ As a professional designer, what do you believe are the greatest barriers to practising sustainable design?
Please rate the following on a score between 1 – 10 where 1 = not a barrier and 10 = a significant barrier.

Lack of knowledge of designers 1 2 3 4 5 6 7 8 9 10

Lack of knowledge of clients	1	2	3	4	5	6	7	8	9	10
Lack of training in design school	1	2	3	4	5	6	7	8	9	10

Other barriers _____

DESIGN VISIONS PROPOSALS AND TOOLS

Less Is More: What Design Against Crime Can Contribute To Sustainability

Professor Lorraine Gamman[1] and Adam Thorpe[2]

Abstract

Crime is a voracious form of premature obsolescence. Replacement of insured stolen items increases levels of product consumption that are unsustainable. Additional to the ecological cost of crime are the social and economic impacts linked to 'courts, cops and corrections' – money better spent on building social innovation and sustainability. The user/ abuser centered methodology of the Design Against Crime Research Centre (DACRC) at University of Arts London as a socially responsive design movement is described in this paper. It argues that DACRC's approach is unique. It addresses social agendas by accommodating consideration of multiple, often competing, user-demands in a given context, and responding in ways that produce both fiscal and social capital through sustainable design.

1. Introduction

This paper argues that design against crime constitutes sustainable design because it attempts to anticipate and design out crime and other problems from the system in the first place, in a sustainable way, rather than solving them after they have arisen, often linked to inconsiderate design. It is written in seven sections that attempt to argue with Paul Cozens that "the ubiquitous issue of crime and the fear of crime are included within some sustainability frameworks, but arguably need to be explicitly integrated" (Cozens 2007, 187-196).

2. Crime And Sustainability: Why Crime Is A Barrier To Sustainable Development

A widely accepted international definition of sustainable development is "development which meets the needs of the present without compromising the ability of future generations to meet their own needs" (Sustainable Development Commission 2008). Crime, clearly contradicts these objectives, and as the UN and most domestic governments acknowledge, is a barrier to sustainable development.

To understand why crime is a barrier to sustainable development, and how it connects to design approaches, it is important to understand its impact at both the macro and micro levels. There are four levels of impact that should be briefly reviewed here including (i) economic (ii) environmental (iii) emotional and (iv) ecological influences.

i. Economic impact of crime

The total burden of costs of crime against individuals and households in England and Wales was estimated by the British Home Office in 2003-4 (the most up to date figures we could find on record) to be around £36.2bn (Home Office 2005). This economic cost estimate is primarily linked to actual crimes measured in the annual British Crime Survey (BCS), rather than those recorded by the British police. This fact is important because, as the report explains: "cost components are effectively weighted by the probability that they will be incurred, which in turn depends on the probability that an offence is reported, recorded, investigated and so on." (p5).

The method by which these costs are calculated are complex and difficult to summarise here. Various metrologies, necessarily speculative in their scope, were used to assess the overall figure of 32.6bn linked to likely costs of crime in England and Wales in 2003-4. To arrive at this figure, the typical costs of crime types covered in the survey were calculated and combined. The elements contributing to the cost of a typical robbery of an individual are reproduced in Fig. 1 below:

See Fig. 1.

In showing the above table that identifies the costs of an individual incident of robbery (including that of services provided by the health service and criminal justice system) we seek to show the extent to which economic impact of crime is not just experienced by victims, but also by

wider society through consumption of public funds. We argue that such costs, in the long term, are not sustainable. Anticipating and designing out crime - using toughened beer glasses, for example, to reduce the effects of wounding in a bar room brawl - can reduce costs of violent assault to the tax payer and the state, as well as the number of victims of serious wounding. Our perspective on the cost of crime is (a) costs are calculated in terms of negative impact and do not include hidden costs of reduced positive impact that may have resulted from the individuals involved in the crime not becoming so i.e. they do not include estimates of the economic or social benefits denied society as a result of the subsequent actions of the victimized or criminalized. However, it is beyond the scope of this paper, and our subject expertise, to formally take issue with the way the economic costs of crime are calculated, but, and more crucially (b) we passionately believe that monies currently spent on policing crime and dealing with its consequences could be better invested developing capacity to successfully design 'out' or 'against' a significant proportion of crimes that occur i.e. prevention rather than cure linked to designing out opportunities for crime.

ii. Environmental impact of crime

The impact of 'fear of crime' by individuals whose response is disproportionate compared with *danger* or the probability of them actually being a victim of crime (Wikipedia 2008a), can also have a negative impact on our individuals and communities. In particular, fear of crime can produce vulnerability-led design responses that operate to negatively influence and determine the aesthetics of the environments we live in, as well as interaction with such environments, by individuals and communities.

Bill Durodie has discussed the "widespread presumption of human vulnerability that influences our discussion of disasters well before they have occurred" (Durodie 2004, 19) and speculates about the negative impact the accentuated focus on vulnerability leads to. Similarly we argue that security-led design responses that display an overt focus on crime and vulnerability can have a negative influence on the built environment and enjoyment of the public realm. One approach to address crimes that make people feel vulnerable has been to keep environments clean and friendly; to tidy up evidence of vandalism or civil disobedience and avoid what has been called the "broken window syndrome" i.e. "One un-repaired window is a signal that no one cares, so breaking more windows costs nothing... Untended property becomes fair game for people out for fun or plunder" (Wilson and Kelling 1982). This can be simplified as bad leads to worse. Similarly we argue that 'bad' design against crime, design that promotes an overt address to security over other considerations leads to fear of crime. Insensitivie fortification of the environment, often from outside, against attack – locks and bolts, fences and gates, cameras and flood lights – exemplify this approach. Whilst we believe security is an appropriate design consideration in certain contexts within society, there is a lot to be said for 'stealth design' responses in which security is provided covertly by 'the invisible hand of the designer' within the objects and environments they design. In short, security issues should be addressed within certain design briefs and responses but should not define them. We believe design briefs and responses for objects, services or spaces should always be developed according to their context, understanding and prioritizing the needs and aims of those that experience them and commission them. Security-led design briefs and response, tend to ignore the importance of users, and instead view the design process as if blocking the abuser's intentions was the primarily goal, more significant than the requirements of others that experience or use such designs. Consequently, vulnerability-led design responses assume a high level of fortification regarding objects, services or spaces. The semiotics of this protection is often over-determined, and contributes to paranoid 'fortress aesthetics that are disproportionate to risk and of detriment to human well-being.

iii. Ecological impact of crime against 'hot' products

Crime trends often follow consumer trends. Those products that are seen as most desirable and 'hot' are often those that are stolen most regularly according to the British Design Council (Design Council 2008).

Recent reports indicate that a third of mobile phone theft is England is linked to theft from children under 18 years of age, who simply replace their phones lost to theft, which may have been stolen but are often also linked to incidents of bullying rather than straightforward robbery incidents (Higgins 2006). Often replacement is with another or newer mobile phone model. Indeed, most individuals who have insurance cover usually replace items stolen – laptops, iPods, games consoles, bikes, mobile phones - with more up to date models. Crime is consequently a voracious promoter of premature obsolescence. It could be argued that the failure of designers to consider, and seek to mitigate, the criminogenic nature of these products is another voracious form of planned obsolescence. Anti theft functionality integrated into objects and buildings, without hindrance to the user, helps not just to design against crime, but also to protect the longevity of object use. Such an approach therefore is compatible, to some extent, with idea that both objects buildings and cities, in designing against crime, constitute more sustainable design (Knights, Pascoe and Henchley 2003).

iv. Emotional impact of crime

We have proposed above that the design of objects, services and environments have an emotional impact on those that experience them. Whilst Situational Crime Prevention (SCP), and the case studies presented by scholars such as Ronald Clarke (Clarke 1992) and Marcus Felson (Felson 2002) have persuasively made the case that environmental manipulation can help design out crime by affecting behaviour, the account of impact of the environment on well-being is also linked to other evidence based research disciplines, not just those from criminology. To give just 2 examples from health care and economics. Roger Ulrich, currently Professor of Architecture at Texas A&M University, has delivered research that demonstrates that hospital patients recovered faster (and their medication demands were lower) when the hospital environment was designed to afford them views of the natural world outside and enjoyment of natural light, compared to those that were afforded no such considerations. Ulrich and his associates also researched the influences of aural surroundings on recovery outcomes in intensive care patients, including how unwanted noise can impact negatively on staff and patients, in order to make the case for the impact of design on well being (Ulrich and Simons 1986). Richard Layard, Professor of Economics at the London School of Economics, comes from a completely different perspective when he argues that negative perceptions of community safety militate against personal happiness. He suggests (Layard 2005) that despite increased prosperity and better material conditions for the majority, British people are no happier now than 50 years ago. Layard discusses many issues relating to why this might be so before observing that post industrial countries with the highest productivity and prosperity are not always the happiest. He goes on to suggest that fear and poor perceptions of community safety may significantly detract from personal happiness (although he does not fully develop this line of argument or test it in the evidence based way Felson's, Clarke's and Ulrich's research has done so).

In drawing attention to such research we are saying that environments can operate to design out crime, but if designers are not careful the visual impact of security design (linked to fear of crime and over fortification) can lead to stress and negative emotions. More significantly we suggest that community cohesion and the forming of meaningful social bonds (that produce social capital as well as fiscal capital) are not facilitated by criminal environments, which militate against trust, cooperation and the creation of community. Moreover, that crime inhibits sustainable development because individuals need to feel **safe,** both personally and publicly, in order to be able to participate in the creation of sustainable communities.

Whilst it is true that not all products that exhibit anti crime functionality (cars for example) have made the best use of resources or materials in relation to ecological impact, in terms of the ***intensity of change*** it brings, DAC is nevertheless compatible with the aims of sustainable design. This paper will go on to argue that models of design that anticipate and attempt to design out crime problems from an environment, system or product life cycle, rather than solve them post design implementation, will be more sustainable in terms of human and economic resources than those that don't.

3. Design Against Crime As Socially Responsive Design

Design Against Crime (DACRC) at CSM is a socially responsive, practice-led research initiative, which uses the processes and products of design to reduce all kinds of crime and promote community safety whilst improving quality-of-life (see www.designagainstcrime.com and www.bikeoff.org). It aims to strategically use design to maximize impact of resources in meeting current and future human needs. This requires tackling design in relation to contexts that offer competing ethical demands, negotiating 'tradeoffs' between the demands of society, the environment and the economy. In crime terms this includes the holistic consideration of the impact of products and consumer desire for objects like the mobile phone that have been linked to crime waves. DAC is linked to the theory of situational crime prevention (Clarke 1992). In a nutshell DAC philosophy suggests that crime is significantly about opportunity, and that IF we can design out opportunity for crimes to occur in the first place, we can reduce crime, and perhaps also the number of people who become criminalized. DAC is a relatively new, interdisciplinary area of enquiry developed through innovative national and international research collaborations. It has four overarching aims:

- To reduce the incidence and adverse consequences of crime through design of products, services, communications and environments that are 'fit for the purpose' and contextually appropriate in all other respects; to this end

- To equip design practitioners with the cognitive and practical tools and resources and

- To prove and promote the social and commercial benefits of designing out crime to manufacturing and service industries, as well at to local and national government, and society at large.

- To address environmental complicity with crime in the built environment to reduce crime and improve individual and community well being.

To realize these aims requires linking two worlds; helping designers to “think thief” and aiding crime prevention experts to ‘draw on design’. It also requires an understanding of multi-stakeholder needs, and ways of working with design in partnership with colleagues from local government and business, as well as the police and the communities they serve. DACRC’s approach is more common to what is traditionally called ‘service design’ i.e. “the activity of planning and organizing people, infrastructure, communication and material components of a service, in order to improve its quality, the interaction between [object or] service provider and customers and the customer's experience” (Wikipedia 2008b).

The service element of design should not be confused with ‘service industries’. DACRC takes a service approach because it views that there are more stakeholders to be considered when reviewing the design process than just the person who primarily uses/ consumes an object, system or environment, the manufacturers and designers who produce it or the client that commissions it. DACRC’s understanding of service design includes ideas about the life cycle of the implemented design, and those that experience and engage with it, lifecycle (including an understanding of user/ abuser requirements/ desires) together with an account of community/public needs and impact. Also, that innovation in design is needed not just in terms of objects and spaces created, but also in terms of the services that are needed to maintain and make sense of them.

This approach seems complicated but it isn’t really, even if it does require more design forethought or what Thackara (Thackara 2005) calls ‘design mindfulness’. For example, when our researchers and designers started to look at bike theft (see bikeoff.org) and how to design against it - because bike theft compromises the use of the cycle as a sustainable transport system - the depth of our research focus into the relationship between bikes and crime, and understanding the entire life cycle of cycling products, led to the generation of:

- Communication designs aimed at informing cyclists how thieves steal bikes with the aim of helping them defend against thieves by registering their bike, using appropriate locks and improving their locking practice.

- Design of exhibitions linked to promotion of cycling but also information about cycle theft as it impacts on bike and bike parking furniture and facility design, aimed at informing architects and designers that cycle theft needs address alongside other cycle design drivers.

- Online design resources aimed at helping practitioners involved in cycling design provision to get smart quick about crime when developing secure bikes, bike parking furniture and bike parking environments.

- Design of anti theft bikes and bike parking furniture aimed at providing DAC benchmarks to be used operationally in the prevention of cycle theft and promotion of cycling, in addition to providing exemplars to the designers and providers of cycling infrastructure.

- Multi-stakeholder (including cyclists, designers, policy makers, private and public sector providers and crime prevention professionals) generated standards used to

brief architects/designers and local authorities about how to provide secure bike parking facilities.

The multi-stakeholder focus described above is applied to all aspects of our design research and iterated within our design process in order to ensure the relevance, efficacy and uptake of our design outputs in the public domain.

4. DACRC Iterative Design Model And The Methodology

The diagram below created in 2007 (itself the result of an iterative process of post rationalization, reflection and consultation on DACRC projects since 1999) helps visualize the iterative process of the DACRC approach to project delivery and management. Our practice-led research process has 2 strands as follows:

See Fig. 2.

The red circles show the research methodology that DACRC starts with is similar to the 'user' focus of interaction design, associated with design consultancies such as IDEO (Myerson 2001) who also fully research user needs. The main difference compared to IDEO is that DACRC reviews material linked to *abuse* and *misuse* as well as *use* in design terms. It also extends the notion of 'user' to include the multiple stakeholders listed above. Competing stakeholder aims are inevitable and are addressed through an iterative review, by a panel of colleagues that reflect the stakeholders involved, who comment on the work. These discussions are led by the researchers and designers, who used user feedback to review the necessary 'tradeoffs' between conflicting requirements according to priorities of the context being designed for.

