Technology adoption news and corporate reputation: sentiment analysis about the introduction of Bitcoin

Abstract:

Purpose

Evidence from previous literature indicates that adopting a new innovative technology has a positive impact on a company's business performance. Much less work has been carried out into examining whether a technology adoption has impact on corporate reputation. This research examines the latter topic in a context where social media is the channel used to share news about the introduction of a new technology. The empirical setting of the study consists of five retail companies located in the USA that decided to include Bitcoin as a payment platform.

Design/methodology/approach

Twitter data were used to measure how sharing news about the adoption of new technology could affect the reputation of the companies selected, keeping a clear distinction between the volume of data relating to social media responses and the sentiment expressed in the tweets. A panel vector autoregression model was employed to incorporate series of data relating to news items, volume and sentiment.

Findings

The results show that the news about the adoption of a new technology has a positive impact on both the volume of tech-related tweets and the sentiment expressed in the tweets themselves, although the patterns of these two effects are different. The resulting impact decreases after a few days, both in volume and in sentiment.

Research limitations/implications

The analysis has limitations that future research could address by extending and diversifying the examined companies and the social media used as data sources. The research suggests that managers in medium-sized companies can leverage on the introduction of new technologies that have a direct impact on their customers and gain reputational benefits in terms of immediate visibility.

Originality/value

The research introduces an additional dimension of analysis to the current stream of corporate reputation. Although the literature has already covered the dynamics of response to events on Twitter, by focusing on the adoption of the new Bitcoin technology, the paper provides novel insights.

Keywords: Corporate Reputation, Technology Adoption, Bitcoin, Social Media Analysis, Sentiment Analysis, Vector Autoregression, Blockchain.

Introduction

Corporate reputation refers to the “admiration and respect a person holds of an organization at a point in time” (Dowling, 2016: p. 218). Previous literature agrees in considering it to be a strategic asset for sustaining a company’s performance (Fombrun and Shanley, 1990; Benjamin and Podolny, 1999; Deephouse, 2000; Gatzert, 2015; Crespo and Inacio, 2018).

Corporate reputation is seen to contribute positively to a firm’s activities through its ability to influence an organization’s relationships with its stakeholders (Lange *et al.*, 2011; Burrows *et al.* 2018). In particular, corporate reputation is a key element of brand equity, when it transmits an accurate and positive company image to stakeholders (Caruana and Chircop, 2000; Heinberg *et al.*, 2018; Burke *et al.*, 2018). Brand-related and product-performance indicators, such as loyalty, sales and profit, can in fact all be influenced by corporate reputation (Gray and Balmer, 1998).

1
2
3
4
5
6
7 Several studies (e.g. Carter, 2006; Rindova *et al.*, 2007) have examined the link between
8 corporate reputation and innovation, covering the positive role played by corporate
9 innovation. The main outcome emerging from these studies is the positive correlation found
10 between perceived innovativeness and brand-related performance (Kunz *et al.* 2011).
11
12 Technological innovation, however, could also be associated to an increase in customer-
13 perceived risks (Johnson *et al.*, 2008), with negative repercussions on the company's brand
14 image.

15
16 A relevant body of literature has investigated the impact of a company adopting a new
17 technology on its business performance (Ahuja and Katila, 2001; Grigoriou and Rothaermel,
18 2017), but relatively few studies have examined the influence of technology adoption on
19 corporate reputation. The purpose of this work is to provide further insights into such a
20 relationship by examining how a company's reputation is affected when news about a
21 technology adoption is released on social media.

22
23 The empirical setting focuses on five companies which decided to introduce Bitcoin as a
24 payment method. Bitcoin is a virtual currency based on blockchain technology and it is
25 predicted to affect the way consumers and brands interact (Boukis, 2019). The interchange
26 between firms and users on the social network "Twitter" was collected and analysed to
27 evaluate the impact of the announcement of the company's adoption of Bitcoin on its
28 reputation.

29
30 A panel vector autoregression (VAR) analysis was performed to investigate the volume and
31 the sentiment of the exchanged messages, "tweets", such as the quantitative and

6
7 qualitative responses to the Bitcoin news. The results suggest that there is a positive impact
8
9 on corporate reputation in terms of both volume and positive sentiment of the associated
10
11 tweets.
12

13
14 This research contributes to the stream of branding literature (e.g. Fombrun and Shanley,
15
16 1990; Deephouse, 2000; Rindova *et al.*, 2007; Lange *et al.*, 2011; Kunz *et al.* 2011; Burke *et*
17
18 *al.*, 2018) by exploring how spreading the news about technology adoption events can have
19
20 an impact on different facets of corporate reputation, which in turn is associated with
21
22 consumer brands and product perception.
23
24

25
26 In terms of management implications, the results have consequences for brand managers.
27
28 Executives could leverage on the fact that their company is going to introduce new
29
30 technologies that impact directly on their customers. Managers could exploit such news
31
32 releases and gain reputational benefits in the short term.
33
34

35 36 **Research framework**

37 38 *Corporate reputation and technology adoption*

39
40 The growing literature on corporate reputation (Dowling, 2016; Gürhan-Canli *et al.*, 2018)
41
42 shows that it is a determinant asset to be established and defended, and that it is connected
43
44 to several business activity aspects. Corporate reputation does not merely emanate from a
45
46 company's distinctive capabilities or expertise, but is the result of an intricate interplay with
47
48 firm's stakeholders (Fombrun and Van Riel, 1997). Several factors can affect a company's
49
50 reputation, from market strategies to employment policies (Cable and Graham, 2000;
51
52 Basdeo *et al.*, 2006; Lange *et al.*, 2011; Ravasi *et al.*, 2018).
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 Because of its complexity as a concept, different authors have presented their own various
8 definitions (Fombrun, 1996; Barnett *et al.*, 2006; Walker, 2010). In essence, **corporate**
9 **reputation can be defined as** the “admiration and respect a person holds of an organization
10 at a point in time” (Dowling, 2016: p. 218).
11
12
13
14
15

16
17 This study follows in the path proposed by Lange *et al.* (2011), **for whom the concept of**
18 **corporate reputation is characterized along three dimensions (Table 1). The first dimension**
19 **refers to the collective perception/awareness of a company or its visibility, i.e. *Being Known*.**
20 **The second, *Being Known for Something*, relates to the perception of a company’s specific**
21 **outcome or behaviour with respect to the beholders’ own interests. The third dimension is**
22 **called *Generalized Favourability* and refers to the perceptions and/or judgments made by**
23 **those who observe the organization, as an aggregate of company attributes.**
24
25
26
27
28
29
30
31
32

33 From the observer’s viewpoint, the construct refers to either a *non-evaluative* or a
34 manifestly *judgmental* perspective. The first case **occurs** when the observer is aware of the
35 company but does not express an opinion, while the second case **occurs** when the observer
36 sets out opinions about the **whole** company or its behaviour, **or else focuses** on one specific
37 trait.
38
39
40
41
42
43
44

45 [Table 1 around here]

46
47 The way third parties perceive a company determines its corporate reputation (Gotsi *et al.*,
48 2001). In this context, customers are a particular group of stakeholders and their evaluation
49 shapes the company’s overall brand image (Lamberti and Lettieri, 2009; Pedeliento and
50 Kavaratzis 2019). **Brand image**, in turn, contributes to the construction of the company’s
51
52
53
54
55
56
57
58
59
60

brand equity (Kayaman and Arasli, 2007; Davcik *et al.*, 2015; Brexendorf and Keller, 2017).