In the nine years since our work started in 1999, our model has significantly been extended through engagement with practice and interaction with our stakeholders to address 'mis-use' as well as 'abuse' in terms of the 'ethnographic' review of factors to be drawn upon in the design process (Barab et al. 2004). In order to move beyond experiential data and interviews with users/abusers at the research stages, DACRC coalesces the conceptual frameworks, methodologies and practices of situational crime prevention, social anthropology, and psychology, among disciplines drawn upon, to offer an interdisciplinary account.

Scoping

This is the crucial stage of projects. Many forms of empirical research, as well as user data (and theory) inform the scoping stages in order to reach understanding of what crime problems or questions can best be addressed by design (rather than social policy). Also it is often the case that the researchers may bring their personal experiences of crime to bear on the scoping phase.

Research

The difference between the practice-led approach to the design process employed by DACRC at CSM and the interaction design focus and methodology that is traditionally drawn upon, is that DACRC starts with a crime problem and researches how best to address it in broad and multidisciplinary ways. It draws on anti crime thinking, in order to adapt the user centered interaction design model to address issues raised by crime. In order to bring some rigour into design thinking and the critical process of decision making in relation to 'troublesome tradeoffs', Paul Ekblom has created a series of questions and prompts in his model of the Conjunction of Criminal Opportunity: A Tool for Joined Up Thinking… (Ekblom 2000) hereinafter called CCO. DACRC at CSM suggests CCO should be applied by designers to ensure that their address and subsequent visualization of the crime and design problem is comprehensive, systematic and well grounded in theory. CCO allows designers to fully understand the problem BEFORE and DURING the generation, selection and refinement of design concepts and solutions aimed at solving the crime problem.

Observe

One of the reasons DACRC has been able to keep staff passionately engaged with the projects we deliver is that it is important to us that our own experience is included at the scoping stage (the idea that the personal is political) and during further observations we make. For example, we as staff have often been victims to the crimes we are trying to design against and we draw on this experience in addition to that of stakeholders. We also draw upon many levels of observation in our consideration of how best to respond in design terms. We also encourage observation in the field, watching how people use objects/ spaces that may eventually generate theft. We do our best to understand theft perpetrator techniques (MO's) in order to design against them.

Visualize

Visualization of these observations are central to the approach and any address to crime through the design process. Visualization aids both individual understanding and group consultation.

When thinking about design against bag theft and pickpockets, for example, the following, MOs well as many other levels of empirical research linked to bag use are researched, observed and visualized by the team. Visualizations are shown to experts, and all comments and fed back to researchers and designers to help us focus on how to best respond to design briefs.

See Fig. 3.

Generation of Prototypes/ Critique

DACRC adopts an iterative and emergent approach to both research and the generation of prototypes and usually appoints stakeholders in advisory groups and expert review panels to help critique both research stages as well as design concept and prototype stages of development. Consequently, DACRC develops hybrid approaches to the quantitative and qualitative specification and evaluation of data to be drawn upon by designers as well as products,

services and environments they produce to maximize the efficacy, relevance and adoption of the proposed solutions.

In this way DACRC delivers an iterative design process, one that has been adapted to include stakeholders such as crime prevention advisors, who have strategic knowledge of the criminal approach to objects, as well as stakeholders from business and local government who experience crime or who have reason and specialist experience about why there is a need to design against it. Like all approaches to design that contain some aspect of ‘forecasting’ DACRC advisors and designers engage, as Ekblom has pointed out, with “practical considerations in handling the uncertainty which by definition surrounds the estimated risk. It is pretty likely that on average, some broad types of product will be riskier than others.” (Ekblom 2005). This strategic stakeholder ‘consultation’ process, that occurs at stages during the development of design resource and design response iterations can help manage such risks and also identify multiple drivers that need to be addressed in order to really solve the crime problem whilst being attentive to other user considerations where desirable and possible.

The grey circles on the diagram (Fig. 2) show how the process is repeated by individual designers in the creation of specific design exemplars for specific contexts. This process eventually leads to prototype creation of a product, system or service. The designer will anticipate the interaction of many types of users (including victims) as well as abusers and mis-users (criminal perpetrator data) connected with the object, system or service, before showing it to the advisory panel for feedback and refinement (or dismissal!) of these ideas. Typically, several prototypes are generated and amended before the final iteration is agreed upon. Design prototyping is of course constrained by project resources and time constraints. What is seen as the ‘best’ or ‘final’ prototype may be linked to funding break points i.e. what can be delivered on budget available. The ‘final’ design prototypes created will aim to get the balance right between ensuring that user flexibility and desire for the output is not compromised by addressing security through modifications to enhance crime resistance. Where possible, once the product is created we will seek to test and observe the product in situ to ensure its efficacy prior to final production prototyping. Whether the design goes into production will also depend on other commercial constraints linked to materials and manufacturing needs that the designer should have addressed as part of the iterative process as well as the economic performance of the business in question. To some extent, the DACRC model moves beyond a functionalist rationale – problem solving is not the only aim of the design process, which seeks to deliver sustainable anti crime design. DACRC also tries to find a pleasing and creative ‘resolution’ for design (rather than compromise) in terms of the way security and criminal behaviour is addressed by the object, service or system, in order to aid adoption by a wide audience. Some testing is necessitated by the process, and it is here that research funding is crucial, as testing of objects for public spaces, in particular, is very expensive and needs to be undertaken to exacting standards with an interdisciplinary team (we often work in partnership with the Jill Dando Institute of Crime Science (JDI) to ensure that anti crime functionality is effective). Again, modification of a small batch of prototypes may be undertaken, before mass production and roll out of an appropriate solution.

5. Reviewing DACRC’s Philosophy And Methodology

Central to the DACRC philosophy is the opinion that design should be linked to the promotion of well being, particularly design that is located or experienced in public space. We believe it is possible to address security issues without compromising functionality and aesthetics (i.e. the simple idea that "secure design doesn't have to look criminal or ugly”) or other forms of performance, nor being oblivious to other ethical design drivers. Our research projects attempt to "... help designers keep up with the adaptive criminal in a changing world" (Ekblom 2000). This generative design research approach has led to much product innovation, discussed in Design

Appendix 1, also to over 15 international design exhibitions DACRC/ Bikeoff has curated and delivered (see www.designagainstcrime.com) in addition to inclusion of our work in many museum shows including *Safe– Design Takes on Risk* exhibition curated by Paola Antonelli (Antonelli 2005) for the Museum of Modern Art, New York.

DACRC's methodology, holistic approach and progressive social aims, have much in common with the 'transformation design' approach delivered by Hilary Cottam and the design agency Red, and more recently Participle. When interviewed about this approach in October 2007, Cottam argued transformation design is "a hybrid approach which combines people-centered methodology with systemic policy thinking". She said: "We start from the individual, unlocking a unique set of insights and motivations, which we then apply to the broad systemic problems we are seeking to answer. Our hybrid approach also means we test and scale in a different way. We rapidly apply our thinking and insights to the development of 'prototypes'. Prototypes differ from pilots: they involve early service models developed in situ, which are then tested and improved in rapid cycles, again in situ. This approach reduces risk and tends to result in new services that work and can be scaled as well as important new policy insights. Our hybrid approach and our person-centered starting point enables us to work beyond existing service silos, efficiently harnessing a broader set of resources contributing to the development of affordable whole system solutions" (Experientia blog, comment posted 20th October 2007).

Also DAC has much in common with the emergent approach described by Barab et al (Barab et al. 2004) who state that:

"As designers with a change agenda…our agenda is always evolving and mutable. In fact, in our work, we have abandoned perspectives and goals that were at one point central to our agenda in favour of new goals and commitments that revealed themselves as more applicable, meaningful, and useful over time."

The negative aspect of the DACRC methodology, which has much in common with both progressive accounts described above should also be reviewed. The DACRC iterative approach can significantly add time and cost of product development to the design account, and may be viewed by business as problematic, because of its insistence on a holistic focus. DACRC do not apologise for this approach as we are research based and research led designers, and in our opinion real innovation is linked to the full exploration (and exploitation) of so-called design problems. A further common criticism of the iterative consultative process and the DACRC approach that should also be understood by the design community is that some designers object to the 'design by committee' approach, which they see as implicit to the iterative process, and expert or multi-stakeholder review process. Indeed, some designers argue that this collective approach limits their creativity. We think this type of feedback is out of step with today's climate and linked to very old-fashioned design thinking. Designers, in our opinion will always be central to the design process, as their visual skills and abilities are much needed (and not everyone can draw or visualize well) but increasingly, across the industry, there is recognition of the value multiple stakeholders bring to understanding of a design's lifecycle and also what they can bring to design innovation, as Charlie Leadbeater has been at pains to point out in his recent account social innovation as the 'We think' approach (Leadbeater 2008). The DACRC recognize with John Thackara that "Complex systems are shaped by all the people who use them, and in this new era of collaborative innovation, designers are having to evolve from [solely] being the individual authors of objects or buildings, to [acknowledge their role as] being the facilitators of change among large groups of people." (Thackara 2005). Additionally, the DACRC iterative process also focuses on post consumption activities linked to designed objects, systems or services, which DACRC also often seek to test and review once they are actually out there – in the market or on the street – to monitor and evidence the change!

We find DACRC projects are rarely ‘finished’, but always in the stage of ‘becoming’ something else, moving on to the next phase. This is because the behaviour of adaptive criminals, competitive rivals and changing social and market requirements (and the evolution of our own insights and understandings) means that we are constantly replenishing the depth of our research focus and developing ideas about how best to design out crime and make the world a better place.

To truly develop DACRC outputs (see Design Appendix 1) we feel we absolutely need to have a relationship with the public sector, and to design for it, but also that we need to make interventions in consumer-led markets to gain evidence of the commercial effectiveness of DAC. Here we may aid providers, via product differentiation in saturated markets, to generated fiscal capital linked to products that just so happen to offer anti crime functionality and so have a USP that also has the potential to create social as well as fiscal capital. Indeed, it is precisely DACRC’s potential for generating ‘innovation’ in terms of the marketplace, that may mean it does not simply equate with purist definitions of socially responsible design, the sort originally associated with the account of those such as Victor Papanek (Papanek 1971). We think, like Nicola Morelli (Morelli 2007) that "the time has come to review Papanek’s recommendations from a new perspective, which reduces the distance between market-based and socially oriented initiatives".

At least 6 years ago, with delivery of the Karrysafe range, DACRC decided to abandon Papanek’s socially respon**sible** account of design for the real world and use the phrase “socially respon**sive** design” to describe our practice-led design model and outputs. This model is ethical in its implication, and in tune with what Thackara calls ‘design mindfulness’ because we recognize that sustainable aims must be applied in social as well as ecological terms if sustainable design is to address the needs of the real world of the 21st century.

Socially responsive design tends to start with designers individually, or as a group, trying to make their intervention through practice, but it offers a collective dimension as a model too. Ultimately, we believe DACRC’s methodology and approach to design research and the generation of products, services and environments, is important and part of the sustainable agenda, and positions DAC alongside other established thematic movements such eco-design and inclusive design.

6. Crime And Market-Led Design

DACRC is research based, but practice-led. This means disseminating design exemplars (see Design Appendix 1) is the ultimate aim of our research, and DAC thinking on this has so far worked in partnership with a market-led model of design aimed ultimately at making profit as well as generating social change. That research has ultimately led to the creation of spin-off products and companies, a phenomenon that is not uncommon in science-led industries. That these activities are designed to create positive social change is less common. Often the market rules design. For example, the pharmaceutical industry is driven by profit and the impetus for even the successful design of security into automobiles partly resulted from the British government publishing lists of the cars most frequently stolen, which shamed manufacturers into improving security and led them to compete in *market-led terms* over their reputations. Subsequently anti-theft designs based on electronically coded ignition keys and immobilizers were made mandatory by EU directive, but were also seen as part of necessary marketing of brands to sell automobiles. DACRC is not market-driven in this simple way. The problems we seek to research and respond to with design, are not market-led but can be positioned to be compatible with some market forces, even if the drive to design out premature obsolescence from products like mobile phones

or iPods means that we are trying to inhibit manufacturers making money from crime in negative ways i.e. we think phone companies regarding theft of mobiles should make profits from anti-theft design not from insurance upgrade linked to stolen mobiles.

Criminogenic designs (those that cause crime) often do so because they are easy to steal as well as being attractive. Criminologists identify a cluster of risk factors, for theft in particular, known as CRAVED - objects that are Concealable, Removable, Available, Enjoyable and Desirable (Clarke 1999). These factors could equally be read as a list of desirable features for mobile products which highlights the need for consideration of 'troublesome tradeoffs'. We do not seek to be against making things desirable (i.e. to always prefix this list of CRAVED characteristics with 'Un-') but rather wish to limit their impact in criminogenic terms – through design.

Of course, it is dumb to 'blame' crime on designers when the culture of consumption where 'having' (things) is more important than 'being' (a decent person) generates greed and obsolescence. But, as John Thackara points out some "of the troubling situations in our world ARE the result of … too many bad design decisions" (Thackara 2005), and so DACRC, as advocates of a pragmatic change movement, starts from the premise that something needs to be done now in order to address poor design decisions and to correct them where possible. Mindful of the idea that manufacturers often have more final choice over final design decisions than the humble designer and also of Papanek's belief that "design has become the most powerful tool with which man shapes his tools and environments (and, by extension, society and himself)." (Papanek 1971).

7. Conclusion

We conclude by arguing the DACRC research model is compatible with the aims of sustainable development. We target crime problems that stand as a barrier to the progress of social and ethical agendas. Our current focus on bag theft (mobile property theft) that detracts from the enjoyment of public spaces and public transport, and bike theft that detracts from cycle use, continue to be on-going areas of enquiry. In future we also plan to expand the design territories our Centre is able to address as socially responsive design "which takes as its primary driver *social issues*, its main consideration *social impact*, and its main objective *social change*." (Gamman and Thorpe 2006).

In describing the socially responsive methods and objects generated by the DACRC and its Bikeoff initiative, this paper has sought to offer a definition and illustration of socially responsive design, that is both design-led, and interventionist in its approach. One that is hopeful that objects, spaces and services and the material culture they produce, can help change consciousness and society for the better. We have also outlined some of the ways that design can address and drive social issues linked to the desire to bring about positive social change. Additionally, one of the academic objectives of this article has been to demonstrate that DACRC offers a sustainable design model. We hope in describing our own practice and how we have attempted to *slow down* crime by promoting secure design (prevention over cure) we have made a strong case as to why DAC constitutes integration into broad and holistic accounts of socially responsive and sustainable design. DAC seeks to secure and sustain a future where responses to negative risks like crime are proportionate to real danger (rather than fears) and are integrated, (by design) within models that seek pragmatic improvement in social prosperity as well as the quality of life for individuals and communities.

Acknowledgements

Lorraine Gamman and Adam Thorpe would very much like to thank the Arts and Humanities Research Council (AHRC)/ Engineering and Physical Sciences Research Council (EPSRC) Designing for the 21st Century Initiative for funding, which enabled research for this paper to happen.