For this reason, any action which can influence the customers' perception of a company in the short-term will have an impact on its corporate reputation in the mid-term. Hence, if customers discern improvements to a company's corporate reputation, their perception will contribute positively to its brand equity (Hur *et al.*, 2014). Enhanced brand equity is then expected to lead to higher performance in sales, market share and loyalty (Cretu and Brodie, 2007; Datta *et al.*, 2017).

A company's ability to innovate is considered to be an element of corporate reputation (Clayton and Turner, 2000; Ahuja and Katila, 2001; Brown and Turner, 2009; Safon, 2009; Lange, 2011; Padgett and Moura-Leite, 2012; Agarwal *et al.*, 2018) and is a common trait in most of the frequently used qualitative and quantitative methods to assess corporate reputation, such as Fortune's World's Most Admired Companies indicator and the reputation index RepTrak™ (Trotta and Cavallaro, 2012; Fombrun *et al.*, 2000; Ponzi *et al.*, 2011; Fombrun *et al.* 2015).

Customers' perceptions that relate to innovation, in fact, impact positively on attitudinal and emotional brand loyalty at both corporate and product levels (Kuntz *et al.*, 2011) and result in higher clients' satisfaction (Rubera and Kirca, 2017). Since technology adoption is inherently an innovation activity (Kim *et al.*, 2018), it can potentially deliver a positive effect on corporate reputation.

Social media and corporate reputation

Although adopting new technology is fundamental for companies operating in innovative and competitive environments, it is only when stakeholders become aware that the

1
2
3
4
5
6
7 innovation is in place that the relative impact on corporate reputation can be identified.

8
9 The relevant scenario is when a newly adopted technology alters the company's
10 product/service content and/or outcome, as has been pointed out in several studies
11 (Meuter *et al.*, 2000; Son and Han, 2011; Ayers *et al.*, 2009; Yen, 2005; Wu *et al.*, 2013;
12 Rindova *et al.*, 2007; Fleming *et al.*, 2018). In this situation, the impact of **adopting a**
13 **technology** emerges when stakeholders learn about **the adoption** and shift their evaluation
14 of that technology onto the company (Hou *et al.*, 2018).
15
16
17
18
19
20
21
22

23 While studies on how the release of news can influence corporate reputation are found in
24 prior literature (Kiousis *et al.*, 2007; Einwiller *et al.*, 2010; Comyns and Franklin-Johnson,
25 2018), as yet there has been no research into the specific topic of sharing technology
26 adoption undertakings **on social media**. This gap in research is surprising, given the role that
27 social media play in corporate reputation and brand performance (Tuškej and Podnar,
28 2018).
29
30
31
32
33
34
35

36 Social media are **a major channel for** generating and spreading opinions about a company
37 and its corporate quality throughout the public domain (Etter *et al.*, 2019). The reaction on
38 social media to news about an organization can amplify the stakeholders' ability to
39 influence corporate reputation and, potentially, brand equity (Barnett and Pollock, 2012).
40
41
42
43
44

45 **For such reasons, companies strive to improve the effects of their presence on social media,**
46 **where user- and firm-generated content are both provided** (Kaplan and Haenlein, 2010; Kim
47 and Chae, 2018). Organizations need to develop specific technical and management skills
48 to reap the reputational benefits **associated** to user-generated content (e.g. flares - Blevins
49 and Ragozzino, 2019) and extract value from these platforms, which are very different from
50

7 classic advertising channels (Peters *et al.*, 2013).
8
9

10 Scholars have revealed the close link between brand reputation and social media. Social
11 media management entails the systematic monitoring of social media to mitigate any risk
12 to reputational assets (Montalvo, 2011; Hajli and Sims, 2015; He *et al.*, 2017). Moreover,
13 when brand reputation is established through effective media management, it can be a
14 powerful resource for competitive advantage (Deephouse, 2000; Rindova *et al.*, 2006).
15 Research has also found that focusing on the preferential channels for electronic word of
16 mouth from customer to customer is a meaningful way to evaluate how external beholders
17 judge and perceive brands online (Xun and Guo, 2017; King *et al.*, 2014). On the contrary, if
18 a company is careless in managing its corporate social media profile, this circumstance can
19 have a direct negative effect on its equity (Yu *et al.*, 2013).
20
21
22

25
26
27
28
29
30
31
32

33 The internet has become a space for expressing opinions on a vast range of topics, and a
34 number of information retrieval techniques are being developed to extrapolate and analyse
35 relevant posts that refer to specific products or brands (Thelwall *et al.*, 2010). A company
36 can apply similar methodologies and evaluate its users'/customers' attitude toward its
37 products and services. The techniques for retrieving information often involve algorithms
38 that can work down to single text elements (Pang and Lee, 2008). The information
39 embedded in social media streams can be investigated through methods that include
40 sentiment analysis, the analysis of trending topics through keywords (*hashtags*) and the
41 automated analysis of shared images combined with machine learning techniques
42 (Tsytsarau *et al.*, 2014; Jensen *et al.*, 2015).

4
5
6
7 The empirical analyses in this study are based on data gathered from Twitter, one of the
8 world's largest social networks. Sentiment analysis applied to Twitter texts can be used to
9 investigate corporate reputation (Jansen *et al.*, 2009) and a growing number of scientific
10 articles now rely on Twitter data (e.g. Castillo *et al.*, 2011; Lerman and Ghosh, 2010;
11 Desmarchelier and Fang, 2016).

12 13 14 15 16 17 18 19 *Research Objectives*

20 Evidence from the previous section indicates **three main factors**. (i) The adoption of an
21 innovative technology can have a significant impact on corporate reputation. (ii) The impact
22 can relate to the resulting products and/or services, but can also be felt beforehand, when
23 users/customers learn that a company is adopting a new technology, as this **awareness** can
24 alter peoples' perceptions about **innovativeness** at corporate level. (iii) Social networks act
25 as "news accelerators" and key levers that can be used to improve corporate reputation.
26 The **previous** evidence paves the way towards setting the objective of this work, which is to
27 evaluate, when users/customers learn that a company is adopting a new technology, how
28 this **fact** stochastically affects the various dimensions of corporate reputation.

29
30
31
32
33
34
35
36
37
38
39
40
41 The framework proposed by Lange *et al.* (2011) **has been adopted to evaluate the different**
42 **aspects of corporate reputation and then** define the appropriate measures for detecting the
43 aforementioned impact. The **framework is based on two** parameters that underpin the
44 concept of corporate reputation, i.e. the beholders' attitude (*judgmental* vs. *non-*
45 *evaluative*) and the kind of relationship they have with the company (*particular* vs.
46 *generalized*). **However, it does not include a definition of corporate reputation that matches**
47 **the desired configuration of non-evaluative and particular parameters. The required fourth**
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 dimension has been, therefore, introduced to cover the entire definitional space and
8
9 termed as *Being Known for Something (non-evaluative)*.