Design Appendix 1: DACRC Design Innovation

1. Why Design Against Cycle Theft?

Cycling helps fight obesity, is good for our hearts as well as offering an important sustainable transport system as an alternative to the gas-guzzling car for urban mobility. No wonder our London Mayors - past and present - with the help of TfL encourage Londoners to cycle more.

Yet Transport Research Laboratory's research shows that 17% of all people that cycle have their bikes stolen – and of this group 24% stop cycling altogether and 66% cycle less often. Worse, our own Bikeoff.org research shows that after making 8,500 observations of cyclists parking on the streets outside our own College that many people are complicit with theft, as they do not appear to know how to lock their bikes securely, making life too easy for thieves. So we felt something needed to be done about cycle theft. Our top 4 anti cycle theft designs – that help block some of the common ways thieves steal bikes - include:

CaMden Stand (M Stand)

The caMden (M) stand was developed to covertly persuade the cyclist to lock low – securing frame, wheel to the stand – because the less secure 'wheel only' or frame only' locking options require more effort to achieve with this design. Unlike the ubiquitous Sheffield (U) stand that tends to inspire people to lock through the top of the frame (making it easy for thieves to steal bikes) the M encourages cyclists to lock their bike in a more secure way. We decided to call this stand the caMden (M) stand because this borough, in partnership with TfL, wanted to be the first to help us design out crime in London and have already installed over 100 stands on their streets. The success of this design has encouraged Brighton and Hove to install and test the design as part of their anti bike theft initiative which we are helping them deliver linked to their Cycle Demonstration Town status.

Front Wheel Enclosure

The front wheel enclosure performs in a similar way to the M-stand whilst also having a sculptural quality – lacking in much street furniture - that in my opinion would not look out of place outside the Tate Modern. For years DAC's shout line has been "secure design doesn't have to look criminal" – this product delivered partly by designers from Vexed Generation (who often work with DAC) illustrates that fact. The best ways to lock up a bike – particularly in cities where bike theft is part of daily life - is not just to "lock both wheels and the frame stand" but also to use 2 different types of lock (as shown here) so the thief is forced to use more than one type of tool if they try to steal your bike.

Our Bikeoff team – led by senior designer Adam Thorpe – designed both stands and the Jill Dando Institute (JDI) of Crime Science, who evaluated our designs, delivered research that shows that the stands do in fact improve the security of cyclists' locking practice. So we have some proof that our designs work in practice - not just in theory - and the stands are now available from Broxap, Britain's biggest cycle furniture manufacturer (www.broxap.com).

Puma Bike

The Puma Bike applies a classic DAC strategy – 'spoiling' – to deter bike theft. The wire cable is a structural part of the bike frame as well as being a 'built in' lock that can secure the bike and its wheels to parking stands or other stationary objects. The idea is simple – if you cut the lock you break the bike – making it less viable or valuable for re-use or resale. But it is not just the anti-theft functionality that is strong is this design, is the way it is delivered. This address to DAC is what led to this bikes most original and distinguishing feature. It's a great example of how the 'different question' of "how to avoid theft" led to the different answer of "integrated cable lock"

that makes this bike so unique, and a USP in the market place. It's great to see DAC contributing to innovation in the 'sports lifestyle' market! See http://www.coolhunting.com/archives/2005/03/first_glimpse_t.php.

'Lock Both Wheels And The Frame To The Stand' Sticker

This simple sticker is important because works to improve cyclist-locking behaviour, as JDI evaluation of it on U stands shows. It offers I economy in design– the idea that you should seek to get as much performance from as little design as possible. These stickers were proposed as a way to improve locking practices of cyclists and thus reduce theft of parked bikes. The graphics and colours are chosen to lend an air of civic identity and familiarity – the graphics are simple and easy to understand even without being able to read the concise messaging that accompanies it. The idea of using small stickers on the bike stands rather than signs in the street surrounding them that deliver more visual clutter is important. It offers as a way of 'talking' to cyclists about how to lock their bikes rather than 'shouting' above the cacophony of other graphics competing for our attentions on our cluttered high streets. This sticker was tested in London and Brighton – again with JDI evaluating the results – and it was found to produce a 10% increase in secure locking practices – small but significant. We have licensed this design to a number of local authorities and are now in discussion as how best to roll these stickers out across London and beyond! See www.bikeoff.org.

2. Designs Against Bag Theft

The British Crime surveys shows that in Britain a bag or mobile phone is stolen every minute. It is annoying to lose all our favourite things – money, mobiles, iPods and more – to sneak thieves. But even more overwhelming than the personal cost of such losses is the extra punishment of time spent canceling credit cards and re-cutting keys. So our Design Against Crime (DAC) Research Centre wanted to do something about pick-pocketing and bag theft, as annoying crimes against the person. Our 3 best designs include:

Design Against Crime Chair

(available winter 2008 from Danish furniture supplier Dan-Form (www.dan-form.dk)

This DAC chair (1) looks lovely as design - no big locks or bars needed your bag safe from thieves and the floor tidy (2). It utilizes the defensible space of the body (the bag-holding slot is located near the genital region) to enable the individual to sit pretty secure on their belongings with the understanding that their unconscious is very awake to infringements in this region! (3) Designers Jackie Piper and Marcus Willcocks helped Lorraine Gamman deliver this design to Dan-form, who have licensed it recently. It will be on market from Winter 2008. We recognize that pickpocket/bag theft problems are not just about poor bag design but also about the furniture we respond to locate in public space. If you leave your bag on the floor or on the chair next to you – you make it too easy for thieves to simply slip away with it. So best to remove opportunities by sitting on your assets, preferable on a DAC chair.

Karrysafe Scroll-Top Backpack

(www.fonehouse.co.uk/feelgood/karrysafe)

Rural backpacks for hiking were re appropriated for urban environments as city bags. What idiot designer first put an insecure bag opening on our urban backpacks away from our natural sightline is unknown to DAC, but he/ she seems to have inspired a million other idiot designers to come up with the same concept, and the rest of us to buy them.

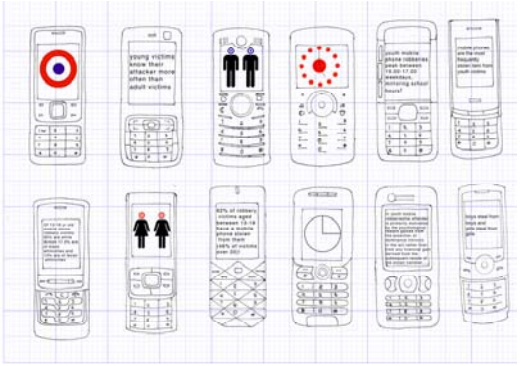
The Karrysafe backpack, delivered for DAC by designers who were commission from Vexed Generation, offers anti crime functionality by (1) putting a simple combination lock on the bag of the bag so no one can get into it when the owner is not looking. (2) It also includes a side lanyard so users can secure their bag a train (Eurostar/) seat or the pub table when they need to go to the toilet/bar without having taking ALL their belongings with them. It also leaves you users

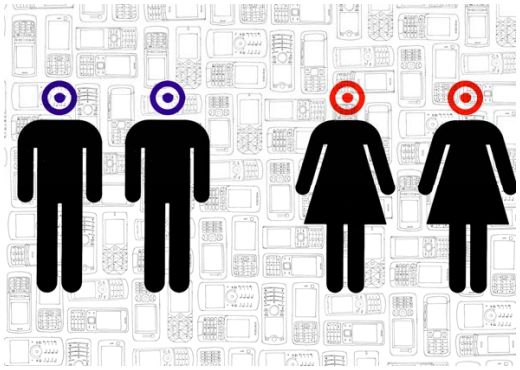
safe in the knowledge that no one can open their bag or remove it from the seat/table before they get back. (3) It takes 2 hands to open it (thieves usually “dip” with one hand) and (4) it uses Cordura – which is not a designated anti-slash material – but one that makes it hard for thieves to slash bags with simple knives or blades and thus get at possessions this way. Why this design hasn’t been copied by every major bag manufacturer/designer out there DAC has no idea – we suppose it is too sensible to catch on? But DAC still think its one of our best anti theft designs on the market and is currently available at £29.99 from www.fonehouse.co.uk/feelgood/karrysafe.

Is Mobility Messy?

The DAC team is still working on a low tech anti mobile phone theft device – and we can’t mention any more about it in this article, as the design won’t be available till the end of the year. Our sponsors, the British Transport Police (BTP), have briefed us to figure out how to make commuting safer from pickpockets and we are developing a relationship with a commercial client too. BTP came to us because our exhibition Secure Design for Safer Travel - at Victoria station successfully communicated via an anti crime wave of anti theft objects - that design can make a difference… even if mobility is invariably messy.

3. Mobile Phone Theft





So we have chosen the DAC anti mobile phone theft poster that appears on our design resource www.inthebag.org.uk (which is currently open to comment from viewers to help redesign the site in a more user-friendly way). Our point in choosing an illustrative design communication, as well as objects, is to remind everything that graphic communication has a role to play in helping to make crime prevention sexy and to design out crime from the world.

Full of facts about crime against young people, the poster reminds us that it's our young that get clobbered most for their phones. (Higgins 2006). But phone theft against young people often appears to be more about bullying than it is about stealing. Even though there are organized phone thieves out there who work in gangs and ship our stolen mobiles abroad after we have been "dipped", when it comes to young people - power (bullying) as well as profit may be the primary motive as to why kids get "taxed" by other kids for their mobiles.

4. Design Against Burglary - Secured By Design Poster

Some part of London look like fortresses – such as Fortress Hackney – with its flats that feature iron bars on windows and barbed wire on supermarket. No wonder DAC feels the need to encourage more architects to think about crime BEFORE they design our buildings, hence this poster.

Retrofitted security looks criminal and worse, contributes to making people feel safe unsafe. Crime is a voracious form of planned obsolescence and a barrier to sustainable development because money spent on insurance up-grade of objects stolen through burglary fuels consuming passions. Worse, the costs of policing this sort of crime and dealing with the consequences of theft and vandalism, across the world, as we have already stated could be better spent on essential social infrastructure such as health, education, transport, and culture.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

The Experiential Experiment:

Is design education sustainable in a changing university environment?

Elizabeth Gaston[1] and Jane Scott[2]

Abstract

This paper aims to question conventional methods of design education in an attempt to create a sustainable design programme suitable for the needs of a 21st century design community.

Most UK design institutions are now part of the university system. This has led to a change in focus on the requirements of teachers and learners. Concurrent to this is the changing needs of the design industry that will employ design graduates.

This paper reports on research funded by The University of Leeds investigating a future strategy for sustainable teaching in design practice. To ensure that a sustainable approach to design education is attained teaching staff must be prepared to embrace change and experiment with new perspectives and new technologies.

[1] The University of Leeds (UK) – The School of Design. Senior Teaching Fellow, e.a.gaston@leeds.ac.uk
[2]The University of Leeds (UK) – The School of Design. Teaching Fellow, j.c.scott@leeds.ac.uk

1. Introduction

As educators we congratulate ourselves on the success of our design programmes but how should we measure success, is it the number of students who obtain excellent marks, or the number of graduates who gain employment in relevant industry positions? A different measure of success could be consistency of design research; perhaps the most relevant measure should be the creation of designers who improve society.

2. Context

The Textile Design programme is changing. The School of Design is changing. The University of Leeds is changing. The University system is changing. Within this state of flux where macro decisions impact on the minute details of a lecture, a project, or an assignment, some sense of balance needs to be restored.

This paper argues for an innovative, sustainable approach to learning and teaching which re-imagines outdated models and methods to engage with the changing university system, providing an appropriate and diverse educational environment. The paper highlights good practice from The University of Leeds with particular reference to the Textile Design Programme, It will consider three areas that are experiencing or will experience imminent dramatic change; staff, space and skills.

3. Skills: sustainable learning

In a review of undergraduate textile design education in the UK the model of tutor led studio practice, supported by lectures and seminars predominates (Gaston 2007). The focus is heavily skills based, producing graduates who have strong specialist skills in a particular area.

Nationally, however, the profile of delivery is changing. Traditionally the unifying feature of textile design programmes was the skills based, experiential learning model. At the beginning of the twentieth century the Bauhaus model emerged in the Basic Course (Itten 1963, 7). With refinement and development of specialisms this model has endured to the beginning of the twenty-first century taking little account of the changing needs of current graduates, the design industry and society. A focus on practice based modules which has conventionally accounted for 80% of the curriculum in an art college model is slowly being eroded due to pressure on time and resources. The reduction in studio based delivery has been seen as detrimental to a student's development, particularly the development of technical and aesthetic subject-specific skills. However this trend is not going to reverse and a sustainable approach considers what the appropriate needs of graduates are within contemporary society.

The experiential model is however supported by the major stakeholders in education; students, tutors and institutions. Students demand skill specific teaching to enhance their immediate employability and staff, who themselves have followed traditional teaching methods, have bias towards their chosen field. Institutions demand leaders in their field to undertake subject specific research.

In the last thirty years the needs of the design industry has changed dramatically yet design education, although following superficial trends in out puts, has remained static. The UK design industry has grown rapidly over the past decade to become the largest in Europe with an annual turnover of £11.6 billion (Design Skills Advisory Panel 2007), however conversely there is also a perceived over supply of design graduates from a raft of similar courses who do not have "the right professional skills" for the design industry (Design Skills Advisory Panel 2007). This suggests that as educators we are failing the needs of our students.

As early as 1970 Papanek suggested that a narrow design education did not provide society with designers who were equipped for the challenges of the twenty first century (Papenek 1984, 285). He argued that society requires broad generalists who can produce integrated design solutions rather than those who re-hash and re-develop old ideas. The specialist trained students may find initial employment with ease but will be left behind in their careers by the generalists. This view was echoed by Hemmingway (Hemmingway 2007) who suggested students needed to take a broad view of education and try to avoid specialism.

3.1 New Approaches: the designer graduate

According to The Quality Assurance Association which is responsible for evaluating standards within UK Higher Education, a graduate will be able to:

- deploy techniques of enquiry
- Comment on current research
- Appreciate uncertainty, ambiguity and the limits of knowledge
- Manage their learning
- Evaluate critically
- Solve problems. (QAA 2007)

These specific qualities are expected of all UK graduates, and places design graduates in a strong position. The nature of design as a problem solving activity implicitly fulfils many of these criteria. Within a practical context students are required to question, analyse and understand a range of issues and evaluate potential outcomes. The cyclic nature of the design process which supports Kolb's Learning Cycle (Kolb 1984) provides structure to student learning creating a framework for students to test a range of ideas and intentions.

"Active learning through project based enquiry has always been a feature of the art and design curriculum in higher education. Through this approach students have been encouraged to develop both the capacity for independent learning and the ability to work with others." (QAA 2007)

Through project-based enquiry the designer graduate applies both theoretical and practical skills to a range of problems, and continually reflects and evaluates work and working processes in order to promote innovation in contemporary practice.