10
11
12 Table 2 sums up the concepts of corporate reputation used in this study. The “generalized”
13
14 concepts address corporate reputation in broad terms, and “particular” concepts are
15
16 specific to the actual technology adopted in the company. “Non-evaluative” measures refer
17
18 to the volume of tweets, while “judgmental” measures refer to the sentiment expressed in
19
20 the tweets.
21
22

23
24 The resulting combinations are the following:
25

- 26
27 • *Being Known* (non-evaluative – generalized) is measured through the “tech-
28
29 unrelated volume” of tweets, which is the number of tweets about a company that
30
31 do not mention the adopted technology (these tweets can refer to any aspect of
32
33 the company, other than the adoption of the specific technology).
34
- 35
36 • *Generalized Favourability* (judgmental – generalized) represents “tech-unrelated
37
38 sentiment”, measured by examining the average sentiment of the tweets about the
39
40 company that do not mention the adopted technology (general sentiment towards
41
42 the company)
43
- 44
45 • *Being Known for Something (non-evaluative)* is an additional concept that analyses
46
47 the specific “Something” (here, the technology adoption) in terms of volume; “tech-
48
49 related volume” is the number of tweets that mention both the company and the
50
51 adopted technology, regardless of the sentiment expressed by the users.
52
53
54
55
56
57
58
59
60

- *Being Known for Something (judgmental – particular)* is a proxy for “tech-related sentiment” and is the average sentiment of tweets that mention both the company and the specific “Something” which, in this framework, is the adopted technology.

Each configuration of parameters can be associated with a specific driver, as shown in Table

2.

[Table 2 around here]

The aim of this analysis is to determine, quantitatively, whether there was any impact on the four individual concepts of corporate reputation at the news that the company had adopted a new technology. A positive impact is expected because technology adoption is inherently an innovation activity (Kim *et al.*, 2018) and innovation is a key asset of corporate reputation (Ponzi *et al.*, 2011; Kuntz *et al.*, 2011; Fombrun *et al.* 2015). However, the proposed framework makes it possible to provide more fine-grained results. It is also possible to distinguish between: i) whether the effect on reputation is limited to the specific event (“Being Known for Something”, that is, the adopted technology) or whether it encompasses a perception of the company as a whole, and ii) whether the sentiment conveyed is significantly positive.

Methodology and data

The aim of this study is to investigate the relationship between the release of news about adopting innovative technology and corporate reputation. The technology adoption in question is the introduction of Bitcoin in five companies, as an additional method of

1
2
3
4
5
6
7 payment. These companies form a useful case study, as they were mentioned in the Twitter
8
9 timeline before and after the date when their Bitcoin news was released.
10
11

12 *Bitcoin as case of technology adoption*

13
14 The Bitcoin protocol was released in autumn 2009, and from then on, the corresponding
15
16 cryptocurrency has reshaped electronic payment systems and redefined the idea of money
17
18 itself (Hughes *et al.*, 2019; Morkunas *et al.*, 2019).
19
20

21
22 Because it is based on blockchain technology, Bitcoin provides the necessary software tools
23
24 to implement a completely decentralized infrastructure for the transfer of money.
25
26 Transaction security is verified through cryptography and the fact that all transactions are
27
28 recorded in shared electronic public ledgers, the blockchain. The users of this peer-to-peer
29
30 architecture transact Bitcoins without the need for a trusted third party, such as a bank or
31
32 any other financial institution. The advantages are associated with enhanced privacy and
33
34 negligible transaction costs, compared to the current payment methods (credit cards,
35
36 PayPal or the like). Bitcoin makes micropayments viable on a large scale, even for
37
38 international transactions.
39
40

41
42 Among the negative aspects, financial speculation is a risk, because of its high volatility but,
43
44 nevertheless, the continuously growing transactions and the constant support of venture
45
46 capital in Bitcoin-related services suggest that it could play an important role in the future
47
48 online payment landscape.
49

50
51 The adoption of Bitcoin is an interesting case for several reasons. First, a number of e-
52
53 commerce companies have implemented this technology platform, and the precise date on
54
55
56
57
58
59
60

1
2
3
4
5
6
7 which they made the relative announcement is known or can be determined. Since the
8
9 technology is quite recent, the implementation time frame in each company is narrow and
10
11 a direct pre and post comparison can be made without too much difficulty. The companies
12
13 that introduced Bitcoin added an additional payment platform as a plugin to their online
14
15 shops. The work necessary to set up the technology is not complex but, while it is not a
16
17 technical issue, it is a strategic, management and behavioural problem, similarly to the e-
18
19 blog case described by Wu *et al.* (2013). In addition, customers who interact with the new
20
21 technology are “e-clients”, and hence they can be reasonably considered in the same
22
23 category as the people who share their thoughts on Twitter.
24
25
26
27

28 Furthermore, there is no uniform opinion about the whole Bitcoin system. Critical
29
30 comments have been made in the media about the risks of financial speculation and the
31
32 privacy of the transactions, exposing the fact that the system could be exploited by
33
34 criminals. The point is interesting, because an *a priori* negative sentiment in response to the
35
36 introduction of Bitcoin cannot be excluded.
37
38
39

40 *Twitter as data source*

41 With more than 300 million active users a month, Twitter is one of the most useful social
42
43 networks for analysing corporate reputation. As observed by Jansen *et al.* (2009), when they
44
45 targeted Twitter corporate accounts, nearly 20% of all branding microblogs contained some
46
47 expression of sentiment relating either to the company in general or expressing an opinion
48
49 on one or more specific products. Among the previous studies that analysed Twitter data to
50
51 investigate the importance of events and associated sentiment, Thelwall *et al.* (2010)
52
53 mentioned the need to be cautious when carrying out sentiment analyses on Twitter
54
55
56
57
58
59
60

1
2
3
4
5
6
7 because the overall level of sentiment seems to be quite low. Nonetheless, when reporting
8 on facts that generate a surge of tweets, including the launching of new products, the
9 authors considered it reasonable to expect some kind of emotional reaction.
10
11
12

13
14 **Over a short time, there has been an increase in** number of scientific articles that rely on
15 Twitter data. These works investigate platform characteristics (Naaman *et al.*, 2010),
16 reliability, diffusion and newsworthiness of information (Castillo *et al.*, 2011; Lerman and
17 Ghosh, 2010; Desmarchelier and Fang, 2016), market efficiency in terms of incorporating
18 information (Sprenger *et al.*, 2014; Williams and Reade, 2016) and the ability to forecast a
19 specific outcome (Treme and VanDerPloeg, 2014; Tumasjan *et al.*, 2010).
20
21
22
23
24
25
26

27
28 In this framework, corporate reputation concepts **can be** measured in terms of number of
29 tweets and corresponding sentiment. Starting from the assumptions set out in Table 1, it
30 was possible to translate reputation-type aspects into observable measures linked to the
31 analyses carried out on the Twitter timeline for the selected companies, as shown in Table
32
33
34
35
36
37 2.
38
39