3.2 New Approaches: the research practitioner

The University of Leeds is ambitious in its goals; within the University's strategy map the key theme for learning and teaching is to "translate excellence in research and scholarship into learning opportunities for students" (University of Leeds, 2008). Research underpins all teaching programmes within the university and supports teaching though engagement with case studies, live projects, and relevant industry based applications. An understanding of process and method is emphasised as key learning outcomes for students at undergraduate and post graduate level.

This provides an exciting environment for learning and teaching within The School of Design. Research within art and design is an evolving field and undergraduate programmes within The School of Design have been re-imagined to focus on internal and external research areas. The School of Design aims to provide an environment where research from a variety of disciplines including textile technology, fine art practice and fashion innovation can be integrated into undergraduate learning and teaching.

3.3 New Approaches: communities and systems

Sustainability requires a trans-disciplinary approach. If it is no longer appropriate to train students to become skills-based designers, students need to consider a range of working methodologies and succeed in applying processes and skills to a variety of natural and virtual applications. Design for the future should be community focused; group work through live projects, virtual communities and peer assessment provides the opportunity to move away from focusing on the individual to community based design where shared ideas evolve into genuine innovation. The power of networks and communities is increasing rapidly as appropriate technologies provide instant access to friends, colleagues and new contacts through social networking sites. Translated into an educational context this is already transforming the student experience at Leeds.

Research in Art and Design already considers the artifact as only one strand of practice. A focus on process and method advocated by collectives such as Fo.am considers that future working outcomes include a focus on design for experience and emotion. To translate this into undergraduate learning and teaching new methods and approaches are required. (Kuzmanovic, and Gaffney 2006). An understanding of the research practice of scientific, technological and cultural researchers is necessary for the new generation of students to fully engage with the needs of both future customers and colleagues and understand the social framework of the community.

3.4 Summary

Problem solving and critical thinking remains vital to design education. A sustainable approach suggests new contexts to work within, different tools to apply, and a shift in approach from the individual to the community. The design graduate is placed in a strong position within UK higher education, and student learning can benefit from an exciting trans-disciplinary approach practice and research.

4. Space: a sustainable studio

External and internal pressure within the university system has lead to increasing pressure on resources. The cost of studio space within design departments has increased exponentially with the growing resource issue of space charges, where departments are charged for the ground space they use. In a non practical subject one lecture theatre can house large numbers of students yet design students need studio space and access to bulky equipment which is far less economical. The inevitable outcome is of a reduction in studio space and the foreseeable end to individual workspaces within the studio environment. At Leeds 'hot desking' has formed part of the design culture for several years, and despite initial concerns from staff a new, flexible approach to space has produced surprising results.

It is not difficult to see the benefits of sharing space; positive results from Leeds include trans-disciplinary project work, a greater sense of group dynamics and wider participation across student cohorts. In addition to this individual projects have tried to respond to student concerns to the changing working environment through novel approaches to the problem.

4.1 New Approaches: redevelopment and the temporary Studio

In order to explore the function of the studio experience, a project was developed in conjunction with a Leeds based development company. The project allowed students to work and showcase work in a vacant city centre office building. Contextually this project supported Bernard Tschumi's theory of event-activated space, in which the space itself is only given meaning through the events that take place within it (Tschumi 1994, 11). The outcome of the project was the first exhibition from the 'knit-fit' collective of designers based in the School of Design.

After an initial visit to the temporary workspace in City House, work was planned and realised over a three week period. The conclusion to the project was an exhibition which opened to the public for an evening reception.

The intention of the Re-development project was to provide a new point of view for students to engage with the concepts of the studio and the city. The University is located on the margins of the city; this experience provided an opportunity for design students to respond to a different perspective of the city, from right in the heart of the commercial sector. The showcase also aimed to promote the potential of design work; not only as part of visual culture, but also as an activity to connect with the wider community and question the cultural significance of the role of design in Leeds.

Re-development as an event is significant on two distinct levels. The elevated city centre location exaggerated a new frame of reference for students to work within, drawing on a different reading of the city of Leeds both from a commercial and a centralised viewpoint. The temporary location provided an opportunity to re-locate studio practice within the vast space of a redundant office building and re-imagine constructed textile design in scale, materials and purpose.

The event raised questions about the role of the studio for design practice. Through a small scale event students were able to engage with the environment as a point of departure for and exploration of working practice. Students were asked to reflect on working practice after the project. The majority of the group agreed that the event had been successful in terms of working outside the studio environment, and that the public nature of the showcase encouraged a professional approach to work. Despite initial perceptions of the space as an 'office environment', the showcase provided a meaningful and creative intervention. The success of this small scale event supports Tschumi's concept of the event-activated environment, and suggests that a variety of locations and spaces can function as temporary transformable studios.

4.2 New Approaches: Knit-Fit and the virtual studio

The University of Leeds aims to provide a flexible, technology rich working environment. To support working practice there has been a shift in focus from communication via email to the use of social networking sites to maintain virtual group dynamics. The Knit-fit collective is an example of an online community created and developed by its members. The group encompasses all knit specialists, both students and tutors, from textiles and fashion backgrounds. Using Facebook as the host knit-fit has provided a space for discussion and engagement with knit based activity both inside and outside of the university. The site is successful when there is a clear purpose to the engagement and peer support is a key driver of this community. The tool works as a site for providing and accessing information. The success of the facility can be monitored through use; after the Re-development event photographic records were uploaded and downloaded regularly. A student visit to Pitti Filati was organised in part via the knit-fit community.

Although on-line activity will never replace face-to-face contact, this is an example of good practice where knit-fit becomes a complement to face-to-face communication in an environment where time is one of the most valuable resources.

4.3 Summary

The two research projects identify that a flexible approach to studio space is necessary. Working in different environments, both real and virtual, not only stimulates new and exciting contexts to work within but challenges the working method, encouraging an exploration of new ideas, environments and experiences design education can offer.

5. Staff: sustainable contact

The change in administration of many UK art colleges in 1992 when many obtained university status compounded the problems of a narrow curriculum. Research dependant funding has generally led to a reduction in the availability of staff teaching time.

It is clear that the traditional art college model is no longer sustainable in terms of staff time and resources. As designers we are innovative thinkers and problem solvers, we are ideally placed to redesign the future education of the next generation of design students; however it is not necessary to redesign the wheel.

5.1 New Approaches: case studies for consideration.

Design is not alone in its use of practice based teaching. At the University of Leeds the Faculty of Biological Sciences was experiencing a resource problem in the delivery of anatomy (Roberts 2007). The traditional method of learning human anatomy involves dissecting real cadavers however this is expensive and an online alternative has been developed using simple and easily accessible software. Although time consuming to set up; the resource has proved successful.

To expand the time available for teaching The School of Medicine is utilising online tutorials in medical ethics (Testa 2007). Over a period of three weeks each group of seven to ten students are required to access a virtual discussion room and respond to a set topic. Tutors commented that contributions were often more considered in the on line setting then in live tutorials and there was more participation from a greater number of students. Students appeared to be more comfortable expressing their views in this form.

A further example of expanding the curriculum has been demonstrated by the School of Earth and Environment (Reed 2007) where the use of podcasts has expanded the traditional lecture. Easily created podcasts can be used to supplement teaching materials by providing lecture summaries, pre-class information, contextual material for example speeches or interviews and multimedia materials. Student feedback has been excellent.

Problems with accessibility of tutors have been overcome at Yorkshire Coast College, Scarborough through SMS technology. Inexpensive software, txttools, links tutors to student mobile phones and laptops. Originally used for information dissemination from institution to student, the system has become two way with students asking questions by text rather than struggling to find a suitable time to talk to the tutor face to face (Hoare 2007).

5.2 New Approaches: application to design

Design courses are also utilising new technologies to over come resource problems. At Leeds College of Art and Design, practice based skills, predominantly CAD skills, are taught with a variety of additional support. Tutor demonstrations of software such as Photoshop are presented on screen interactively and are supported by a PowerPoint presentation of step by step actions. Video tutorials are created using Adobe Captivate. The tutorials promote active involvement of the student as they can be slowed down or repeated and help to reinforce the tutor demonstration. They have also been shown to promote understanding of the application of software in a textile context.

5.3: New Approaches: studio-based support

Despite the move towards a broader education it is still necessary for students to develop subject specific skills. Students are often required to operate complex, studio based equipment to facilitate the production of textile designs. Video tutorials were not felt to be useful in this context. The model of producing online video tutorials has been proved successful for CAD software (Hughes 2007). They can be accessed immediately at the point of need whilst using the CAD software. Under present University of Leeds arrangements the structured textile studios are not networked and are remote from the PC clusters and so access to tutorials would be separated geographically and in time. This was corroborated by staff at the University of Brighton who agreed that video tutorials were less useful for active use in the studio (Haffenden 2007).

Additional information was delivered to students in the form of high quality photographic images to supplement the text based information given during classes. These were stored within the subject specific rooms in the University of Leeds' virtual learning environment. The reason was two fold. Students had to be proactive in obtaining the extra information and the cost of producing large colour hand outs was prohibitive. Although "low tech" the simplicity and portability of paper handouts can add great value to the learning experience (Walker 2007).

Student feedback collected at the end of the semester indicated that this method of delivery had been successful. The extra information had been accessed by four out of five of the cohort, the majority of whom found the resource valuable. The success of delivering information visually is congruent with the preferred learning style of textile design students in which 95% of students chose visual/kinesthetic as their dominant style after taking the VARK characteristic test (Flemming1996). These types of students learn best using images, examples and activities rather than listening to a wholly aural presentation.

The same cohort were invited to test podcasts as a support to their learning, however this technology was less successful. Evidence from learning style analysis suggests that this technology would benefit aural rather than visual/kinesthetic learners, and the student group felt that the podcast format did not provide additional information beyond the initial demonstrations, highlighting that not all technologies are appropriate for all student cohorts.

5.4: Summary

As pressure on staff time increases within the university environment technology can provide flexible support for studio based learning. A range of tools currently being tested across universities provide different types of support. Online tutorials and guides provide access to information on demand in a variety of formats to suit different learning styles and working environments.

6: Conclusions and Recommendations

The University system continues to change, supporting a wider and increasingly diverse community of design students and graduates. The University of Leeds is proud to be changing. Learning and teaching is underpinned in the strategy map by research and a commitment to innovation. The Textile Design programme is already changing. The School of design has responded to market needs to create a broader design portfolio.

However a sustainable approach cannot be designed into education unless it is supported by changing attitudes and approaches. Novel solutions highlighted in this paper underline opportunities afforded by these changes, enhanced by technology and innovation. In a climate where resources are more precious than ever before, staff, space and skills, must adapt and evolve to create a sustainable environment for design education.

DESIGN VISIONS PROPOSALS AND TOOLS

Design for Social Innovation[1]

Enabling replication of promising initiatives for sustainable living in Brussels and Paris

Jégou François[2], Liberman Joëlle[3], Girardi Sara[4], Bernagozzi Anna[5]

Abstract

This paper will present and compare the results of two parallel research projects focusing in design for social innovation. Teams of designers in Brussels and Paris experimented real size participative design processes with two groups of citizens willing to start or improve collaborative solutions:

- car drivers promoting local urban hitchhiking initiatives around different areas of Brussels.

- single seniors offering spare rooms through cohabitation opportunities to students in Paris;

In particular this presentation will focus on the start-up phase and the projective approach used by the designers to stimulate social conversation between players involved and support them with a tool called *enabling cards* in the discussion and construction of their customized solution.

1. Introduction

Shared housing, alternative mobility… spontaneous social innovation may reveal new and more sustainable solutions in daily urban ways of living.

How to improve these initiatives and make them more accessible for a larger share of users keeping their initial social qualities? How to scale them up fostering their duplication at the local scale maintaining their environmental benefits? What can strategic design bring to support these social innovators? Which are the new approaches to co-design within a social fabric of creative users?

This paper will present and compare results of two parallel research projects in Brussels and Paris, focusing on design for social innovation. Teams of designers together with the École Supérieure des Arts Visuels of La Cambre in Brussels and the École Nationale Supérieure des Arts Décoratifs in Paris experimented participative design processes with groups of citizens willing to start or improve collaborative solutions. The two cases groups focused on are respectively:

- car drivers promoting local-urban hitchhiking initiatives around different areas of Brussels[6].

- single seniors offering cohabitation opportunities in their spare rooms to students in Paris[7];

In particular this paper will focus on the start-up phase catalysing new solutions and on the projective approach used by the designers to stimulate social conversation between involved players and support them in the discussion and construction of their customized solution. These collaborative design sessions with existing and future promoters allow to describe the key-characteristics and possible options of a 'meta' or 'generic solution' used during workshops or interview sessions to facilitate appropriation of complex product-service systems and to enable non-professionals to design their life's solutions.

2. Promising initiatives of social innovation

This first part will describe the different starting points of the two parallel experimentations: whether a solution was in a launching phase as for the urban hitchhiking or already implemented, as the cohabitation of seniors-students. The analysis of these solutions will focus on the different barriers to diffusion of these initiatives and possible up-scaling strategies.

VAP

Voitures à partager (VAP), born in 2005, were determined to make auto-stopping in the city easy and safe. Claire Van Bellinghen who is the project initiator, was motivated by her commune's « Mobility week » to set this urban-hitchhiking system. They considered two problem levels as challenges: some more largely shared ones like global warming -combined with transport accessibility issues; and more local ones like profiting from not fully occupied commuting cars, enhancing solidarity between pedestrians and drivers, whilst generating more social links in a commune that already has quite an open mind set.

[6] VAP, Comobil, Kotvoiturage/Taxistop and Myoto, Brussels, Belgium.

[7] Logement Intergénération, Paris and Rouen, France e Prendi uno studente a casa, Milan, Italy.

It needs little infrastructure to accomplish its objective: Users subscribe to the service - free of charge- receiving a registration number plus a variety of VAP identification elements as a car sticker, ribbon, member card, all made to be easily recognizable. The service was meant within members only: they can participate as pedestrians, as drivers or they can be listed as both.

The pedestrians then are able to hitchhike, card in hand, so VAP drivers can recognize hikers as fellow users; encouraging them to stop. The car, showing VAP ID elements, is made visibly reliable to hitchhikers; thus, through mutual recognition, the spontaneous car pool is concreted. This urban hitchhiking service is founded on reciprocal identification and trust, encouraging spontaneous social contact yet keeping a safety element in mind.

VAP is thought more as a complement to urban transport than a substitute. This system was intended to accelerate connection to bus stop's in a suburban city area, as the service's native Watermael-Boitsfort, who has only 3 bus lines for 80 km of streets. The members are currently around 720: 550 in Watermael-Boitsfort and 170 resident in other communes.

Effectively, this system has shown some specific problems: the quantity of members is still growing but critical mass has not yet been reached to produce a fluid service. Members are in disproportion between drivers and pedestrians[8]. However, work is being done to improve and develop service quality such as destination cards for hitchhikers in the form of a booklet and 3 signaled pick-up points installed in the streets of Boitsfort.

Set as a bottom-up open *collaborative service* (Jégou, Manzini, 2008), the service aspects are then reduced to registering subscriptions and sending VAP cards to each user. This activity and the promotion of it are based on the involvement of a small group of early promoters around the solution's inventor. VAP promoters also make sure at subscription level that basic security requirements exist to both driver and passenger: They verify that all members are above 18, that the driver has proper insurance, a valid driver's licence number and all members remain registered in the service's database.

None of the involved wins anything in the growing of the service except the satisfaction of less traffic and more voluntary work to be done. The municipal subsidies are covering part of the expenses (cards and leaflets printing, or the sending through post mail) implicates that the core group of promoters should grow in number to cope with multiplication of members. Therefore, to scale-up VAP means fostering the replication of the initiative, assembling or assisting other groups of motivated potential users located in other places in Brussels and its surroundings. VAP may then replicate through *dissemination, affiliation or branching (*Dees, Battle Anderson and Wei-skillern, 2004) of a series of more of less similar VAP antennas.

Contrary to the more usual design of a commercial service taking into account possible evolutions from launch through growth and maturation, enabling new VAP antennas to emerge requires extracting all the knowledge and procedures gathered by the initiative in order to make it available to new groups of potential promoters. But profiting from the accumulated experience of promoters is not enough: on the one hand, some improvement may be made questioning the current VAP setting, and on the other hand, a new implementation may have to face new contexts of use and the initial solution should be presented in a sufficiently flexible way to allow eventual adaptations. So the 'design question' VAP therefore faces is to create new VAP antennas supported by new groups of promoters in other urban contexts. Moreover, the replication process should be self-supporting: the strategic design will then empower new candidate promoters with a replication process that they may afterwards handle autonomously, passing by both the flexible specification of service and the process to implement it.

Logement Intergénération

[8] this figure seems to be the repeating the actual state of mobility in Belgium: 80% moves by car, 8% on buses and trams, 6% by train and 6% on foot or bike.

Logement Intergénération was born in 2004 with the aim of encouraging single seniors to offer spare rooms through cohabitation opportunities to students in Paris. This initiative is supported by three mediators and part of a national network of 14 associations offering similar services under the name of «Logement Intergénérationnel et Solidaire» (L.I.S.). The president of the Parisian association, Chantal Dorval, explains been inspired by similar initiatives already existing in Barcelona for about fifteen years. These initiatives are trying to tackle a more local problem of scarcity and excessive prices of student bed offers on one side and the more global issue of reducing the loneliness of elderly people living on their own on the other in the Catalan city.

The challenge of Logement Intergénération is tightening the precious bonds between different generations in a society where these are becoming more and more loose. The older person and the student form a kind of “new family” and the affection that they share makes both forget their respective feeling of loneliness (students often have to move miles away from home and feel lost in a metropolis like Paris) and help them sharing unexpected interests and passions. This new stimulus helps the elderly to feel the need of improving his social life (going out, etc.), sharing his feelings with somebody ready to listen and tackling daily actions that isolation normally discourages (cooking, cleaning, etc.). On the other side, they also help the student having a solid point of reference on which they can count on. Nowadays, the association has helped forming about sixty "couples" that of course continue their "family relationship" even after their co-housing period.

Logement Intergénérationnel is based on the principle of reciprocity: students are offered a room (and often a bath and an individual kitchen) during a school year in exchange of a certain number of services (and sometimes water, gas or electricity expenses). The fact that these engagements are listed in a personalized chart, signed by the two sides before the cohabitation starts, prevents possible abuses from both sides but also helps the parties not to forget to take care of the other despite any unforeseeable event. The room is often offered in exchange of a common dinner or lunch twice a week, daily dog walks and some shopping.

The service comprises 100 euros for each party and, according to the founder, the sum covers the costs of professional shows (Salon des Seniors, etc.) and Internet, flyers, press and television expenses.

This relationship, based on solidarity, implies discretion, respect and trustfulness and requires both parties to be meticulously understood and coached by the association. During the visit of an apartment, aimed at checking standard quality requirements, the elderly person is registered while explaining his or her motivations. On the other side, the student has to undergo a thorough interview during which he or she has to prove his understanding of the service and show his willingness to support his future host. Logement Intergénérationnel accepts the « new families » only when intentions on both sides are fully complementary and a harmonious co-housing is then envisaged.

The profiles of the two parties is generally is as follows: the elderly are often open-minded and lively women living alone in large flats with one or several empty rooms that used to belong to their sons and daughters; suffering from loneliness and afraid of being alone (especially during the night) the are happy to be useful to other people (they never do it for money reasons). The young ones are generally responsible, good students of both sexes (even if old women often prefer sharing their homes with female students), often just arrived in Paris, belonging to large families.

Up-scaling the solution goes through growing the capacity of the initiative to match more couples of students and elderly people also tanking into consideration the need of students to live with seniors of all ages (even younger than 60!). Nowadays the number of students asking for this service is much higher than that of elderly people, and the promoters are working on balancing offer and demand. They are also taking into consideration the opportunity to offer the service to young workers and not only students.

These developments are limited by the work that the 3 mediators are able to produce and

by the time and involvement required to create sufficient dialogue between the 2 parties to ensure the relational quality for a durable relationship;

The 'design question' Logement Intergénération is therefore facing is to enable each couple of student and elder person to explore more autonomously their mutual expectations and agreement for a co-habitation.

3. Co-design of enabling solutions...

This second part will describe the definition of generic solutions and its tentative decomposition into a set of *solution elements*. Teams of designers together with the École Supérieure des Arts Visuels of La Cambre in Brussels[9] and the École Nationale Supérieure des Arts Décoratifs in Paris[10] where involved in co-design sessions with the respective promoters of the initiatives. Tentative implementation loops with groups of future promoters or users allow to progressively explore the different facets of the solution beyond its current implemented forms and embed it into a set of enabling cards to support their up-scaling.

VAP

In order to define and discuss characteristics and boundaries of the generic urban hitchhiking service, co-design working sessions were organized first with the VAP promoters and then with different actors of alternative mobility in Brussels. Being VAP the first and more experimented service, the aim of the session was to register and use confirm all the experience collected during its three years of activity. A first representative scheme of the service focused more in the dimension of the service's characteristics and related options were proposed to tease conversation. VAP, like most cases of social innovation, tends to be an informal initiative growing organically with low capitalisation material where the essential knowledge is stored in the memory of main actors. Therefore stimulating conversation with a tentative decomposition of the solution was of great help.

A second co-design session involved most representatives of alternative mobility initiatives in Brussels and representatives of two candidate groups to implement new VAP antennas in Ottigny and Villers-la-ville (both in the close periphery of Brussels). The objective of this second session was to fine tune a second version of the solution elements and to introduce it to these new groups of promoters that will be the first users of the tool. The support of a semi-structured approach was particularly discussed and appreciated. It answered a typical issue of voluntary user's attitude, characterized both by a high level of requirement as users or potential users, (their preoccupation reflects a very fine level of expectation in usability, problem analysis, critical approach...) and at the same time a lack of project management capabilities -except for some involved professionally in similar activities, the difficulties to adopt a structured approach, to turn critics into problem solving, to prioritize actions... tends to result in a much longer negotiation process that directly enters in competition with the willingness-to-do of volunteers.

The final format, agreed with the different actors in order to decompose the generic urban hitchhiking service, is structured into a solution on two levels: *solution elements and solution options*.

[9] ENSAV La Cambre (National High School of Visual Arts), course of "Eco-design & Sustainable Development" 2007-08 coordinated by F. Jégou including students from Interior Architecture (Bux R., Cailleaux J., Carchon S., Nys M., Su L., Verhelpen C., Seutin S., Busiau A.) and Industrial Design (Casale A., De Brouwer B., de Smet M., Floriet G., Kunysz N., Senny A., Vallejo C., Van Ravestyn M., Von Ostrowski J.)

[10] Workshop "Scenarios building for a more sustainable everyday" hold by F. Jégou and A. Bernagozzi with a group of fourth year students in product design. In particular, the group who worked on the Logement Intergénération initiative was composed by Bayon L., Jaloux M. and Willerval V.

By solution elements, we intend to describe different components necessary and sufficient to constitute any particular urban hitchhiking service: This first level of decomposition focuses on what is intrinsically characteristic to the service, including all dimensions that are mostly emblematic and that differentiate it from other service categories. In other words, this level corresponds to what is necessary to mention when described by any external observer. For example: *particular 'vehicle & hiker identifications' are provided by the service; no specific 'picking-up point' are defined, but an 'identification of destination' is shown through signs held by pedestrians; the 'trip type' is focused inside a city sub area and no "benefits and payments' are exchanged; etc...*

The second more profound level of decomposition shows various options available for each dimension described in the first level. They correspond to possible alternatives within the service's design, as various exclusive or complementary choices to be made, defining a particular instance of the service. For instance: the 'hiker identification' dimension could be established as users raising his/her thumb and thus, 'no particular hiker identification' will exist; or as a 'discreet identification' such as a hiker card; or also a 'highly visible identification' such as a jacket for more efficiency, security and promotional reasons.

In order to facilitate appropriation by users and manipulation during discussion of a possible antenna, the solution elements have been shaped as pocket size cards. 40 cards have been defined covering 12 main dimensions of a urban hitchhiking service. The two dimension levels and options are written on the cards as well as examples when necessary. A visualisation is added: both facilitating the identification of each solution element and helping users to differentiate cards easily. The visualisation is made out of a photograph of a current situation (i.e. cars in the street; street curve...) on which the possible solution elements are added in a simple, visible sketch form. This mix is useful to produce a balanced feeling between a semi-finished service still to be adapted and an already implemented or feasible solution. The name and logo of a generic service has been set to maintain both connection and distinction from the already on-going initiatives naming it "CityStop". Blank cards were also provided.

More than helping to structure and formalize the solution, the progressive construction of the cards reveals some problems in the core definition of the VAP service. VAP members are progressively growing from its launch in 2005 reaching now around 670 persons and the raising interest in the service seems to confirm this trend. As previously mentioned, other groups of promoters intend to launch VAP antennas in other areas in Brussels and in local towns around. The different initiatives on alternative mobility listed before are discussing an agreement and a platform of action around urban hitchhiking. Nevertheless the critical mass of users still needs to be reached in order to consider it as a fluid alternative in urban transport.

Among the different initiatives, VAP is the more representative of what an average urban hitchhiking service may be and the most advanced in field experience. As said, VAP members can sign-up choosing between three options: as drivers, as pedestrians or as both. The VAP database counts at the moment approximately a quarter registered exclusive drivers, a quarter as exclusive pedestrians and half the members being sometimes drivers and sometimes pedestrians. The feedback collected by the service's promoter shows a different reality: more than 70 % of VAP members are most of the time drivers and only 30% tends to use the service as regular pedestrians. The figures of Comobil, a second and smaller initiative of urban hitchhiking in Brussels, 2/3 drivers and 1/3 pedestrians, seems to confirm this phenomenon. This remarkable difference reveals an important `inequity` in the distribution of members, equal to the national mobility panorama, and probably a less positive picture about the service's success than the growing membership tends to demonstrate. "Drivers are desperately seeking for pedestrians to give a lift to..." reports one VAP driver. Although no formal inquiry has been made, this remark seems to portray a shared feeling among members of the service. But, if this problem is true for most of the drivers, some of them -mostly the core group of promoters who initiated VAP- demonstrates a completely different situation: when driving, they tend to give pedestrian's a lift 3 to 4 time per day. Observing more carefully their behaviour reveals that they are actively looking for pedestrians. A video observation is currently in progress to define more precisely their

strategies of behaviour but it is already obvious that they look carefully at pedestrians; they spontaneously stop to ask people if they need a lift without any explicit signs that they were auto-stopping. It seems they have developed a particular acuteness to guess potential hikers in the similar way a taxi driver recognises potential clients through their body language before they call for a stop. In other words, they are hunting for pedestrians!

This remark leads to a radical change in the service definition. The difficulties are due to a lack of pedestrians and not lack of cars drivers. If at a mature stage of the service (beyond a critical mass of members) urban hitchhiking could be understood as "a service that fair-play drivers give to pedestrians"; yet during launching stage, to install the service habit, should be undoubtedly interpreted in a totally opposite way as: "a service that pedestrians give to conscientious car owners that feel guilty to drive alone in their cars..."

This fundamental finding triggers deep rethinking of VAP service, and opens brand new possibilities in the decomposition of solutions elements and options. The development could now focus particularly on drivers. Being a VAP member, they potentially change status from mainstream car-owners to car-owners making an effort towards alternative mobility. This motivation is certainly very interesting and should be used in the service's promotion. If drivers seek pedestrians, would they agree to do some efforts to look for more actively and therefore support the efficiency and development of the VAP?

In terms of matching offer and demand, traditional hitchhiking is based on long stretches of common journey along main roads. In urban-street environments, the difference between the destinations of driver and hiker tend to be not very significant and most of the time a driver would shift his/her route to drop the hiker at final destination. Barring in mind that VAP drivers are offering lifts, they could be asked to systematically make the effort of a slight detour in their route and pass more often where lifts are needed accordingly to their destination: zones lacking from public transports, lines terminus or commuter railway stations... The VAP promoters are therefore discussing with the Watermael-Boitsford municipality, where this service is based, for the installation of three VAP pick-up points to test this hypothesis (see figure 1, fine tuning the enabling solution).

In terms of service promotion, VAP promoters have a very limited budget. The initiative develops mainly thanks to their word of mouth efforts and some small subsidies to print leaflets. The VAP stickers on the cars are probably the highest point of visibility of the initiative. Knowing that drivers potentially change their mindset thanks to VAP, from mainstream car-owners to car-owners making efforts towards alternative mobility, they would be happy to promote the service even more than through a small sticker on their windshield. They are then described in the new definition of the service as 'ambassadors': they are given VAP leaflets to distribute and some of them will apply a large VAP promotion to their cars (see figure 1, fine tuning the enabling solution).

We could multiply the examples of shifts in most dimensions of VAP service, as it should be seen. This strategic design operation leads to a conceptual redefinition of the service and a change in it's meaning: **"VAP is an initiative of drivers",** not pedestrians. This simple working definition shows the essence of the initiative. One of the initial motivations to create VAP, as afterwards reported by Claire van Bellingen (VAP creator), were on the one hand "solidarity to people on foot in a rush, carrying heavy shopping, waiting too long for their bus" and on the other hand "the feeling of absurdity of driving alone in a four seat car".

This mindset shift will allow to reshape and reorient the service development. It points clearly as we already said, at a set of motivated drivers to promote and further expand the solution. They embody the current 'strength' of the initiative who should be definitely activated. The target of VAP could also be refocused following the same mindset: the service's core objective are only short occasional trips in dense urban environments. Any regular commuting or longer journey is out of focus.