40 *Sampling process*

41
42 The five companies were selected through a purposive sampling process (as defined in Short
43 *et al.*, 2002) **to determine** whether they **satisfied** specific requirements. **The** methodological
44 approach **is similar to that** presented in the study by Xun and Guo (2017). The aim was to
45 identify **a sample of** US companies which adopted Bitcoin as a form of online payment in
46 2013 and 2014. This was achieved by searching through the Google News repository using
47 the keywords “Bitcoin” and “adopt” (or synonyms and derivations such as “adoption” or
48 “acceptance”) and then screening the results manually.
49
50
51
52
53
54

4
5
6
7 As mentioned, the five companies analysed are all based in the US. The focus on a single
8 market/country provides a coherent framework and reduces any variation in terms of
9 regulations, economic conditions and the kind of Twitter users who potentially interacted
10 with the companies. The US is an ideal choice for this purpose, because of its economic
11 system, access to new technologies and diffusion of Twitter.
12
13
14
15
16
17

18
19 Only companies selling online were selected. These companies are particularly suited to the
20 analysis because they expect to receive a relatively high level of attention from social media
21 users and also to engage with them. In addition, internet vendors rely heavily on their
22 reputation (Kim *et al.*, 2008; Biswas and Biswas, 2004; Caruana and Ewing, 2010). Lastly,
23 large corporations were excluded (companies such as Microsoft and Dell or listed on
24 Fortune 500) because there would have been far too many tweets to trawl through,
25 estimated in the millions, but only limited sample accuracy. The preliminary analyses on the
26 retrieved news items and tweets have, in fact, indicated the non-negligible presence of
27 false-positive associations (e.g. frequent cases where "Bitcoin" and "Microsoft" appeared
28 in the same news item/tweet, despite being unrelated). As a consequence, the
29 corresponding volume of traffic made it virtually impossible to carry out the manual
30 consistency check during data processing.
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45

46 The selection process identified five companies which were among the first to introduce the
47 Bitcoin payment channel as part of their online sales process (see Table 3; further details in
48 the appendix: Table 6). The small size of the sample is a clear limitation of the empirical
49 exercise and, in future research, the analysis could be expanded to a larger set of companies
50 in different countries and different sectors. However, the positive aspect of a small sample
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 is that it gave greater control over the data, as the number of examined records was kept
8
9 at a level where it was still possible to carry out consistency checks by reading the text fields
10
11 of the sampled tweets directly, and thereby improve the automated sentiment analysis.
12
13

14 [Table 3 around here]
15

16
17 Two sets of data were collected for each company. These were i) all online news items about
18
19 the introduction of Bitcoin and ii) all the tweets mentioning the companies. The records in
20
21 both datasets covered a four-month time frame, centred on the adoption date. The process
22
23 only covered news items in English and tweets geo-localized in the USA.
24
25

26
27 The first dataset was created by retrieving news items from agencies, blogs and the
28
29 aggregators available from the Google News repository and contained communications in
30
31 which customers were told about the adoption of Bitcoin. The second dataset contained all
32
33 the single tweets about the companies, which were provided by The Fool S.r.l., a company
34
35 with expertise in social media analysis. The tweets collected mentioned either the
36
37 company's account name (e.g. "@intuit", "@overstock", "@overstockCEO", etc.) or a
38
39 corresponding hashtag (e.g. "#cheapair", "#tigerdirect", "#overstock", etc.). All tweets
40
41 posted from the companies' official accounts or by executives and managers were excluded.
42
43
44

45 A second search was carried out on the contents of the tweets, looking for inherent
46
47 keywords (e.g. "bitcoin", "BTC", "Coinbase", "BitPay", etc.) to extrapolate the tweets
48
49 discussing Bitcoin technology. A "sentiment analysis" was then run on each tweet.
50
51

52 Sentiment analysis is a consolidated technique in scientific literature, and its application has
53
54 soared with the diffusion of the internet and social media (among the several reviews and
55
56
57
58
59
60

1
2
3
4
5
6
7 taxonomies; see Singh and Dubey, 2014; Mäntylä *et al.*, 2018). A “sentiment score” was
8 assigned to each tweet, which was elaborated by combining the results of three different
9 tools: MeaningCloud (<https://www.meaningcloud.com/>), Semantria
10 (<https://www.lexalytics.com>) and SentiStrength (<http://sentistrength.wlv.ac.uk/>). Once all
11 the tweets were processed and a sentiment score assigned by each tool, the results were
12 standardized to deal with the different sentiment scales and define a single measure
13 ranging from -1 to +1.
14
15
16
17
18
19
20
21
22

23 Sentiment analysis is used to process a large amount of data within a reasonable period of
24 time. However, there can be difficulties in how it interprets ironic sentences, jokes, unusual
25 terms or the use of slang (Mostafa, 2013; Bhuta *et al.*, 2014). As an additional accuracy
26 control, the sentiment score of a random sample of tweets was checked, which involved
27 reading more than 10,000 tweets (25% of the sample). The positive and neutral sentiment
28 scores were accurate in 97% and 80% of the cases, respectively. Only 1% of the tweets
29 presumed to express a positive or neutral sentiment were marked-up wrongly and were, in
30 fact, negative. The accuracy was slightly lower for the negative tweets (75%) and, since
31 negative tweets were particularly relevant to the analyses, all the negative tweets were
32 controlled and, when necessary, re-marked correctly.
33
34
35
36
37
38
39
40
41
42
43
44
45

46 The tweets collected were associated to the dimensions of corporate reputation (Table 2).
47 For example, a tweet such as “Thanks to @Newegg for handling an issue quickly and
48 professionally. Always a pleasure doing business with you :)” will increase Newegg.com’s
49 tech-unrelated volume, i.e. the dimension of *Being Known*. The same tweet also expresses
50 a positive tech-unrelated sentiment that contributes to *Generalized Favourability*. The
51
52
53
54
55
56
57
58
59
60

1
2
3

5
6
7 message “Bitcoin being accepted by online retailers is a huge deal, especially with major
8 retailers like @Overstock. I can't wait to see how this unfolds” is specific to the technology
9 adoption (*Being Known for Something*) and so positively affects both volume (*non-*
10 *evaluative*) and sentiment (*judgmental*).
11
12
13
14
15

16
17 The whole process identified a set of 7,766 news items and 43,497 tweets. Table 4 provides
18 some basic statistics on the observations in total and broken down by company.
19
20

21
22 [Table 4 around here]
23

24
25 The two datasets (news items and tweets) were, lastly, combined and the data grouped into
26 different time frequencies of 6, 12 and 24 hours. It was, therefore, possible to calculate the
27 number of news items and a set of indicators, based on the identified tweets, for each
28 company in any given period. The indicators represent how corporate reputation, as
29 described in the “Research Objectives” section, is expressed operationally. Specifically, they
30
31
32
33
34
35
36 are:

- 37
38 • the number of technology-related tweets (about Bitcoin) defined as tech-related
39 volume; within corporate reputation, it is “*Being Known*” (generalized and non-
40 evaluative);
41
42
- 43
44 • the number of other tweets (with no reference to Bitcoin) defined as tech-
45 unrelated volume; within corporate reputation, it is “*Being Known for Something*
46 (non-evaluative)” (particular and non-evaluative);
47
48
49
50
51
52
53
54
55
56
57
58
59
60

- the average sentiment score of the Bitcoin-related tweets defined as tech-related sentiment; within corporate reputation, it is “*Being Known for Something (judgmental)*” (particular and judgmental);
- the average sentiment score of all the other tweets defined as tech-unrelated sentiment; within corporate reputation, it is “*Generalized Favourability*” (generalized and judgmental).