If the objective of promoting VAP and its antennas is at the end to reduce the number of current drivers and make them jump in someone else's car, the public targeted by the service are certainly to be found amongst single and young couples with no car yet, elderly with time and reduce mobility, inhabitants of saturated urban areas, etc… ; in fact, anyone who is sensible to the issue but has no interest to own a car. But it is obviously not amongst the current and future VAP drivers; that if they subscribe is because they feel 'guilty' to drive alone, which subsequently also means that they don't intend to stop driving. So they agree to give up part of their comfort by taking hikers on board to go on using their car...

The first set of cards developed has been entirely revisited and up-graded on the basis of the first experience of dissemination with a new group of promoters in the suburb of Brussels. It is now being tested with a second group of new promoters in Wallonie.

Logement Intergénération

The first analysis of the initiative Logement Intergénération as described in the previous section, shows a bottleneck in the capacity of the current 3 mediators of the association to match demands of students and elderly people. This activity requires much more involvement than simple requests matching on the base of localisation and time; the viability and success of a cohabitation depends on multiple factors from: the association of profiles between the two parties, the agreement on the use of space, respect of schedules, nature of the help provided in exchange of logging... going to more psychological issues such as the compatibility of personality of elderly and student, the building of a family-like relationship matching each parties' expectations but respecting their respective cultures, freedom, privacy... Reaching this level of mediation is also time consuming both in the careful choice between offer and demand and meeting time necessary to explain the principle of exchange of Logement Intergénération: introducing elderly and students, starting communication between them and ensuring a follow-up assistance in case of difficulties or even conflicts.

On the side of mediator's activities, the system uses very few tools but a contract that defines and establishes key elements of the agreement between elderly and student. The document is based on 2 pages of fill-in questions according to the type of agreement decided, signed by both parties. At first sight, this very concise document may appear somewhat difficult to frame: half way between an excessively formal questionnaire, raising issues to be discussed before settling an agreement; and a rather primitive contract to define precisely rights and duties of both parties. But it's interest lays probably in its ambiguous nature; on the one hand it's a contract with all its official weight, complementing mutual interests and friendship that may rise spontaneously between an elderly person and a student. It shifts the solution from an informal social agreement from person to person to ensure both parties a certain level of involvement and reliability in time. On the other hand, it recalls the nature of a support to prompt social and psychological conversation much more than the one of a formal contract. In the detail, a large part of its content seems to tackle with secondary issues for a co-habitation such as what will happen during holidays or who will be there for the other's birthday... This type of question seems to embed the experience collected along repeated mediations trying to avoid misunderstandings and raise discussion over potential conflicts.

The nature of the relationship between an old and a young person is somewhat ambiguous in comparison with an owner-tenant agreement which results in a sort of mutual adoption between an elderly person and an a student far away from his or her family, both often lonely, so the starting point of the relationship is already far from away from renting a logging on

an economical basis. The exchange of mutual help recalls a relationship between friends or relatives: the first offers to share his/her own living place and the second offers to support household chores in return that the first cannot do alone anymore. As established, this potentially deep and rich agreement may also lead to misunderstanding and excessive expectations from one or the other (i.e. it is natural to think that if people are sharing their everyday life all along the year, one is expecting that the other will not leave him or her alone during holydays or during his or her birthday...)

On the basis of the analysis of necessary mediation, it was decided to propose a set of cards to support in a more extended and autonomous way the social conversation between elderly people and students. Compared to the set of enabling cards described before for the multiplication of the VAP initiative, the situation in Logement Intergénérations is similar but slightly different. The diffusion of the solution is expected here at user level and not at promoter level: the 3 mediators may use the cards to enable each potential elderly/student couples to discuss and build their agreement. But the same kind of adaptation of the initial service idea is needed to each specific context of co-habitation. The service's decomposition into solution elements may therefore follow a similar structure: a first level of solution characteristics lists what are the key-issues to constitute a solution (i.e. private/collective space; nature of the help provided in exchange of logging; repartition of the collective tasks...). A second level enumerates possible agreement basis for each of the first level characteristics (i.e. the help provided by the student may be to do the shopping, to cook, to help in the cleaning of or even to simply spend some time with the elderly person if he or she feels lonely...).

The main difference between facilitating the dissemination of VAP antennas and supporting the matching process of Logement Intergénérations probably is in the formulation of the design demand. VAP is a rather specific solution with a precise articulation of characteristic solution elements and a limited number of options for each. The cards should then enable promoters of a new VAP antenna to grasp the concept's solution composing an adaptation between the presented options, to a point of public agreement translated into a service's offer. For Logement Intergénérations the solution's concept is more simple and based on the research of balanced personal agreement on all topics regarding co-habitation. The design demand is then to provide an extended check-list of these issues to be raised in the discussion between elderly and student. The agreement that should be reached on each of these issues is then private, between parties, therefore no list of possible options can be really pre-defined. The key-point of a robust and durable agreement is that none of the issues touching co-habitation should remain unclear or not discussed. As there is a need for concrete conclusions of action and behaviour, mutually the most difficult thing to rise in conversation is the point of view of the other without preconception or *a priori*. And that's probably where matchmaking is tricky: the common social representation of such a co-habitation and of the related problems it may raise is often distorted and full of clichés: is the student trustable? Will he/she respect the place where he/she is hosted? Is the elderly not too invasive? Will he/she respect freedom of the student? etc...

Instead of options for each solution elements shown in the cards, it was proposed to show for each issue the point of view of both parts inducing a certain reciprocity, starting with simple things (i.e. the student "Doesn't smoke in the living room, the bathroom..." versus the elderly "Smokes in his/her room, the balcony..."). Lots of cards are focusing on daily chores, trying not to forget anything (i.e. "Carry the shopping", "Wash-up", "Organise collective spaces", "Share expanses", "Feeding the cat", etc...). Certain topics are proposing related points of view without referring them explicitly to one of the parties (i.e. "Helping in the kitchen, for me, for both, when I feel like it" and "Prepare the meals time to time, as pleasure"). The concepts are chosen to already suggest a balanced agreement (i.e. the space should be kept between "Clean enough" and "Not too dirty"). An effort is made also to talk about all points (i.e. "Pick-up a drug at the pharmacy, time to time, helping out" "Alert the doctor if something goes wrong"), to avoid taboo (i.e. the question of behaving with boy/girlfriends, "Staying overnight", "Hosting the partner" is not only a matter for students but also for the elderly couples). Beyond questions of domestic chores

and territories, emphasis is also made on feelings (i.e. "to rely on the other" and "to simpathise with the other") and mutual enrichment (i.e. "Transmit knowledge" and "Exchange know-how").

Each enabling card is printed on both sides picturing the duality of each issue presented: every idea has its contrary, each point of view has its opposite... It plays with the symbolic aspect of card games turning a card upside-down: it reveals something unexpected, challenging, a key-issue or a simple friendly wink... they are illustrated with pictures showing a student and an elderly character evolving in their shared household, pointing out details of private everyday life as well as social relationships with friends. Each situation is described with some key-words to clearly point out an issue but also playing with humour or irony. A blank space is available below the text to complete or customize it. Empty cards are also available for specific issues (i.e. "My expectations" "Your expectations"). The all set of cards displayed on a table give the impression of a sort of possible photo-story of a relationship between a student and an elderly person: it suggest a scenario of co-habitation full of love, attention and respect... (see figure 2).

All together, the set of cards tries to go beyond the social cliché and proposes a renewed image of both youth and old age, an image of a balanced co-habitation based on equity and collaboration between generations, a new kind of relationship half way between the warmth of a family and clear agreement between parties.

Finally, when both parts have "played" enough with the cards, discarded some, overwritten others, bargained on expectations and agreed on a possible cohabitation, they conclude in a set of cards that anticipates their story of life together. They will keep them and maybe sometimes come back to them to discuss problems or misunderstandings. The cards therefore have a hole on top so they can be collected and attached, sealed together as sort of "visual contract" between the two parts, as a promising agreement.

A first set of 48 cards has been developed and fine-tuned by a group of 3 students (Linda Bayon L., Mathilde Jaloux and Virginie Willerval) within a workshop at ENSAD in Paris. The cards are currently being tested by the 3 mediators of Logement Intergénération.

4. Conclusion

These on-going experiences show different characteristics and applications of strategic design to support diffusion of promising social innovation and the development of *enabling solutions*. In particular, the use of *enabling cards* allows supporting two steps of development of an existing initiative starting from the context of use where it currently develops into a new one.

First in the introduction of the initiative, the cards allow to present and give visibility to an enabling solution. Social initiatives as the ones described in this text, often reveal to be complex services. This complexity tends to disappear behind the informal setting of the solution, but going further into detail shows a subtle balance between flexible organization and social involvement, slowly evolving into experience embedded into the promoters' practice. Explaining properly the solution, showing its reliability and social qualities it activates, requires describing its complete panorama of characteristics. *Enabling cards* are very useful for that: they allow showing multiple facets of a solution, to present them progressively to any interlocutor entering into important details without threatening with too technical language.

Second in the fine-tuning of the initiative, the cards allow to support the strategic conversation between groups of participative promoters, to customise solutions to particular contexts of use, to set a temporary *visual agreement* between the actors involved, finally to

discuss and organize progressive development stages of the initiative from launch to a mature service. Within a dissemination action, it's important to question each dimension of the service using a set showing different option-cards to tease reflection amongst people with knowledge of local context. Then the physicality of enabling cards as building blocs, easy to manipulate, compose, and reorder, made them an ideal tool to empower people who are not accustomed to project thinking, to feel confident in composing a customized solution, and from there, to involve in implementing it.

To conclude, if we look now at these experiences from a broader point of view, we see the appearance of situations of co-creation both from the point of view of users; taking more and more part in ideation and implementation of products and services they use; and from the designers' task, evolving towards *open design processes* enabling these users to design their own daily living. An *enabling solution* in this context can assume different settings and scopes.

Design teams working on facilitating the dissemination of a grassroots initiative may choose to start from experiences as analysed above to develop an *open solution*, a package or toolkit containing all the material and immaterial elements such as guides, rules, programmes, specific products, dedicated software... to facilitate the construction of a new solution. This solution is open in the sense that all proposed instruments offered in the package may be used or not, up-graded and modified by new promoters or users of the solution. This flexibility allows the necessary adaptations to multiply the initial initiative in different contexts.

The experiences reported above suggests to go one step further and consider the interest of an *open design process* on top of the *open solution*. In both cases of VAP and Logements Intergénération, the definition of the enabling cards as one first tool toward the constitution of *enabling solutions* provoque important feed-back and redefinition of the solution itself. The contract initially used to prompt social conversation between elderly persons and students from Logement Intergénération expands into a much longer list of issues instantiated in the cards. The dissemination process of the VAP as Claire van Bellinghen stated after the initials meetings with the group of new promoters of the solution "taught me more about my initiative than I am able to teach about it". The transposition process is a redesign process. New promoters 'rediscover' the recipe more than they 'apply' or 'interpret' it. The existence of enabling cards (or any other enabling tool) speed-up this redesign process, asking the key-design demands, guiding the development steps and suggesting sets of already generated ideas... And the result is even more promising both because the very nature of the 'ingredients' of the solution is deeply questioned at each transposition loop and because new promoters feel to be deeply empowered by the 'new' solutions they develop more as 'creative cooks' than 'recipe preparers'.

Changing the change
DESIGN VISIONS PROPOSALS AND TOOLS

Real-time layouting

A design "way of doing" to improve participatory process tool-kit, applied to the conversion of buildings

Elena Enrica Giunta[1]

Abstract

The **topic** of the paper is to make a connection between design discipline (and interior design as specific field), the contemporary phenomenon of abandoning urban areas and participatory processes. The aim is to clear that urban re-functionalization may represent an opportunity for design to research on "how" to deal with these types of systems. As the basis of the design discipline is to produce innovation strategies and design method, according to own proper dialogical skills (briefing methodology, lateral thinking and other forms of brainstorming, problem setting/finding attitude etc.), it becomes an essential instrument which may intervene in reshaping urban abandoned areas.

*iper*industrial age[2]

"*Economists predict that the biggest industries of the 21st century will be the social industries, health, education, wellbeing etc. These will contribute 30% to the economy. The old industries such as cars, IT, telecoms will contribute 5%*" (Green 2006). According to this vision, **social involvement** can be read as the key to predict success or failure of a project[3].

All over the world, there is an increasing demand from all sides for a deeper local involvement in planning and dealing with spaces. This is the only way for people to be satisfied with the environment they live in, and it is the best way of ensuring that communities become safer, stronger, wealthier and more sustainable. *"Considerare la dimensione dell'interazione sociale ci rimanda alle questioni del punto di vista e del potere"*[4] (Pozzobon 1994). This statement underlines the necessity to develop a design strategy able to analyze, to understand and to solve the project's need from an ***emic* point of view**. The term "emic" is referred to anthropology: it means the inner point of view of natives, with their beliefs and values.

"Anche qualora vi fossero i fondi sufficienti per istituire nuovi servizi, costruire nuove forme organizzative non co-progettate con la gente rischia di colludere con quella diffusa spinta alla delega e alla rivendicazione che finisce con il nascondere il fatto che le persone verso la comunità non hanno solo diritti ma anche doveri, e che l'esercizio della solidarietà, da sostenere con grande discernimento e consapevolezza delle ambivalenze e dei conflitti che vi si annidano, è oggi l'unica via per dare un nome e gestire i nuovi problemi che si stanno presentando"[5] (Mazzoli 2005). This is the way researchers and professionals in general should approach research and briefing collection. This approach is similar to the ethnographic one; it represents what the psychological discipline calls *theoretical participant*, i.e. one who is able to develop empathy with the context, yet with a detachment which is functional to its effectiveness.

Furthermore, it is possible to demonstrate that processes of local involvement, based on the 'designing *with* people' approach, are able to support signification processes. As it is well illustrated in the research carried out by the psychologist Mihaly Csikszentmihalyi and his colleague Eugene Rochberg-Halton, material possession in contemporary urban life is one of the most powerful ways for people to build their identity, carving meaning out of things and environment. Their work is based on an analysis of some families in Chicago who were interviewed about their domestic environment. The survey contributed to draw on a series of transactions between people and things and to develop a *model of "personhood"* in which goal-directed action and the conferring of meaning through signs assume vital importance. This piece of work outlines two interesting ties, useful for the design project: first, the distinction between object valued for action and object valued for contemplation or, in other words, the co-existence of a functional environment and a symbolic one; secondly, the role of **emotional attachments** to things and environment in order to develop relational patterns. The relationship "subject *to* object", or more specifically the one "people *to* environment", may represent a real model of non-verbal relationship (Veronese 1998)[6] by which men try to secure themselves the possibility to recognize and to self-construct, while keeping an open dialog with the *habitat*.

All previous thoughts are coherent with the features of the current *iper*industrial age, whose main concepts are briefly resumed in Fig. 1.

---

[2] As defined by Ubaldo Fadini, professor of Aesthetics at the University of Florence.

[3] As example if education, engineering, policy or design are 'done *to* people, not *with* them' (Worpole 2000), they fail.

[4] "Considering the dimension of social interaction brings us back to the issue of the point of view and the power."

[5] "Even if sufficient funds were available to introduce new services, building new organizational forms which are not designed together with people is a risk. It might in fact collude with the input to delegate, which hides the fact that people not only have rights, but also duties in regards of the community, and that solidarity is the only way to define and deal with new problems".

Fig. 1: Key words about the change of paradigm, in epistemological terms, of current age. Contemporary attitude is defined, by a series of authors[7], as a "barbaric mutation" age with own proper characteristics.

Participation is meant as a way of designing and managing urban transformations. In the field of physical transformations, the citizen participates only to profess him/herself against something he/she considers penalizing. The non-paticipation trend can be identified in the *"difficoltà a riconoscersi nei luoghi della città, in spazi che non possono definirsi né identitari, né relazionali, né storici"*[8] (Augé, 1993). **Participatory processes** should be necessary to make public spaces evolve into collective ones; indeed, participatory processes intervene to refresh a design practice which is no longer able to preview *"le istanze di qualità di vita, di fondazione di identità, di rapporto equilibrato e profondo con il territorio e la storia dei luoghi"*[9] (Ferraresi 1995). Over the past few decades, a wide range of methods has been pioneered in different countries: these include new ways of interaction among human beings, new kinds of events, different types of organizations, new services and support frameworks. At the time being, teams that deal with participatory processes are interdisciplinary; the équipe is often composed by sociologists, architects and planners, commonalities, citizens. The design process is structured in five phases: formulation, actuation, planning, realization and verification. The concerted approach gives more emphasis to the actuation phase, as it is the one that involves many decision-makers, who together identify needs, define objectives, write projects; this process represents the co-design dynamics. This kind of approach starts from the hypothesis that a given reality changes when confronted, negotiated and concerted together with the receivers of such change. The following phases are a consequence of these actions and of their common influence.

Recently, even designers have found their role in these team-works: their strength is mainly identified with their strategic attitude and visioning activity. In particular, an interior designer may provide a specific professional support in participatory processes applied to re-funcionalization of abandoned buildings, playing the role of **technician-facilitator**. The designer might develop a reflective skill and a willingness to fit his disciplinal knowledge (as well as know-how), due to local attitude and needs. The purpose is to generate maximum involvement, throughout formal and informal strategies, in order to build a real dialogue between community and government, linking each other's mutual expectations. Consequently, the **purpose** of the paper is to clear how the interior design practice can play an active role in participatory processes

[7] like Delzìo, 2007; Baricco, 2006; Corretti, 2006; and Goleman 1995.
[8] "Difficulty to identify oneself in the city spaces, which cannot be defined neither as relational, nor historical".
[9] "The insistence on the quality of life, on foundation of an identity, on the creation of a deep and balanced relationship with the territory and the history of places".

with an own proper instrument, which can be added to the existing ones to improve the specific methodology.

collective outsourcer

"L'analisi dei bisogni non è più una accurata classificazione delle esigenze del sistema. E' piuttosto un processo dialettico che coinvolge gli utenti -portatori di domanda, i tecnici e gli altri decisori deputati a fornire una risposta, che si sviluppa secondo un percorso di progressiva e reciproca chiarificazione delle esigenze degli uni e degli altri"[10] (Bellaviti 1994). In order to identify the nature of the outsourcer addressed in such type of design processes, we refer to the definition of **local community** as *"dimensione territoriale, luogo di vita e di scambio e ambito di relazioni, spazio privilegiato per la partecipazione sociale"*[11] (Martini and Torti 2003). Such definition highlights the three knots that found the sense of a community subject: places, shared value component and participation. We must learn to identify the community as a social subject, not only as a catchment; this simple shift in our point of view allows the designer to imagine the consumer as a series of active citizens, that have resources and skills, a self-defined identity and that tend to self-determination; able to stimulate a sense and forms of responsibility. Referring to models of social planning (Leone and Prezza, 1999) and trying to transfer and translate them into design practices, we can observe how the participated project for building reconversion moves with a certain freedom on the axis of the design pre-structuring. We can tackle this type of process emphasizing the planning or the actuation and the continuous re-orientation of the project praxis, i.e. choosing a synoptic-rational approach or aiming at the heuristic project[12]. The synoptic-rational approach does not help to think the project as a flexible instrument, able to direct decisional processes along the way; what comes out is the image of a designer who can predict a definite future. The failing consideration of social interaction, of the variables of the process and, last but not least, of the cognitive and emotional levels of the actors involved (multiple outsourcer and designer together), disconcert the thoroughness of such approach. Moving from one extreme to the other, we come across the **concerted approach**, a dialogical-participated design form that, according to the author, is the feasible and meaningful way to orient design processes. The models of participated design derive from the concerted approach.

The promotion of an individual's direct participation should facilitate the transformation of a citizen into an inhabitant; such concept *"allude anche al radicamento in un luogo fisico e simbolico, contiene il riconoscimento della particolarità, a volte dell'unicità, del luogo vissuto, difeso progettato, prodotto trasformato, abitato"*[13] (Giusti 1995). **The subjects** obtain a higher and higher importance, as the operational outcome of the demand must be negotiated with them. Design is a process of identification of the alternatives; it must avail itself of the creative contribution of stakeholders[14] as the chosen solution should be verified on the basis of long-term effects that transformation produces on the urban and territorial context, which includes the possibility of appropriative mechanisms on behalf of the inhabitants. The inhabitant is a resource which enriches the decision-making process, being the only subject that is able to elaborate the new quality indicators[15] together with the designer. The inhabitant is therefore able to link such indicators directly to the objectives of the project.

[10] "The analysis of needs is no longer a classification of the system's needs. It is rather a dialectic process which involves users-carriers of a demand, the technicians and other subjects who are supposed to give an answer, which develops into a mutual clarification of each other's needs."

[11] "Territorial dimension, a place of life, exchange and relationship, a privileged space for social participation".

[12] With the term "approach" is intended a framework, both practice and theory, for participation which could be applied to various experiences and it is not defined by a unique 'way of doing'.

[13] "Refers to the entrenchment in a physical and symbolic space, contains the acknowledgement of specificity, sometimes of the uniqueness of the lived space, sheltered by the project, a transformed product, which can be lived".

[14] Or all those bearers of information and interests with respect to potential targets, these individuals are identified as particularly important interlocutors of the territory.

[15] Which should be necessarily emic and situated.

the phenomenon of abandonment as *field*

The urban adaptive re-use[16], due to the abandonment of industrial areas and new forms of entrepreneurship, develops new research fields within the interior design discipline, that can also be applied to designing a new habitat. Urban re-structuring has become a huge phenomenon of our century, which concerns Europe as a whole. This dynamic process taking place is "*a phenomenon of enlargement in appropriation of space for private use, able to generate a positive and creative movement of urban and social renewing, in which each person can find out own proper life project*" (Mello 2002).

The processes of urban re-functionalization, due to the abandonment of industrial areas, give space (and provide spaces) to develop innovation. In fact, the re-use of these structures requires internal transformation of a large part of the still existing ones. Industrial areas often contain fine, sturdy structures which contribute to local character. *"Usually, these kinds of places are huge open spaces that can be set up according to different situations and needs; they have not historical decorations, but at the same time they have a clear identity related to the industrial history of the place; they present a flexible space and system setting that allows a co-existence of many events"* (Telli 2008). Often, they are ideally suited for conversion for other purposes. The difficulty is in making a sufficiently bold transformation of an area to change its image, attract new uses and persuade landowners and others to invest in it. In this scenario, a partnership is established between the main parties, and an academic institution plays a key role in raising the profile of the area, assembling expertise and helping organise an action planning event to firm up a strategy that all actors agree upon. This may represent a rich potential for the design discipline (and for interior design in particular), becoming a wide field for applied research; a potential field for testing the capabilities of the discipline and its crucial role. Indeed, the co-design of a place's physical dimension may contribute to activate local community in terms of learning and self-meaning processes. New forms of coexistence and feeling of belonging shape themselves in the conception and organization of the community spaces, in which forms of participation, responsibility and self-organization need to be improved. The way public and common spaces are used stands for the feeling of belonging; participated design is in fact related to secondary urban works[17].

As we have already mentioned, the concerted approach represents an heterogeneous series of theoretical approaches, which refers to different disciplinary fields; their common assumption is that knowledge is not based on a parallelism with external reality, but on the observer's understanding of it. First of all, working with a community means shaping its images and representations, which derive from the community's self-observation, which embody its identity. Therefore, the initial phase of **the briefing collection** is vital for the project; in particular, it is fundamental in relation to what has been defined the *collective outsourcer,* in order for the designer to focus on the features of the community itself, before focusing on the ones related to service/space, which define the design activity. The re-foundation of listening techniques and analysis is of vital importance in order to oppose the separation of real needs and their interpretation.

At this point, interior design practice clarifies its essential importance as a "catalyst", which adapts the existing spaces to new roles and functions, trying to keep the identity of the outsourcer/community. The request of conversion of buildings would be answered with design working instruments and not only referring to the building industry. Rehabilitation of public and private open spaces responds in new ways also to the requirements of contemporary lifestyles, creating local centres in the outskirts, that concentrate activity around higher quality and more accessible public spaces. This action concerns the use of urban spaces, both from the standpoint

[16] Considering the needs of the National territory.
[17] Or in other words not concerning housing, but collective services and places.

of their pleasantness and attraction, and in terms of removing physical barriers, in order to include the weaker social categories. The quality of the urban environment can be regarded in a diffuse and pervasive manner (*housing quality*), or in a discrete and aggregate manner, to form features of central value (*quality of polycentrism*); the choice between these two modes is reached as a function of the features of the context, of the objectives of the policies, of economic availability and of presumed effectiveness[18]. For the design discipline, the **quality of a contemporary environment**, or in other words, the requirements the designer could add (trough the project) to make space livable and to allow a series of happenings in its interiors[19], is provided by the way the designer links the three actors of the system one to the other:

_*bodies* or the social component,

that is both individual and communities. The social component needs spaces designed for an individual use and also for group/community action; in each case space should be a vehicle of belonging.

_*objects* or inanimate actors on inhabited stage,

referring to the theory of expanded field, we can illustrate how "things" operate, as fragments, in a semantic symbiosis with their surroundings (space), due to their use (bodies);

_*spaces* or system of containers;

if conjunction is the current logic which defines the meeting of space with space, we can state that this interaction generates a threshold: a sort of blended area as interface. In these places of opportunity and transformation, we can experience the dialogue with objects and bodies, in an endless game between foreground and background elements.

interior design *challenge*

"Il tema dell'attrezzatura urbana e dei servizi collettivi è uno dei campi in cui si amplia e si intensifica lo scollamento esistente tra visione oggettiva del fabbisogno ed il reale interesse comune ovvero di una possibile condivisione collettiva, da parte di una comunità locale, di fabbisogni e desideri legati al territorio, alle pratiche di utilizzo dello stesso"[20] (Roncayolo 1978). More and more governments are willing to include their citizens, and have therefore shown a particular interest for inclusive planning processes.

In Italy, the diffusion of participatory practices in the urban transformation processes expressed itself through the development of single local experiences. National urban politics suffer from the effects of some European policies; in the same way, the revival of participatory approaches is due to the movement of sustainable cities and to the implementation of processes foreseen by *Local Agenda 21*[21]. The European Community, thanks to specific programs and funding[22], has promoted the logic of environmental regeneration, looking at the urban environment as the sum of physical as well as social components. On a national scale instead, it exists a political tool called **Neighbourhood contracts**[23], a typology of complex programs dedicated to the recovery of degraded residential neighbourhoods. Such contracts are made of

[18] The SURPrISE project, through its practices, constitutes an excellent workshop in which to try out and verify these principles. SURPrISE (sustainability on urban regeneration programs in southern Europe) is a project developed by OQR progreSDEC – 2007. Ref. http://www.progresdec.org.

[19] Also "urban interiors" are considered as interior spaces as well, due to their reference to city tissue.

[20] "The issue of urban equipment and collective services is one of the fields where the separation between an objective vision of the need and the real common interest of the local community related to use and visions of the territory becomes wider."

[21] Also in Italy is active, by a few years, a Coordination of these *Agendas.*

[22] Reference is to complex programs, firstly Pilot Projects (1993) then replaced by the European Urban.

[23] conceived in 1996 as experimental programmes (L.662, 23/12/1996) they were activated with the enactment of Decree 22/10/97 by the Ministry of Public Works. A second ministerial decree (n.2522 of 27/12/2001) initiated practical steps for the implementation of programmes called "Neighbourhood contracts II".

prescriptive regulations, which suggest the creation of equipped permanent venues on the territory, called *Laboratori di Quartiere* (Neighbourhood Workshops)[24], and the use of a participated approach in the recovery project of the community and it habitat, through forms of self promotion and self management. From the observation of political tools shaped *ad hoc*, emerges that the quality of cotemporary living is necessarily connected (if not dependent on) to that of social life.

"Individual acts and activities would become the new criteria of relevance" (Bauman 2001). Briefly, the assumption that "meaning by doing" is expression of the contemporary living attitude does not exclude any project! On the contrary, the new generation of interior designers should develop a working method able to operate both with a *systemic*[25] and *emic approach.* A crisis of the classical analytical and descriptive disciplinary processes emerges in the light of features and values with which we express the *iper*industrial era: the need to build open predictive models or criteria arises. The challenge is to simplify the analytical complexity without reducing it, by using a common and shared language; it becomes necessary to build a new relation among interpretative categories of urban space, the tools for intervention and the inhabitants themselves.