The results reported in the next section refer to the analyses carried out with 12-hour data points. The other time frequencies showed coherent patterns and are available on request. Table 5 shows the summary statistics of the examined variables with a 12-hour interval.

[Table 5 around here]

VAR models

A “narrative method” based on a set of vector autoregressive (VAR) models was used to evaluate how adopting the Bitcoin technology - proxied by the number of related news items - impacts on a company’s reputation (for a recent overview, see Ramey, 2016; Favero and Giavazzi, 2012). The models account for the linear interdependencies that occur among data series under specific assumptions related to the causal structure of the examined variables (Fernandez-Villaverde *et al.*, 2007).

Two types of analyses were conducted. The first was carried out on volume drivers, which are the number of tweets that include the two reputational dimensions of *Being Known for Something (non-evaluative)* and *Being Known*, and the second examined the sentiment score of the tweets, measuring both *Being Known for Something (judgmental)* and

1
2
3
4
5
6
7 *Generalized Favourability.* A panel VAR model (Cagala and Glogowsky, 2014) was first
8 applied to the whole sample and the analysis was then repeated on firm-specific
9 subsamples to highlight the presence of different patterns at a company level.
10
11

12
13
14 VAR models are commonly applied when there is the need to analyse financial and
15 macroeconomic variables (e.g. Blanchard and Perotti, 2002; Perotti, 2011). The first step of
16 the method involves estimating the coefficients in the VAR model, which can be
17 represented as the linear relation of a set of variables, depending on their value in the past,
18 plus an innovation vector (Lütkepohl, 1991; Hamilton, 1994). In the model specification,
19 rather than relying only on past values in the two “tweet” series, the “news” variable was
20 introduced to improve the estimate of future expectations. The combination of tweet
21 sentiment scoring and VAR models is similar to the method employed by Xun and Guo
22 (2017) to study company financial performance. Here, the investigation relates to the
23 companies included in the panel VAR model specification. The test was performed using the
24 Stata “xtvar” command developed by Cagala and Glogowsky (2014), which applies a least-
25 squares dummy variable estimator (Canova and Ciccarelli, 2013): the model fits a
26 multivariate panel regression for each dependent variable on lags of itself and on lags of all
27 the other dependent variables.
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44

45
46 After having estimated the model, the news variable was shocked at equilibrium and the
47 impulse response on corporate reputation drivers was then evaluated. The impact level was
48 assessed stochastically by applying the Monte Carlo simulation algorithm, with 200
49 repetitions, to the estimated model (Bachmann *et al.*, 2010) and then by plotting the VAR
50 Impulse Response Functions (IRF).
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 Various lags were used in the tests, but the results reported are those with lag 2, according
8
9 to the Schwarz Bayesian Information Criterion associated to the VAR models (further
10
11 information on the estimation of the panel VAR model can be found in Tables 7, 8, 9, 10 and
12
13
14 11 in the Appendix).

15 16 17 **Results**

18
19 The descriptive results in Table 4 show that 2.8% of all tweets expressed a negative
20
21 sentiment, with small differences across the companies. The largest variations with respect
22
23 to the sample average refer to TigerDirect (4.1%) and CheapAir.com (0.3%). With respect to
24
25 the subset of tweets about Bitcoin technology, the share of negative messages was much
26
27 lower (0.7%).
28
29

30
31 Concerning the econometric analyses, the IRFs of interest are those where the impulse
32
33 variable consists of the number of news items. The IRFs resulting from the panel VAR are
34
35 charted in Figure 1 and were calculated with reference to one-unit shocks. The figure plots
36
37 the effect of the shock (i.e. the announcement of the adoption of Bitcoin) on the number of
38
39 news items, and the volume of technology-related and -unrelated tweets, respectively.
40
41

42 [Figure 1 around here]
43
44

45 As expected, any additional news items covering the technology adoption has, on average,
46
47 a positive effect on the number of Bitcoin tweets for each company. This is particularly true
48
49 for the first interval after the news is released (first 12 hours). The effect declines
50
51 progressively and loses significance after three and a half days (that is, at step 7), with a
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 95% confidence interval. The effect of the news on the number of tech-unrelated tweets is
8
9 not significant.

10
11
12 The IRFs of the other impulse variables (number of tech-related and tech-unrelated tweets)
13
14 are given in the Appendix (Figures 3, 4, 5 and 6). It should be noted that the number of tech-
15
16 related tweets impacts positively on the number of news items from step 1 onwards, while
17
18 the effect on the number of tech-unrelated tweets is negative, a fact that suggests a
19
20 substitute relationship (the Twitter discussion on the company's timeline shifts towards the
21
22 adoption of Bitcoin).
23
24

25
26 The same approach is replicated for the sentiment analysis and the results are shown in the
27
28 following charts. The number of news items was normalized between 0 and 1 to improve
29
30 the readability of the results. Figure 2 plots the effect on the number of news items and on
31
32 the average sentiment for the technology-related and -unrelated tweets, respectively. Any
33
34 additional news about the technology adoption has, on average, a positive effect on the
35
36 average sentiment of Bitcoin tweets at a company level. The effect increases until step 3
37
38 after the release of the news (the first 36 hours) and then declines over the following time
39
40 intervals (although it is possible to see a small but significant positive effect in step 15). The
41
42 effect of the news on the average sentiment of tech-unrelated tweets is not significant.
43
44

45
46 The IRFs of the other impulse variables (average sentiment of tech-related and -unrelated
47
48 tweets) are given in the Appendix; no significant relationship is found.
49
50

51
52 [Figure 2 around here]
53
54
55
56
57
58
59
60

Specific VAR models were tested on each company. The IRFs for volume and sentiment drivers are given in the Appendix. The results show some differences in the level of significance and in the pattern of the IRFs, but they are coherent with the result of the panel VAR, when considering the concept of *Being Known for Something (non-evaluative)* (tech-related volume). One partial exception concerns CheapAir.com, which shows a similar but not significant curve at the 95% confidence interval. *Being Known for Something (judgmental)* shows similar results across the companies, but those for Intuit and TigerDirect are not significant. When the analyses were carried out on one company at a time, the level of significance for the results concerning the tech-unrelated drivers (both *Being Known* and *Generalized Favourability*) was low.

Discussion and Conclusions

Previous works dealing with corporate reputation have focused on understanding the impact of perceived innovativeness on brand-related performance (Kunz et al. 2011). However, no previous study had focused on the role played by a company's decision to adopt a technology as an event that could affect its corporate reputation. The aim of this research was to fill the gap by modelling an empirical experiment based on data collected from Twitter. The social media response experienced by five US-based companies when they introduced the Bitcoin cryptocurrency provided quantitative measures of corporate reputation.