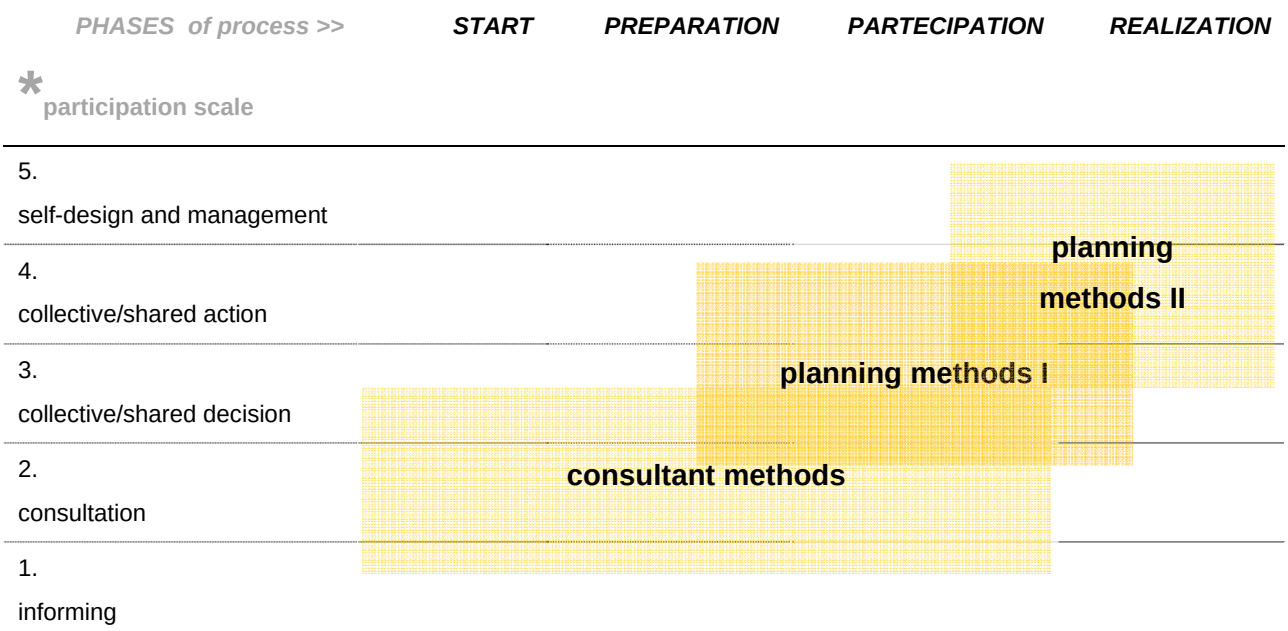
From the overview, we can suggest *exhibit design* as a specific approach of the interior design discipline, which is able to deal with these variables. To develop an interior design project in a non-exhaustive way opens various fields of application[26] to the discipline: physical environment should be organized with architectural supports and subsystems that could be freely combined by users. The principle very well meets the reconfiguration request of interiors, typical of the nomadic character of contemporary society, which is **designed and lived almost in *real time.*** Therefore, the temporal dimension becomes the new scale for the contemporary project. *"The vision of perfect reality argues both with space and with time, deleting qualitative dimension of space itself. However, space is expression of a specific time/age, which is similarly complex and historical"* (Bauman 2001). The term "real-time" must be read in two different ways, that lead to two visions of the contemporary project praxis. On one hand, *real-time* is an attribute of a tool that expresses its effectiveness in progress, i.e. in real-time with the project for which it is used for; on the other, the project outcomes are coherent only temporarily (*situativeness*), operating within a performance logics.

The performance logics shifts the project's focus from "how" to build to "why" build, and therefore invites us to consider real needs, i.e. the demand which determines actions aimed at quality building[27]. The concept of quality connected to the capacity of identifying and answering the local collective needs in therefore reinforced. Moreover, the idea of quality is strictly related to sustainability in relation to its three dimensions; in fact, it is not sufficient to improve the quality of the urban environment and help the collective outsourcer being economically independent[28]. In order to achieve the desired effects of urban regeneration, renewal measures should not only remove degradation, but especially involve the inhabitants in a strategy of local e*mpowerment*. With this term we intend the capacity of design processes to promote a new local identity by means of broadening the decision-making process; sustaining territorial awareness and social "belonging". The issue of social forms of involvement, previously dealt with, becomes even more evident: the users contribute significantly to determine not only the function of interior space, but the meaning itself. In this semiotic process, user and designer are both operating on environmental systems, as in a co-design process realized just at the end of the project flow.

[24] Real operational units which manage programs of Urban Regeneration. The latter are increasingly developed in conjunction with plans of Social Accompaniment.
[25] With the term "system" is indicated the whole object and at the same time the relationship between them.
[26] More concerning "everyday-life" compared to traditional museum or exhibition fairs. For example workplaces, enlarged hotelling (communities, schools, hospitals) and forms of temporary housing.
[27] Expressed solutions would result temporarily defined, open to changes in culture and therefore dynamic. Design answers, once implemented, could be made again in crisis.
[28] Or in other words to "produce by themselves" responses to their needs.

Furthermore, a percentage of unpredictability, which derives from **individual creativity,** is typical of this kind of projects, which interact with spontaneous behaviours[29].

Looking at the participatory processes as a chain of value, it is possible to outline a precise point where to insert something new and to make it longer and more useful (perhaps not complete), especially in the participatory experiences applied to the conversion of building processes. Design discipline has already developed a long series of techniques to visualize and construct shared scenarios. However, at a certain point, it is necessary to translate the common vision built up with these activities in a real strategy of space management; hopefully, at a second stage, this theoretical "manifesto" will be realized. An **interior designer** can have a precise role in these latter phases. *"It becomes decisive to be able to determine a design approach capable of recognizing the specificities of the context within which the project is called to intervene and, on this basis, determine the possible intervention strategies"* (Crespi and Rebaglio 2007). In order to better identify the designer's potential input and that of the set tool, we will briefly identify the currently available tools. The structure of the participated model connects the phases of the concerted project with different levels of active involvement of the social component. In order to take part in a transformation process, i.e. to actively influence it, it is necessary to differentiate the possible intensity levels[30].



In some circumstances, the lower levels, as for example the diffusion of information, are themselves essential elements of more complex participation strategies. Information, even if interactive, is much different from what we have here identified as consultation. The difference between the two modalities of involvement does not consist in a practical distance, but whether the opinions of the citizens in the real decision-making process are considered or not.

In order to comment the involvement of the superior levels, we would like to present a brief overview of the methods and techniques[31] used in the participated project, that are closely related to the architectural and/or design praxis[32].

[29] In use.
[30] "Ladder of participation" (Arnstein 1969). In addition to the five levels cast, the scale admits intermediate situations which include additional degrees and providing for the inclusion or exclusion of voices and local interests that in this paper, has chosen not to consider.
[31] Methods are different interpretations and alternative operational approaches. Techniques are tools designed to manage precise steps of methodology, with cultural, analytical, representative or communicational purposes.
[32] Collected data to illustrate this overview are mainly referred to: Neighbourhood Initiatives Foundation; and to *The Community Planning Website* (www.communityplanning.net/index.htm).

consultant methods: data search and listening

By consultation we mean the transformation of the communication flow into a structured interaction, with regard to a specific topic or problem. This implies the inclination to and the management of a multidirectional process of information exchange. The term “consultation” is often associated with forms of collective confrontation, and mistakenly identified with “participation”. Meetings, assemblies, discussion tables, internet consultations, referendums etc. are all forms of consultation. In such model, the power to decide the best solution belongs to the designer-decider (top-down), but the adoption of a more or less structured listening and comparison system allows the introduction of real cognitive local resources that contribute to the decision-making process.

Within the universe of active consultation, we can distinguish two approaches in data collection: an open methodology and a structured and closed listening. In the first one, collecting opinions and preferences aims at using the local knowledge heritage as well as perceptions and evaluations of the inhabitants as a starting point for the identification of design hypothesis.

choice catalogue	photographs or simple sketches about various design solutions (both urban and building scale) are collected in albums, which are used by little groups of residents to express their preferences.
field methods *as Suggestions box or Video box*	are instruments of discussion or investigation into the views of the community: people express their ideas about specific issues (by written form or video). Contents are immediately shared on large screens, generally in public places, in order to arouse the debate.
community appraisal	technique promoted by ACRE (Action with Communities in Rural England); it provides the establishment of an evaluation questionnaire on issues of territory drawn up by experts and representative citizens (of the local community). The analysis of that results is addressed to encourage action of local authorities and volunteers.
Parish maps	technique promoted by ACRE; it allows citizens to represent (by maps of different size, scale and material) the characteristics of human and natural interest that each attaches to the place where he lives.

When the technicians that guide the participated process, instead, have already defined the problem and formulated design hypothesis aimed at solving it, the listening activity is structured upon fixed alternatives, which are therefore close. Such techniques should illustrate the potential solutions in function of sharing, and afterwards give a priority to the preferences.

Open Space Technology	more than 20 years old, this technique is by H.Owen, an anthropologist lent to business advice. The OST has been tested in over 100 countries around the world to animate initiatives with a number of participants between 5 and 2000 persons. Particularly suitable to open a comparison on complex issues for which there is no unique solution; this technique allows participants to experience a highly innovative way of working together.
Priority Search *by Focus group or Philips*	a micro-team which represent the population has to structure a survey questionnaire. Data collected are as an overview summarizing the different priorities, hopes and opinions, criticisms in the community, and also the contradictions and conflicts between social groups.

The following participation phases represent the actual shift to a bottom up approach in the definition of strategic choices, which outline the needs and aspirations of the participants. The sharing of the decision-making process and the active involvement are close to the concept of empowerment, and promote a process of common work, able to create a frame for shared values and to identify the direction of development. Such projects perform decisional and strategic functions, but also procedural and planning ones; the two dimensions are often tackled together.

The concerted action occurs in form of brainstorming[33] or workshops, less formal and more creative than public meetings. The level of collaboration stimulates the hypothesis of a "partnership" between all actors that can put their resources at stake.

At this stage of the process, before moving on to any kind of strategic planning, it is necessary to create common visions. The term *visioning* combines the will to build a shared set of values, a system of objectives, and strategies and actions able to orient the development of the project. Through the visioning activity, citizens meet and build a concrete image of their future; the community visioning techniques are in fact based on a cooperative government system.

Future Search	members of different social groups, aided by experts facilitators, carry out four classic stages of the method: review the past + explore the present, create ideal futures, identify common round and, finally, make action plans. The community reflects on possible scenarios, future development (with a time horizon between 5 and 20 years). This identifies a preferable and determine the actions that you must take to achieve it. The future search allows you to achieve high degrees of consensus in a pre-trial phase and therefore can more easily take the subsequent development actions.
Community Visioning	stakeholders are divided in small working groups, in order to more easily develop a set of ideas and graphic representations on the possible and desirable state.

The citizens' involvement is important also in terms of making their vision of a desirable future more "concrete", at different depth levels. The methods used for this type of participated design will therefore vary according to the territorial scale of intervention.

planning methods I: *L and M design scale*

or, in other words, planning tool for landscape and urban project.

Action Planning Event	structured set of methods which provide for the definition of shared objectives and strategies for development. In order to achieve those objectives, it is generally directed to representatives of different local groups (sometimes extended to the whole community).
Planning for Real	is a role play method, created by the Neighbourhood Initiatives Foundation. Highly visible, hands-on community development and empowerment tool; provides for the start-up of the local community to improve its environment. PfR uses a simple 3D model as the centre of attention, on which proposal cards are arranged by the inhabitants. Suggestions are then priorized and options card are commented. Cards should be used on a diagram "Now, Soon, Later" due to enable the community district to outline its own strategy. After decisionmaking, local community actives its resources (and any external resource available) for the realization. To use the method, the NIF advise is to use experts or who have attended special training courses.
Strategic Choice	this approach is a research result of a work by some scholars of the Institute of Operational Research (IOR). The participants of the process are divided into groups of actors which are separated by criteria of: location (internal / external to the process) and role (political / technical). It is a process of plan able to strike a balance between the need to decide with urgency and at the same time make choices flexible and effective. In Italy, this method has been developed in particular by A.Giangrande (University "Roma Tre") and applied in some projects addressed to the Municipal Laboratory of Marconi district.
EASW *European Awareness Scenario workshop*	developed and promoted by DG XIII of the European Commission; it is based on identification process of different combinations of technology, public policy and actions brought by individuals and society, to achieve a model of sustainable local development. The Workshop lasting three days and it is divided into two phases: development of visions and proposed ideas, both are analysed on the basis of a specific plot "HOW*WHO."

[33] Conceived by A.Osborn is a method that stimulate the creativity of individual or groups. It is a procedure of problem-setting which makes possible the re-framing of the issue, transforming the initial unworkable proposals (formed by association of ideas) into tangible solutions.

microplanning or *CAP* *(Community Action Planning)* [34]	developed by R.Goethert and N.Hamdi, Department of Architecture at MIT; the method has been applied mainly in developing countries. A small group of local representatives engage a structured process of comparison; participants helped by experts contribute not only to content but also to build up the program. For each strategy, various operational solutions are formulated and, finally, the most appropriate are selected due to their feasibility and desirability. The process is referred to a specific location and directed by the interests of the community. The group of applying technicians are asked to provide an opinion on technical feasibility, chances of success, and so on.

planning methods II: *S and XS design scale*

or, in other words, planning tool for district/area and building project. Moving down in scale of planning level, we reach programming and transformative activities aimed directly at the action, no longer giving simple indications, strategic guidelines and constraints. These are design processes linked to intervention in the field of new construction or recovery of existing estates, characterized by different levels of complexity and multi-functionality. Usually, a design studio plans a complex without knowing the users of such spaces. The final product is often very far from the needs of the users, and is therefore due to be transformed and readapted in the future[35].

At this point, the implementation of participated planning activities might mean a higher level of effectiveness, efficiency and sustainability of the interventions, especially in the long run.

Pattern Language	concept developed by C.Alexander in 70s. It is a set of instructions (pattern), upon them the community, with the help of technicians, have to chose the most appropriate to the context of intervention, the aim is to design a satisfactory environment and ecologically appropriate for themselves and their activities, focusing on a single building or on a more general element of the context.
Design Workshop	small groups of professionals and inhabitants are working together in a creative way (through problem finding, project proposals, drawings), the most significant ideas are then summarized and fixed in design diagrams.
Design Game	this methods reminds jigsaw puzzles: participants are divided into working groups; different design elements are distribute on project plans up to define shared solutions of space. A highly visual way of allowing people to explore physical design options for a site or internal space; materials for making pieces are kept at hand to allow new items to be made as desired. Layouts produced by different individuals or groups are discussed and analysed as a basis for drawing up sketch designs.
Building Design & Conversion Kit	is a role play created by the Neighbourhood Initiatives Foundation; it is a design tool directly developed from PfR. It is based on the same concept but the kit is addressed to operate in a smaller scale. To best manage the method, the NIF advised to use the official kit: the Pack provides all materials to make a 3D physical model (including moveable walls, doors, windows, and some fixtures and fittings). It has been used for many types of projects, for example health and community centres, self-build and redesign of council housing.

Finally, the self-design level and management implies the highest involvement: it determines the (current and future) inhabitants direct control. Such level focuses on the direct involvement in the building and territorial production[36] and transformation process. The concept of self-management in such philosophical framework shifts responsibility and decision-making power to the final users themselves. In such perspective, the role of technicians changes: they no longer meet the needs of the public or private sector, but those of the citizens. Interior design practice should operate in this contest; particularly, it might be able to solve a primary function: to give the definition for new ways of using space (linked to the evolution of the more traditional functional categories). The

[34] Reference is the work of the research group SIGUS - Special Interest Group in Urban Settlement (teamwork of MIT School of architecture and planning, Boston).

[35] an example are projects for social housing, which in the past decades, often cause problems of vandalism and damage. In some extreme situations commonalities perceived to the demolition of buildings as unique possible solution.