The results show that adopting a Bitcoin payment platform had a positive impact above all on the tech-related aspects of corporate reputation. In particular, as consumers become aware of the news, *Being Known for Something (non-evaluative)* immediately has a high

1
2
3
4
5
6
7 positive impact, which then decreases until it loses significance after about three and a half
8 days. This kind of behaviour is consistent with the concept **underlying the examined**
9 **dimension of corporate reputation of being** event-triggered and circumscribed. *Being*
10 *Known for Something (judgmental)* is positively affected, with an increasing response
11 function **that** peaks after 36 hours and then decreases.

12
13
14
15
16
17
18
19 The effect on the tech-unrelated drivers is less significant, with only a potential spill-over
20 for *Being Known*, which shows an immediate positive response to the news. Global
21 perception with judgment, that is, *Generalized Favourability*, does not seem to register any
22 significant impact as a result of the event.

23
24
25
26
27
28
29 The analyses were repeated for each company. Coherent results were observed when
30 looking at the tech-related drivers, while the effects on the tech-unrelated drivers showed
31 low significance and different patterns. These differences call for further investigation
32 because they could depend on sector and company specificities (e.g. size, performance,
33 other events that occurred over the timeline in question).

34
35
36
37
38
39
40 **The results suggest that the volume of messages about technology adoptions does not**
41 **replace the general traffic on social media about the companies, but adds to it favourably.**

42
43
44
45 Although the news and the associated phenomenon on social media have a short lifecycle,
46 the analyses found evidence that adopting a new technology has an **immediate** positive
47 effect on **corporate reputation and contributes to the company's brand image.**

48
49
50
51
52 **These findings have** potential managerial implications for other companies similar to those
53 examined in this study. **With respect to** medium-sized companies introducing a new
54
55
56
57
58
59
60

1
2
3
4
5
6
7 technology that will have a direct effect on customers, management can leverage on the
8 undertaking to the benefit of their corporate reputation, gaining a direct response
9 immediately and an indirect contribution in the longer term. The event could be seen as a
10 trigger for gaining short-term momentum, as well as being a driver for the longer-term goal
11 of building a positive reputation. Companies with a positive reputation signal their
12 trustworthiness, thereby reducing transaction costs and customer perceived risk (Walsh et
13 al., 2016). The technology adoption can also help them to raise their brand image in the
14 short term and their brand equity in the mid to long term (Ogba and Tan, 2009). The
15 expected effect is not negligible, since perceptions about a company's reputation for non-
16 financial aspects can create more shareholder value in the longer term than perceptions
17 about previous financial performance (Raithel and Schwaiger, 2015).

18
19
20
21
22
23
24
25
26
27
28
29
30
31
32 Given that it has been demonstrated that sharing news on social media about technology
33 adoptions has an impact on corporate reputation - which is, in turn, an antecedent of brand
34 performance - managing public relations correctly when a new technology is introduced
35 onto the market is a fundamental brand building activity. A proactive approach to online
36 brand management is, thus, recommended (Cooper et al., 2019). Although literature shows
37 that the long-term effects of adopting a new technology on reputation are caused by
38 changes to the outcome of products or services that arise from the new technology (e.g.
39 Son and Han, 2011; Wu et al., 2013), this study highlights that there is also an immediate
40 effect that is driven by news of an event/undertaking.

41
42
43
44
45
46
47
48
49
50
51
52
53 The identified dynamics can interest both brand management literature and also corporate
54 communication studies (e.g. Ageeva et al., 2018; Dijkmans et al., 2015), which deal with
55
56
57
58
59
60

1
2
3
4
5
6
7 learning about the timing of technology adoption announcements and that of possible
8 communication follow-ups.
9

10
11
12 The analyses on the selected sample confirm that perceived innovativeness can increase
13 customer engagement (Henard and Dacin, 2010) and suggest that reputational dimensions
14 follow distinct patterns. The impact of the news about a technology adoption on the
15 particular dimension of reputation is higher than its effect on general aspects. The findings
16 suggest a potential dichotomy between the customers' perception of innovation, at a
17 company level (i.e. stand alone, made before a specific product/service evaluation) and at
18 a product level (i.e. derived from the specific evaluation of a product/service) (e.g. Cavazos
19 and Rutherford, 2015).
20
21

22
23
24
25
26
27
28
29
30
31 Previous literature indicates that product/service innovation can introduce paradoxes and
32 ambiguity with regards as to how the brand is perceived (e.g. Johnson *et al.*, 2008; Parker
33 and Krause, 2018), caused by, for instance, a certain level of performance ambivalence
34 induced by novelty. This stream of literature has mainly analysed the "encounter" between
35 customers/consumers and new technology, i.e. product-level perception. Interestingly,
36 other literature has shown that perceived innovativeness (at a corporate level) has a
37 positive impact on both product-level and corporate-level brand performance (Kunz *et al.*,
38 2011). The results of the present study support the latter view, although they do not
39 encompass the customers' actual "encounter" with technology. It should be noted that
40 recent studies (e.g. Pappu and Quester, 2016) put forward the view that actual positive
41 perceived quality, i.e. product-level performance, is a mediator between perceived brand
42 innovativeness and brand loyalty.

4
5
6
7 This study suffers from some limitations that could be addressed in future research. Other
8 studies could expand the scope and robustness of the analyses and consider a larger
9 number of companies, other technologies and different types of corporate news. They
10 could also introduce a larger data set that could focus on longer time windows. It would
11 also be useful to examine a wider set of sentiment tools, including any new and more
12 advanced instruments, as this exercise should result in the sentiment scores being more
13 accurate.

Table 1 Distinguishing among the three dimensions of corporate reputation (source: Lange et al., 2011)

Parameters	Conceptualizations of corporate reputation		
	Being known	Being known for something	Generalized favorability
Particular vs. Generalized	Generalized	Particular	Generalized
Judgment vs non evaluative	Non-evaluative	Judgment	Judgment

Table 2 Corporate reputation conceptualizations and operationalized drivers in Twitter

Conceptualizations	Parameters		Driver (Tweets)
	Particular vs. Generalized	Judgment vs. Non-evaluative	
Being known	Generalized	Non-evaluative	tech-unrelated volume
Generalized favorability	Generalized	Judgment	tech-unrelated sentiment
Being known for something (non-evaluative)	Particular	Non-evaluative	tech-related volume
Being known for something (judgment)	Particular	Judgment	tech-related sentiment

Table 3 Selected companies, main information

Company	Industry	Founded	Turnover (billions USD)	Employees	Bitcoin adoption date	Bitcoin Provider
CheapAir.com	Travel agency	1989	Not available	90	22/11/2013	Coinbase
Intuit	IT services	1983	4.2 (2013)	8,200	25/06/2014	Coinbase
Newegg.com	Retailing (Electronics)	2001	2.7 (2013)	2,600	01/07/2014	BitPay
Overstock.com	Retailing (General)	1997	1.5 (2014)	1,500	09/01/2014	Coinbase
TigerDirect	Retailing (Electronics)	1987	Not available	Not available	23/01/2014	BitPay

Table 4 Number of news and tweets, percentage of tweets by sentiment (positive, neutral, negative) and about Bitcoin on total tweets. Values provided by company and as total

Company	News	Total Tweets	Positive tweets	Neutral tweets	Negative tweets	Tweets About Bitcoin Perc. on Tot. tweets
CheapAir.com	271	1,773	20.6%	79.1%	0.3%	19.5%
Intuit	225	6,523	18.8%	78.4%	2.8%	3.2%
Newegg.com	584	20,036	17.0%	80.2%	2.8%	18.0%
Overstock.com	6,087	9,602	11.2%	86.5%	2.3%	50.5%
TigerDirect	599	6,013	9.7%	86.2%	4.1%	40.7%
TOTAL	7,766	43,947	15.1%	82.1%	2.8%	26.1%

Table 5 Summary statistics of the variables employed in the econometric analyses, when aggregation frequency is 12 hours

Variable	Description	Obs.	Mean	Std. Dev.	Min	Max
btc_vol _{i,t}	Number of tweets related to the technology (Bitcoin) for firm <i>i</i> at time <i>t</i>	1,310	8.754	54.988	0	895
rest_vol _{i,t}	Number of tweets un-related to technology for firm <i>i</i> at time <i>t</i>	1,310	24.782	40.399	0	483
news_nr _{i,t}	Number of news related to technology (Bitcoin) for firm <i>i</i> at time <i>t</i>	1,310	5.928	19.548	0	222
btcsenfavg _t	Average sentiment score of the tweets related to the technology (Bitcoin) for firm <i>i</i> at time <i>t</i>	1,310	0.056	0.185	-1	1
Restsenfavg _t	Average sentiment score of the tweets un-related to the technology for firm <i>i</i> at time <i>t</i>	1,310	0.105	0.184	-0.66	1

Table 6 Selected companies, main information

Company	Founded
CheapAir.com	<p>Californian online travel agency founded in 1989. A proprietary algorithmic engine provides the cheapest travel solution available online. CheapAir's online service offers a search interface that makes also possible to purchase flights and accommodation.</p> <p>On November 22nd, 2013, CheapAir announced to be the first travel agency in the world to accept Bitcoin. In 2014, the company announced to have surpassed \$1.5 million sales in bitcoin.</p>
Intuit	<p>Californian software company founded in 1983. Intuit provides financial software for corporate accounting, income tax preparation, personal finance and expense tracking. Intuit services have reached more than 45 million customers, with an annual turnover exceeding \$4 billion. The company is publicly traded on the NASDAQ Stock Market (INTU).</p> <p>On June 25th, 2013, the company integrated bitcoin payments into one of its main accounting software (QuickBooks): since then merchants can convert and receive payments in bitcoin.</p>
Newegg.com	<p>Newegg Inc. is a Californian leading online retailer, founded in 2001. The typical products sold in Newegg's website are computer hardware, software, peripherals, gaming and mass electronics.</p> <p>On June 1st, 2014, Newegg announced to have integrated Bitcoin as a form of payment, in response to the increasing demand from customers.</p>
Overstock.com	<p>Overstock is a publicly listed company on NASDAQ. Overstock was launched in 1999, quickly becoming an online market leader in the e-commerce space, counting over one million products in its catalogue, with product categories varying from home accessories to furniture, health & beauty, electronics and garden tools.</p> <p>The company started accepting bitcoin on January 9th, 2014. In August 2014, the CEO declared that about 0,25% Overstock's sales were in bitcoins.</p>
TigerDirect	<p>TigerDirect was founded in 1987. It started as a software developer then turned to online retailer of electronics, computer hardware and software. The company was acquired in 2015, closed the online sales but the website was relaunched in 2016.</p> <p>TigerDirect announced the bitcoin adoption during the end of January 2014, together with a tutorial about the cryptocurrency and some incentives for GPU card buyers in order to start mining bitcoins with their own devices. Bitcoin transactions were limited to online purchases and not accepted inside the physical stores. 18 months later, TigerDirect reported that orders purchased with bitcoins were 30% larger than the expected order value.</p>

Table 7 Results of the panel VAR model concerning volumes

Equation	Parms	RMSE	R-sq	F	P > F
News	11	13.943	0.499	128.549	0.000
Bitcoin related tweets	11	46.416	0.298	86.406	0.000
Other tweets	11	28.090	0.523	124.570	0.000

Table 8 Panel VAR model on volumes: contemporary coefficients.

Contemporary coefficients	News	Bitcoin related tweets	Other tweets
News	1	0	0
Bitcoin related tweets	0.806	1	0
Other tweets	0.118	-0.042	1

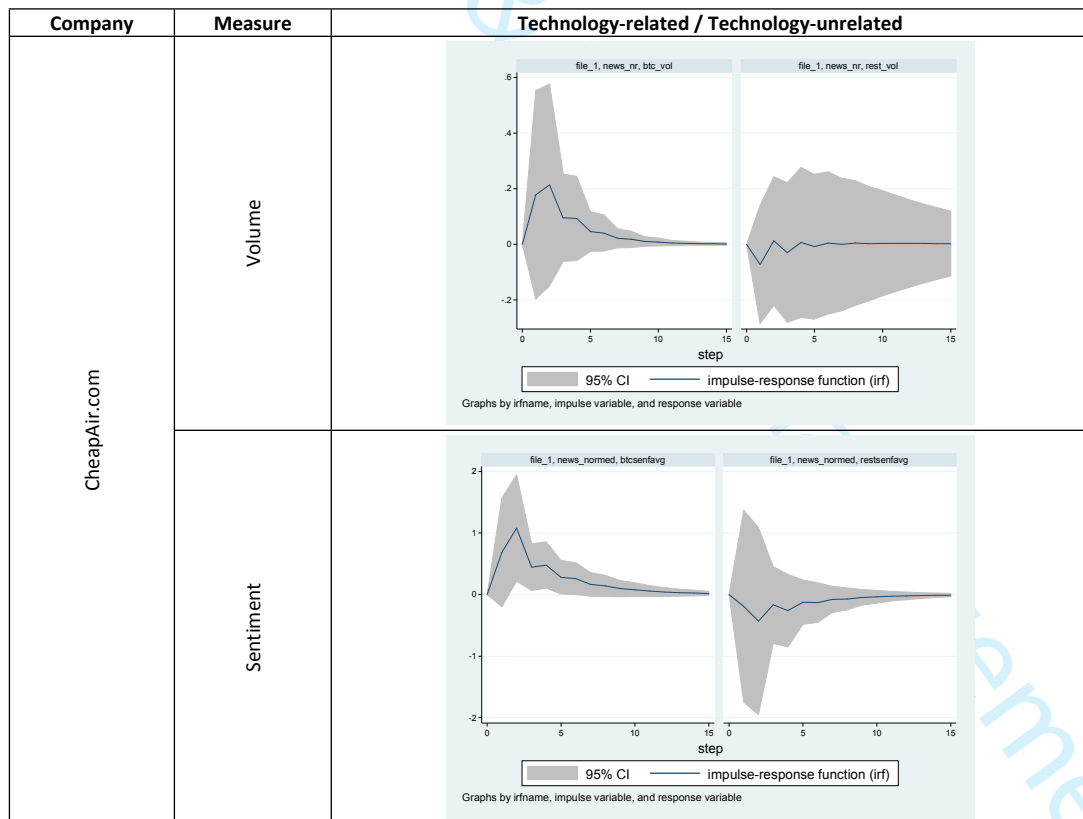

Table 9 Results of the panel VAR model concerning sentiment

Equation	Parms	RMSE	R-sq	F	P > F
News	11	0.063	0.493	124.871	0.000
Bitcoin related tweets	11	0.175	0.116	19.675	0.000
Other tweets	11	0.178	0.079	4.210	0.000

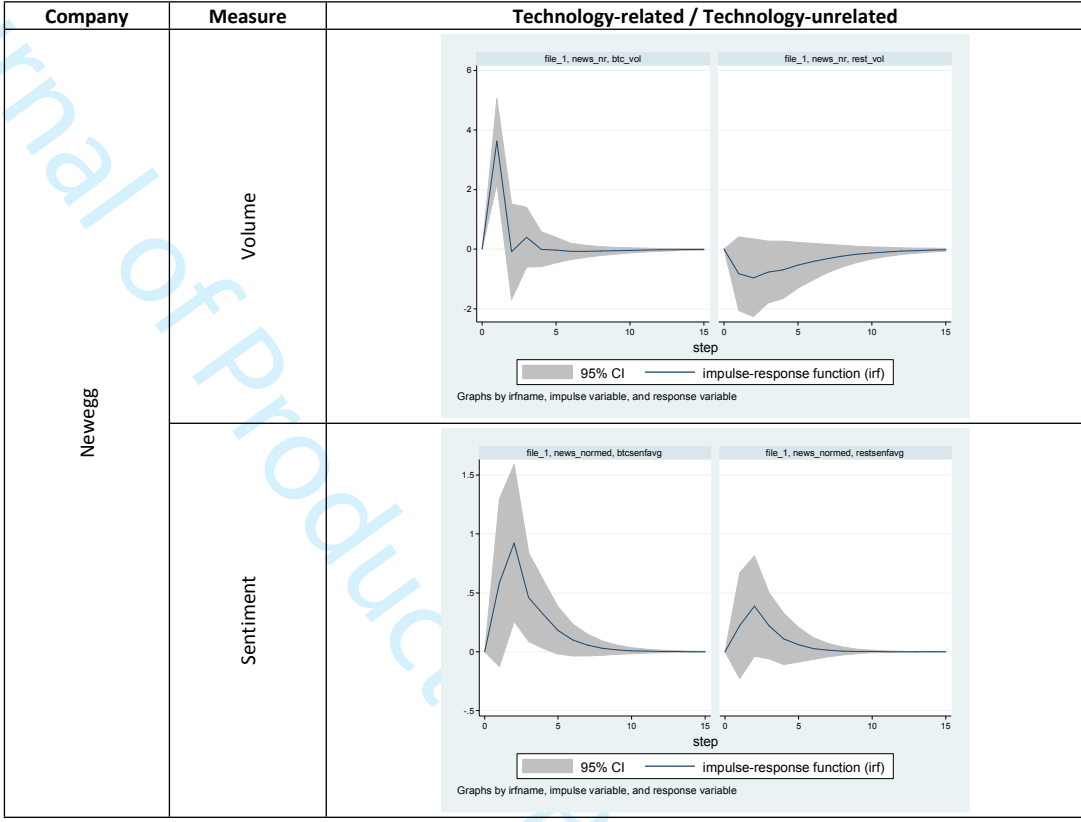

Table 10 Panel VAR model on sentiment: contemporary coefficients.

Contemporary coefficients	News	Bitcoin related tweets	Other tweets
News	1	0	0
Bitcoin related tweets	0.174	1	0
Other tweets	0.033	0.024	1

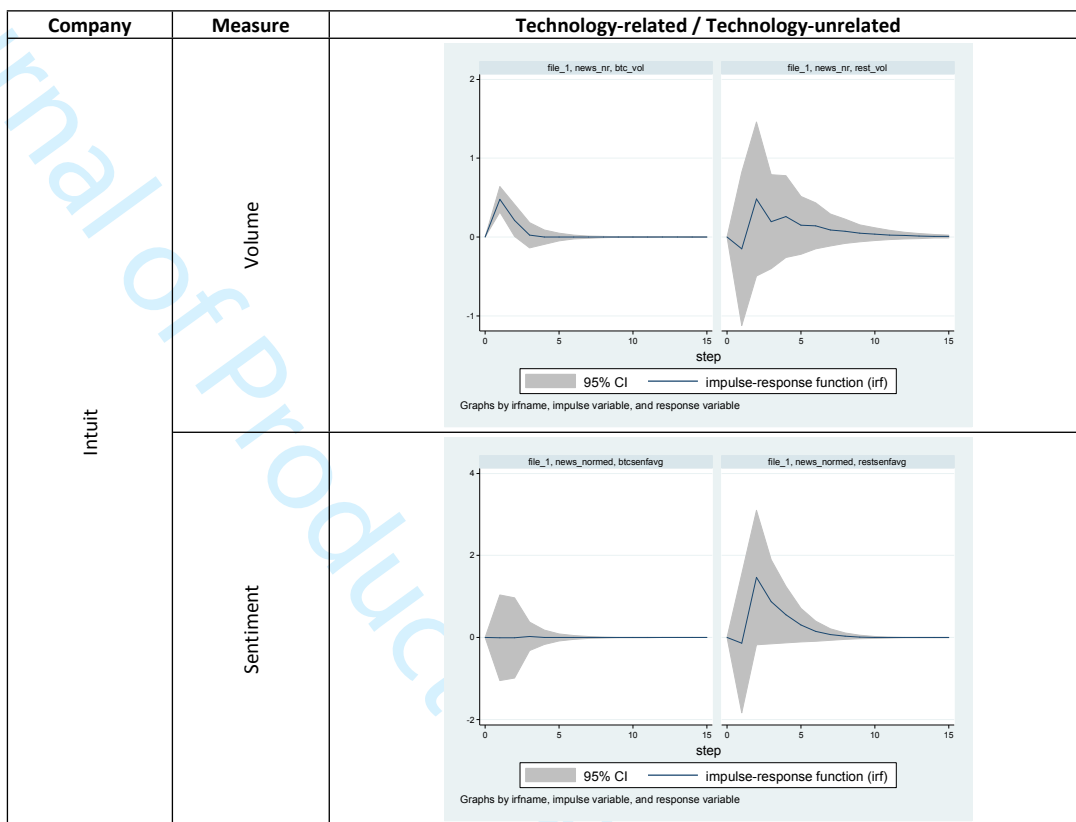

Table 11 IRFs resulting from VAR models limited to each company. The impulse is the number of Bitcoin news. The plotted effects are respectively on the number of tech-related and -unrelated tweets (“Volume” rows) and on the average sentiment of tech-related and -unrelated tweets (“Sentiment” rows)
